MINDSPORE

1.1 Data Presentation

1.1.1 Tensor

mindspore.Tensor	Tensor is a data structure that stores an n-dimensional array.
mindspore.tensor	Create a new Tensor in Cell.construct() or function decorated by @jit.
mindspore.COOTensor	A sparse representation of a set of nonzero elements from a tensor at given indices, where the indices indicate the position of each non-zero element.
mindspore.CSRTensor	Constructs a sparse tensor in CSR (Compressed Sparse Row) format, with specified values indicated by *values* and row and column positions indicated by *indptr* and *indices*.
mindspore.RowTensor	A sparse representation of a set of tensor slices at given indices.
mindspore.SparseTensor	A sparse representation of a set of nonzero elements from a tensor at given indices.
mindspore.is_tensor	Check whether the input object is *mindspore.Tensor* .
mindspore.from_numpy	Convert numpy array to Tensor.

mindspore.Tensor

class mindspore.**Tensor**(*input_data=None*, *dtype=None*, *shape=None*, *init=None*, *const_arg=False*, *device=None*)

Tensor is a data structure that stores an n-dimensional array.

Note:

- If *init* interface is used to initialize *Tensor*, the *Tensor.init_data* API needs to be called to load the actual data to *Tensor*.
- All modes of CPU and GPU, and Atlas training series with graph mode (mode=mindspore.GRAPH_MODE) do not supported in-place operations yet.
- The default value `None` of *input_data* works as a placeholder, it does not mean that we can create a NoneType Tensor.
- Tensor with *shape* contains 0 is not fully tested and supported.

Warning: To convert dtype of a *Tensor*, it is recommended to use *Tensor.astype()* rather than *Tensor(sourceTensor, dtype=newDtype)*.

Parameters

- **input_data** (Union[Tensor, float, int, bool, tuple, list, numpy.ndarray]) - The data to be stored. It can be another Tensor, Python number or NumPy ndarray. Default: `None` .
- **dtype** (*mindspore.dtype*) - Used to indicate the data type of the output Tensor. The argument should be defined in *mindspore.dtype*. If it is `None` , the data type of the output Tensor will be the same as the *input_data*. Default: `None` .
- **shape** (Union[tuple, list, int, *mindspore.Symbol*]) - Used to indicate the shape of the output Tensor. If *input_data* is available, *shape* doesn't need to be set. If `None` or *Symbol* exists in *shape* , a tensor of dynamic shape is created, *input_data* doesn't need to be set; if only integers exist in *shape*, a tensor of static shape is created, *input_data* or *init* must be set. Default: `None` .
- **init** (Initializer) - The information of init data. *init* is used for delayed initialization in parallel mode, when using init, *dtype* and *shape* must be set. Default: `None` .
- **const_arg** (bool) - Whether the tensor is a constant when it is used for the argument of a network. Default: `False` .
- **device** (str) - This parameter is reserved and does not need to be configured. Default: `None` .

Outputs:

Tensor.

Examples:

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> from mindspore.common.initializer import One
>>> # initialize a tensor with numpy.ndarray
>>> t1 = Tensor(np.zeros([1, 2, 3]), ms.float32)
>>> print(t1)
[[[0. 0. 0.]
[0. 0. 0.]]]
>>> print(type(t1))
<class 'mindspore.common.tensor.Tensor'>
>>> print(t1.shape)
(1, 2, 3)
>>> print(t1.dtype)
Float32
>>>
>>> # initialize a tensor with a float scalar
>>> t2 = Tensor(0.1)
>>> print(t2)
0.1
>>> print(type(t2))
<class 'mindspore.common.tensor.Tensor'>
>>> print(t2.shape)
()
>>> print(t2.dtype)
Float32
>>>
>>> # initialize a tensor with a tuple
>>> t3 = Tensor((1, 2))
>>> print(t3)
[1 2]
>>> print(type(t3))
<class 'mindspore.common.tensor.Tensor'>
```

(continues on next page)

(continued from previous page)

```
>>> print(t3.shape)
(2,)
>>> print(t3.dtype)
Int64
...
>>> # initialize a tensor with init
>>> t4 = Tensor(shape = (1, 3), dtype=ms.float32, init=One())
>>> print(t4)
[[1. 1. 1.]]
>>> print(type(t4))
<class 'mindspore.common.tensor.Tensor'>
>>> print(t4.shape)
(1, 3)
>>> print(t4.dtype)
Float32
```

mindspore.Tensor.abs	For details, please refer to *mindspore.ops.abs()*.
mindspore.Tensor.absolute	Alias for `Tensor.abs()`.
mindspore.Tensor.acos	For details, please refer to *mindspore.ops.acos()*.
mindspore.Tensor.acosh	For details, please refer to *mindspore.ops.acosh()*.
*mindspore.Tensor.add_*	In-place version of *mindspore.Tensor.add()*.
mindspore.Tensor.add	Adds other value to *self* element-wise.
mindspore.Tensor.addbmm	For details, please refer to *mindspore.ops.addbmm()*.
mindspore.Tensor.addcdiv	For details, please refer to *mindspore.ops.addcdiv()*.
mindspore.Tensor.addcmul	For details, please refer to *mindspore.ops.addcmul()*.
mindspore.Tensor.addmm	For details, please refer to *mindspore.ops.addmm()*.
*mindspore.Tensor.addmm_*	In-place version of *mindspore.Tensor.addmm()*.
mindspore.Tensor.addmv	For details, please refer to *mindspore.ops.addmv()*.
mindspore.Tensor.addr	For details, please refer to *mindspore.ops.addr()*.
mindspore.Tensor.adjoint	For details, please refer to *mindspore.ops.adjoint()*.
mindspore.Tensor.all	Tests if all element in tensor evaluates to *True* along the given axes.
mindspore.Tensor.allclose	Returns a new Tensor with boolean elements representing if each element of *self* is "close" to the corresponding element of *other*.
mindspore.Tensor.amax	For details, please refer to *mindspore.ops.amax()*.
mindspore.Tensor.amin	For details, please refer to *mindspore.ops.amin()*.
mindspore.Tensor.aminmax	For details, please refer to *mindspore.ops.aminmax()*.
mindspore.Tensor.any	Tests if any element in tensor evaluates to *True* along the given axes.
mindspore.Tensor.angle	For details, please refer to *mindspore.ops.angle()*.
mindspore.Tensor.approximate_equal	For details, please refer to *mindspore.ops.approximate_equal()*, The parameter *other* of current interface is the same as the parameter *y* of the reference interface.
mindspore.Tensor.arccos	Alias for *mindspore.Tensor.acos()*.
mindspore.Tensor.arccosh	Alias for *mindspore.Tensor.acosh()*.
mindspore.Tensor.arcsin	Alias for *mindspore.Tensor.asin()*.
mindspore.Tensor.arcsinh	Alias for *mindspore.Tensor.asinh()*.
mindspore.Tensor.arctan	Alias for *mindspore.Tensor.atan()*.
mindspore.Tensor.arctan2	Alias for `Tensor.atan2()`.
mindspore.Tensor.arctanh	Alias for *mindspore.Tensor.atanh()*.

continues on next page

Table 2 – continued from previous page

mindspore.Tensor.argmax	Return the indices of the maximum values along the given axis of the tensor.
mindspore.Tensor.argmax_with_value	Return the maximum values and their indices along the given axis of the tensor.
mindspore.Tensor.argmin	Returns the indices of the minimum values along the given axis of the tensor.
mindspore.Tensor.argmin_with_value	Return the minimum values and their indices along the given axis of the tensor.
mindspore.Tensor.argsort	Sorts *self* along the given dimension in specified order and return the sorted indices.
mindspore.Tensor.argwhere	For details, please refer to mindspore.ops.argwhere().
mindspore.Tensor.asin	For details, please refer to mindspore.ops.asin().
mindspore.Tensor.asinh	For details, please refer to mindspore.ops.asinh().
mindspore.Tensor.asnumpy	Convert tensor to numpy array.
mindspore.Tensor.assign_value	Assign another tensor value to this tensor.
mindspore.Tensor.astype	Return a copy of the tensor, cast to a specified type.
mindspore.Tensor.atan	For details, please refer to mindspore.ops.atan().
mindspore.Tensor.atan2	For details, please refer to mindspore.ops.atan2().
mindspore.Tensor.atanh	For details, please refer to mindspore.ops.atanh().
mindspore.Tensor.baddbmm	For details, please refer to mindspore.ops.baddbmm().
mindspore.Tensor.bernoulli	For details, please refer to mindspore.mint.bernoulli().
mindspore.Tensor.bfloat16	Converts input tensor dtype to *bfloat16*.
mindspore.Tensor.bincount	For details, please refer to mindspore.ops.bincount().
mindspore.Tensor.bitwise_and	Returns bitwise *and* of two tensors element-wise.
mindspore.Tensor.bitwise_not	Returns bitwise *not* of *self*.
mindspore.Tensor.bitwise_left_shift	For details, please refer to mindspore.ops.bitwise_left_shift().
mindspore.Tensor.bitwise_or	Returns bitwise *or* of two tensors element-wise.
mindspore.Tensor.bitwise_right_shift	For details, please refer to mindspore.ops.bitwise_right_shift().
mindspore.Tensor.bitwise_xor	Returns bitwise *xor* of two tensors element-wise.
mindspore.Tensor.bmm	For details, please refer to mindspore.ops.bmm().
mindspore.Tensor.bool	Converts input tensor dtype to *bool*.
mindspore.Tensor.broadcast_to	For details, please refer to mindspore.ops.broadcast_to().
mindspore.Tensor.byte	Converts input tensor dtype to *uint8*.
mindspore.Tensor.cauchy	Fills the tensor with numbers drawn from the Cauchy distribution.
mindspore.Tensor.ceil	For details, please refer to mindspore.ops.ceil().
mindspore.Tensor.cholesky	For details, please refer to mindspore.ops.cholesky().
mindspore.Tensor.cholesky_solve	For details, please refer to mindspore.ops.cholesky_solve().
mindspore.Tensor.choose	Construct a tensor from an index tensor and a list of tensors to choose from.
mindspore.Tensor.chunk	Cut the self Tensor into *chunks* sub-tensors along the specified dimension.
mindspore.Tensor.clamp	For details, please refer to mindspore.ops.clamp().
mindspore.Tensor.clamp_	In-place version of mindspore.Tensor.clamp().
mindspore.Tensor.clip	Alias for mindspore.Tensor.clamp().
mindspore.Tensor.clone	Returns a copy of self.
mindspore.Tensor.col2im	For details, please refer to mindspore.ops.col2im().

continues on next page

Table 2 – continued from previous page

mindspore.Tensor.conj	For details, please refer to mindspore.ops.conj().
mindspore.Tensor.contiguous	Converts a Tensor into a continuous-memory Tensor that contains the same data as the original Tensor.
mindspore.Tensor.copy	Return a copy of the tensor.
mindspore.Tensor.copy_	Copies the elements from *src* into *self* tensor and returns *self*.
mindspore.Tensor.copysign	For details, please refer to mindspore.ops.copysign().
mindspore.Tensor.cos	For details, please refer to mindspore.ops.cos().
mindspore.Tensor.cosh	For details, please refer to mindspore.ops.cosh().
mindspore.Tensor.count_nonzero	Counts the number of non-zero values in the tensor input along the given dim.
mindspore.Tensor.cov	For details, please refer to mindspore.ops.cov().
mindspore.Tensor.cross	For details, please refer to mindspore.ops.cross().
mindspore.Tensor.cummax	For details, please refer to mindspore.ops.cummax().
mindspore.Tensor.cummin	For details, please refer to mindspore.ops.cummin().
mindspore.Tensor.cumprod	For details, please refer to mindspore.ops.cumprod().
mindspore.Tensor.cumsum	Computes the cumulative sum of self Tensor along *dim*.
mindspore.Tensor.deg2rad	For details, please refer to mindspore.ops.deg2rad().
mindspore.Tensor.diag	For details, please refer to mindspore.ops.diag().
mindspore.Tensor.diagflat	For details, please refer to mindspore.ops.diagflat().
mindspore.Tensor.diagonal	For details, please refer to mindspore.ops.diagonal().
mindspore.Tensor.diagonal_scatter	For details, please refer to mindspore.ops.diagonal_scatter().
mindspore.Tensor.diff	For details, please refer to mindspore.ops.diff().
mindspore.Tensor.digamma	For details, please refer to mindspore.ops.digamma().
mindspore.Tensor.div	For details, please refer to mindspore.ops.div().
mindspore.Tensor.div_	In-place version of mindspore.Tensor.div().
mindspore.Tensor.divide	Alias for mindspore.Tensor.div().
mindspore.Tensor.dot	Computes the dot product of two 1D tensor.
mindspore.Tensor.double	Converts input tensor dtype to *float64*.
mindspore.Tensor.dsplit	For details, please refer to mindspore.ops.dsplit().
mindspore.Tensor.dtype	Return the dtype of the tensor (mindspore.dtype).
mindspore.Tensor.eigvals	For details, please refer to mindspore.ops.eigvals().
mindspore.Tensor.eq	For details, please refer to mindspore.ops.eq().
mindspore.Tensor.equal	For details, please refer to mindspore.ops.equal().
mindspore.Tensor.erf	For details, please refer to mindspore.ops.erf().
mindspore.Tensor.erfc	For details, please refer to mindspore.ops.erfc().
mindspore.Tensor.erfinv	For details, please refer to mindspore.ops.erfinv().
mindspore.Tensor.exp	For details, please refer to mindspore.ops.exp().
mindspore.Tensor.exp_	Inplace version of mindspore.Tensor.exp().
mindspore.Tensor.expand	For details, please refer to mindspore.ops.broadcast_to().
mindspore.Tensor.expand_as	Expand the shape of the input tensor to be the same as the another input tensor.
mindspore.Tensor.expand_dims	For details, please refer to mindspore.ops.expand_dims().
mindspore.Tensor.expm1	For details, please refer to mindspore.ops.expm1().
mindspore.Tensor.exponential_	Fills *self* tensor with elements drawn from the exponential distribution:
mindspore.Tensor.fill_	Fills *self* tensor with the specified *value* .
mindspore.Tensor.fill_diagonal	Fills the main diagonal of a Tensor with a specified value and returns the result.

continues on next page

Table 2 – continued from previous page

mindspore.Tensor.flatten	Flatten a tensor along dimensions from *start_dim* to *end_dim*.
mindspore.Tensor.flip	For details, please refer to mindspore.ops.flip().
mindspore.Tensor.fliplr	For details, please refer to mindspore.ops.fliplr().
mindspore.Tensor.flipud	For details, please refer to mindspore.ops.flipud().
mindspore.Tensor.float	Converts input tensor dtype to *float32*.
mindspore.Tensor.float_power	For details, please refer to mindspore.ops.float_power().
mindspore.Tensor.floor	For details, please refer to mindspore.ops.floor().
mindspore.Tensor.floor_	In-place version of mindspore.Tensor.floor().
mindspore.Tensor.floor_divide	Divides the self tensor by the other input tensor element-wise and round down to the closest integer.
mindspore.Tensor.floor_divide_	Divides the self tensor by the other tensor element-wise and round down to the closest integer.
mindspore.Tensor.flush_from_cache	Flush cache data to host if tensor is cache enable.
mindspore.Tensor.fmax	For details, please refer to mindspore.ops.fmax().
mindspore.Tensor.fmod	For details, please refer to mindspore.ops.fmod().
mindspore.Tensor.fold	For details, please refer to mindspore.ops.fold().
mindspore.Tensor.frac	For details, please refer to mindspore.ops.frac().
mindspore.Tensor.from_numpy	Convert numpy array to Tensor.
mindspore.Tensor.gather	Gather data from a tensor by indices.
mindspore.Tensor.gather_elements	For details, please refer to mindspore.ops.gather_elements().
mindspore.Tensor.gather_nd	For details, please refer to mindspore.ops.gather_nd().
mindspore.Tensor.gcd	For details, please refer to mindspore.ops.gcd().
mindspore.Tensor.ge	Alias for mindspore.Tensor.greater_equal().
mindspore.Tensor.geqrf	For details, please refer to mindspore.ops.geqrf().
mindspore.Tensor.ger	For details, please refer to mindspore.ops.ger().
mindspore.Tensor.greater	For details, please refer to mindspore.ops.greater().
mindspore.Tensor.greater_equal	For details, please refer to mindspore.ops.greater_equal().
mindspore.Tensor.gt	For details, please refer to :func:'mindspore.Tensor.greater'.
mindspore.Tensor.H	Returns a view of a matrix (2-D tensor) conjugated and transposed.
mindspore.Tensor.half	Converts input tensor dtype to *float16*.
mindspore.Tensor.hardshrink	For details, please refer to mindspore.ops.hardshrink().
mindspore.Tensor.has_init	Whether tensor is initialized.
mindspore.Tensor.heaviside	For details, please refer to mindspore.ops.heaviside().
mindspore.Tensor.histc	For details, please refer to mindspore.ops.histc().
mindspore.Tensor.hsplit	For details, please refer to mindspore.ops.hsplit().
mindspore.Tensor.hypot	For details, please refer to mindspore.ops.hypot().
mindspore.Tensor.i0	For details, please refer to mindspore.ops.bessel_i0().
mindspore.Tensor.igamma	For details, please refer to mindspore.ops.igamma().
mindspore.Tensor.igammac	For details, please refer to mindspore.ops.igammac().
mindspore.Tensor.imag	For details, please refer to mindspore.ops.imag().
mindspore.Tensor.index_add	Adds tensor *y* to specified axis and indices of tensor *self*.
mindspore.Tensor.index_add_	Accumulate the elements of *alpha* times *source* into the *self* by adding to the index in the order given in *index*.

continues on next page

Table 2 – continued from previous page

mindspore.Tensor.index_fill	For details, please refer to mindspore.ops.index_fill().
mindspore.Tensor.index_put	Based on the indices in *indices*, replace the corresponding elements in Tensor *self* with the values in *values*.
mindspore.Tensor.index_put_	Based on the indices in *indices*, replace the corresponding elements in Tensor *self* with the values in *values*.
mindspore.Tensor.index_select	Generates a new Tensor that accesses the values of *self* along the specified *axis* dimension using the indices specified in *index*.
mindspore.Tensor.init_data	Get the tensor format data of this Tensor.
mindspore.Tensor.inner	For details, please refer to mindspore.ops.inner().
mindspore.Tensor.inplace_update	For details, please refer to mindspore.ops.inplace_update().
mindspore.Tensor.int	Converts input tensor dtype to *int32*.
mindspore.Tensor.inv	For details, please refer to mindspore.ops.inv().
mindspore.Tensor.inverse	For details, please refer to mindspore.ops.inverse().
mindspore.Tensor.invert	For details, please refer to mindspore.ops.invert().
mindspore.Tensor.isclose	Returns a tensor of Boolean values indicating whether each element of *input* is "close" to the corresponding element of *other*.
mindspore.Tensor.isfinite	For details, please refer to mindspore.ops.isfinite().
mindspore.Tensor.is_complex	For details, please refer to: func:'mindspore.ops.is_complex'.
mindspore.Tensor.is_contiguous	Determines whether the memory of tensor is contiguous.
mindspore.Tensor.is_floating_point	For details, please refer to mindspore.ops.is_floating_point().
mindspore.Tensor.isinf	For details, please refer to mindspore.ops.isinf().
mindspore.Tensor.isnan	For details, please refer to mindspore.ops.ne().
mindspore.Tensor.isneginf	For details, please refer to mindspore.ops.isneginf().
mindspore.Tensor.isposinf	For details, please refer to mindspore.ops.isposinf().
mindspore.Tensor.isreal	For details, please refer to mindspore.ops.isreal().
mindspore.Tensor.is_signed	Judge whether the data type of tensor is a signed data type.
mindspore.Tensor.item	Return the value of this tensor as standard Python number.
mindspore.Tensor.itemset	Insert scalar into a tensor (scalar is cast to tensor's dtype, if possible).
mindspore.Tensor.itemsize	Return the length of one tensor element in bytes.
mindspore.Tensor.lcm	For details, please refer to mindspore.ops.lcm().
mindspore.Tensor.ldexp	For details, please refer to mindspore.ops.ldexp().
mindspore.Tensor.le	For details, please refer to mindspore.ops.le().
mindspore.Tensor.lerp	For more details, please refer to mindspore.ops.lerp().
mindspore.Tensor.less	For details, please refer to mindspore.ops.less().
mindspore.Tensor.less_equal	For details, please refer to mindspore.ops.less_equal().
mindspore.Tensor.log	For details, please refer to mindspore.ops.log().
mindspore.Tensor.log10	For details, please refer to mindspore.ops.log10().
mindspore.Tensor.log1p	For details, please refer to mindspore.ops.log1p().
mindspore.Tensor.log2	For details, please refer to mindspore.ops.log2().
mindspore.Tensor.logaddexp	For details, please refer to mindspore.ops.logaddexp().
mindspore.Tensor.logaddexp2	For details, please refer to mindspore.ops.logaddexp2().
mindspore.Tensor.logcumsumexp	For details, please refer to mindspore.ops.logcumsumexp().
mindspore.Tensor.logdet	For details, please refer to mindspore.ops.logdet().

continues on next page

Table 2 – continued from previous page

mindspore.Tensor.logical_and	For details, please refer to mindspore.ops.logical_and().
mindspore.Tensor.logical_not	For details, please refer to mindspore.ops.logical_not().
mindspore.Tensor.logical_or	For details, please refer to mindspore.ops.logical_or().
mindspore.Tensor.logical_xor	Computes the "logical XOR" of two tensors element-wise.
mindspore.Tensor.logit	For details, please refer to mindspore.ops.logit().
mindspore.Tensor.logsumexp	For details, please refer to mindspore.ops.logsumexp().
mindspore.Tensor.log_normal	Fills the elements of the input tensor with log normal values initialized by given mean and std:
mindspore.Tensor.long	Converts input tensor dtype to *int64*.
mindspore.Tensor.lt	For more details, please refer to mindspore.Tensor.less().
mindspore.Tensor.lu_solve	For details, please refer to mindspore.ops.lu_solve().
mindspore.Tensor.masked_fill	For details, please refer to mindspore.ops.masked_fill().
mindspore.Tensor.masked_fill_	In-place version of mindspore.Tensor.masked_fill().
mindspore.Tensor.masked_scatter	Updates the value in the "self Tensor" with the *tensor* value according to the mask, and returns a Tensor.
mindspore.Tensor.masked_select	For details, please refer to mindspore.ops.masked_select().
mindspore.Tensor.matmul	Returns the matrix product of two tensors.
mindspore.Tensor.max	Returns the maximum value of the self tensor.
mindspore.Tensor.maximum	For details, please refer to mindspore.ops.maximum().
mindspore.Tensor.mean	Reduces all dimension of a tensor by averaging all elements in the dimension, by default.
mindspore.Tensor.median	Computes the median and indices of input tensor.
mindspore.Tensor.t	Transpose *self* .
mindspore.Tensor.mH	Accessing this property is equivalent to Calling self.adjoint().
mindspore.Tensor.min	Returns the minimum value of the self tensor.
mindspore.Tensor.minimum	For details, please refer to mindspore.ops.minimum().
mindspore.Tensor.mm	Returns the matrix product of two arrays.
mindspore.Tensor.moveaxis	For details, please refer to mindspore.ops.moveaxis().
mindspore.Tensor.movedim	For details, please refer to mindspore.ops.movedim().
mindspore.Tensor.move_to	Copy Tensor to target device synchronously or asynchronously, default synchronously.
mindspore.Tensor.msort	For details, please refer to mindspore.ops.msort().
mindspore.Tensor.mT	Returns the Tensor that exchanges the last two dimensions.
mindspore.Tensor.mul	For details, please refer to mindspore.ops.mul().
mindspore.Tensor.mul_	Multiplies two tensors element-wise.
mindspore.Tensor.multinomial	For details, please refer to mindspore.ops.multinomial().
mindspore.Tensor.multiply	For details, please refer to mindspore.ops.mul().
mindspore.Tensor.mvlgamma	For details, please refer to mindspore.ops.mvlgamma().
mindspore.Tensor.nan_to_num	For details, please refer to mindspore.ops.nan_to_num().
mindspore.Tensor.nanmean	For details, please refer to mindspore.ops.nanmean().

continues on next page

Table 2 – continued from previous page

mindspore.Tensor.nanmedian	For details, please refer to mindspore.ops.nanmedian().
mindspore.Tensor.nansum	Computes sum of input Tensor over a given dimension, treating NaNs as zero.
mindspore.Tensor.narrow	Obtains a tensor of a specified length at a specified start position along a specified axis.
mindspore.Tensor.nbytes	Return the total number of bytes taken by the tensor.
mindspore.Tensor.ndim	Return the number of tensor dimensions.
mindspore.Tensor.ndimension	Alias for mindspore.Tensor.ndim.
mindspore.Tensor.ne	Alias for mindspore.Tensor.not_equal().
mindspore.Tensor.neg	For details, please refer to mindspore.ops.neg().
mindspore.Tensor.negative	Alias for mindspore.Tensor.neg().
mindspore.Tensor.nelement	Alias for mindspore.Tensor.numel().
mindspore.Tensor.new_ones	Return a tensor of *size* filled with ones.
mindspore.Tensor.new_zeros	Return a tensor of *size* filled with zeros.
mindspore.Tensor.nextafter	For details, please refer to mindspore.ops.nextafter().
mindspore.Tensor.nonzero	Return the positions of all non-zero values.
mindspore.Tensor.norm	For details, please refer to mindspore.ops.norm().
mindspore.Tensor.normal_	Update the *self* tensor in place by generating random numbers sampled from the normal distribution which constructed by the parameters *mean* and *std*.
mindspore.Tensor.not_equal	For details, please refer to mindspore.ops.ne().
mindspore.Tensor.numel	For details, please refer to mindspore.ops.numel().
mindspore.Tensor.numpy	Alias for mindspore.Tensor.asnumpy().
mindspore.Tensor.orgqr	For details, please refer to mindspore.ops.orgqr().
mindspore.Tensor.ormqr	For details, please refer to mindspore.ops.ormqr(), Args *input2* and *input3* correspond to the args *tau* and *other* of mindspore.ops.ormqr().
mindspore.Tensor.outer	For details, please refer to mindspore.ops.outer().
mindspore.Tensor.permute	Tensor.permute supports unpacking the *axis* argument automatically when it is passed as an indefinite number of positional arguments, which has a slight difference from the input parameter of mindspore.ops.permute().
mindspore.Tensor.positive	For details, please refer to mindspore.ops.positive().
mindspore.Tensor.pow	For details, please refer to mindspore.ops.pow().
mindspore.Tensor.prod	Reduces a dimension of a tensor by multiplying all elements in the dimension, by default.
mindspore.Tensor.ptp	The name of the function comes from the acronym for "peak to peak".
mindspore.Tensor.rad2deg	For details, please refer to mindspore.ops.rad2deg().
mindspore.Tensor.random_	Fill the tensor with numbers sampled from a discrete uniform distribution over an interval $[from\_, to - 1]$.
mindspore.Tensor.random_categorical	For details, please refer to mindspore.ops.random_categorical().
mindspore.Tensor.ravel	Return a contiguous flattened tensor.
mindspore.Tensor.real	For details, please refer to mindspore.ops.real().
mindspore.Tensor.reciprocal	For details, please refer to mindspore.ops.reciprocal().
mindspore.Tensor.register_hook	Registers a backward hook for tensor.
mindspore.Tensor.remainder	Computes the remainder of *self* divided by *other* element-wise.

continues on next page

Table 2 – continued from previous page

mindspore.Tensor.renorm	For details, please refer to mindspore.ops.renorm().
mindspore.Tensor.repeat	Copy the elements in each dimension of a Tensor based on the specified number of repetition times.
mindspore.Tensor.repeat_interleave	Repeat elements of a tensor along a dim, like mindspore.numpy.repeat().
mindspore.Tensor.reshape	For details, please refer to mindspore.ops.reshape().
mindspore.Tensor.reshape_as	Change the shape of the Tensor to the shape of *other* without changing the data.
mindspore.Tensor.resize	Changes shape and size of tensor in-place.
mindspore.Tensor.reverse	For details, please refer to mindspore.ops.flip().
mindspore.Tensor.reverse_sequence	For details, please refer to mindspore.ops.reverse_sequence().
mindspore.Tensor.roll	For details, please refer to mindspore.ops.roll().
mindspore.Tensor.rot90	For details, please refer to mindspore.ops.rot90().
mindspore.Tensor.round	For details, please refer to mindspore.ops.round().
mindspore.Tensor.rsqrt	For details, please refer to mindspore.ops.rsqrt().
mindspore.Tensor.scatter	Update the value in *src* to *self* according to the specified index.
mindspore.Tensor.scatter_	Update the value in *src* to update *self* according to the specified *index*.
mindspore.Tensor.scatter_add	Add all elements in *src* to the index specified by *index* to *self* along dimension specified by *dim*.
mindspore.Tensor.scatter_add_	Add all elements in *src* to the index specified by *index* to *self* along dimension specified by *dim*, *scatter_add* is an in-place operation.
mindspore.Tensor.scatter_div	For details, please refer to mindspore.ops.scatter_div().
mindspore.Tensor.scatter_max	For details, please refer to mindspore.ops.scatter_max().
mindspore.Tensor.scatter_min	For details, please refer to mindspore.ops.scatter_min().
mindspore.Tensor.scatter_mul	For details, please refer to mindspore.ops.scatter_mul().
mindspore.Tensor.scatter_sub	For details, please refer to mindspore.ops.tensor_scatter_sub().
mindspore.Tensor.searchsorted	For details, please refer to mindspore.ops.searchsorted().
mindspore.Tensor.select	Slices the *self* tensor along the selected dimension at the given index.
mindspore.Tensor.select_scatter	For details, please refer to mindspore.ops.select_scatter().
mindspore.Tensor.set_const_arg	Specify whether the tensor is a constant when it is used for the argument of a network.
mindspore.Tensor.sgn	For details, please refer to mindspore.ops.sgn().
mindspore.Tensor.shape	For details, please refer to mindspore.ops.shape().
mindspore.Tensor.short	Return a copy of the tensor, cast to int16 type, equivalent to self.astype(mstype.int16).
mindspore.Tensor.sigmoid	For details, please refer to mindspore.ops.sigmoid().
mindspore.Tensor.sign	For details, please refer to mindspore.ops.sign().
mindspore.Tensor.signbit	For details, please refer to mindspore.ops.signbit().
mindspore.Tensor.sin	For details, please refer to mindspore.ops.sin().
mindspore.Tensor.sinc	For details, please refer to mindspore.ops.sinc().
mindspore.Tensor.sinh	For details, please refer to mindspore.ops.sinh().

continues on next page

Table 2 – continued from previous page

mindspore.Tensor.size	For details, please refer to mindspore.ops.size().
mindspore.Tensor.slice_scatter	For details, please refer to mindspore.ops.slice_scatter().
mindspore.Tensor.slogdet	For details, please refer to mindspore.ops.slogdet().
mindspore.Tensor.softmax	For details, please refer to mindspore.ops.softmax().
mindspore.Tensor.sort	Sorts the elements of the self tensor along the given dimension in the specified order.
mindspore.Tensor.split	Splits the Tensor into chunks along the given dim.
mindspore.Tensor.sqrt	For details, please refer to mindspore.ops.sqrt().
mindspore.Tensor.square	For details, please refer to mindspore.ops.square().
mindspore.Tensor.squeeze	For details, please refer to mindspore.ops.squeeze().
mindspore.Tensor.std	For details, please refer to mindspore.ops.std().
mindspore.Tensor.storage_offset	Tensor's offset in the underlying storage in terms of the number of storage elements.
mindspore.Tensor.stride	The stride to jump from one element to the next in the input dim.
mindspore.Tensor.strides	Return the tuple of bytes to step in each dimension when traversing a tensor.
mindspore.Tensor.sub	Subtracts scaled other value from self Tensor.
mindspore.Tensor.sub_	For details, please refer to mindspore.mint.sub().
mindspore.Tensor.subtract	This interface is deprecated from version 2.4 and will be removed in a future version.
mindspore.Tensor.sum	Calculate sum of Tensor elements over a given dim.
mindspore.Tensor.sum_to_size	Sum self Tensor to the *size*.
mindspore.Tensor.svd	For details, please refer to mindspore.ops.svd().
mindspore.Tensor.swapaxes	For details, please refer to mindspore.ops.swapaxes().
mindspore.Tensor.swapdims	For details, please refer to mindspore.ops.swapdims().
mindspore.Tensor.T	Return the transposed tensor.
mindspore.Tensor.t	Transpose *self* .
mindspore.Tensor.take	Takes elements from a tensor along an axis.
mindspore.Tensor.tan	For details, please refer to mindspore.ops.tan().
mindspore.Tensor.tanh	For details, please refer to mindspore.ops.tanh().
mindspore.Tensor.tensor_split	For details, please refer to mindspore.ops.tensor_split().
mindspore.Tensor.tile	Replicates an tensor with given dims times.
mindspore.Tensor.to	Performs tensor dtype conversion.
mindspore.Tensor.to_coo	Convert a Tensor to COOTensor.
mindspore.Tensor.to_csr	Convert a Tensor to CSRTensor.
mindspore.Tensor.tolist	Convert a Tensor to List.
mindspore.Tensor.topk	Finds the *k* largest or smallest element along the given dimension and returns its value and corresponding index.
mindspore.Tensor.trace	Return the sum along diagonals of the tensor.
mindspore.Tensor.transpose	Interchange two axes of a tensor.
mindspore.Tensor.triangular_solve	For details, please refer to mindspore.mint.triangular_solve().
mindspore.Tensor.tril	For details, please refer to mindspore.ops.tril().
mindspore.Tensor.triu	For details, please refer to mindspore.ops.triu().
mindspore.Tensor.true_divide	Alias for Tensor.div() with $rounding\_mode = None$.
mindspore.Tensor.trunc	For details, please refer to mindspore.ops.trunc().
mindspore.Tensor.type	Change the dtype of the Tensor to the *dtype* .
mindspore.Tensor.type_as	Returns self tensor cast to the type of the with the input other tensor.

continues on next page

Table 2 – continued from previous page

mindspore.Tensor.unbind	For details, please refer to mindspore.ops.unbind().
mindspore.Tensor.unfold	For details, please refer to mindspore.ops.unfold().
mindspore.Tensor.uniform	Generates random numbers that follows a uniform distribution within the half-open interval $[from\_, to)$.
mindspore.Tensor.uniform_	Update the *self* Tensor in place by generating random numbers sampled from uniform distribution in the half-open interval $[from\_, to)$.
mindspore.Tensor.unique	Returns the unique elements of *self*.
mindspore.Tensor.unique_consecutive	For details, please refer to mindspore.ops.unique_consecutive().
mindspore.Tensor.unsorted_segment_max	For details, please refer to mindspore.ops.unsorted_segment_max().
mindspore.Tensor.unsorted_segment_min	For details, please refer to mindspore.ops.unsorted_segment_min().
mindspore.Tensor.unsorted_segment_prod	For details, please refer to mindspore.ops.unsorted_segment_prod().
mindspore.Tensor.unsqueeze	For details, please refer to mindspore.ops.unsqueeze().
mindspore.Tensor.var	Compute the variance along the specified axis.
mindspore.Tensor.view	Reshape the tensor according to the input shape.
mindspore.Tensor.view_as	View *self* Tensor as the same shape as *other* .
mindspore.Tensor.vsplit	For details, please refer to mindspore.ops.vsplit().
mindspore.Tensor.where	For details, please refer to mindspore.ops.where().
mindspore.Tensor.xdivy	For details, please refer to mindspore.ops.xdivy().
mindspore.Tensor.xlogy	For details, please refer to mindspore.ops.xlogy().
mindspore.Tensor.zero_	Return a tensor filled with zeros.

mindspore.Tensor.abs

Tensor.**abs**() → *Tensor*

For details, please refer to mindspore.ops.abs().

mindspore.Tensor.absolute

Tensor.**absolute**() → *Tensor*

Alias for Tensor.abs().

mindspore.Tensor.acos

Tensor.**acos**() → *Tensor*

For details, please refer to mindspore.ops.acos().

mindspore.Tensor.acosh

Tensor.**acosh**() → *Tensor*

For details, please refer to *mindspore.ops.acosh()*.

mindspore.Tensor.add_

Tensor.**add_**(*other*) → *Tensor*

In-place version of *mindspore.Tensor.add()*.

mindspore.Tensor.add

Tensor.**add**(*other*) → *Tensor*

Adds other value to *self* element-wise.

$$out_i = self_i + other_i$$

Note:

- When *self* and *other* have different shapes, they must be able to broadcast to a common shape.
- *self* and *other* can not be bool type at the same time, [True, Tensor(True, bool_), Tensor(np.array([True]), bool_)] are all considered bool type.
- *self* and *other* comply with the implicit type conversion rules to make the data types consistent.
- The dimension of *self* should be greater than or equal to 1.

Parameters

other (*Union[Tensor, number.Number, bool]*) – *other* is a number.Number or a bool or a tensor whose data type is number or bool_.

Returns

Tensor with a shape that is the same as the broadcasted shape of *self* and *other*, and the data type is the one with higher precision or higher digits between *self* and *other*.

Raises

TypeError – If *other* is not one of the following: Tensor, number.Number, bool.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> # case 1: x and y are both Tensor.
>>> x = Tensor(np.array([1, 2, 3]).astype(np.float32))
>>> y = Tensor(np.array([4, 5, 6]).astype(np.float32))
>>> output = Tensor.add(x, y)  # x.add(y)
>>> print(output)
[5. 7. 9.]
>>> # case 2: x is a scalar and y is a Tensor
>>> x = Tensor(1, mindspore.int32)
>>> y = Tensor(np.array([4, 5, 6]).astype(np.float32))
>>> output = Tensor.add(x, y)  # x.add(y)
>>> print(output)
[5. 6. 7.]
>>> # the data type of x is int32, the data type of y is float32,
>>> # and the output is the data format of higher precision float32.
>>> print(output.dtype)
Float32
```

`Tensor.`**`add`**(*other*, *, *alpha=1*) → *Tensor*

Adds scaled other value to *self*.

$$out_i = self_i + alpha \times other_i$$

Note:

- When *self* and *other* have different shapes, they must be able to broadcast to a common shape.
- *self*, *other* and alpha comply with the implicit type conversion rules to make the data types consistent.

Parameters

`other` (*`Union[Tensor, number.Number, bool]`*) – *other* is a number.Number or a bool or a tensor whose data type is number or bool_.

Keyword Arguments

`alpha` (*`number.Number`*) – A scaling factor applied to *other*, default 1.

Returns

Tensor with a shape that is the same as the broadcasted shape of the *self* and *other*, and the data type is the one with higher precision or higher digits among *self*, *other* and *alpha*.

Raises

- **`TypeError`** – If the type of *other* or *alpha* is not one of the following: Tensor, number.Number, bool.
- **`TypeError`** – If *alpha* is of type float but *self* and *other* are not of type float.
- **`TypeError`** – If *alpha* is of type bool but *self* and *other* are not of type bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor(1, mindspore.int32)
>>> y = Tensor(np.array([4, 5, 6]).astype(np.float32))
>>> alpha = 0.5
>>> output = Tensor.add(x, y, alpha=alpha)  # x.add(y, alpha=alpha)
>>> print(output)
[3. 3.5 4.]
>>> # the data type of x is int32, the data type of y is float32,
>>> # alpha is a float, and the output is the data format of higher precision float32.
>>> print(output.dtype)
Float32
```

mindspore.Tensor.addbmm

Tensor.**addbmm**(*batch1*, *batch2*, *, *beta=1*, *alpha=1*) → *Tensor*

For details, please refer to *mindspore.ops.addbmm()*.

mindspore.Tensor.addcdiv

Tensor.**addcdiv**(*tensor1*, *tensor2*, *, *value=1*) → *Tensor*

For details, please refer to *mindspore.ops.addcdiv()*.

Supported Platforms:

Ascend

mindspore.Tensor.addcmul

Tensor.**addcmul**(*tensor1*, *tensor2*, *value=1*)

For details, please refer to *mindspore.ops.addcmul()*.

mindspore.Tensor.addmm

Tensor.**addmm**(*mat1*, *mat2*, *, *beta=1*, *alpha=1*) → *Tensor*

For details, please refer to *mindspore.ops.addmm()*.

mindspore.Tensor.addmm_

Tensor.**addmm_**(*mat1*, *mat2*, *, *beta=1*, *alpha=1*)

In-place version of *mindspore.Tensor.addmm()*.

Warning: This is an experimental API that is subject to change or deletion.

mindspore.Tensor.addmv

Tensor.**addmv**(*mat*, *vec*, *, *beta=1*, *alpha=1*) → *Tensor*

For details, please refer to *mindspore.ops.addmv()*.

Supported Platforms:

Ascend

mindspore.Tensor.addr

Tensor.**addr**(*vec1*, *vec2*, *beta=1*, *alpha=1*)

For details, please refer to *mindspore.ops.addr()*.

mindspore.Tensor.adjoint

Tensor.**adjoint**()

For details, please refer to *mindspore.ops.adjoint()*.

mindspore.Tensor.all

Tensor.**all**(*axis=None*, *keep_dims=False*) → *Tensor*

Tests if all element in tensor evaluates to *True* along the given axes.

Parameters

- **axis** (*Union[int, tuple(int), list(int), Tensor], optional*) –The dimensions to reduce. If None , all dimensions are reduced. Default None .
- **keep_dims** (*bool, optional*) –Whether the output tensor has dim retained or not. Default False .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[True, False], [True, True]])
>>>
>>> # case 1:  By default, mindspore.Tensor.all tests along all the axes.
>>> x.all()
Tensor(shape=[], dtype=Bool, value= False)
>>>
>>> # case 2: Reduces a dimension along axis 1, with keep_dims False.
>>> x.all(axis=1)
Tensor(shape=[2], dtype=Bool, value= [False,  True])
>>>
>>> # case 3: Reduces a dimension along axis (0, 1), with keep_dims False.
>>> x.all(axis=(0,1))
```

(continues on next page)

(continued from previous page)

```
Tensor(shape=[], dtype=Bool, value= False)
>>>
>>> # case 4: Reduces a dimension along axis [0, 1], with keep_dims True.
>>> x.all(axis=[0,1], keep_dims=True)
Tensor(shape=[1, 1], dtype=Bool, value=
[[False]])
```

`Tensor.all`(*dim=None*, *keepdim=False*) → *Tensor*

Tests if all element in tensor evaluates to *True* along the given axes.

Parameters

- **dim** (*Union[int, tuple(int), list(int), Tensor], optional*) –The dimensions to reduce. If `None` , all dimensions are reduced. Default `None` .
- **keepdim** (*bool, optional*) –Whether the output tensor has dim retained or not. Default `False` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[True, False], [True, True]])
>>>
>>> # case 1:  By default, mindspore.Tensor.all tests along all the axes.
>>> x.all()
Tensor(shape=[], dtype=Bool, value= False)
>>>
>>> # case 2: Reduces a dimension along dim 1, with keepdim False.
>>> x.all(dim=1)
Tensor(shape=[2], dtype=Bool, value= [False,  True])
>>>
>>> # case 3: Reduces a dimension along dim (0, 1), with keepdim False.
>>> x.all(dim=(0,1))
Tensor(shape=[], dtype=Bool, value= False)
>>>
>>> # case 4: Reduces a dimension along dim [0, 1], with keepdim True.
>>> x.all(dim=[0,1], keepdim=True)
Tensor(shape=[1, 1], dtype=Bool, value=
[[False]])
```

mindspore.Tensor.allclose

`Tensor.allclose`(*other*, *rtol=1e-05*, *atol=1e-08*, *equal_nan=False*) → *Tensor*

Returns a new Tensor with boolean elements representing if each element of *self* is "close" to the corresponding element of *other*. Closeness is defined as:

$$|self - other| <= atol + rtolx|other|$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **other** (Tensor) – Tensor to compare. Dtype must be same as *self*.
- **rtol** (*Union[float, int, bool], optional*) – Relative tolerance. Default: `1e-05` .
- **atol** (*Union[float, int, bool], optional*) – Absolute tolerance. Default: `1e-08` .
- **equal_nan** (*bool, optional*) – If `True` , then two NaNs will be considered equal. Default: `False`.

Returns

A bool Scalar.

Raises

- **TypeError** – *self* or *other* is not Tensor.
- **TypeError** – Data types of *self* and *other* are not in the list of supported types.
- **TypeError** – *atol* or *rtol* is not float, int or bool.
- **TypeError** – *equal_nan* is not bool.
- **TypeError** – *self* and *other* have different dtypes.
- **ValueError** – *self* and *other* cannot broadcast.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.array([1.3, 2.1, 3.2, 4.1, 5.1]), mindspore.float16)
>>> other = Tensor(np.array([1.3, 3.3, 2.3, 3.1, 5.1]), mindspore.float16)
>>> output = input.allclose(other)
>>> print(output)
False
```

mindspore.Tensor.amax

Tensor.**amax**(*axis=None*, *keepdims=False*, *, *initial=None*, *where=None*)
For details, please refer to *mindspore.ops.amax()*.

mindspore.Tensor.amin

Tensor.**amin**(*axis=None*, *keepdims=False*, *, *initial=None*, *where=None*)
For details, please refer to *mindspore.ops.amin()*.

mindspore.Tensor.aminmax

Tensor.**aminmax**(*, *axis=0*, *keepdims=False*)
For details, please refer to *mindspore.ops.aminmax()*.

mindspore.Tensor.any

Tensor.**any**(*axis=None*, *keep_dims=False*) → *Tensor*
Tests if any element in tensor evaluates to *True* along the given axes.

Parameters

- **axis** (*Union[int, tuple(int), list(int), Tensor], optional*) – The dimensions to reduce. If `None` , all dimensions are reduced. Default `None` .
- **keep_dims** (*bool, optional*) – Whether the output tensor has dim retained or not. Default `False` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[True, False], [True, True]])
>>>
>>> # case 1:  By default, mindspore.Tensor.any tests along all the axes.
>>> x.any()
Tensor(shape=[], dtype=Bool, value= True)
>>>
>>> # case 2: Reduces a dimension along axis 1, with keep_dims False.
>>> x.any(axis=1)
Tensor(shape=[2], dtype=Bool, value= [ True,  True])
>>>
>>> # case 3: Reduces a dimension along axis (0, 1), with keep_dims False.
>>> x.any(axis=(0,1))
Tensor(shape=[], dtype=Bool, value= True)
>>>
>>> # case 4: Reduces a dimension along axis [0, 1], with keep_dims True.
```

(continues on next page)

(continued from previous page)

```
>>> x.any(axis=[0,1], keep_dims=True)
Tensor(shape=[1, 1], dtype=Bool, value=
[[ True]])
```

`Tensor.`**`any`**(*dim=None*, *keepdim=False*) → *Tensor*

Tests if any element in tensor evaluates to *True* along the given axes.

Parameters

- **dim** (*Union[int, tuple(int), list(int), Tensor], optional*) –The dimensions to reduce. If `None` , all dimensions are reduced. Default `None` .
- **keepdim** (*bool, optional*) –Whether the output tensor has dim retained or not. Default `False` .

Returns

Tensor

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[True, False], [True, True]])
>>>
>>> # case 1:  By default, mindspore.Tensor.any tests along all the axes.
>>> x.any()
Tensor(shape=[], dtype=Bool, value= True)
>>>
>>> # case 2: Reduces a dimension along dim 1, with keepdim False.
>>> x.any(dim=1)
Tensor(shape=[2], dtype=Bool, value= [ True,  True])
>>>
>>> # case 3: Reduces a dimension along dim (0, 1), with keepdim False.
>>> x.any(dim=(0,1))
Tensor(shape=[], dtype=Bool, value= True)
>>>
>>> # case 4: Reduces a dimension along dim [0, 1], with keepdim True.
>>> x.any(dim=[0,1], keepdim=True)
Tensor(shape=[1, 1], dtype=Bool, value=
[[ True]])
```

mindspore.Tensor.angle

`Tensor.`**`angle`**()

For details, please refer to *mindspore.ops.angle()*.

mindspore.Tensor.approximate_equal

Tensor.**approximate_equal**(*other*, *tolerance=1e-5*)
For details, please refer to *mindspore.ops.approximate_equal()*, The parameter *other* of current interface is the same as the parameter *y* of the reference interface.

mindspore.Tensor.arccos

Tensor.**arccos**() → *Tensor*
Alias for *mindspore.Tensor.acos()*.

mindspore.Tensor.arccosh

Tensor.**arccosh**() → *Tensor*
Alias for *mindspore.Tensor.acosh()*.

mindspore.Tensor.arcsin

Tensor.**arcsin**() → *Tensor*
Alias for *mindspore.Tensor.asin()*.

mindspore.Tensor.arcsinh

Tensor.**arcsinh**() → *Tensor*
Alias for *mindspore.Tensor.asinh()*.

mindspore.Tensor.arctan

Tensor.**arctan**() → *Tensor*
Alias for *mindspore.Tensor.atan()*.

mindspore.Tensor.arctan2

Tensor.**arctan2**(*other*) → *Tensor*
Alias for *Tensor.atan2()*.

mindspore.Tensor.arctanh

Tensor.**arctanh**() → *Tensor*
Alias for *mindspore.Tensor.atanh()*.

mindspore.Tensor.argmax

Tensor.**argmax**(*axis=None*, *keepdims=False*) → *Tensor*

Return the indices of the maximum values along the given axis of the tensor.

Parameters

- **axis** (*Union[int, None], optional*) –Specify the axis for computation. If None , compute all elements in the tensor. Default None .
- **keepdims** (*bool, optional*) –Whether the output tensor has dim retained. Default False .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[9, 3, 4, 5],
...                       [5, 2, 7, 4],
...                       [8, 1, 3, 6]])
>>> # case 1: By default, compute the maximum of all elements.
>>> x.argmax()
Tensor(shape=[], dtype=Int64, value= 0)
>>>
>>> # case 2: Compute the maximum along axis 1.
>>> x.argmax(axis=1)
Tensor(shape=[3], dtype=Int64, value= [0, 2, 0])
>>>
>>> # case 3: If keepdims=True, the output shape will be same of that of the input.
>>> x.argmax(axis=1, keepdims=True)
Tensor(shape=[3, 1], dtype=Int64, value=
[[0],
 [2],
 [0]])
```

Tensor.**argmax**(*dim=None*, *keepdim=False*) → *Tensor*

Return the maximum values along the given dimension of the tensor.

Parameters

- **dim** (*Union[int, None], optional*) –Specify the dim for computation. If None , compute all elements in the tensor.
- **keepdim** (*bool, optional*) –Whether the output tensor has dim retained.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[9, 3, 4, 5],
...                       [5, 2, 7, 4],
...                       [8, 1, 3, 6]])
>>> # case 1: By default, compute the maximum of all elements.
>>> x.argmax()
Tensor(shape=[], dtype=Int64, value= 0)
>>>
>>> # case 2: Compute the maximum along dim 1.
>>> x.argmax(dim=1)
Tensor(shape=[3], dtype=Int64, value= [0, 2, 0])
>>>
>>> # case 3: If keepdim=True, the output shape will be same of that of the input.
>>> x.argmax(dim=1, keepdim=True)
Tensor(shape=[3, 1], dtype=Int64, value=
[[0],
 [2],
 [0]])
```

mindspore.Tensor.argmax_with_value

Tensor.**argmax_with_value**(*axis=0*, *keep_dims=False*)

Return the maximum values and their indices along the given axis of the tensor.

Parameters

- **axis** (*Union[int, None], optional*) – Specify the axis for computation. If `None` , compute all elements in the tensor. Default `0` .
- **keep_dims** (*bool, optional*) – Whether the output tensor has dim retained. Default `False` .

Returns

Tuple(max, max_indices) of 2 tensors.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[9, 3, 4, 5],
...                       [5, 2, 7, 4],
...                       [8, 1, 3, 6]])
>>> # case 1: By default, compute the maximum along axis 0.
>>> x.argmax_with_value()
(Tensor(shape=[4], dtype=Int64, value= [9, 3, 7, 6]),
 Tensor(shape=[4], dtype=Int64, value= [0, 0, 1, 2]))
>>>
>>> # case 2: Compute the maximum along axis 1.
>>> x.argmax_with_value(axis=1)
(Tensor(shape=[3], dtype=Int64, value= [9, 7, 8]),
 Tensor(shape=[3], dtype=Int64, value= [0, 2, 0]))
```

(continues on next page)

(continued from previous page)

```
>>>
>>> # case 3: If keep_dims=True, the output shape will be same of that of the input.
>>> x.argmax_with_value(axis=1, keep_dims=True)
(Tensor(shape=[3, 1], dtype=Int64, value=
 [[9],
  [7],
  [8]]),
 Tensor(shape=[3, 1], dtype=Int64, value=
 [[0],
  [2],
  [0]]))
>>>
>>> # case 4: If axis=None, compute the maximum of all elements.
>>> x.argmax_with_value(axis=None, keep_dims=True)
(Tensor(shape=[], dtype=Int64, value= 9),
 Tensor(shape=[], dtype=Int64, value= 0))
```

mindspore.Tensor.argmin

`Tensor.`**`argmin`**(*axis=None*, *keepdims=False*) → *Tensor*

Returns the indices of the minimum values along the given axis of the tensor.

Parameters

- **`axis`** (*`Union[int, None], optional`*) – Specify the axis for computation. If `None` , compute all elements in the tensor. Default `None` .
- **`keepdims`** (*`bool, optional`*) – Whether the output tensor has dim retained. Default `False` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[2, 5, 1, 6],
...                       [3, -7, -2, 4],
...                       [8, -4, 1, -3]])
>>> # case 1: By default, compute the minimum of all elements.
>>> x.argmin()
Tensor(shape=[], dtype=Int32, value= 5)
>>>
>>> # case 2: Compute the minimum along axis 1.
>>> x.argmin(axis=1)
Tensor(shape=[3], dtype=Int32, value= [2, 1, 1])
>>>
>>> # case 3: If keepdims=True, the output shape will be same of that of the input.
>>> x.argmin(axis=1, keepdims=True)
Tensor(shape=[3, 1], dtype=Int32, value=
[[2],
```

(continues on next page)

(continued from previous page)

```
 [1],
 [1]])
```

`Tensor.`**`argmin`**(*dim=None*, *keepdim=False*) → *Tensor*

Returns the indices of the minimum values along the given axis of the tensor.

Parameters

- **dim** (*Union[int, None], optional*) –Specify the axis for computation. If `None` , compute all elements in the tensor.
- **keepdim** (*bool, optional*) –Whether the output tensor has dim retained.

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[2, 5, 1, 6],
...                       [3, -7, -2, 4],
...                       [8, -4, 1, -3]])
>>> # case 1: By default, compute the minimum of all elements.
>>> x.argmin()
Tensor(shape=[], dtype=Int32, value= 5)
>>>
>>> # case 2: Compute the minimum along dim 1.
>>> x.argmin(dim=1)
Tensor(shape=[3], dtype=Int32, value= [2, 1, 1])
>>>
>>> # case 3: If keepdim=True, the output shape will be same of that of the input.
>>> x.argmin(dim=1, keepdim=True)
Tensor(shape=[3, 1], dtype=Int32, value=
[[2],
 [1],
 [1]])
```

mindspore.Tensor.argmin_with_value

`Tensor.`**`argmin_with_value`**(*axis=0*, *keep_dims=False*)

Return the minimum values and their indices along the given axis of the tensor.

Parameters

- **axis** (*Union[int, None], optional*) –Specify the axis for computation. If `None` , compute all elements in the tensor. Default `0` .
- **keep_dims** (*bool, optional*) –Whether the output tensor has dim retained. Default `False` .

Returns

Tuple(min, min_indices) of 2 tensors.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[2, 5, 1, 6],
...                       [3, -7, -2, 4],
...                       [8, -4, 1, -3]])
>>> # case 1: By default, compute the minimum along axis 0.
>>> x.argmin_with_value()
(Tensor(shape=[4], dtype=Int64, value= [ 2, -7, -2, -3]),
 Tensor(shape=[4], dtype=Int64, value= [0, 1, 1, 2]))
>>>
>>> # case 2: Compute the minimum along axis 1.
>>> x.argmin_with_value(axis=1)
(Tensor(shape=[3], dtype=Int64, value= [ 1, -7, -4]),
 Tensor(shape=[3], dtype=Int64, value= [2, 1, 1]))
>>>
>>> # case 3: If keep_dims=True, the output shape will be same of that of the input.
>>> x.argmin_with_value(axis=1, keep_dims=True)
(Tensor(shape=[3, 1], dtype=Int64, value=
 [[ 1],
  [-7],
  [-4]]),
 Tensor(shape=[3, 1], dtype=Int64, value=
 [[2],
  [1],
  [1]]))
>>>
>>> # case 4: If axis=None, compute the minimum of all elements.
>>> x.argmin_with_value(axis=None, keep_dims=True)
(Tensor(shape=[], dtype=Int64, value= -7),
 Tensor(shape=[], dtype=Int64, value= 0))
```

mindspore.Tensor.argsort

`Tensor.`**`argsort`**(*axis=- 1*, *descending=False*) → *Tensor*

Sorts *self* along the given dimension in specified order and return the sorted indices.

Parameters

- **`axis`** (*int, optional*) – The axis to sort along. Default: `-1` , means the last dimension. The Ascend backend only supports sorting the last dimension.
- **`descending`** (*bool, optional*) – The sort order. If *descending* is True then the elements are sorted in descending order by value. Otherwise sort in ascending order. Default: `False` .

Returns

Tensor, the indices of sorted *self*. Data type is int32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[8, 2, 1], [5, 9, 3], [4, 6, 7]]), mindspore.float16)
>>> sort = Tensor.argsort(x)  # x.argsort()
>>> print(sort)
[[2 1 0]
 [2 0 1]
 [0 1 2]]
```

Tensor.**argsort**(*dim=- 1*, *descending=False*, *stable=False*) → *Tensor*

Sorts *self* along the given dimension in specified order and return the sorted indices.

Warning: This is an experimental optimizer API that is subject to deletion or change.

Parameters

- **dim** (*int, optional*) –The dim to sort along. Default: `-1` , means the last dimension. The Ascend backend only supports sorting the last dimension.
- **descending** (*bool, optional*) –The sort order. If *descending* is `True` then the elements are sorted in descending order by value. Otherwise sort in ascending order. Default: `False` .
- **stable** (*bool, optional*) –Whether to use stable sorting algorithm. Default: `False`.

Returns

Tensor, the indices of sorted *self*. Data type is int64.

Raises

- **ValueError** –If *dim* is out of range.
- **TypeError** –If dtype of *dim* is not int32.
- **TypeError** –If dtype of *descending* is not bool.
- **TypeError** –If dtype of *stable* is not bool.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[8, 2, 1], [5, 9, 3], [4, 6, 7]]), mindspore.float16)
>>> sort = Tensor.argsort(x)  # x.argsort()
>>> print(sort)
[[2 1 0]
 [2 0 1]
 [0 1 2]]
```

mindspore.Tensor.argwhere

Tensor.**argwhere**()
For details, please refer to *mindspore.ops.argwhere()*.

mindspore.Tensor.asin

Tensor.**asin**() → *Tensor*
For details, please refer to *mindspore.ops.asin()*.

mindspore.Tensor.asinh

Tensor.**asinh**() → *Tensor*
For details, please refer to *mindspore.ops.asinh()*.

mindspore.Tensor.asnumpy

Tensor.**asnumpy**()
Convert tensor to numpy array. Returns self tensor as a NumPy ndarray. This tensor and the returned ndarray share the same underlying storage. Changes to self tensor will be reflected in the ndarray.

Returns

A numpy ndarray which shares the same underlying storage with the tensor.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([1, 2], dtype=np.float32))
>>> y = x.asnumpy()
>>> y[0] = 11
>>> print(x)
[11.  2.]
>>> print(y)
[11.  2.]
```

mindspore.Tensor.assign_value

Tensor.**assign_value**(*value*)
Assign another tensor value to this tensor.

Parameters

value (Tensor) – Tensor for assignment.

Returns

Tensor, Tensor that's been assigned.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor([1, 2, 3, 4])
>>> y = Tensor(np.array([[1, 2], [3, 4]]))
>>> output = x.assign_value(y)
>>> print(x)
[[1 2]
[3 4]]
```

mindspore.Tensor.astype

Tensor.**astype**(*dtype*, *copy=True*)

Return a copy of the tensor, cast to a specified type.

Parameters

- **dtype** (Union[*mindspore.dtype*, numpy.dtype, str]) –Designated tensor dtype, can be in format of *mindspore.dtype.float32* or *numpy.float32* or *float32*.
- **copy** (*bool, optional*) –By default, astype always returns a newly allocated tensor. If this is set to `false` , the input tensor is returned instead of a copy. Default: `True` .

Returns

Tensor, with the designated dtype.

Raises

TypeError –If the specified dtype cannot be understood.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.ones((1,2,2,1), dtype=np.float32))
>>> x = x.astype("int32")
>>> print(x.dtype)
Int32
```

mindspore.Tensor.atan

Tensor.**atan**() → *Tensor*

For details, please refer to *mindspore.ops.atan()*.

mindspore.Tensor.atan2

Tensor.**atan2**(*other*) → *Tensor*

For details, please refer to *mindspore.ops.atan2()*.

mindspore.Tensor.atanh

Tensor.**atanh**() → *Tensor*

For details, please refer to *mindspore.ops.atanh()*.

mindspore.Tensor.baddbmm

Tensor.**baddbmm**(*batch1*, *batch2*, *, *beta=1*, *alpha=1*) → *Tensor*

For details, please refer to *mindspore.ops.baddbmm()*.

mindspore.Tensor.bernoulli

Tensor.**bernoulli**(*, *generator=None*)

For details, please refer to *mindspore.mint.bernoulli()*.

mindspore.Tensor.bfloat16

Tensor.**bfloat16**()

Converts input tensor dtype to *bfloat16*.

Returns

Tensor, converted to the *bfloat16* dtype.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> input_x = Tensor(np.ones([2,2]), mindspore.int32)
>>> output = input_x.bfloat16()
>>> print(output.dtype)
BFloat16
```

mindspore.Tensor.bincount

Tensor.**bincount**(*weights=None*, *minlength=0*) → *Tensor*

For details, please refer to *mindspore.ops.bincount()*.

mindspore.Tensor.bitwise_and

Tensor.**bitwise_and**(*other*) → *Tensor*

Returns bitwise *and* of two tensors element-wise.

Note: *self* and *other* comply with the type conversion rules to make the data types consistent.

Parameters

other (Tensor, *Number.number*) – The shape is the same as the *self* or can be broadcast to the shape of *self*.

Returns

Tensor, has the same type as the *self* and has the same shape as after broadcasting.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.array([0, 0, 1, -1, 1, 1, 1]), mindspore.int16)
>>> other = Tensor(np.array([0, 1, 1, -1, -1, 2, 3]), mindspore.int16)
>>> output = input.bitwise_and(other)
>>> print(output)
[ 0  0  1 -1  1  0  1]
```

mindspore.Tensor.bitwise_not

Tensor.**bitwise_not**() → *Tensor*

Returns bitwise *not* of *self*.

Warning: This is an experimental API that is subject to change or deletion.

Returns

Tensor, has the same shape and type as *self*.

Raises

- **TypeError** – If *self* is not a Tensor.
- **RuntimeError** – If dtype of *self* is not int or bool.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.array([True, False, True, False]))
>>> output = input.bitwise_not()
>>> print(output)
[False True False True]
```

mindspore.Tensor.bitwise_left_shift

Tensor.**bitwise_left_shift**(*other*)

For details, please refer to *mindspore.ops.bitwise_left_shift()*.

mindspore.Tensor.bitwise_or

Tensor.**bitwise_or**(*other*) → *Tensor*

Returns bitwise *or* of two tensors element-wise.

Note: *self* and *other* comply with the type conversion rules to make the data types consistent.

Parameters

other (Tensor, *Number.number*) – The shape is the same as the *self* or can be broadcast to the shape of *self*.

Returns

Tensor, has the same type as the *self* and has the same shape as after broadcasting.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.array([0, 0, 1, -1, 1, 1, 1]), mindspore.int16)
>>> other = Tensor(np.array([0, 1, 1, -1, -1, 2, 3]), mindspore.int16)
>>> output = input.bitwise_or(other)
>>> print(output)
[ 0  1  1 -1 -1  3  3]
```

mindspore.Tensor.bitwise_right_shift

Tensor.**bitwise_right_shift**(*other*)
For details, please refer to *mindspore.ops.bitwise_right_shift()*.

mindspore.Tensor.bitwise_xor

Tensor.**bitwise_xor**(*other*) → *Tensor*
Returns bitwise *xor* of two tensors element-wise.

Note: *self* and *other* comply with the type conversion rules to make the data types consistent.

Parameters

other (Tensor, *Number.number*) – The shape is the same as the *self* or can be broadcast to the shape of *self*.

Returns

Tensor, has the same type as the *self* and has the same shape as after broadcasting.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.array([0, 0, 1, -1, 1, 1, 1]), mindspore.int16)
>>> other = Tensor(np.array([0, 1, 1, -1, -1, 2, 3]), mindspore.int16)
>>> output = input.bitwise_xor(other)
>>> print(output)
[ 0  1  0  0 -2  3  2]
```

mindspore.Tensor.bmm

Tensor.**bmm**(*mat2*)
For details, please refer to *mindspore.ops.bmm()*.

mindspore.Tensor.bool

Tensor.**bool**()
Converts input tensor dtype to *bool*. If the value in tensor is zero, it will be *False*, otherwise it will be *True*.

Returns

Tensor, converted to the *bool* dtype.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> input_x = Tensor(np.ones([2,2]), mindspore.float32)
>>> output = input_x.bool()
>>> print(output.dtype)
Bool
```

mindspore.Tensor.broadcast_to

Tensor.**broadcast_to**(*shape*)

For details, please refer to *mindspore.ops.broadcast_to()*.

mindspore.Tensor.byte

Tensor.**byte**()

Converts input tensor dtype to *uint8*.

Returns

Tensor, converted to the *uint8* dtype.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> input_x = Tensor(np.ones([2,2]), mindspore.float32)
>>> output = input_x.byte()
>>> print(output.dtype)
UInt8
```

mindspore.Tensor.cauchy

Tensor.**cauchy**(*median=0.0*, *sigma=1.0*)

Fills the tensor with numbers drawn from the Cauchy distribution. It is defined as follows:

$$f(x) = \frac{1}{\pi} \frac{\sigma}{(x - median)^2 + \sigma^2}$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **median** (*float, optional*) – the location parameter, specifying the location of the peak of the distribution. Default: 0.0.
- **sigma** (*float, optional*) – the scale parameter which specifies the half-width at half-maximum. Default: 1.0.

Returns

Tensor. A Tensor with the same type and shape of input.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> x = mindspore.Tensor(np.zeros((1, 2)), dtype=mindspore.float32)
>>> x.cauchy()
Tensor(shape=[1, 2], dtype=Float32, value=
[[8.79836142e-01, 9.37541723e-01]])
```

mindspore.Tensor.ceil

`Tensor.ceil()` → *Tensor*

For details, please refer to *mindspore.ops.ceil()*.

mindspore.Tensor.cholesky

`Tensor.cholesky`(*upper=False*)

For details, please refer to *mindspore.ops.cholesky()*.

mindspore.Tensor.cholesky_solve

`Tensor.cholesky_solve`(*input2*, *upper=False*)

For details, please refer to *mindspore.ops.cholesky_solve()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

mindspore.Tensor.choose

`Tensor.choose`(*choices*, *mode='clip'*)

Construct a tensor from an index tensor and a list of tensors to choose from.

Parameters

- **choices** (*Union[tuple, list, Tensor]*) – Choice tensors. The input tensor and all of the *choices* must be broadcasted to the same shape. If *choices* is itself a tensor, then its outermost dimension (i.e., the one corresponding to `choices.shape[0]`) is taken as defining the "sequence".

- **mode** (*str, optional*) –Specifies how indices outside `[0, n-1]` will be treated. Support `'raise'`, `'wrap'`, `'clip'`.
  - `raise`: Raises an error;
  - `wrap`: Wraps around;
  - `clip`: Clips to the range. The values greater than n-1 will be mapped to n-1. Note that this mode disables indexing with negative numbers.

  Default: `'clip'`.

Returns

Tensor, the merged result.

Raises

ValueError –If the input tensor and any of the *choices* cannot be broadcast.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> choices = [[0, 1, 2, 3], [10, 11, 12, 13], [20, 21, 22, 23], [30, 31, 32, 33]]
>>> x = Tensor(np.array([2, 3, 1, 0]))
>>> print(x.choose(choices))
[20 31 12  3]
```

mindspore.Tensor.chunk

`Tensor.`**chunk**(*chunks*, *dim=0*) → Tuple of Tensors

Cut the self Tensor into *chunks* sub-tensors along the specified dimension.

Note: The number of sub-tensors returned by this function may be less than the number of sub-tensors specified by *chunks*.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **chunks** (*int*) –Number of sub-tensors to cut.
- **dim** (*int, optional*) –Specify the dimensions that you want to split. Default: `0` .

Returns

A tuple of sub-tensors.

Raises

- **TypeError** –The sum of *chunks* is not int.
- **TypeError** –If argument *dim* is not int.

- **ValueError** –If argument *dim* is out of range of $[-self.ndim, self.ndim)$.
- **ValueError** –If argument *chunks* is not positive number.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> input_x = Tensor(np.arange(9).astype("float32"))
>>> output = input_x.chunk(3, dim=0)
>>> print(output)
(Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  1.00000000e+00,  2.
↪00000000e+00]),
    Tensor(shape=[3], dtype=Float32, value= [ 3.00000000e+00,  4.00000000e+00,  5.
↪00000000e+00]),
    Tensor(shape=[3], dtype=Float32, value= [ 6.00000000e+00,  7.00000000e+00,  8.
↪00000000e+00]))
```

`Tensor.`**`chunk`**(*chunks*, *axis=0*) → Tuple of Tensors

Cut the self Tensor into *chunks* sub-tensors along the specified axis.

Note: This function may return less than the specified number of chunks!

Parameters

- **chunks** (*int*) –Number of sub-tensors to cut.
- **axis** (*int, optional*) –Specify the dimensions that you want to split. Default: `0` .

Returns

A tuple of sub-tensors.

Raises

- **TypeError** –The sum of *chunks* is not int.
- **TypeError** –If argument *axis* is not int.
- **ValueError** –If argument *axis* is out of range of $[-self.ndim, self.ndim)$.
- **ValueError** –If argument *chunks* is not positive number.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> input_x = Tensor(np.arange(9).astype("float32"))
>>> output = input_x.chunk(3, axis=0)
>>> print(output)
(Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  1.00000000e+00,  2.
↪00000000e+00]),
    Tensor(shape=[3], dtype=Float32, value= [ 3.00000000e+00,  4.00000000e+00,  5.
↪00000000e+00]),
    Tensor(shape=[3], dtype=Float32, value= [ 6.00000000e+00,  7.00000000e+00,  8.
↪00000000e+00]))
```

mindspore.Tensor.clamp

Tensor.**clamp**(*min=None*, *max=None*) → *Tensor*

For details, please refer to *mindspore.ops.clamp()*.

mindspore.Tensor.clamp_

Tensor.**clamp_**(*min=None*, *max=None*)

In-place version of *mindspore.Tensor.clamp()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

mindspore.Tensor.clip

Tensor.**clip**(*min=None*, *max=None*) → *Tensor*

Alias for *mindspore.Tensor.clamp()*.

mindspore.Tensor.clone

Tensor.**clone**() → *Tensor*

Returns a copy of self.

> **Warning:** This is an experimental API that is subject to change or deletion.

Note: This function is differentiable, and gradients will flow back directly from the calculation result of the function to the *self*.

Returns

Tensor, with the same data, shape and type as *self*.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.ones((3,3)).astype("float32"))
>>> output = input.clone()
>>> print(output)
[[1. 1. 1.]
 [1. 1. 1.]
 [1. 1. 1.]]
```

mindspore.Tensor.col2im

Tensor.**col2im**(*output_size*, *kernel_size*, *dilation*, *padding_value*, *stride*)

For details, please refer to *mindspore.ops.col2im()*.

mindspore.Tensor.conj

Tensor.**conj**()

For details, please refer to *mindspore.ops.conj()*.

mindspore.Tensor.contiguous

Tensor.**contiguous**()

Converts a Tensor into a continuous-memory Tensor that contains the same data as the original Tensor.

Returns

A contiguous in memory tensor containing the same data as self tensor.

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor([[1, 2, 3], [4, 5, 6]], dtype=ms.float32)
>>> y = ops.transpose(x, (1, 0))
>>> z = y.contiguous()
>>> print(z.is_contiguous())
True
```

mindspore.Tensor.copy

Tensor.**copy**()
Return a copy of the tensor.

Note: The current implementation does not support *order* argument.

Returns

Copied tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> a = Tensor(np.ones((3,3)).astype("float32"))
>>> output = a.copy()
>>> print(output)
[[1. 1. 1.]
[1. 1. 1.]
[1. 1. 1.]]
```

mindspore.Tensor.copy_

Tensor.**copy_**(*src*, *non_blocking=False*) → *Tensor*
Copies the elements from *src* into *self* tensor and returns *self*.

Warning: This is an experimental API that is subject to change or deletion. The *src* tensor must be broadcastable with the *self* tensor. It may be of a different data type.

Parameters

- **src** (Tensor) – the source tensor to copy from.
- **non_blocking** (*bool, optional*) – no effect currently. Default: False.

Returns

Return self Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> a = Tensor(np.ones((3, 3)).astype("float32"))
>>> b = Tensor(np.zeros((3, 3)).astype("float32"))
>>> a.copy_(b)
>>> print(a)
[[0. 0. 0.]
 [0. 0. 0.]
 [0. 0. 0.]]
```

mindspore.Tensor.copysign

Tensor.**copysign**(*other*)

For details, please refer to *mindspore.ops.copysign()*.

mindspore.Tensor.cos

Tensor.**cos**() → *Tensor*

For details, please refer to *mindspore.ops.cos()*.

mindspore.Tensor.cosh

Tensor.**cosh**() → *Tensor*

For details, please refer to *mindspore.ops.cosh()*.

mindspore.Tensor.count_nonzero

Tensor.**count_nonzero**(*dim=None*) → *Tensor*

Counts the number of non-zero values in the tensor input along the given dim. If no dim is specified then all non-zeros in the tensor are counted.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

dim (*Union[None, int, tuple(int), list(int)], optional*) – The dimension to reduce. Default value: None, which indicates that the number of non-zero elements is calculated. If *dim* is None, all elements in the tensor are summed up.

Returns

Tensor, number of nonzero element across dim specified by *dim*.

Raises

- **TypeError** – If *dim* is not int, tuple(int), list(int) or None.
- **ValueError** – If any value in *dim* is not in range $[-self.ndim, self.ndim)$.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> import mindspore
>>> # case 1: each value specified.
>>> x = Tensor(np.array([[0, 1, 0], [1, 1, 0]]).astype(np.float32))
>>> nonzero_num = x.count_nonzero(dim=[0, 1])
>>> print(nonzero_num)
[[3]]
>>> # case 2: all value is default.
>>> nonzero_num = x.count_nonzero()
>>> print(nonzero_num)
3
>>> # case 3: dim value was specified 0.
>>> nonzero_num = x.count_nonzero(dim=[0,])
>>> print(nonzero_num)
[1 2 0]
>>> # case 4: dim value was specified 1.
>>> nonzero_num = x.count_nonzero(dim=[1,])
>>> print(nonzero_num)
[1 2]
```

`Tensor.`**`count_nonzero`**(*axis=()*, *keep_dims=False*, *dtype=None*) → *Tensor*

Count number of nonzero elements across axis of input tensor.

Parameters

- **`axis`** (*`Union[int, tuple(int), list(int)], optional`*) – The dimensions to reduce. Default: `()`, reduce all dimensions.
- **`keep_dims`** (*`bool, optional`*) – Whether to maintain dimensions specified by *axis*. If true, keep these reduced dimensions and the length is 1. If false, don't keep these dimensions. Default: `False`.
- **`dtype`** (*`Union[Number, mindspore.bool_], optional`*) – The data type of the output tensor. Default: `None`.

Returns

Tensor, number of nonzero element across axis specified by *axis*. The data type is specified by *dtype*.

Raises

- **`TypeError`** – If *axis* is not int, tuple or list.
- **`ValueError`** – If any value in *axis* is not in range $[-self.ndim, self.ndim)$.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> import mindspore
>>> # case 1: each value specified.
>>> x = Tensor(np.array([[0, 1, 0], [1, 1, 0]]).astype(np.float32))
>>> nonzero_num = x.count_nonzero(x=x, axis=[0, 1], keep_dims=True, dtype=mindspore.int32)
>>> print(nonzero_num)
[[3]]
>>> # case 2: all value is default.
>>> nonzero_num = x.count_nonzero()
>>> print(nonzero_num)
3
>>> # case 3: axis value was specified 0.
>>> nonzero_num = x.count_nonzero(axis=[0,])
>>> print(nonzero_num)
[1 2 0]
>>> # case 4: axis value was specified 1.
>>> nonzero_num = x.count_nonzero(axis=[1,])
>>> print(nonzero_num)
[1 2]
>>> # case 5: keep_dims value was specified.
>>> nonzero_num = x.count_nonzero(keep_dims=True)
>>> print(nonzero_num)
[[3]]
>>> # case 6: keep_dims and axis value was specified.
>>> nonzero_num = x.count_nonzero(axis=[0,], keep_dims=True)
>>> print(nonzero_num)
[[1 2 0]]
```

mindspore.Tensor.cov

Tensor.**cov**(*, *correction=1*, *fweights=None*, *aweights=None*)

For details, please refer to *mindspore.ops.cov()*.

mindspore.Tensor.cross

Tensor.**cross**(*other*, *dim=None*)

For details, please refer to *mindspore.ops.cross()*.

mindspore.Tensor.cummax

Tensor.**cummax**(*axis*)

For details, please refer to *mindspore.ops.cummax()*.

mindspore.Tensor.cummin

Tensor.**cummin**(*axis*)
For details, please refer to *mindspore.ops.cummin()*.

mindspore.Tensor.cumprod

Tensor.**cumprod**(*dim*, *dtype=None*)
For details, please refer to *mindspore.ops.cumprod()*.

mindspore.Tensor.cumsum

Tensor.**cumsum**(*dim*, *, *dtype=None*) → *Tensor*
Computes the cumulative sum of self Tensor along *dim*.

$$y_i = x_1 + x_2 + x_3 + ... + x_i$$

Parameters

dim (*int*) −Dim along which the cumulative sum is computed.

Keyword Arguments

dtype (*mindspore.dtype*, optional) −The desired dtype of returned Tensor. If specified, the self Tensor will be cast to *dtype* before the computation. This is useful for preventing overflows. If not specified, stay the same as original Tensor. Default: None .

Returns

Tensor, the shape of the output Tensor is consistent with the self Tensor's.

Raises

ValueError −If the *dim* is out of range.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[3, 4, 6, 10], [1, 6, 7, 9], [4, 3, 8, 7], [1, 3, 7, 9]]).astype(np.
↪float32))
>>> # case 1: along the dim 0
>>> y = x.cumsum(dim=0)
>>> print(y)
[[ 3.  4.  6. 10.]
 [ 4. 10. 13. 19.]
 [ 8. 13. 21. 26.]
 [ 9. 16. 28. 35.]]
>>> # case 2: along the dim 1
>>> y = x.cumsum(dim=1)
>>> print(y)
```

(continues on next page)

(continued from previous page)

```
[[ 3.  7. 13. 23.]
 [ 1.  7. 14. 23.]
 [ 4.  7. 15. 22.]
 [ 1.  4. 11. 20.]]
```

`Tensor.`**`cumsum`**(*axis=None*, *dtype=None*) → *Tensor*

Computes the cumulative sum of self Tensor along *axis*.

$$y_i = x_1 + x_2 + x_3 + ... + x_i$$

Note: On Ascend, the dtype of *self* only supports :int8, uint8, int32, float16 or float32 in case of static shape. For the case of dynamic shape, the dtype of *self* only supports int32, float16 or float32.

Parameters

- **`axis`** (*int*) −Axis along which the cumulative sum is computed.
- **`dtype`** (*mindspore.dtype*, optional) −The desired dtype of returned Tensor. If specified, the self Tensor will be cast to *dtype* before the computation. This is useful for preventing overflows. If not specified, stay the same as original Tensor. Default: `None` .

Returns

Tensor, the shape of the output Tensor is consistent with the self Tensor's.

Raises

`ValueError` −If the axis is out of range.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[3, 4, 6, 10], [1, 6, 7, 9], [4, 3, 8, 7], [1, 3, 7, 9]]).astype(np.
↪float32))
>>> # case 1: along the axis 0
>>> y = x.cumsum(axis=0)
>>> print(y)
[[ 3.  4.  6. 10.]
 [ 4. 10. 13. 19.]
 [ 8. 13. 21. 26.]
 [ 9. 16. 28. 35.]]
>>> # case 2: along the axis 1
>>> y = x.cumsum(axis=1)
>>> print(y)
[[ 3.  7. 13. 23.]
 [ 1.  7. 14. 23.]
 [ 4.  7. 15. 22.]
 [ 1.  4. 11. 20.]]
```

mindspore.Tensor.deg2rad

Tensor.**deg2rad**()
For details, please refer to *mindspore.ops.deg2rad()*.

mindspore.Tensor.diag

Tensor.**diag**() → *Tensor*
For details, please refer to *mindspore.ops.diag()*.

Tensor.**diag**(*diagonal=0*) → *Tensor*

If input is a vector (1-D tensor), then returns a 2-D square tensor with the elements of input as the diagonal.

If input is a matrix (2-D tensor), then returns a 1-D tensor with the diagonal elements of input.

The argument diagonal controls which diagonal to consider:

- If *diagonal* = 0, it is the main diagonal.
- If *diagonal* > 0, it is above the main diagonal.
- If *diagonal* < 0, it is below the main diagonal.

Warning:

- This is an experimental API that is subject to change or deletion.
- The graph mode and CPU/GPU backends do not support non-zero values for the diagonal parameter.

Parameters

diagonal (*int, optional*) – the diagonal to consider. Default: 0.

Returns

- If *input* shape is (x_0): then output shape is $(x_0 + |diagonal|, x_0 + |diagonal|)$ 2-D Tensor.
- If *input* shape is (x_0, x_1): then output shape is main diagonal to move $(|diagonal|)$ elements remains elements' length 1-D Tensor.

Return type

Tensor, has the same dtype as the *input*, its shape is up to *diagonal*

Raises

ValueError – If shape of *input* is not 1-D and 2-D.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import Tensor
>>> input = Tensor([1, 2, 3, 4]).astype('int32')
>>> output = input.diag()
>>> print(output)
[[1 0 0 0]
 [0 2 0 0]
 [0 0 3 0]
 [0 0 0 4]]
```

mindspore.Tensor.diagflat

Tensor.**diagflat**(*offset=0*)
For details, please refer to *mindspore.ops.diagflat()*.

mindspore.Tensor.diagonal

Tensor.**diagonal**(*offset=0*, *axis1=0*, *axis2=1*)
For details, please refer to *mindspore.ops.diagonal()*. The parameter *axis1* of the current interface is the same as the parameter *dim1* of the reference interface, the parameter *axis2* of the current interface is the same as the parameter *dim2* of the reference interface.

mindspore.Tensor.diagonal_scatter

Tensor.**diagonal_scatter**(*src*, *offset=0*, *dim1=0*, *dim2=1*)
For details, please refer to *mindspore.ops.diagonal_scatter()*.

mindspore.Tensor.diff

Tensor.**diff**(*n=1*, *axis=- 1*, *prepend=None*, *append=None*)
For details, please refer to *mindspore.ops.diff()*.

mindspore.Tensor.digamma

Tensor.**digamma**()
For details, please refer to *mindspore.ops.digamma()*.

mindspore.Tensor.div

Tensor.**div**(*other*, *, *rounding_mode=None*) → *Tensor*
For details, please refer to *mindspore.ops.div()*.

mindspore.Tensor.div_

Tensor.**div_**(*other*, *, *rounding_mode=None*) → *Tensor*

In-place version of *mindspore.Tensor.div()*.

mindspore.Tensor.divide

Tensor.**divide**(*other*, *, *rounding_mode=None*) → *Tensor*

Alias for *mindspore.Tensor.div()*.

mindspore.Tensor.dot

Tensor.**dot**(*other*) → *Tensor*

Computes the dot product of two 1D tensor.

Parameters

other (Tensor) – The input in the dot product, must be 1D.

Returns

Tensor, the shape is [] and the data type is same as *self*.

Raises

- **TypeError** – If *other* is not tensor.
- **RuntimeError** – If dtypes of *self* and *other* are not same.
- **RuntimeError** – If shapes of *self* and *other* are not same.
- **RuntimeError** – If shapes of *self* and *other* are not 1D.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> input = Tensor([2.0, 3.0], mindspore.float32)
>>> other = Tensor([2.0, 1.0], mindspore.float32)
>>> output = Tensor.dot(input, other)  # input.dot(other)
>>> print(output)
[7.        ]
>>> print(output.dtype)
Float32
```

mindspore.Tensor.double

Tensor.**double**()

Converts input tensor dtype to *float64*.

Returns

Tensor, converted to the *float64* dtype.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> input_x = Tensor(np.ones([2,2]), mindspore.int32)
>>> output = input_x.double()
>>> print(output.dtype)
Float64
```

mindspore.Tensor.dsplit

Tensor.**dsplit**(*indices_or_sections*)

For details, please refer to *mindspore.ops.dsplit()*.

mindspore.Tensor.dtype

property Tensor.**dtype**

Return the dtype of the tensor (*mindspore.dtype*).

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([1, 2], dtype=np.float32))
>>> print(x.dtype)
Float32
```

mindspore.Tensor.eigvals

Tensor.**eigvals**()
For details, please refer to *mindspore.ops.eigvals()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

mindspore.Tensor.eq

Tensor.**eq**(*other*) → *Tensor*
For details, please refer to *mindspore.ops.eq()*.

mindspore.Tensor.equal

Tensor.**equal**(*other*)
For details, please refer to *mindspore.ops.equal()*.

mindspore.Tensor.erf

Tensor.**erf**() → *Tensor*
For details, please refer to *mindspore.ops.erf()*.

mindspore.Tensor.erfc

Tensor.**erfc**() → *Tensor*
For details, please refer to *mindspore.ops.erfc()*.

mindspore.Tensor.erfinv

Tensor.**erfinv**()
For details, please refer to *mindspore.ops.erfinv()*.

mindspore.Tensor.exp

Tensor.**exp**() → *Tensor*
For details, please refer to *mindspore.ops.exp()*.

mindspore.Tensor.exp_

Tensor.**exp_**() → *Tensor*

Inplace version of *mindspore.Tensor.exp()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

mindspore.Tensor.expand

Tensor.**expand**(*size*)

For details, please refer to *mindspore.ops.broadcast_to()*. The parameter *size* of the current interface is the same as the parameter *shape* of the reference interface.

mindspore.Tensor.expand_as

Tensor.**expand_as**(*other*) → *Tensor*

Expand the shape of the input tensor to be the same as the another input tensor. The dim of the input shape must be smaller than or equal to that of another and the broadcast rules must be met.

Parameters

other (Tensor) –The target Tensor. It's shape is the target shape that input tensor need to be expanded.

Returns

Tensor, with the given shape of *other* and the same data type as *self*.

Raises

- **TypeError** –If *other* is not a tensor.
- **ValueError** –If the shapes of *other* and *self* are incompatible.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[1, 2, 3], [1, 2, 3]]).astype(np.float32))
>>> other = Tensor(np.array([[1, 1, 1], [1, 1, 1]]).astype(np.float32))
>>> output = x.expand_as(other)
>>> print(output)
[[1. 2. 3.]
 [1. 2. 3.]]
```

Tensor.**expand_as**(*x*) → *Tensor*

Expand the dimension of input tensor to the dimension of target tensor.

Parameters

x (Tensor) –The target tensor. The shape of the target tensor must obey the broadcasting rule.

Returns

Tensor, has the same dimension as target tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import dtype as mstype
>>> input = Tensor([1, 2, 3], dtype=mstype.float32)
>>> x = Tensor(np.ones((2, 3)), dtype=mstype.float32)
>>> output = input.expand_as(x=x)
>>> print(output)
[[1. 2. 3.]
 [1. 2. 3.]]
```

mindspore.Tensor.expand_dims

`Tensor.`**`expand_dims`**(*axis*)
For details, please refer to *mindspore.ops.expand_dims()*.

mindspore.Tensor.expm1

`Tensor.`**`expm1`**`()` → *Tensor*
For details, please refer to *mindspore.ops.expm1()*.

mindspore.Tensor.exponential_

`Tensor.`**`exponential_`**(*lambd=1*, *, *generator=None*)
Fills *self* tensor with elements drawn from the exponential distribution:

$$f(x) = \lambda \exp(-\lambda x)$$

Warning:

- It is only supported on Atlas A2 Training Series Products.
- This is an experimental API that is subject to change or deletion.

Parameters

`lambd` (*float, optional*) – Parameters of exponential distribution. Default: `1`.

Keyword Arguments

`generator` (*Generator, optional*) – a pseudorandom number generator. Default: `None` .

Returns

Tensor, with same shape and same data type with input.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> x = mindspore.Tensor([1, 2, 3.0])
>>> out = x.exponential_(2)
>>> print(out.shape)
(3,)
```

mindspore.Tensor.fill_

`Tensor.`**`fill_`**`(`*value*`)` → *Tensor*

Fills *self* tensor with the specified *value* .

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

value (*Union[Tensor, number.Number, bool]*) −Value to fill the *self* .

Returns

Tensor.

Raises

- **RunTimeError** −The data type of *self* or *value* is not supported.
- **RunTimeError** −When the *value* is Tensor, it should be 0-D Tensor or 1-D Tensor with shape=[1].

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import ops
>>> x = ops.zeros((3, 3))
>>> print(x)
[[0. 0. 0.]
 [0. 0. 0.]
 [0. 0. 0.]]
>>> output = x.fill_(1.0)
>>> print(output)
[[1. 1. 1.]
 [1. 1. 1.]
 [1. 1. 1.]]
```

(continues on next page)

(continued from previous page)

```
>>> print(x)
[[1. 1. 1.]
 [1. 1. 1.]
 [1. 1. 1.]]
```

mindspore.Tensor.fill_diagonal

Tensor.**fill_diagonal**(*fill_value*, *wrap=False*)

Fills the main diagonal of a Tensor with a specified value and returns the result. The input has at least 2 dimensions, and all dimensions of input must be equal in length when the dimension of input is greater than 2.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **fill_value** (*float*) –The value to fill with the diagonal of *self*.
- **wrap** (*bool, optional*) –Controls whether the diagonal elements continue onto the remaining rows in case of a tall matrix(a matrix has more rows than columns). Default: False.

Returns

- **y** (Tensor) - Tensor, has the same shape and data type as *self*.

Raises

- **TypeError** –If data type of *self* is not one of the following: float32, int32, int64.
- **ValueError** –If the dimension of *self* is not greater than 1.
- **ValueError** –If the size of each dimension is not equal, when the dimension is greater than 2.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor(np.ones((6, 3)), mindspore.float32)
>>> output = x.fill_diagonal(5.0, wrap=True)
>>> print(output)
[[5. 1. 1.]
 [1. 5. 1.]
 [1. 1. 5.]
 [1. 1. 1.]
 [5. 1. 1.]
 [1. 5. 1.]]
```

mindspore.Tensor.flatten

Tensor.**flatten**(*start_dim=0*, *end_dim=- 1*) → *Tensor*

Flatten a tensor along dimensions from *start_dim* to *end_dim*.

Parameters

- **start_dim** (*int, optional*) – The first dimension to flatten. Default: `0` .
- **end_dim** (*int, optional*) – The last dimension to flatten. Default: `-1` .

Returns

Tensor. If no dimensions are flattened, returns the original *self*, otherwise return the flattened Tensor. If *self* is a 0-dimensional Tensor, a 1-dimensional Tensor will be returned.

Raises

- **TypeError** – If *start_dim* or *end_dim* is not int.
- **ValueError** – If *start_dim* is greater than *end_dim* after canonicalized.
- **ValueError** – If *start_dim* or *end_dim* is not in range of [-self.dim, self.dim-1].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input_x = Tensor(np.ones(shape=[1, 2, 3, 4]), mindspore.float32)
>>> output = input_x.flatten(0, -1)
>>> print(output.shape)
(24,)
```

Tensor.**flatten**(*order='C'*, ***, *start_dim=0*, *end_dim=- 1*) → *Tensor*

Flatten a tensor along dimensions from *start_dim* to *start_dim*.

Parameters

order (*str, optional*) – Only `'C'` and `'F'` are supported. `'C'` means to flatten in row-major (C-style) order. `'F'` means to flatten in column-major (Fortran-style) order. Default: `'C'` .

Keyword Arguments

- **start_dim** (*int, optional*) – The first dimension to flatten. Default: `0` .
- **end_dim** (*int, optional*) – The last dimension to flatten. Default: `-1` .

Returns

Tensor. If no dimensions are flattened, returns the original *self*, otherwise return the flattened Tensor. If *self* is a 0-dimensional Tensor, a 1-dimensional Tensor will be returned.

Raises

- **TypeError** – If *order* is not string type.
- **ValueError** – If *order* is string type, but not `'C'` or `'F'`.

- **TypeError** – If *start_dim* or *end_dim* is not int.
- **ValueError** – If *start_dim* is greater than *end_dim* after canonicalized.
- **ValueError** – If *start_dim* or *end_dim* is not in range of [-self.dim, self.dim-1].

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input_x = Tensor(np.ones(shape=[1, 2, 3, 4]), mindspore.float32)
>>> output = input_x.flatten(order='C')
>>> print(output.shape)
(24,)
```

mindspore.Tensor.flip

Tensor.**flip**(*dims*)

For details, please refer to *mindspore.ops.flip()*.

mindspore.Tensor.fliplr

Tensor.**fliplr**()

For details, please refer to *mindspore.ops.fliplr()*.

mindspore.Tensor.flipud

Tensor.**flipud**()

For details, please refer to *mindspore.ops.flipud()*.

mindspore.Tensor.float

Tensor.**float**()

Converts input tensor dtype to *float32*.

Returns

Tensor, converted to the *float32* dtype.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> input_x = Tensor(np.ones([2,2]), mindspore.int32)
>>> output = input_x.float()
>>> print(output.dtype)
Float32
```

mindspore.Tensor.float_power

Tensor.**float_power**(*other*)

For details, please refer to *mindspore.ops.float_power()*.

mindspore.Tensor.floor

Tensor.**floor**() → *Tensor*

For details, please refer to *mindspore.ops.floor()*.

mindspore.Tensor.floor_

Tensor.**floor_**()

In-place version of *mindspore.Tensor.floor()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

mindspore.Tensor.floor_divide

Tensor.**floor_divide**(*other*) → *Tensor*

Divides the self tensor by the other input tensor element-wise and round down to the closest integer.

self and *other* comply with the implicit type conversion rules to make the data types consistent. Inputs must be two tensors or one tensor and one scalar. When the *self* and *other* are two tensors, dtypes of them cannot be bool at the same time, and the shapes of them could be broadcast. When the *self* and *other* are one tensor and one scalar, the scalar could only be a constant.

$$out_i = \text{floor}(\frac{self_i}{other_i})$$

where the $floor$ indicates the Floor operator. For more details, please refer to the *mindspore.mint.floor* operator.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

other (*Union[Tensor, Number, bool]*) – The other input is a number or a bool or a tensor whose data type is number or bool.

Returns

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision or higher digits between *self* and *other*.

Raises

TypeError – If *self* and *other* are not the following: Tensor, number.Number or bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> import numpy as np
>>> input = Tensor(np.array([2, 4, -1]), mindspore.int32)
>>> other = Tensor(np.array([3, 3, 3]), mindspore.int32)
>>> output = input.floor_divide(other)
>>> print(output)
[ 0  1 -1]
>>> input = Tensor(2.0, mindspore.float32)
>>> other = Tensor(2.0, mindspore.float32)
>>> output = input.floor_divide(other)
>>> print(output)
1.0
```

mindspore.Tensor.floor_divide_

Tensor.**floor_divide_**(*other*) → *Tensor*

Divides the self tensor by the other tensor element-wise and round down to the closest integer.

$$out_i = \text{floor}(\frac{self_i}{other_i})$$

where the $floor$ indicates the Floor operator. For more details, please refer to the *mindspore.mint.floor* operator.

Warning: This is an experimental API that is subject to change or deletion.

Note: When *self* and *other* have different shapes, *other* should be able to broadcast to *self*.

Parameters

other (*Union[Tensor, Number, bool]*) – The other input is a number or a bool or a tensor whose data type is number or bool.

Returns

Tensor, the shape is the same as *self* , and the data type is the same as *self* .

Raises

- **TypeError** – If *other* is not one of the following: Tensor, number.Number or bool.

- **RuntimeError** – If *other* cannot be broadcast to *self*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([2, 4, -1]), mindspore.int32)
>>> other = Tensor(np.array([3, 3, 3]), mindspore.int32)
>>> output = x.floor_divide_(other)
>>> print(output)
[ 0  1 -1]
>>> print(x)
[ 0  1 -1]
```

mindspore.Tensor.flush_from_cache

`Tensor.`**`flush_from_cache`**`()`

Flush cache data to host if tensor is cache enable.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([1, 2], dtype=np.float32))
>>> y = x.flush_from_cache()
>>> print(y)
None
```

mindspore.Tensor.fmax

`Tensor.`**`fmax`**`(`*other*`)`

For details, please refer to *mindspore.ops.fmax()*.

mindspore.Tensor.fmod

`Tensor.`**`fmod`**`(`*other*`)` → *Tensor*

For details, please refer to *mindspore.ops.fmod()*.

mindspore.Tensor.fold

Tensor.**fold**(*output_size*, *kernel_size*, *dilation=1*, *padding=0*, *stride=1*)
For details, please refer to *mindspore.ops.fold()*.

mindspore.Tensor.frac

Tensor.**frac**() → *Tensor*
For details, please refer to *mindspore.ops.frac()*.

mindspore.Tensor.from_numpy

static Tensor.**from_numpy**(*array*)
Convert numpy array to Tensor. If the data is not C contiguous, the data will be copied to C contiguous to construct the tensor. Otherwise, The tensor will be constructed using this numpy array without copy.

Parameters

array (*numpy.array*) –The input array.

Returns

Tensor, has the same data type as input array.

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = np.array([1, 2])
>>> output = Tensor.from_numpy(x)
>>> print(output)
[1 2]
```

mindspore.Tensor.gather

Tensor.**gather**(*dim*, *index*) → *Tensor*
Gather data from a tensor by indices.

$$output[(i_0, i_1, ..., i_{dim}, i_{dim+1}, ..., i_n)] = input[(i_0, i_1, ..., index[(i_0, i_1, ..., i_{dim}, i_{dim+1}, ..., i_n)], i_{dim+1}, ..., i_n)]$$

Warning: On Ascend, the behavior is unpredictable in the following cases:

- the value of *index* is not in the range *[-self.shape[dim], self.shape[dim])* in forward;
- the value of *index* is not in the range *[0, self.shape[dim])* in backward.

Parameters

- **dim** (*int*) –the axis to index along, must be in range *[-self.rank, self.rank)*.
- **index** (Tensor) –The index tensor, with int32 or int64 data type. A valid *index* should be:

- $index.rank == self.rank$;
- for $axis != dim$, $index.shape[axis] <= self.shape[axis]$;
- the value of *index* is in range $[-self.shape[dim], self.shape[dim])$.

Returns

Tensor, has the same type as *self* and the same shape as *index*.

Raises

- **ValueError** – If the shape of *index* is illegal.
- **ValueError** – If *dim* is not in $[-self.rank, self.rank)$.
- **ValueError** – If the value of *index* is out of the valid range.
- **TypeError** – If the type of *index* is illegal.

Supported Platforms:

`Ascend GPU CPU`

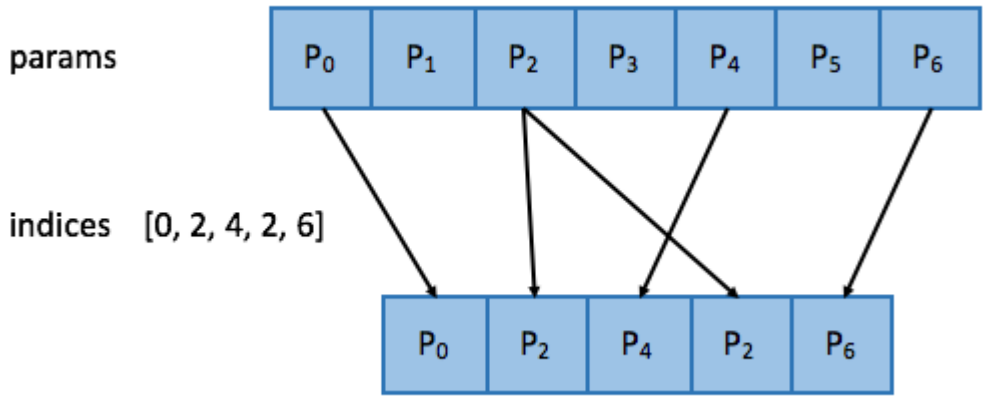
Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]), mindspore.float32)
>>> index = Tensor(np.array([[0, 0], [1, 1]]), mindspore.int32)
>>> output = input.gather(1, index)
>>> print(output)
[[-0.1 -0.1]
 [0.5   0.5]]
```

`Tensor.`**`gather`**(*input_indices*, *axis*, *batch_dims=0*) → *Tensor*

Returns the slice of the input tensor corresponding to the elements of *input_indices* on the specified *axis*.

The following figure shows the calculation process of Gather commonly:



where params represents the input *input_params*, and indices represents the index to be sliced *input_indices*.

Note:

- The value of input_indices must be in the range of *[0, input_param.shape[axis])*. On CPU and GPU, an error is raised if an out of bound indice is found. On Ascend, the results may be undefined.
- The data type of self cannot be bool_ on Ascend platform currently.

Parameters

- **input_indices** (Tensor) –Index tensor to be sliced, the shape of tensor is $(y_1, y_2, ..., y_S)$. Specifies the indices of elements of the original Tensor. The data type can be int32 or int64.
- **axis** (*Union(int, Tensor[int])*) –Specifies the dimension index to gather indices. It must be greater than or equal to *batch_dims*. When *axis* is a Tensor, the size must be 1.
- **batch_dims** (*int, optional*) –Specifies the number of batch dimensions. It must be less than or euqal to the rank of *input_indices*. Default: 0 .

Returns

Tensor, the shape of tensor is $input\_params.shape[:axis] + input\_indices.shape[batch\_dims:] + input\_params.shape[axis+1:]$.

Raises

- **TypeError** –If *axis* is not an int or Tensor.
- **ValueError** –If *axis* is a Tensor and its size is not 1.
- **TypeError** –If *self* is not a tensor.
- **TypeError** –If *input_indices* is not a tensor of type int.
- **RuntimeError** –If *input_indices* is out of range $[0, input_param.shape[axis])$ on CPU or GPU.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> # case1: input_indices is a Tensor with shape (5, ).
>>> input_params = Tensor(np.array([1, 2, 3, 4, 5, 6, 7]), mindspore.float32)
>>> input_indices = Tensor(np.array([0, 2, 4, 2, 6]), mindspore.int32)
>>> axis = 0
>>> output = input_params.gather(input_indices=input_indices, axis=axis)
>>> print(output)
[1. 3. 5. 3. 7.]
>>> # case2: input_indices is a Tensor with shape (2, 2). When the input_params has one␣
↪dimension,
>>> # the output shape is equal to the input_indices shape.
>>> input_indices = Tensor(np.array([[0, 2], [2, 6]]), mindspore.int32)
>>> axis = 0
>>> output = input_params.gather(input_indices=input_indices, axis=axis)
>>> print(output)
```

[ 1.  7. 10.]
```

mindspore.Tensor.gather_elements

Tensor.**gather_elements**(*dim*, *index*)

For details, please refer to *mindspore.ops.gather_elements()*.

mindspore.Tensor.gather_nd

Tensor.**gather_nd**(*indices*)

For details, please refer to *mindspore.ops.gather_nd()*.

mindspore.Tensor.gcd

Tensor.**gcd**(*other*) → *Tensor*

For details, please refer to *mindspore.ops.gcd()*.

mindspore.Tensor.ge

Tensor.**ge**(*other*) → *Tensor*

Alias for *mindspore.Tensor.greater_equal()*.

mindspore.Tensor.geqrf

Tensor.**geqrf**()
For details, please refer to *mindspore.ops.geqrf()*.

mindspore.Tensor.ger

Tensor.**ger**(*vec2*)
For details, please refer to *mindspore.ops.ger()*.

mindspore.Tensor.greater

Tensor.**greater**(*other*) → *Tensor*
For details, please refer to *mindspore.ops.greater()*.

mindspore.Tensor.greater_equal

Tensor.**greater_equal**(*other*) → *Tensor*
For details, please refer to *mindspore.ops.greater_equal()*.

mindspore.Tensor.gt

Tensor.**gt**(*other*) → *Tensor*
For details, please refer to :func:'mindspore.Tensor.greater'.

mindspore.Tensor.H

property Tensor.**H**
Returns a view of a matrix (2-D tensor) conjugated and transposed. x.H is equivalent to *mindspore.Tensor.swapaxes(0, 1).conj()* for complex matrices and *mindspore.Tensor.swapaxes(0, 1)* for real matrices.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([[1, 2], [3, 4]]))
>>> output = x.H
>>> print(output)
[[1 3]
[2 4]]
```

mindspore.Tensor.half

Tensor.**half**()

Converts input tensor dtype to *float16*.

Returns

Tensor, converted to the *float16* dtype.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> input_x = Tensor(np.ones([2,2]), mindspore.int32)
>>> output = input_x.half()
>>> print(output.dtype)
Float16
```

mindspore.Tensor.hardshrink

Tensor.**hardshrink**(*lambd=0.5*) → *Tensor*

For details, please refer to *mindspore.ops.hardshrink()*.

mindspore.Tensor.has_init

property Tensor.**has_init**

Whether tensor is initialized.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([[1, 2], [3, 4]]))
>>> output = x.has_init
>>> print(output)
False
```

mindspore.Tensor.heaviside

Tensor.**heaviside**(*values*)
For details, please refer to *mindspore.ops.heaviside()*.

mindspore.Tensor.histc

Tensor.**histc**(*bins=100*, *min=0*, *max=0*) → *Tensor*
For details, please refer to *mindspore.ops.histc()*.

Supported Platforms:

Ascend GPU CPU

mindspore.Tensor.hsplit

Tensor.**hsplit**(*indices_or_sections*)
For details, please refer to *mindspore.ops.hsplit()*.

mindspore.Tensor.hypot

Tensor.**hypot**(*other*)
For details, please refer to *mindspore.ops.hypot()*.

mindspore.Tensor.i0

Tensor.**i0**()
For details, please refer to *mindspore.ops.bessel_i0()*.

mindspore.Tensor.igamma

Tensor.**igamma**(*other*)
For details, please refer to *mindspore.ops.igamma()*.

mindspore.Tensor.igammac

Tensor.**igammac**(*other*)
For details, please refer to *mindspore.ops.igammac()*.

mindspore.Tensor.imag

Tensor.**imag**()
For details, please refer to *mindspore.ops.imag()*.

mindspore.Tensor.index_add

Tensor.**index_add**(*indices*, *y*, *axis*, *use_lock=True*, *check_index_bound=True*) → *Tensor*
Adds tensor *y* to specified axis and indices of tensor *self*. The axis should be in [-len(self.dim), len(self.dim) - 1], and indices should be in [0, the size of *self* - 1] at the axis dimension.

Parameters

- **indices** (Tensor) –Add the value of *self* and *y* along the dimension of the *axis* according to the specified index value, with data type int32. The *indices* must be 1D with the same size as the size of *y* in the *axis* dimension. The values of *indices* should be in [0, b), where the b is the size of *self* in the *axis* dimension.
- **y** (Tensor) –The input tensor with the value to add.
- **axis** (*int*) –The dimension along which to index.
- **use_lock** (*bool, optional*) –Whether to enable a lock to protect the updating process of variable tensors. If True , when updating the value of *self*, this process will be protected by a lock by using atomic operation. If False , the result may be unpredictable. Default: True .
- **check_index_bound** (*bool, optional*) –If True , check indices boundary. If False , don't check indices boundary. Default: True .

Returns

Tensor, has the same shape and dtype as *self*.

Raises

- **TypeError** –If neither *indices* nor *y* is a Tensor.
- **ValueError** –If axis is out of the range of *self* shape.
- **ValueError** –If *self* rank is not the same as *y* rank.
- **ValueError** –If shape of *indices* is not 1D or size of *indices* is not equal to dimension of y[axis].
- **ValueError** –If *y*'s shape is not the same as *self* except the *axis* th dimension.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), mindspore.float32)
>>> indices = Tensor(np.array([0, 2]), mindspore.int32)
>>> y = Tensor(np.array([[0.5, 1.0], [1.0, 1.5], [2.0, 2.5]]), mindspore.float32)
>>> output = x.index_add(indices, y, axis = 1)
>>> print(output)
[[ 1.5  2.   4. ]
```

(continues on next page)

(continued from previous page)

```
 [ 5.   5.   7.5]
 [ 9.   8.  11.5]]
```

`Tensor.`**`index_add`**(*dim*, *index*, *source*, *, *alpha=1*) → *Tensor*

For details, please refer to `mindspore.ops.index_add()`. The corresponding relationships between the parameters of *Tensor.index_add* and `mindspore.ops.index_add()` are as follows: *dim* -> *axis*, *index* -> *indices*, *source* * *alpha* -> *y*.

mindspore.Tensor.index_add_

`Tensor.`**`index_add_`**(*dim*, *index*, *source*, *, *alpha=1*)

Accumulate the elements of *alpha* times *source* into the *self* by adding to the index in the order given in *index*. For example, if *dim* == *0*, *index[i]* == *j*, and *alpha* = *-1*, then the *i* th row of *source* is subtracted from the *j* th row of *self* . The *dim* th dimension of *source* must have the same size as the length of *index* , and all other dimensions must match *self*, or an error will be raised. For a 3-D tensor the output is defined as follows:

$$
\begin{aligned}
self[index[i],\ :,\ :] \mathrel{+}= alpha * src[i,\ :,\ :] \quad & \#if\ dim == 0 \\
self[:,\ index[i],\ :] \mathrel{+}= alpha * src[:,\ i,\ :] \quad & \#if\ dim == 1 \\
self[:,\ :,\ index[i]] \mathrel{+}= alpha * src[:,\ :,\ i] \quad & \#if\ dim == 2
\end{aligned}
$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **`dim`** (*`int`*) −The dimension along which to index.
- **`index`** (`Tensor`) −Add the value of *self* and *source* along the dimension of the *dim* according to the specified index value, with data type int32. The *index* must be 1D with the same size as the size of *source* in the *dim* dimension. The values of *index* should be in [0, b), where the b is the size of *self* in the *dim* dimension.
- **`source`** (`Tensor`) −The input tensor with the value to add. Must have same data type as *self*. The shape must be the same as *self* except the *dim* th dimension.

Keyword Arguments

`alpha` (*`number, optional`*) −The scalar multiplier for source. Default: `1`.

Returns

Tensor, has the same shape and dtype as *self*.

Raises

- **`TypeError`** −If neither *index* nor *source* is a Tensor.
- **`ValueError`** −If dim is out of *self* rank's range.
- **`ValueError`** −If *self* rank is not the same as *source* rank.
- **`ValueError`** −If shape of *index* is not 1D or size of *index* is not equal to dimension of *source[dim]*.
- **`ValueError`** −If *source*'s shape is not the same as *self* except the *dim* th dimension.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), mindspore.float32)
>>> index = Tensor(np.array([0, 2]), mindspore.int32)
>>> y = Tensor(np.array([[0.5, 1.0], [1.0, 1.5], [2.0, 2.5]]), mindspore.float32)
>>> output = x.index_add_(1, index, y, alpha=1)
>>> print(output)
[[ 1.5  2.   4. ]
 [ 5.   5.   7.5]
 [ 9.   8.  11.5]]
>>> print(x)
[[ 1.5  2.   4. ]
 [ 5.   5.   7.5]
 [ 9.   8.  11.5]]
```

mindspore.Tensor.index_fill

Tensor.**index_fill**(*axis*, *index*, *value*)

For details, please refer to *mindspore.ops.index_fill()*.

mindspore.Tensor.index_put

Tensor.**index_put**(*indices*, *values*, *accumulate=False*)

Based on the indices in *indices*, replace the corresponding elements in Tensor *self* with the values in *values*. Outplace version of *mindspore.Tensor.index_put_()* 。

> **Warning:** The behavior is unpredictable in the following scenario:
>
> - If *accumulate* is *False* and *indices* contains duplicate elements.

Parameters

- **indices** (*tuple[Tensor], list[Tensor]*) – the indices of type int32 or int64, used to index into the *self*. The rank of tensors in indices should be 1-D, size of indices should <= *self.rank* and the tensors in indices should be broadcastable.
- **values** (Tensor) – 1-D Tensor with the same type as *self*. *values* should be broadcastable with size 1.
- **accumulate** (*bool, optional*) – If *accumulate* is *True*, the elements in *values* will be added to *self*, otherwise the elements in *values* will replace the corresponding elements in the *self*. Default: False.

Returns

Tensor, with the same type and shape as the "self Tensor".

Raises

- **TypeError** – If the dtype of the *self* is not equal to the dtype of *values*.
- **TypeError** – If the dtype of *indices* is not tuple[Tensor], list[Tensor].
- **TypeError** – If the dtype of tensors in *indices* are not int32 or int64.

- **TypeError** –If the dtype of tensors in *indices* are inconsistent.
- **TypeError** –If the dtype of *accumulate* is not bool.
- **ValueError** –If rank(*values*) is not 1-D.
- **ValueError** –If size(*values*) is not 1 or max size of the tensors in *indices* when rank(*self*) == size(*indices*).
- **ValueError** –If size(*values*) is not 1 or *self*.shape[-1] when rank(*self*) > size(*indices*).
- **ValueError** –If the rank of tensors in *indices* is not 1-D.
- **ValueError** –If the tensors in *indices* is not be broadcastable.
- **ValueError** –If size(*indices*) > rank(*self*).

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6]]).astype(np.int32))
>>> values = Tensor(np.array([3]).astype(np.int32))
>>> indices = [Tensor(np.array([0, 1, 1]).astype(np.int32)), Tensor(np.array([1, 2, 1]).
↪astype(np.int32))]
>>> accumulate = True
>>> output = x.index_put(indices, values, accumulate)
>>> print(output)
[[1 5 3]
[4 8 9]]
```

mindspore.Tensor.index_put_

`Tensor.`**`index_put_`**(*indices*, *values*, *accumulate=False*)

Based on the indices in *indices*, replace the corresponding elements in Tensor *self* with the values in *values*. The expression *Tensor.index_put_(indices, values)* is equivalent to *tensor[indices] = values*. Update and return *self*.

> **Warning:** The behavior is unpredictable in the following scenario:
>
> - If *accumulate* is *False* and *indices* contains duplicate elements.

Parameters

- **indices** (*tuple[Tensor], list[Tensor]*) –the indices of type is bool, uint8, int32 or int64, used to index into the *self*. The size of indices should <= the rank of *self* and the tensors in indices should be broadcastable.
- **values** (`Tensor`) –Tensor with the same type as *self*. If size == 1, it will be broadcastable.
- **accumulate** (*bool, optional*) –If *accumulate* is *True*, the elements in *values* will be added to *self*, otherwise the elements in *values* will replace the corresponding elements in the *self*. Default: `False`.

Returns

Tensor *self*.

Raises

- **TypeError** –If the dtype of the *self* is not equal to the dtype of *values*.
- **TypeError** –If the dtype of *indices* is not tuple[Tensor], list[Tensor].
- **TypeError** –If the dtype of tensors in *indices* are not bool, uint8, int32 or int64.
- **TypeError** –If the dtypes of tensors in *indices* are inconsistent.
- **TypeError** –If the dtype of *accumulate* is not bool.
- **ValueError** –If size(*values*) is not 1 or max size of the tensors in *indices* when rank(*self*) == size(*indices*).
- **ValueError** –If size(*values*) is not 1 or *self*.shape[-1] when rank(*self*) > size(*indices*).
- **ValueError** –If the tensors in *indices* is not be broadcastable.
- **ValueError** –If size(*indices*) > rank(*self*).

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6]]).astype(np.int32))
>>> values = Tensor(np.array([3]).astype(np.int32))
>>> indices = [Tensor(np.array([0, 1, 1]).astype(np.int32)), Tensor(np.array([1, 2, 1]).
↪astype(np.int32))]
>>> accumulate = True
>>> x.index_put_(indices, values, accumulate)
>>> print(x)
[[1 5 3]
 [4 8 9]]
```

mindspore.Tensor.index_select

`Tensor.`**`index_select`**(*axis*, *index*) → *Tensor*

Generates a new Tensor that accesses the values of *self* along the specified *axis* dimension using the indices specified in *index*. The new Tensor has the same number of dimensions as *self*, with the size of the *axis* dimension being equal to the length of *index*, and the size of all other dimensions will be unchanged from the original *self* Tensor.

Note: The value of index must be in the range of *[0, self.shape[axis])*, the result is undefined out of range.

Parameters

- **axis** (*int*) –The dimension to be indexed.
- **index** (Tensor) –A 1-D Tensor with the indices to access in *self* along the specified axis.

Returns

Tensor, has the same dtype as *self* Tensor.

Raises

- **TypeError** –If *index* is not a Tensor.
- **TypeError** –If *axis* is not int number.
- **ValueError** –If the value of *axis* is out the range of *[-self.ndim, self.ndim - 1]*.
- **ValueError** –If the dimension of *index* is not equal to 1.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> import numpy as np
>>> input = Tensor(np.arange(16).astype(np.float32).reshape(2, 2, 4))
>>> print(input)
[[[ 0.  1.  2.  3.]
  [ 4.  5.  6.  7.]]
 [[ 8.  9. 10. 11.]
  [12. 13. 14. 15.]]]
>>> index = Tensor([0,], mindspore.int32)
>>> y = input.index_select(1, index)
>>> print(y)
[[[ 0.  1.  2.  3.]]
 [[ 8.  9. 10. 11.]]]
```

`Tensor.`**`index_select`**(*dim*, *index*) → *Tensor*

Generates a new Tensor that accesses the values of *self* along the specified *dim* dimension using the indices specified in *index*. The new Tensor has the same number of dimensions as *self*, with the size of the *dim* dimension being equal to the length of *index*, and the size of all other dimensions will be unchanged from the original *self* Tensor.

Note: The value of index must be in the range of *[0, self.shape[dim])*, the result is undefined out of range.

Parameters

- **dim** (*int*) –The dimension to be indexed.
- **index** (`Tensor`) –A 1-D Tensor with the indices to access in *self* along the specified dim.

Returns

Tensor, has the same dtype as *self* Tensor.

Raises

- **TypeError** –If *index* is not a Tensor.
- **TypeError** –If *dim* is not int number.
- **ValueError** –If the value of *dim* is out the range of *[-self.ndim, self.ndim - 1]*.
- **ValueError** –If the dimension of *index* is not equal to 1.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> import numpy as np
>>> input = Tensor(np.arange(16).astype(np.float32).reshape(2, 2, 4))
>>> print(input)
[[[ 0.  1.  2.  3.]
  [ 4.  5.  6.  7.]]
 [[ 8.  9. 10. 11.]
  [12. 13. 14. 15.]]]
>>> index = Tensor([0,], mindspore.int32)
>>> y = input.index_select(1, index)
>>> print(y)
[[[ 0.  1.  2.  3.]]
 [[ 8.  9. 10. 11.]]]
```

mindspore.Tensor.init_data

Tensor.**init_data**(*slice_index=None*, *shape=None*, *opt_shard_group=None*)

Get the tensor format data of this Tensor.

Note: The init_data function can be called once for the same tensor.

Parameters

- **slice_index** (*int*) – Slice index of a parameter's slices. It is used when initialize a slice of a parameter, it guarantees that devices using the same slice can generate the same tensor. Default: None.
- **shape** (*list[int]*) – Shape of the slice, it is used when initialize a slice of the parameter. Default: None.
- **opt_shard_group** (*str*) – Optimizer shard group which is used in auto or semi auto parallel mode to get one shard of a parameter's slice. For more information about optimizer parallel, please refer to: Optimizer Parallel. Default: None.

Returns

Initialized Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore.common.initializer import initializer, Constant
>>> x = initializer(Constant(1), [2, 2], ms.float32)
>>> out = x.init_data()
>>> print(out)
[[1. 1.]
 [1. 1.]]
```

mindspore.Tensor.inner

Tensor.**inner**(*other*)

For details, please refer to *mindspore.ops.inner()*.

mindspore.Tensor.inplace_update

Tensor.**inplace_update**(*v*, *indices*)

For details, please refer to *mindspore.ops.inplace_update()*.

mindspore.Tensor.int

Tensor.**int**()

Converts input tensor dtype to *int32*. If the value in tensor is float or half, the decimal will be discarded.

Returns

Tensor, converted to the *int32* dtype.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> input_x = Tensor(np.ones([2,2]), mindspore.float32)
>>> output = input_x.int()
>>> print(output.dtype)
Int32
```

mindspore.Tensor.inv

Tensor.**inv**()
For details, please refer to *mindspore.ops.inv()*.

mindspore.Tensor.inverse

Tensor.**inverse**() → *Tensor*
For details, please refer to *mindspore.ops.inverse()*.

Supported Platforms:

Ascend GPU CPU

mindspore.Tensor.invert

Tensor.**invert**()
For details, please refer to *mindspore.ops.invert()*.

mindspore.Tensor.isclose

Tensor.**isclose**(*other*, *rtol=1e-05*, *atol=1e-08*, *equal_nan=False*) → *Tensor*
Returns a tensor of Boolean values indicating whether each element of *input* is "close" to the corresponding element of *other*. Closeness is defined as:

$$|input - other| <= atol + rtol * |other|$$

Parameters

- **other** (Tensor) –Second tensor to compare.
- **rtol** (*float, optional*) –Relative tolerance. Default: 1e-05 .
- **atol** (*float, optional*) –Absolute tolerance. Default: 1e-08 .
- **equal_nan** (*bool, optional*) –If True , then two NaNs will be considered equal. Default: True .

Returns

Tensor, with the same shape as *input* and *other* after broadcasting, its dtype is bool.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.array([1.3, 2.1, 3.2, 4.1, 5.1]), mindspore.float16)
>>> other = Tensor(np.array([1.3, 3.3, 2.3, 3.1, 5.1]), mindspore.float16)
>>> output = Tensor.isclose(input, other)
>>> print(output)
[ True False False False  True]
```

Tensor.**isclose**(*x2*, *rtol=1e-05*, *atol=1e-08*, *equal_nan=False*) → *Tensor*

Returns a new Tensor with boolean elements representing if each element of *input* is "close" to the corresponding element of *x2*. Closeness is defined as:

$$|input - x2| <= atol + rtol * |x2|$$

Parameters

- **x2** (Tensor) – Second tensor to compare. Dtype must be same as *input*.
- **rtol** (*Union[float, int, bool], optional*) – Relative tolerance. Default: `1e-05` .
- **atol** (*Union[float, int, bool], optional*) – Absolute tolerance. Default: `1e-08` .
- **equal_nan** (*bool, optional*) – If `True` , then two NaNs will be considered equal. Default: `False`.

Returns

A bool Tensor, with the shape as broadcasted result of the input *input* and *x2*.

Raises

- **TypeError** – *x2* is not Tensor.
- **TypeError** – *input* or *x2* dtype is not support. Support dtype: float16, float32, float64, int8, int16, int32, int64 and uint8. On Ascend, more dtypes are support: bool and bfloat16.
- **TypeError** – *atol* or *rtol* is not float, int or bool.
- **TypeError** – *equal_nan* is not bool.
- **TypeError** – *input* and *x2* have different dtypes.
- **ValueError** – *input* and *x2* cannot broadcast.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.array([1.3, 2.1, 3.2, 4.1, 5.1]), mindspore.float16)
>>> x2 = Tensor(np.array([1.3, 3.3, 2.3, 3.1, 5.1]), mindspore.float16)
>>> output = Tensor.isclose(input, x2)
>>> print(output)
[ True False False False  True]
```

mindspore.Tensor.isfinite

Tensor.**isfinite**() → *Tensor*

For details, please refer to *mindspore.ops.isfinite()*.

mindspore.Tensor.is_complex

Tensor.**is_complex**()

For details, please refer to: func:'mindspore.ops.is_complex'.

Examples

```
>>> x = mindspore.Tensor([1 + 1j], dtype=mindspore.complex128)
>>> y = mindspore.Tensor([1], dtype=mindspore.int32)
>>> print(x.is_complex())
True
>>> print(y.is_complex())
False
```

mindspore.Tensor.is_contiguous

Tensor.**is_contiguous**()

Determines whether the memory of tensor is contiguous.

Returns

Bool, True if tensor memory is contiguous, False otherwise.

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor([[1, 2, 3], [4, 5, 6]], dtype=ms.float32)
>>> y = ops.transpose(x, (1, 0))
>>> print(y.is_contiguous())
False
```

mindspore.Tensor.is_floating_point

Tensor.**is_floating_point**()

For details, please refer to *mindspore.ops.is_floating_point()*.

mindspore.Tensor.isinf

Tensor.**isinf**() → *Tensor*

For details, please refer to *mindspore.ops.isinf()*.

Supported Platforms:

Ascend CPU GPU

mindspore.Tensor.isnan

Tensor.**isnan**()
For details, please refer to *mindspore.ops.ne()*.

mindspore.Tensor.isneginf

Tensor.**isneginf**() → *Tensor*
For details, please refer to *mindspore.ops.isneginf()*.

mindspore.Tensor.isposinf

Tensor.**isposinf**()
For details, please refer to *mindspore.ops.isposinf()*.

mindspore.Tensor.isreal

Tensor.**isreal**()
For details, please refer to *mindspore.ops.isreal()*.

mindspore.Tensor.is_signed

Tensor.**is_signed**()
Judge whether the data type of tensor is a signed data type.

Returns

Bool. If the dtype of the tensor is a signed data type, return True. Otherwise, return False.

Examples

```
>>> import mindspore as ms
>>> x = ms.Tensor([1, 2, 3], ms.int64)
>>> y = ms.Tensor([1, 2, 3], ms.uint64)
>>> output = x.is_signed()
>>> output2 = y.is_signed()
>>> print(output)
True
>>> print(output2)
False
```

mindspore.Tensor.item

Tensor.**item**()

Return the value of this tensor as standard Python number. This only works for tensors with one element.

Returns

A scalar, type is defined by the dtype of the Tensor.

Raises

- **ValueError** –If the count of value in tensor is more than one.
- **TypeError** –The type of element in tensor is not supported.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> x = Tensor(1.2, ms.float32)
>>> print(x.item())
1.2
```

mindspore.Tensor.itemset

Tensor.**itemset**(**args*)

Insert scalar into a tensor (scalar is cast to tensor's dtype, if possible).

There must be at least 1 argument, and define the last argument as item. Then, tensor.itemset(*args) is equivalent to $Tensor[args] = item$.

Parameters

args (*Union[(numbers.Number), (int/tuple(int), numbers.Number)]*) –The arguments that specify the index and value. If *args* contain one argument (a scalar), it is only used in case tensor is of size 1. If *args* contains two arguments, the last argument is the value to be set and must be a scalar, the first argument specifies a single tensor element location. It is either an int or a tuple.

Returns

A new tensor that doesn't affect the original tensor, with value set by $Tensor[args] = item$.

Raises

- **ValueError** –If the length of the first argument is not equal to self.ndim.
- **IndexError** –If only one argument is provided, and the original Tensor is not scalar.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[1,2,3],[4,5,6]], dtype=np.float32))
>>> print(x.itemset((0,1), 4))
[[1. 4. 3.]
[4. 5. 6.]]
>>> print(x)
[[1. 2. 3.]
[4. 5. 6.]]
```

mindspore.Tensor.itemsize

property Tensor.**itemsize**

Return the length of one tensor element in bytes.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([[1, 2], [3, 4]]))
>>> output = x.itemsize
>>> print(output)
8
```

mindspore.Tensor.lcm

Tensor.**lcm**(*other*)

For details, please refer to *mindspore.ops.lcm()*.

mindspore.Tensor.ldexp

Tensor.**ldexp**(*other*)

For details, please refer to *mindspore.ops.ldexp()*.

mindspore.Tensor.le

Tensor.**le**(*other*) → *Tensor*

For details, please refer to *mindspore.ops.le()*.

mindspore.Tensor.lerp

Tensor.**lerp**(*end*, *weight*) → *Tensor*
For more details, please refer to *mindspore.ops.lerp()*.

mindspore.Tensor.less

Tensor.**less**(*other*) → *Tensor*
For details, please refer to *mindspore.ops.less()*.

mindspore.Tensor.less_equal

Tensor.**less_equal**(*other*) → *Tensor*
For details, please refer to *mindspore.ops.less_equal()*.

mindspore.Tensor.log

Tensor.**log**() → *Tensor*
For details, please refer to *mindspore.ops.log()*.

mindspore.Tensor.log10

Tensor.**log10**() → *Tensor*
For details, please refer to *mindspore.ops.log10()*.

mindspore.Tensor.log1p

Tensor.**log1p**() → *Tensor*
For details, please refer to *mindspore.ops.log1p()*.

mindspore.Tensor.log2

Tensor.**log2**() → *Tensor*
For details, please refer to *mindspore.ops.log2()*.

mindspore.Tensor.logaddexp

Tensor.**logaddexp**(*other*) → *Tensor*
For details, please refer to *mindspore.ops.logaddexp()*.

mindspore.Tensor.logaddexp2

Tensor.**logaddexp2**(*other*) → *Tensor*
For details, please refer to *mindspore.ops.logaddexp2()*.

mindspore.Tensor.logcumsumexp

Tensor.**logcumsumexp**(*axis*)
For details, please refer to *mindspore.ops.logcumsumexp()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

mindspore.Tensor.logdet

Tensor.**logdet**()
For details, please refer to *mindspore.ops.logdet()*.

mindspore.Tensor.logical_and

Tensor.**logical_and**(*other*) → *Tensor*
For details, please refer to *mindspore.ops.logical_and()*.

mindspore.Tensor.logical_not

Tensor.**logical_not**() → *Tensor*
For details, please refer to *mindspore.ops.logical_not()*.

mindspore.Tensor.logical_or

Tensor.**logical_or**(*other*) → *Tensor*
For details, please refer to *mindspore.ops.logical_or()*.

mindspore.Tensor.logical_xor

Tensor.**logical_xor**(*other*) → *Tensor*
Computes the "logical XOR" of two tensors element-wise.

$$out_i = self_i \oplus other_i$$

Note:

- *self* and *other* comply with the type conversion rules to make the data types consistent.
- When the *other* is bool, it could only be a constant.

Parameters

other (*Union[Tensor, bool]*) – A bool or a tensor whose data type can be implicitly converted to bool.

Returns

Tensor, the shape is the same as the *self* and *other* after broadcasting, and the data type is bool.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.array([True, False, True]), mindspore.bool_)
>>> other = Tensor(np.array([True, True, False]), mindspore.bool_)
>>> output = input.logical_xor(other)
>>> print(output)
[ False True True]
>>> x = Tensor(1, mindspore.bool_)
>>> other = Tensor(0, mindspore.bool_)
>>> output = input.logical_xor(other)
>>> print(output)
True
```

mindspore.Tensor.logit

`Tensor.`**`logit`**(*eps=None*)

For details, please refer to *mindspore.ops.logit()*.

mindspore.Tensor.logsumexp

`Tensor.`**`logsumexp`**(*dim*, *keepdim=False*) → *Tensor*

For details, please refer to *mindspore.ops.logsumexp()*.

mindspore.Tensor.log_normal

`Tensor.`**`log_normal`**(*mean=1.0*, *std=2.0*)

Fills the elements of the input tensor with log normal values initialized by given mean and std:

$$f(x; 1.0, 2.0) = \frac{1}{x\delta\sqrt{2\pi}} e^{-\frac{(\ln x-\mu)^2}{2\delta^2}}$$

where μ, δ is mean and standard deviation of lognormal distribution respectively.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **mean** (*float, optional*) – the mean of normal distribution. With float data type. Default: 1.0.
- **std** (*float, optional*) – the std of normal distribution. With float data type. Default: 2.0.

Returns

Tensor. A Tensor with the same type and shape of input.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> x = mindspore.Tensor(np.array([[1, 2], [3, 4]]), dtype=mindspore.float32)
>>> output = x.log_normal()
>>> print(output)
[[1.2788825 2.3305743]
[14.944194 0.16303174]]
```

mindspore.Tensor.long

`Tensor.long()`

Converts input tensor dtype to *int64*. If the value in tensor is float or half, the decimal will be discarded.

Returns

Tensor, converted to the *int64* dtype.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> input_x = Tensor(np.ones([2,2]), mindspore.int32)
>>> output = input_x.long()
>>> print(output.dtype)
Int64
```

mindspore.Tensor.lt

Tensor.**lt**(*other*) → *Tensor*

For more details, please refer to *mindspore.Tensor.less()*.

mindspore.Tensor.lu_solve

Tensor.**lu_solve**(*LU_data*, *LU_pivots*)

For details, please refer to *mindspore.ops.lu_solve()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

mindspore.Tensor.masked_fill

Tensor.**masked_fill**(*mask*, *value*) → *Tensor*

For details, please refer to *mindspore.ops.masked_fill()*.

mindspore.Tensor.masked_fill_

Tensor.**masked_fill_**(*mask*, *value*) → *Tensor*

In-place version of *mindspore.Tensor.masked_fill()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

mindspore.Tensor.masked_scatter

Tensor.**masked_scatter**(*mask*, *x*)

Updates the value in the "self Tensor" with the *tensor* value according to the mask, and returns a Tensor. The shape of *mask* and the "self Tensor" must be the same or *mask* is broadcastable.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **mask** (Tensor[bool]) −A bool tensor with a shape broadcastable to the "self Tensor".
- **x** (Tensor) −A tensor with the same data type as the "self Tensor". The number of elements must be greater than or equal to the number of True's in *mask*.

Returns

Tensor, with the same type and shape as the "self Tensor".

Raises

- **TypeError** −If *mask* or *x* is not a Tensor.
- **TypeError** −If data type of the "self Tensor" is not be supported.

- **TypeError** –If dtype of *mask* is not bool.
- **TypeError** –If the dim of the "self Tensor" less than the dim of *mask*.
- **ValueError** –If *mask* can not be broadcastable to the "self Tensor".
- **ValueError** –If the number of elements in *x* is less than the number required for the updates.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor(np.array([1., 2., 3., 4.]), mindspore.float32)
>>> mask = Tensor(np.array([True, True, False, True]), mindspore.bool_)
>>> tensor = Tensor(np.array([5., 6., 7.]), mindspore.float32)
>>> output = x.masked_scatter(mask, tensor)
>>> print(output)
[5. 6. 3. 7.]
```

mindspore.Tensor.masked_select

Tensor.**masked_select**(*mask*) → *Tensor*

For details, please refer to *mindspore.ops.masked_select()*.

mindspore.Tensor.matmul

Tensor.**matmul**(*tensor2*) → Union[*Tensor*, numbers.Number]

Returns the matrix product of two tensors.

Note:

- Numpy arguments *out*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.
- The dtype of *self* and *tensor2* must be same.
- On Ascend platform, the dims of *self* and *tensor2* must be between 1 and 6.
- On GPU platform, the supported dtypes of *self* and *tensor2* are ms.float16 and ms.float32.

Parameters

tensor2 (Tensor) –Input tensor, scalar not allowed. The last dimension of *self* must be the same size as the second last dimension of *tensor2*. And the shape of tensor and other could be broadcast.

Returns

Tensor or scalar, the matrix product of the inputs. This is a scalar only when both *self* and *tensor2* are 1-d vectors.

Raises

- **TypeError** –If the dtype of *self* and the dtype of *tensor2* are not the same.

- **ValueError** –If the last dimension of *self* is not the same size as the second-to-last dimension of *tensor2*, or if a scalar value is passed in.
- **ValueError** –If the shape of *self* and *tensor2* could not broadcast together.
- **RuntimeError** –On Ascend platforms, the dims of *self* or *tensor2* is less than 1 or greater than 6.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> # case 1 : Reasonable application of broadcast mechanism
>>> input = Tensor(np.arange(2 * 3 * 4).reshape(2, 3, 4), mindspore.float32)
>>> other = Tensor(np.arange(4 * 5).reshape(4, 5), mindspore.float32)
>>> output = input.matmul(other)
>>> print(output)
[[[  70.   76.   82.   88.   94.]
  [ 190.  212.  234.  256.  278.]
  [ 310.  348.  386.  424.  462.]]
 [[ 430.  484.  538.  592.  646.]
  [ 550.  620.  690.  760.  830.]
  [ 670.  756.  842.  928. 1014.]]]
>>> print(output.shape)
(2, 3, 5)
>>> # case 2 : the rank of `tensor2` is 1
>>> input = Tensor(np.ones([1, 2]), mindspore.float32)
>>> other = Tensor(np.ones([2,]), mindspore.float32)
>>> output = input.matmul(other)
>>> print(output)
[2.]
>>> print(output.shape)
(1,)
```

mindspore.Tensor.max

Tensor.**max**() → *Tensor*

Returns the maximum value of the self tensor.

Returns

Scalar Tensor with the same dtype as *input*, the maximum value of the input.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([0.0, 0.4, 0.6, 0.7, 0.1]), mindspore.float32)
>>> output = x.max()
>>> print(output)
[0.7]
```

`Tensor.max`(*dim*, *keepdim=False*)

Calculates the maximum value along with the given dim for the input tensor, and returns the maximum values and indices.

Parameters

- **dim** (*int*) –The dimension to reduce.
- **keepdim** (*bool, optional*) –Whether to keep dimension, if `True` the output will keep the same dimension as the *self* , the output will reduce dimension if `False`. Default: `False`.

Returns

tuple (Tensor), tuple of 2 tensors, containing the maximum value of the self tensor along the given dimension *dim* and the corresponding index.

- **values** (Tensor) - The maximum value of self tensor, with the same shape as *index*, and same dtype as *self*.
- **index** (Tensor) - The index for the maximum value of the self tensor, with dtype int64. If *keepdim* is `True` , the shape of output tensors is $(self_1, self_2, ..., self_{dim-1}, 1, self_{dim+1}, ..., self_N)$. Otherwise, the shape is $(self_1, self_2, ..., self_{dim-1}, self_{dim+1}, ..., self_N)$.

Raises

- **TypeError** –If *keepdim* is not a bool.
- **TypeError** –If *dim* is not an int.
- **TypeError** –If self tensor data type is Complex.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([0.0, 0.4, 0.6, 0.7, 0.1]), mindspore.float32)
>>> output, index = x.max(0, keepdim=True)
>>> print(output, index)
[0.7] [3]
```

`Tensor.max`(*axis=None*, *keepdims=False*, *, *initial=None*, *where=True*, *return_indices=False*)

Return the maximum of a tensor or maximum along an axis.

Note: When *axis* is `None`, *keepdims* and subsequent parameters have no effect. At the same time, the index is fixed to return 0.

Parameters

- **axis** (*Union[None, int, list, tuple of ints], optional*) – Axis or axes along which to operate. By default, flattened input is used. If this is a tuple of ints, the maximum is selected over multiple axes, instead of a single axis or all the axes as before. Default: `None` .
- **keepdims** (*bool, optional*) – If this is set to `True` , the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array. Default: `False` .

Keyword Arguments

- **initial** (*scalar, optional*) – The minimum value of an output element. Must be present to allow computation on empty slice. Default: `None` .
- **where** (*bool Tensor, optional*) – A boolean tensor which is broadcasted to match the dimensions of array, and selects elements to include in the reduction. If non-default value is passed, initial must also be provided. Default: `True` .
- **return_indices** (*bool, optional*) – Whether to return the index of the maximum value. Default: `False` . If *axis* is a list or tuple of ints, it must be `False` .

Returns

Tensor or scalar, maximum of self tensor. If *axis* is `None` , the result is a scalar value. If *axis* is given, the result is a tensor of dimension `self.ndim - 1`.

Raises

TypeError – If arguments have types not specified above.

See also:

- *mindspore.Tensor.argmin()*: Return the indices of the minimum values along an axis.
- *mindspore.Tensor.argmax()*: Return the indices of the maximum values along an axis.
- *mindspore.Tensor.min()*: Return the minimum of a tensor or minimum along an axis.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> a = Tensor(np.arange(4).reshape((2, 2)).astype('float32'))
>>> output = a.max()
>>> print(output)
3.0
>>> value, indices = a.max(axis=0, return_indices=True)
>>> print(value)
[2. 3.]
>>> print(indices)
[1 1]
```

mindspore.Tensor.maximum

Tensor.**maximum**(*other*) → *Tensor*

For details, please refer to *mindspore.ops.maximum()*.

mindspore.Tensor.mean

Tensor.**mean**(*dim=None*, *keepdim=False*, *, *dtype=None*) → *Tensor*

Reduces all dimension of a tensor by averaging all elements in the dimension, by default. And reduce a dimension of *self* along the specified *dim*. *keepdim* determines whether the dimensions of the output and self are the same.

Note: The *dim* with tensor type is only used for compatibility with older versions and is not recommended.

Parameters

- **dim** (*Union[int, tuple(int), list(int), Tensor], optional*) –The dimensions to reduce. Default: None , reduce all dimensions. Only constant value is allowed. Assume the rank of *self* is r, and the value range is [-r,r).
- **keepdim** (*bool, optional*) –If True , keep these reduced dimensions and the length is 1. If False , don't keep these dimensions. Default: False .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The desired data type of returned Tensor. Default: None .

Returns

Tensor, has the same data type as self tensor.

- If *dim* is None , and *keepdim* is False , the output is a 0-D tensor representing the product of all elements in the self tensor.
- If *dim* is int, set as 1, and *keepdim* is False , the shape of output is $(x_0, x_2, ..., x_R)$.
- If *dim* is tuple(int), set as (1, 2), and *keepdim* is False , the shape of output is $(x_0, x_3, ..., x_R)$.
- If *dim* is 1-D Tensor, set as [1, 2], and *keepdim* is False , the shape of output is $(x_0, x_3, ..., x_R)$.

Raises

- **TypeError** –If *dim* is not one of the following: int, tuple, list or Tensor.
- **TypeError** –If *keepdim* is not a bool.
- **ValueError** –If *dim* is out of range.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.random.randn(3, 4, 5, 6).astype(np.float32))
>>> output = Tensor.mean(x, 1, keepdim=True)
>>> result = output.shape
>>> print(result)
(3, 1, 5, 6)
>>> # case 1: Reduces a dimension by averaging all elements in the dimension.
>>> x = Tensor(np.array([[[2, 2, 2, 2, 2, 2], [2, 2, 2, 2, 2, 2], [2, 2, 2, 2, 2, 2]],
... [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
... [[6, 6, 6, 6, 6, 6], [8, 8, 8, 8, 8, 8], [10, 10, 10, 10, 10, 10]]]),
... mindspore.float32)
>>> output = Tensor.mean(x)
>>> print(output)
5.0
>>> print(output.shape)
()
>>> # case 2: Reduces a dimension along the dim 0
>>> output = Tensor.mean(x, 0, True)
>>> print(output)
[[[4. 4. 4. 4. 4. 4.]
  [5. 5. 5. 5. 5. 5.]
  [6. 6. 6. 6. 6. 6.]]]
>>> # case 3: Reduces a dimension along the dim 1
>>> output = Tensor.mean(x, 1, True)
>>> print(output)
[[[2. 2. 2. 2. 2. 2.]]
 [[5. 5. 5. 5. 5. 5.]]
 [[8. 8. 8. 8. 8. 8.]]]
>>> # case 4: Reduces a dimension along the dim 2
>>> output = Tensor.mean(x, 2, True)
>>> print(output)
[[[ 2.]
  [ 2.]
  [ 2.]]
 [[ 4.]
  [ 5.]
  [ 6.]]
 [[ 6.]
  [ 8.]
  [10.]]]
```

`Tensor.`**`mean`**(*axis=None*, *keep_dims=False*) → *Tensor*

For details, please refer to *`mindspore.ops.mean()`* .

mindspore.Tensor.median

Tensor.**median**(*axis=- 1*, *keepdims=False*) → Tuple of Tensors

Computes the median and indices of input tensor.

Warning:

- *indices* does not necessarily contain the first occurrence of each median value found in the *input*, unless it is unique. The specific implementation of this API is device-specific. The results may be different on CPU and GPU.

Parameters

- **axis** (*int, optional*) –Specify the axis for calculation. Default: `-1` .
- **keepdims** (*bool, optional*) –Whether the output tensor need to retain *axis* dimension or not. Default: `False` .

Returns

- y (Tensor) - Returns the median value along the specified dimension. And It has the same dtype as the *input*.
- indices (Tensor) - The index of the median. And the dtype is int64.

Raises

- **TypeError** –If *axis* is not an int.
- **TypeError** –If *keepdims* is not a bool.
- **ValueError** –If *axis* is not in range of [-x.dim, x.dim-1].

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[0.57, 0.11, 0.21],[0.38, 0.50, 0.57], [0.36, 0.16, 0.44]]).
↪astype(np.float32))
>>> y = x.median(axis=0, keepdims=False)
>>> print(y)
(Tensor(shape=[3], dtype=Float32, value= [ 3.79999995e-01,  1.59999996e-01,  4.39999998e-
↪01]),
Tensor(shape=[3], dtype=Int64, value= [1, 2, 2]))
```

Tensor.**median**() → *Tensor*

Return the median of the input.

Returns

- y (Tensor) - Output median.

Supported Platforms:

Ascend

Tensor.**median**(*dim=- 1*, *keepdim=False*) → Tuple of Tensors

Output the median on the specified dimension `dim` and its corresponding index. If `dim` is None, calculate the median of all elements in the Tensor.

Parameters

- **dim** (*int, optional*) –Specify the axis for calculation. Default: `None` .
- **keepdim** (*bool, optional*) –Whether the output tensor need to retain `dim` dimension or not. Default: `False` .

Returns

- y (Tensor) - Output median, with the same data type as `input` .
  - If `dim` is `None` , `y` only has one element.
  - If `keepdim` is `True` , the `y` has the same shape as the `input` except the shape of `y` in dimension *dim* is size 1.
  - Otherwise, the `y` lacks *dim* dimension than input.
- indices (Tensor) - The index of the median. Shape is consistent with `y` , with a data type of int64.

Raises

- **TypeError** –If `dim` is not an int.
- **TypeError** –If `keepdim` is not a bool.
- **ValueError** –If `dim` is not in range of [-x.dim, x.dim-1].

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[0.57, 0.11, 0.21],[0.38, 0.50, 0.57], [0.36, 0.16, 0.44]]).
↪astype(np.float32))
>>> y = x.median(dim=0, keepdim=False)
>>> print(y)
(Tensor(shape=[3], dtype=Float32, value= [ 3.79999995e-01,  1.59999996e-01,  4.39999998e-
↪01]),
Tensor(shape=[3], dtype=Int64, value= [1, 2, 2]))
```

mindspore.Tensor.t

`Tensor.t()`

Transpose *self* .

For details, please refer to *mindspore.ops.t()*.

Supported Platforms:

`Ascend`

mindspore.Tensor.mH

property Tensor.**mH**

Accessing this property is equivalent to Calling self.adjoint(). For details, please refer to *mindspore.ops.adjoint()*.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([[0. + 0.j, 1. + 1.j], [2. + 2.j, 3. + 3.j]]))
>>> output = x.mH
>>> print(output)
[[0.-0.j 2.-2.j]
 [1.-1.j 3.-3.j]]
```

mindspore.Tensor.min

Tensor.**min**() → *Tensor*

Returns the minimum value of the self tensor.

Returns

Scalar Tensor with the same dtype as *self*, the minimum value of the self.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([0.0, 0.4, 0.6, 0.7, 0.1]), mindspore.float32)
>>> output = Tensor.min(x)
>>> print(output)
0.0
```

Tensor.**min**(*dim*, *keepdim=False*)

Calculates the minimum value along with the given dim for the self tensor, and returns the minimum values and indices.

Parameters

- **dim** (*int*) −The dimension to reduce.
- **keepdim** (*bool, optional*) −Whether to reduce dimension, if True the output will keep the same dimension as the *self* , the output will reduce dimension if False. Default: False.

Returns

tuple (Tensor), tuple of 2 tensors, containing the minimum value of the self tensor along the given dimension *dim* and the corresponding index.

- **values** (Tensor) - The minimum value of self tensor along the given dimension *dim*, with the same shape as *index*, and same dtype as *self*.
- **index** (Tensor) - The index for the minimum value of the self tensor, with dtype int64. If *keepdim* is `True`, the shape of output tensors is $(self_1, self_2, ..., self_{dim-1}, 1, self_{dim+1}, ..., self_N)$. Otherwise, the shape is $(self_1, self_2, ..., self_{dim-1}, self_{dim+1}, ..., self_N)$.

Raises

- **TypeError** – If *keepdim* is not a bool.
- **TypeError** – If *dim* is not an int.
- **TypeError** – If self tensor data type is Complex.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([0.0, 0.4, 0.6, 0.7, 0.1]), mindspore.float32)
>>> output, index = x.min(0, keepdim=True)
>>> print(output, index)
[0.0] [0]
```

`Tensor.`**`min`**(*axis=None*, *keepdims=False*, *, *initial=None*, *where=True*, *return_indices=False*) → *Tensor* | number.Number

Return the minimum of a tensor or minimum along an axis.

Note: When *axis* is `None`, *keepdims* and subsequent parameters have no effect. At the same time, the index is fixed to return 0.

Parameters

- **axis** (*Union[None, int, list, tuple of ints], optional*) – An axis or axes along which to operate. By default, flattened input is used. If *axis* is a tuple of ints, the minimum is selected over multiple axes, instead of a single axis or all the axes as before. Default: `None`.
- **keepdims** (*bool, optional*) – If `True`, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array. Default: `False`.

Keyword Arguments

- **initial** (*scalar, optional*) – The minimum value of an output element. Must be present to allow computation on empty slice. Default: `None`.
- **where** (*Tensor[bool], optional*) – A boolean tensor which is broadcasted to match the dimensions of array, and selects elements to include in the reduction. If non-default value is passed, initial must also be provided. Default: `True`.
- **return_indices** (*bool, optional*) – Whether to return the index of the minimum value. Default: `False`. If *axis* is a list or tuple of ints, it must be `False`.

Returns

Tensor or scalar, minimum of self tensor. If *axis* is `None` , the result is a scalar value. If *axis* is given, the result is a tensor of dimension `self.ndim - 1`.

Raises

`TypeError` –If arguments have types not specified above.

See also:

- *`mindspore.Tensor.argmin()`*: Return the indices of the minimum values along an axis.
- *`mindspore.Tensor.argmax()`*: Return the indices of the maximum values along an axis.
- *`mindspore.Tensor.max()`*: Return the minimum of a tensor or minimum along an axis.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> a = Tensor(np.arange(4).reshape((2, 2)).astype('float32'))
>>> output = Tensor.min(a)
>>> print(output)
0.0
>>> output = Tensor.min(a, axis=0)
>>> print(output)
[0. 1.]
>>> output = Tensor.min(a, axis=0, initial=9, where=Tensor([False]))
>>> print(output)
[9. 9.]
>>> output = Tensor.min(a, axis=0, initial=9, where=Tensor([False, True]))
>>> print(output)
[9. 1.]
>>> value, indices = Tensor.min(a, axis=0, return_indices=True)
>>> print(value)
[0. 1.]
>>> print(indices)
[0 0]
```

mindspore.Tensor.minimum

`Tensor.`**`minimum`**(*other*) → *Tensor*

For details, please refer to *`mindspore.ops.minimum()`*.

mindspore.Tensor.mm

Tensor.**mm**(*mat2*) → *Tensor*

Returns the matrix product of two arrays. If *self* is a $(n \times m)$ Tensor, *mat2* is a $(m \times p)$ Tensor, *out* will be a $(n \times p)$ Tensor.

Note: This function cannot support broadcasting. Refer to *mindspore.ops.matmul()* instead if you need a broadcastable function.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

mat2 (Tensor) −The second matrix of matrix multiplication. The last dimension of *self* must be the same size as the first dimension of *mat2*.

Returns

Tensor, the matrix product of the inputs.

Raises

- **TypeError** −If *self* or *mat2* is not a Tensor.
- **RuntimeError** −If the last dimension of *self* is not the same size as the second-to-last dimension of *mat2*.
- **RuntimeError** −If dtype of *self* or *mat2* is not float16, float32 or bfloat16.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> x1 = ms.Tensor(np.random.rand(2, 3), ms.float32)
>>> x2 = ms.Tensor(np.random.rand(3, 4), ms.float32)
>>> out = x1.mm(x2)
>>> print(out.shape)
(2, 4)
```

mindspore.Tensor.moveaxis

Tensor.**moveaxis**(*source*, *destination*)

For details, please refer to *mindspore.ops.moveaxis()*.

mindspore.Tensor.movedim

Tensor.**movedim**(*source*, *destination*)
For details, please refer to *mindspore.ops.movedim()*.

mindspore.Tensor.move_to

Tensor.**move_to**(*to*, *blocking=True*)
Copy Tensor to target device synchronously or asynchronously, default synchronously. only support PyNative mode.

Parameters

- **to** (*str*) –a string type value, one of "Ascend", "GPU", "CPU".
- **blocking** (*bool*) –a bool type value, using synchronous copy or asynchronous copy. Default: True , synchronous copy.

Returns

New Tensor, storged on target device which with the same type and shape as the "self Tensor".

Raises

- **ValueError** –If the type of *blocking* is not bool type.
- **ValueError** –If the value of *to* is not one of "Ascend", "GPU", "CPU".
- **ValueError** –If the run mode is not PyNative mode.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> x = ms.Tensor([1, 2, 3], ms.int64)
>>> new_tensor = x.move_to("CPU")
```

mindspore.Tensor.msort

Tensor.**msort**()
For details, please refer to *mindspore.ops.msort()*.

mindspore.Tensor.mT

property Tensor.**mT**

Returns the Tensor that exchanges the last two dimensions. Accessing the attribute, x.mT, is equal to calling the method, x.swapaxes(-2, -1). For details, please refer to *mindspore.Tensor.swapaxes()*.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.ones((2, 3, 4)))
>>> output = x.mT
>>> print(output.shape)
(2, 4, 3)
```

mindspore.Tensor.mul

Tensor.**mul**(*other*) → *Tensor*

For details, please refer to *mindspore.ops.mul()*.

mindspore.Tensor.mul_

Tensor.**mul_**(*other*) → *Tensor*

Multiplies two tensors element-wise.

$$out_i = tensor_i * other_i$$

Warning: This is an experimental API that is subject to change or deletion.

Note:

- When *self* and *other* have different shapes, *other* be able to broadcast to a *self*.
- *self* and *other* can not be bool type at the same time, [True, Tensor(True, bool_), Tensor(np.array([True]), bool_)] are all considered bool type.

Parameters

other (*Union[Tensor, number.Number, bool]*) – *other* is a number.Number or a bool or a tensor whose data type is number.Number and bool.

Returns

Tensor, the shape is the same as *self* , and the data type is the same as *self* .

Raises

- **TypeError** – If *other* is not one of the following: Tensor, number.Number, bool.
- **RuntimeError** – If *other* cannot be broadcast to *self*.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([1.0, 2.0, 3.0]), mindspore.float32)
>>> y = Tensor(np.array([4.0, 5.0, 6.0]), mindspore.float32)
>>> output = x.mul_(y)
>>> print(output)
[ 4. 10. 18.]
>>> print(x)
[ 4. 10. 18.]
```

mindspore.Tensor.multinomial

Tensor.**multinomial**(*num_samples*, *replacement=True*, *seed=None*)

For details, please refer to *mindspore.ops.multinomial()*.

mindspore.Tensor.multiply

Tensor.**multiply**(*value*)

For details, please refer to *mindspore.ops.mul()*. The parameter *value* of the current interface is the same as the parameter *other* of the reference interface.

mindspore.Tensor.mvlgamma

Tensor.**mvlgamma**(*p*)

For details, please refer to *mindspore.ops.mvlgamma()*.

mindspore.Tensor.nan_to_num

Tensor.**nan_to_num**(*nan=None*, *posinf=None*, *neginf=None*) → *Tensor*

For details, please refer to *mindspore.ops.nan_to_num()*.

Supported Platforms:

Ascend CPU

mindspore.Tensor.nanmean

Tensor.**nanmean**(*axis=None*, *keepdims=False*, *, *dtype=None*)
For details, please refer to *mindspore.ops.nanmean()*.

mindspore.Tensor.nanmedian

Tensor.**nanmedian**(*axis=- 1*, *keepdims=False*)
For details, please refer to *mindspore.ops.nanmedian()*.

mindspore.Tensor.nansum

Tensor.**nansum**(*dim=None*, *keepdim=False*, *, *dtype=None*) → *Tensor*
Computes sum of input Tensor over a given dimension, treating NaNs as zero.

Warning:

- It is only supported on Atlas A2 Training Series Products.
- This is an experimental API that is subject to change or deletion.

Parameters

- **dim** (*Union[int, tuple(int)], optional*) –The dimensions to sum. Dim must be in the range [-rank(self), rank(self)). Default: None, which indicates the sum of all elements in a tensor.
- **keepdim** (*bool, optional*) –Whether the output Tensor keeps dimensions or not. Default: False, indicating that no dimension is kept.

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The dtype of output Tensor. Default: None.

Returns

Tensor, the sum of input Tensor in the given dimension dim, treating NaNs as zero.

- If dim is None, keepdim is False, the output is a 0-D Tensor representing the sum of all elements in the self Tensor.
- If dim is int, set as 2, and keepdim is False, the shape of output is $(self_1, self_3, ..., self_R)$.
- If dim is tuple(int) or list(int), set as (2, 3), and keepdim is False, the shape of output is $(self_1, self_4, ..., self_R)$.

Raises

- **TypeError** –If *keepdim* is not a bool.
- **TypeError** –If the dtype of *self* or *dtype* is complex type.
- **ValueError** –If *dim* is not in [-rank(self), rank(self)).

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[float("nan"), 2, 3], [1, 2, float("nan")]]), mindspore.float32)
>>> output1 = x.nansum(dim=0, keepdim=False, dtype=mindspore.float32)
>>> output2 = x.nansum(dim=0, keepdim=True, dtype=mindspore.float32)
>>> print(output1)
[1. 4. 3.]
>>> print(output2)
[[1. 4. 3.]]
```

Tensor.**nansum**(*axis=None*, *keepdims=False*, *, *dtype=None*) → *Tensor*

Computes sum of *input* over a given dimension, treating NaNs as zero.

Parameters

- **axis** (*Union[int, tuple(int)], optional*) – The dimensions to reduce. Supposed the rank of *self* is r, axis must be in the range [-r,r). Default: None, all dimensions are reduced.
- **keepdims** (*bool, optional*) – Whether the output Tensor keeps dimensions or not. Default: False.

Keyword Arguments

dtype (*mindspore.dtype*, optional) – The dtype of output Tensor. Default: None.

Returns

Tensor, the sum of input Tensor in the given dimension dim, treating NaNs as zero.

- If axis is None, keepdims is False, the output is a 0-D Tensor representing the sum of all elements in the input Tensor.
- If axis is int, set as 2, and keepdims is False, the shape of output is $(self_1, self_3, ..., self_R)$.
- If axis is tuple(int) or list(int), set as (2, 3), and keepdims is False, the shape of output is $(self_1, self_4, ..., self_R)$.

Raises

- **TypeError** – If *keepdims* is not a bool.
- **TypeError** – If the dtype of *self* or *dtype* is complex type.
- **ValueError** – If *axis* not in [-rank(self), rank(self)).

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[float("nan"), 2, 3], [1, 2, float("nan")]]), mindspore.float32)
>>> output1 = x.nansum(axis=0, keepdims=False, dtype=mindspore.float32)
>>> output2 = x.nansum(axis=0, keepdims=True, dtype=mindspore.float32)
>>> print(output1)
[1. 4. 3.]
```

(continues on next page)

(continued from previous page)

```
>>> print(output2)
[[1. 4. 3.]]
```

mindspore.Tensor.narrow

Tensor.**narrow**(*dim*, *start*, *length*) → *Tensor*

Obtains a tensor of a specified length at a specified start position along a specified axis.

Parameters

- **dim** (*int*) – the axis along which to narrow.
- **start** (*Union[int, Tensor]*) – the starting dimension.
- **length** (*int*) – the distance to the ending dimension.

Returns

output (Tensors) - The narrowed tensor.

Raises

- **ValueError** – The value of *dim* is out of range [-self.ndim, self.ndim).
- **ValueError** – The value of *start* is out of range [-self.shape[dim], self.shape[dim]].
- **ValueError** – The value of *length* is out of range [0, self.shape[dim] - start].

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor([[1, 2, 3], [4, 5, 6], [7, 8, 9]], mindspore.int32)
>>> output = x.narrow(0, 0, 2)
>>> print(output)
[[ 1 2 3]
 [ 4 5 6]]
>>> output = x.narrow(1, 1, 2)
>>> print(output)
[[ 2 3]
 [ 5 6]
 [ 8 9]]
```

mindspore.Tensor.nbytes

property Tensor.**nbytes**

Return the total number of bytes taken by the tensor.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([[1, 2], [3, 4]]))
>>> output = x.nbytes
>>> print(output)
32
```

mindspore.Tensor.ndim

property Tensor.**ndim**

Return the number of tensor dimensions.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([[1, 2], [3, 4]]))
>>> output = x.ndim
>>> print(output)
2
```

mindspore.Tensor.ndimension

Tensor.**ndimension**()

Alias for *mindspore.Tensor.ndim*.

mindspore.Tensor.ne

Tensor.**ne**(*other*) → *Tensor*

Alias for *mindspore.Tensor.not_equal()*.

mindspore.Tensor.neg

Tensor.**neg**() → *Tensor*

For details, please refer to *mindspore.ops.neg()*.

mindspore.Tensor.negative

Tensor.**negative**() → *Tensor*
Alias for *mindspore.Tensor.neg()*.

mindspore.Tensor.nelement

Tensor.**nelement**()
Alias for *mindspore.Tensor.numel()*.

mindspore.Tensor.new_ones

Tensor.**new_ones**(*size*, *dtype=None*) → *Tensor*
Return a tensor of *size* filled with ones.

Parameters

- **size** (*Union[int, tuple(int), list(int)]*) – An int, list or tuple of integers defining the output shape.
- **dtype** (*mindspore.dtype*, optional) – The desired dtype of the output tensor. If None, the returned tensor has the same dtype as *self*. Default: None.

Returns

Tensor, the shape and dtype is defined above and filled with ones.

Raises

- **TypeError** – If *size* is neither an int nor a tuple/list of int.
- **TypeError** – If *dtype* is not a MindSpore dtype.
- **ValueError** – If *size* contains negative values.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor((), mindspore.int32)
>>> x.new_ones((2, 3))
Tensor(shape=[2, 3], dtype=Int32, value=
[[1, 1, 1],
 [1, 1, 1]])
```

mindspore.Tensor.new_zeros

Tensor.**new_zeros**(*size*, *dtype=None*) → *Tensor*

Return a tensor of *size* filled with zeros.

Parameters

- **size** (*Union[int, tuple(int), list(int)]*) – An int, list or tuple of integers defining the output shape.
- **dtype** (*mindspore.dtype*, optional) – The desired dtype of the output tensor. If None, the returned tensor has the same dtype as *self*. Default: None.

Returns

Tensor, the shape and dtype is defined above and filled with zeros.

Raises

- **TypeError** – If *size* is neither an int nor a tuple/list of int.
- **TypeError** – If *dtype* is not a MindSpore dtype.
- **ValueError** – If *size* contains negative values.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor((), mindspore.int32)
>>> x.new_zeros((2, 3))
Tensor(shape=[2, 3], dtype=Int32, value=
[[0, 0, 0],
 [0, 0, 0]])
```

mindspore.Tensor.nextafter

Tensor.**nextafter**(*other*)

For details, please refer to *mindspore.ops.nextafter()*.

mindspore.Tensor.nonzero

Tensor.**nonzero**(*, *as_tuple=False*)

Return the positions of all non-zero values.

Note: The rank of *self*.

- Ascend: its rank can be equal to 0 except O2 mode.
- CPU/GPU: its rank should be greater than or eaqual to 1.

Keyword Arguments

as_tuple (bool, *optional*) –Whether the output is tuple. If `False` , return Tensor. Default: `False` . If `True` , return Tuple of Tensor, only support `Ascend` .

Returns

- If *as_tuple* is `False`, return the Tensor, a 2-D Tensor whose data type is int64, containing the positions of all non-zero values of the *self* .
- If *as_tuple* is `True`, return the Tuple of Tensor and data type is int64. The Tuple length is the dimension of the *self* tensor, and each element is the 1D tensor of the subscript of all non-zero elements of the *self* tensor in that dimension.

Raises

- **TypeError** –If *self* is not Tensor.
- **TypeError** –If *as_tuple* is not bool.
- **RuntimeError** –On GPU or CPU or Ascend O2 mode, if dim of *input* equals to 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[[1,  0], [-5, 0]]]), mindspore.int32)
>>> output = x.nonzero()
>>> print(output)
[[0 0 0]
[0 1 0]]
>>> x = Tensor(np.array([1, 0, 2, 0, 3]), mindspore.int32)
>>> output = x.nonzero(as_tuple=False)
>>> print(output)
[[0]
[2]
[4]]
>>> x = Tensor(np.array([[[1,  0], [-5, 0]]]), mindspore.int32)
>>> output = x.nonzero(as_tuple=True)
>>> print(output)
(Tensor(shape=[2], dtype=Int64, value=[0, 0]),
Tensor(shape=[2], dtype=Int64, value=[0, 1]),
Tensor(shape=[2], dtype=Int64, value=[0, 0]))
>>> x = Tensor(np.array([1, 0, 2, 0, 3]), mindspore.int32)
>>> output = x.nonzero(as_tuple=True)
>>> print(output)
(Tensor(shape=[3], dtype=Int64, value=[0, 2, 4]), )
```

mindspore.Tensor.norm

Tensor.**norm**(*ord=None*, *dim=None*, *keepdim=False*, *, *dtype=None*)
For details, please refer to *mindspore.ops.norm()*.

mindspore.Tensor.normal_

Tensor.**normal_**(*mean=0*, *std=1*, *, *generator=None*)
Update the *self* tensor in place by generating random numbers sampled from the normal distribution which constructed by the parameters *mean* and *std*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **mean** (*number, optional*) – the mean of normal distribution. With float data type. Default: 0.
- **std** (*number, optional*) – the std of normal distribution. With float data type. Default: 1.

Keyword Arguments

generator (*mindspore.Generator*, optional) – a pseudorandom number generator. Default: None, uses the default pseudorandom number generator.

Returns

A tensor that is filled with random numbers that follow a normal distribution and that has the same type and shape as the *self* tensor.

Raises

TypeError – If the dtype of *mean* or *std* is not one of: bool, int, float, complex.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> x = mindspore.Tensor(np.array([[1, 2], [3, 4]]), dtype=mindspore.float32)
>>> output = x.normal_()
>>> print(output)
[[0.2788825 1.3305743]
 [1.244194 1.16303174]]
```

mindspore.Tensor.not_equal

Tensor.**not_equal**(*other*) → *Tensor*
For details, please refer to *mindspore.ops.ne()*.

mindspore.Tensor.numel

Tensor.**numel**()
For details, please refer to *mindspore.ops.numel()*.

mindspore.Tensor.numpy

Tensor.**numpy**()
Alias for *mindspore.Tensor.asnumpy()*.

mindspore.Tensor.orgqr

Tensor.**orgqr**(*input2*)
For details, please refer to *mindspore.ops.orgqr()*.

mindspore.Tensor.ormqr

Tensor.**ormqr**(*input2*, *input3*, *left=True*, *transpose=False*)
For details, please refer to *mindspore.ops.ormqr()*, Args *input2* and *input3* correspond to the args *tau* and *other* of *mindspore.ops.ormqr()*.

mindspore.Tensor.outer

Tensor.**outer**(*vec2*) → *Tensor*
For details, please refer to *mindspore.ops.outer()*.

mindspore.Tensor.permute

Tensor.**permute**(**axis*)
Tensor.permute supports unpacking the *axis* argument automatically when it is passed as an indefinite number of positional arguments, which has a slight difference from the input parameter of *mindspore.ops.permute()*. For details, please refer to *mindspore.ops.permute()*.

mindspore.Tensor.positive

Tensor.**positive**()
For details, please refer to *mindspore.ops.positive()*.

mindspore.Tensor.pow

Tensor.**pow**(*exponent*) → *Tensor*
For details, please refer to *mindspore.ops.pow()*.

mindspore.Tensor.prod

Tensor.**prod**(*dim=None*, *keepdim=False*, *dtype=None*) → *Tensor*
Reduces a dimension of a tensor by multiplying all elements in the dimension, by default. And also can reduce a dimension of *self* along the *dim*. Determine whether the dimensions of the output and self are the same by controlling *keepdim*.

Parameters

- **dim** (*Union[int, tuple(int), list(int), Tensor], optional*) –The dimensions to reduce. Default: None , reduce all dimensions. Only constant value is allowed. Assume the rank of *self* is r, and the value range is [-r,r).
- **keepdim** (*bool, optional*) –If True , keep these reduced dimensions and the length is 1. If False , don't keep these dimensions. Default: False .
- **dtype** (*mindspore.dtype*, optional) –The desired data type of returned Tensor. Default: None .

Returns

Tensor.

- If *dim* is None , and *keepdim* is False , the output is a 0-D tensor representing the product of all elements in the self tensor.
- If *dim* is int, set as 1, and *keepdim* is False , the shape of output is $(self_0, self_2, ..., self_R)$.
- If *dim* is tuple(int) or list(int), set as (1, 2), and *keepdim* is False , the shape of output is $(self_0, self_3, ..., self_R)$.
- If *dim* is 1-D Tensor, set as [1, 2], and *keepdim* is False , the shape of output is $(self_0, self_3, ..., self_R)$.

Raises

- **TypeError** –If *dim* is not one of the following: int, Tuple, list or Tensor.
- **TypeError** –If *keepdim* is not a bool.
- **ValueError** –If *dim* is out of range.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.random.randn(3, 4, 5, 6).astype(np.float32))
>>> output = Tensor.prod(x, 1, True)
>>> result = output.shape
>>> print(result)
(3, 1, 5, 6)
>>> # case 1: Reduces a dimension by multiplying all elements in the dimension.
>>> x = Tensor(np.array([[[1, 1, 1, 1, 1, 1], [2, 2, 2, 2, 2, 2], [3, 3, 3, 3, 3, 3]],
...                      [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
...                      [[7, 7, 7, 7, 7, 7], [8, 8, 8, 8, 8, 8], [9, 9, 9, 9, 9, 9]]]),␣
↪mindspore.float32)
>>> output = Tensor.prod(x)
>>> print(output)
2.2833798e+33
>>> print(output.shape)
()
>>> # case 2: Reduces a dimension along axis 0.
>>> output = Tensor.prod(x, 0, True)
>>> print(output)
[[[ 28.  28.  28.  28.  28.  28.]
  [ 80.  80.  80.  80.  80.  80.]
  [162. 162. 162. 162. 162. 162.]]]
>>> # case 3: Reduces a dimension along axis 1.
>>> output = Tensor.prod(x, 1, True)
>>> print(output)
[[[  6.   6.   6.   6.   6.   6.]]
 [[120. 120. 120. 120. 120. 120.]]
 [[504. 504. 504. 504. 504. 504.]]]
>>> # case 4: Reduces a dimension along axis 2.
>>> output = Tensor.prod(x, 2, True)
>>> print(output)
[[[1.00000e+00]
  [6.40000e+01]
  [7.29000e+02]]
 [[4.09600e+03]
  [1.56250e+04]
  [4.66560e+04]]
 [[1.17649e+05]
  [2.62144e+05]
  [5.31441e+05]]]
```

`Tensor.`**`prod`**(*axis=None*, *keep_dims=False*, *dtype=None*) → *Tensor*

For more details, please refer to *`mindspore.ops.prod()`*.

mindspore.Tensor.ptp

Tensor.**ptp**(*axis=None*, *keepdims=False*)

The name of the function comes from the acronym for "peak to peak". Calculate the difference between the maximum value and the minimum value along the axis.

Note: Numpy argument *out* is not supported.

Parameters

- **axis** (*Union[None, int, tuple(int)]*) – Axis or axes along which the range is computed. The default is to compute the variance of the flattened tensor. Default: `None` .
- **keepdims** (*bool*) – If this is set to `True` , the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the tensor. Default is `False` .

Returns

Tensor.

Raises

TypeError – If *self* is not a tensor, or *axis* and *keepdims* have types not specified above.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor
>>> x = Tensor([[4.0, 9.0, 2.0, 10.0], [6.0, 9.0, 7.0, 12.0]]).astype("float32")
>>> print(x.ptp(axis=1))
[8. 6.]
>>> print(x.ptp(axis=0))
[2. 0. 5. 2.]
```

mindspore.Tensor.rad2deg

Tensor.**rad2deg**()

For details, please refer to *mindspore.ops.rad2deg()*.

mindspore.Tensor.random_

Tensor.**random_**(*from_=0*, *to=None*, ***, *generator=None*)

Fill the tensor with numbers sampled from a discrete uniform distribution over an interval $[from\_, to - 1]$.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **from_** (*Union[number.Number, Tensor], optional*) –the lower bound of the generated random number. It can be a scalar value or a Tensor of any dimension with only a single element. Default: 0.
- **to** (*Union[number.Number, Tensor], optional*) –the upper bound of the generated random number. By default it's the upper limit of the input data type. It can be a scalar value or a Tensor of any dimension with only a single element. Default: None.

Keyword Arguments

generator (*mindspore.Generator*, optional) –a pseudorandom number generator. Default: None, uses the default pseudorandom number generator.

Returns

The input tensor.

Raises

- **TypeError** –If *from_* or *to* is not integer.
- **RuntimeError** –If *from_* >= *to*.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import Tensor
>>> a = Tensor([[2, 3, 4], [1, 2, 3]])
>>> from_ = 0
>>> to = 5
>>> print(a.random_(from_, to).shape)
(2, 3)
```

mindspore.Tensor.random_categorical

Tensor.**random_categorical**(*num_sample*, *seed=0*, *dtype=mstype.int64*)

For details, please refer to *mindspore.ops.random_categorical()*.

mindspore.Tensor.ravel

Tensor.**ravel**()

Return a contiguous flattened tensor.

Returns

Tensor, a 1-D tensor, containing the same elements of the input.

See also:

- *mindspore.Tensor.reshape()*: Give a new shape to a tensor without changing its data.
- *mindspore.Tensor.flatten()*: Return a copy of the tensor collapsed into one dimension.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.ones((2,3,4), dtype=np.float32))
>>> output = x.ravel()
>>> print(output.shape)
(24,)
```

mindspore.Tensor.real

Tensor.**real**()
For details, please refer to *mindspore.ops.real()*.

mindspore.Tensor.reciprocal

Tensor.**reciprocal**() → *Tensor*
For details, please refer to *mindspore.ops.reciprocal()*.

mindspore.Tensor.register_hook

Tensor.**register_hook**(*hook*)
Registers a backward hook for tensor.

Note:

- The *hook* must be defined as the following code. *grad* is the gradient passed to the tensor, which may be modified by returning a new output gradient.
- The *hook* should have the following signature: hook(grad) -> New output gradient, but can not return None or not set return value.
- Higher-order differentiation does not support tensor *register_hook*.
- The following constraints must be met under graph mode:
  - The *hook* must satisfy the syntax constraints of the graph mode.
  - It is not supported to delete *hook* inside graph.
  - It is not supported to register *hook* after the *Tensor* is used before.
  - It is not supported to register multiple *hooks* for a *Tensor* inside graph.
  - Register *hook* in the graph will return then *Tensor* it self.

Parameters

hook (*function*) –Python function. Tensor backward hook function.

Returns

A handle corresponding to the *hook* . The handle can be used to remove the added *hook* by calling *handle.remove()* .

Raises

TypeError –If the *hook* is not a function of python.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> ms.set_context(mode=ms.PYNATIVE_MODE)
>>> def hook_fn(grad):
...     return grad * 2
...
>>> def hook_test(x, y):
...     z = x * y
...     z.register_hook(hook_fn)
...     z = z * y
...     return z
...
>>> ms_grad = ms.grad(hook_test, grad_position=(0,1))
>>> output = ms_grad(Tensor(1, ms.float32), Tensor(2, ms.float32))
>>> print(output)
(Tensor(shape=[], dtype=Float32, value=8), Tensor(shape=[], dtype=Float32, value=6))
```

mindspore.Tensor.remainder

Tensor.**remainder**(*other*) → *Tensor*

Computes the remainder of *self* divided by *other* element-wise. The result has the same sign as the divisor and its absolute value is less than that of *other*.

Supports broadcasting to a common shape and implicit type promotion.

```
remainder(input, other) == input - input.div(other, rounding_mode="floor") * other
```

Note: Complex inputs are not supported. At least one input need to be tensor, but not both are bool tensors.

The dividend *self* is a tensor whose data type is number or bool_.

Parameters

other (*Union[Tensor, numbers.Number, bool]*) –The divisor is a numbers.Number or a bool or a tensor whose data type is number or bool_ when the dividend is a tensor.

Returns

Tensor, with dtype promoted and shape broadcasted.

Raises

- **TypeError** –If *self* and *other* are not of types: (Tensor, Tensor), (Tensor, Number), (Tensor, bool), (Number, Tensor) or (bool, Tensor).
- **ValueError** –If *self* and *other* are not broadcastable.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([-4.0, 5.0, 6.0]).astype(np.float32))
>>> y = Tensor(np.array([3.0, 2.0, 3.0]).astype(np.float64))
>>> output = x.remainder(y)
>>> print(output)
[2.  1.  0.]
```

Tensor.**remainder**(*divisor*) → *Tensor*

Computes the remainder of dividing the first input tensor by the second input tensor element-wise.

Inputs of *self* and *divisor* comply with the implicit type conversion rules to make the data types consistent. The inputs must be two tensors or one tensor and one scalar. When the inputs are two tensors, both dtypes cannot be bool, and the shapes of them could be broadcast. When the inputs are one tensor and one scalar, the scalar could only be a constant.

```
remainder(input, other) == input - input.div(other, rounding_mode="floor") * other
```

Warning:

- When the elements of input exceed 2048, there might be accuracy problems.
- The calculation results of this operator on Ascend and CPU might be inconsistent.
- If shape is expressed as (D1,D2⋯,Dn), then D1*D2⋯*DN<=1000000,n<=8.

Note: The first input *self* is a tensor whose data type is number.

Parameters

divisor (*Union[Tensor, numbers.Number, bool]*) – When the first input is a tensor, The second input could be a number, a bool or a tensor whose data type is number.

Returns

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision.

Raises

- **TypeError** – If neither *self* nor *divisor* is one of the following: Tensor, Number, bool.
- **ValueError** – If the shape of *self* and *divisor* cannot be broadcasted to each other.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([-4.0, 5.0, 6.0]).astype(np.float16))
>>> y = Tensor(np.array([3.0, 2.0, 3.0]).astype(np.float16))
>>> output = x.remainder(divisor=y)
>>> print(output)
[2.  1.  0.]
```

mindspore.Tensor.renorm

Tensor.**renorm**(*p*, *axis*, *maxnorm*)

For details, please refer to *mindspore.ops.renorm()*.

mindspore.Tensor.repeat

Tensor.**repeat**(**repeats*)

Copy the elements in each dimension of a Tensor based on the specified number of repetition times.

This function copies the tensor's data.

The shape of the output tensor can be described as follows, where n is the number of elements in *repeats*.

$$shape_i = \begin{cases} repeats_i * input.shape_i & \text{if } 0 \le i < input.rank \\ repeats_i & \text{if } input.rank \le i < n \end{cases}$$

Warning: This is an experimental API that is subject to change or deletion.

Note: If need to specify the number of repetition times for each element of a single dimension, please refer to *mindspore.Tensor.repeat_interleave()*.

Parameters

***repeats** (*int*) −Number of repetitions of *self* in each dimension. The value must be a non-negative number. `1` indicates that the dimension remains unchanged. The number of elements in *repeats* must be greater than or equals to the number of dimensions in *self* . When the number of dimensions of *self* is less than the number of elements of *repeats* , *self* is broadcasted to the number of dimensions with the same number of elements of *repeats* (as shown in the example).

Returns

Tensor, the new Tensor after the element is copied from the specified number of repetitions.

Raises

- **RuntimeError** −If the number of elements of *repeats* is less than the number of dimensions of *self* . Or *repeats* has negative element.
- **RuntimeError** −If the number of elements of *repeats* or the number of dimensions of *self* is larger than 8.
- **TypeError** −If type of *repeats* is unsupported.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor
>>> a = Tensor([[0, 1, 2], [3, 4, 5]])
>>> print(a.repeat(3, 2))
[[0 1 2 0 1 2]
 [3 4 5 3 4 5]
 [0 1 2 0 1 2]
 [3 4 5 3 4 5]
 [0 1 2 0 1 2]
 [3 4 5 3 4 5]]
>>> print(a.repeat(2, 1, 3))  # a is treated as a shape [1, 2, 3]
[[[0 1 2 0 1 2 0 1 2]
  [3 4 5 3 4 5 3 4 5]]
 [[0 1 2 0 1 2 0 1 2]
  [3 4 5 3 4 5 3 4 5]]]
```

`Tensor.`**`repeat`**(*repeats*) → *Tensor*

Copy the elements in each dimension of a Tensor based on the specified number of repetition times.

This function copies the tensor's data.

Expect that a variable-length int parameter is changed to a parameter which type is list or tuple, other operations are the same as the overload with **repeats* parameter.

The shape of the output tensor can be described as follows, where n is the number of elements in *repeats*.

$$shape_i = \begin{cases} repeats_i * input.shape_i & \text{if } 0 \leq i < input.rank \\ repeats_i & \text{if } input.rank \leq i < n \end{cases}$$

Warning: This is an experimental API that is subject to change or deletion.

Note: If need to specify the number of repetition times for each element of a single dimension, please refer to *mindspore.Tensor.repeat_interleave()*.

Parameters

repeats (*Union[tuple[int], list[int]]*) – Number of repetitions of *self* in each dimension. The value must be a non-negative number. `1` indicates that the dimension remains unchanged. The number of elements in *repeats* must be greater than or equals to the number of dimensions in *self* . When the number of dimensions of *self* is less than the number of elements of *repeats* , *self* is broadcasted to the number of dimensions with the same number of elements of *repeats* (as shown in the example).

Returns

Tensor, the new Tensor after the element is copied from the specified number of repetitions.

Raises

- **RuntimeError** –If the number of elements of *repeats* is less than the number of dimensions of *self* . Or *repeats* has negative element.
- **RuntimeError** –If the number of elements of *repeats* or the number of dimensions of *self* is larger than 8.
- **TypeError** –If type of *repeats* is unsupported.

See also:

- *mindspore.Tensor.reshape()*: Give a new shape to a tensor without changing its data.
- *mindspore.Tensor.resize()*: Changes shape and size of tensor in-place.
- *mindspore.Tensor.repeat_interleave()*: Repeats each element on the specified axis of a Tensor based on the specified number of times.
- *mindspore.Tensor.tile()*: Repeats a Tensor on each dimension for a specified number of times. And there is no requirement on the number of parameters *repeats* .

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor
>>> a = Tensor([[0, 1, 2], [3, 4, 5]])
>>> print(a.repeat([3, 2]))
[[0 1 2 0 1 2]
 [3 4 5 3 4 5]
 [0 1 2 0 1 2]
 [3 4 5 3 4 5]
 [0 1 2 0 1 2]
 [3 4 5 3 4 5]]
>>> print(a.repeat(repeats=(2, 1, 3)))  # a is treated as a shape [1, 2, 3]
[[[0 1 2 0 1 2 0 1 2]
  [3 4 5 3 4 5 3 4 5]]
 [[0 1 2 0 1 2 0 1 2]
  [3 4 5 3 4 5 3 4 5]]]
```

mindspore.Tensor.repeat_interleave

`Tensor.`**`repeat_interleave`**(*repeats*, *dim=None*, *, *output_size=None*) → *Tensor*

Repeat elements of a tensor along a dim, like *mindspore.numpy.repeat()*.

> **Warning:** Only support on Atlas A2 training series.

Note: The self tensor to repeat values for. Must be of type: float16, float32, int8, uint8, int16, int32, or int64.

Parameters

- **repeats** (*Union[int, tuple, list, Tensor]*) –The number of times to repeat, must be positive.

- **dim** (*int, optional*) –The dim along which to repeat, Default: `None`. if dim is None, the self Tensor will be flattened and the output will alse be flattened.

Keyword Arguments

output_size (*int, optional*) –Total output size for the given axis (e.g. sum of repeats), Default: `None`.

Returns

One tensor with values repeated along the specified dim. If self has shape ($s1, s2, ..., sn$) and dim is i, the output will have shape ($s1, s2, ..., si * repeats, ..., sn$). The output type will be the same as the type of *self*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input1 = Tensor(np.array([[0, 1, 2], [3, 4, 5]]), mindspore.int32)
>>> output1 = input1.repeat_interleave(repeats=2, dim=0, output_size=None)
>>> input2 = Tensor(np.array([[1, 2], [3, 4]]), mindspore.int32)
>>> output2 = input2.repeat_interleave(Tensor(np.array([1, 2])), dim=0, output_size=None)
>>> print(output1)
>>> print(output2)
[[0 1 2]
 [0 1 2]
 [3 4 5]
 [3 4 5]]
[[1 2]
 [3 4]
 [3 4]]
```

`Tensor.`**repeat_interleave**(*repeats*, *dim=None*) → *Tensor*

Repeat elements of a tensor along an dim, like *mindspore.numpy.repeat()*.

Note: The tensor to repeat values for. Must be of type: float16, float32, int8, uint8, int16, int32, or int64.

Parameters

- **repeats** (*Union[int, tuple, list, Tensor]*) –The number of times to repeat, must be positive.
- **dim** (*int, optional*) –The dim along which to repeat, Default: `None`. if dim is None, the self Tensor will be flattened and the output will alse be flattened.

Returns

One tensor with values repeated along the specified dim. If self has shape ($s1, s2, ..., sn$) and dim is i, the output will have shape ($s1, s2, ..., si * repeats, ..., sn$). The output type will be the same as the type of *self*.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input1 = Tensor(np.array([[0, 1, 2], [3, 4, 5]]), mindspore.int32)
>>> output1 = input1.repeat_interleave(repeats=2, dim=0)
>>> input2 = Tensor(np.array([[1, 2], [3, 4]]), mindspore.int32)
>>> output2 = input2.repeat_interleave(Tensor(np.array([1, 2])), dim=0)
>>> print(output1)
>>> print(output2)
[[0 1 2]
 [0 1 2]
 [3 4 5]
 [3 4 5]]
[[1 2]
 [3 4]
 [3 4]]
```

mindspore.Tensor.reshape

Tensor.**reshape**(**shape*) → *Tensor*

For details, please refer to *mindspore.ops.reshape()*.

mindspore.Tensor.reshape_as

Tensor.**reshape_as**(*other*)

Change the shape of the Tensor to the shape of *other* without changing the data.

Parameters

other (Tensor) –The result tensor has the same shape as *other*.

Returns

Tensor, has the same shape as *other*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]], dtype=ms.float32)
>>> y = Tensor(np.arange(6).reshape(3,2))
>>> output = x.reshape_as(y)
>>> print(output)
[[-0.1  0.3]
 [ 3.6  0.4]
 [ 0.5 -3.2]]
```

mindspore.Tensor.resize

Tensor.**resize**(**new_shape*)

Changes shape and size of tensor in-place.

If the shape of the new tensor is larger than the shape of the original tensor, the new tensor will be filled with 0. And if the shape of the new tensor is smaller than the shape of the original tensor, the new tensor is filled with the elements of the original tensor in order.

Note: Instead of changing the size of the input tensor and returns nothing as in numpy, this method returns a new Tensor with the input size. Numpy argument *refcheck* is not supported.

Parameters

new_shape (*Union[ints, tuple of ints]*) –Shape of resized tensor.

Returns

Tensor.

See also:

- *mindspore.Tensor.reshape()*: Give a new shape to a tensor without changing its data.
- *mindspore.Tensor.repeat()*: Repeat elements of a tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6]], dtype=np.float32))
>>> y = x.resize(3, 3)
>>> print(y)
[[1. 2. 3.]
[4. 5. 6.]
[0. 0. 0.]]
>>> y = x.resize(2, 2)
>>> print(y)
[[1. 2.]
[3. 4.]]
```

mindspore.Tensor.reverse

Tensor.**reverse**(*axis*)

For details, please refer to *mindspore.ops.flip()*. The *axis* parameter in *Tensor.reverse* is equivalent to the *dims* parameter in *mindspore.ops.flip()*.

mindspore.Tensor.reverse_sequence

Tensor.**reverse_sequence**(*seq_lengths*, *seq_dim=0*, *batch_dim=0*)

For details, please refer to *mindspore.ops.reverse_sequence()*.

mindspore.Tensor.roll

Tensor.**roll**(*shifts*, *dims*) → *Tensor*

For details, please refer to *mindspore.ops.roll()*.

mindspore.Tensor.rot90

Tensor.**rot90**(*k*, *dims*)

For details, please refer to *mindspore.ops.rot90()*.

mindspore.Tensor.round

Tensor.**round**(*decimals=0*) → *Tensor*

For details, please refer to *mindspore.ops.round()*.

mindspore.Tensor.rsqrt

Tensor.**rsqrt**() → *Tensor*

For details, please refer to *mindspore.ops.rsqrt()*.

mindspore.Tensor.scatter

Tensor.**scatter**(*dim*, *index*, *src*) → *Tensor*

Update the value in *src* to *self* according to the specified index. For a 3-D tensor, the output will be:

```
output[index[i][j][k]][j][k] = src[i][j][k]  # if dim == 0

output[i][index[i][j][k]][k] = src[i][j][k]  # if dim == 1

output[i][j][index[i][j][k]] = src[i][j][k]  # if dim == 2
```

Note: The backward is supported only for the case *src.shape* == *index.shape* when *src* is a tensor. The rank of the input tensor *self* must be at least 1.

Parameters

- **dim** (*int*) −Which axis to scatter. Accepted range is [-r, r) where r = rank(self).
- **index** (Tensor) −The index to do update operation whose data must be positive number with type of int32 or int64. Same rank as *self* . And accepted range is [-s, s) where s is the size along axis.
- **src** (Tensor, *float*) −The data doing the update operation with *self*. Can be a tensor with the same data type as *self* or a float number to scatter.

Returns

Tensor, has the same shape and type as *self* .

Raises

- **TypeError** −If *index* is neither int32 nor int64.
- **ValueError** −If rank of any of *self* , *index* and *src* is less than 1.
- **ValueError** −If the rank of *src* is not equal to the rank of *self* .
- **TypeError** −If the data types of *self* and *src* have different dtypes.
- **RuntimeError** −If *index* has negative elements.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> input = Tensor(np.array([[1, 2, 3, 4, 5]]), dtype=ms.float32)
>>> src = Tensor(np.array([[8, 8]]), dtype=ms.float32)
>>> index = Tensor(np.array([[2, 4]]), dtype=ms.int64)
>>> out = input.scatter(dim=1, index=index, src=src)
>>> print(out)
[[1. 2. 8. 4. 8.]]
>>> input = Tensor(np.zeros((5, 5)), dtype=ms.float32)
>>> src = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), dtype=ms.float32)
>>> index = Tensor(np.array([[0, 0, 0], [2, 2, 2], [4, 4, 4]]), dtype=ms.int64)
>>> out = input.scatter(dim=0, index=index, src=src)
>>> print(out)
[[1. 2. 3. 0. 0.]
 [0. 0. 0. 0. 0.]
 [4. 5. 6. 0. 0.]
 [0. 0. 0. 0. 0.]
 [7. 8. 9. 0. 0.]]
>>> input = Tensor(np.zeros((5, 5)), dtype=ms.float32)
>>> src = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), dtype=ms.float32)
>>> index = Tensor(np.array([[0, 2, 4], [0, 2, 4], [0, 2, 4]]), dtype=ms.int64)
>>> out = input.scatter(dim=1, index=index, src=src)
>>> print(out)
[[1. 0. 2. 0. 3.]
 [4. 0. 5. 0. 6.]
 [7. 0. 8. 0. 9.]
 [0. 0. 0. 0. 0.]
 [0. 0. 0. 0. 0.]]
```

Tensor.**scatter**(*axis*, *index*, *src*) → *Tensor*

Update the value in *src* to *self* according to the specified index. Refer to *mindspore.ops.tensor_scatter_elements()* for more details.

Note: The backward is supported only for the case *src.shape* == *index.shape*. The rank of the input tensor *self* must be at least 1.

Parameters

- **axis** (*int*) −Which axis to scatter. Accepted range is [-r, r) where r = rank(self).
- **index** (Tensor) −The index to do update operation whose data must be positive number with type of int32 or int64. Same rank as *self* . And accepted range is [-s, s) where s is the size along axis.
- **src** (Tensor, *float*) −The data doing the update operation with *self*. Can be a tensor with the same data type as *self* or a float number to scatter.

Returns

Tensor, has the same shape and type as *self* .

Raises

- **TypeError** −If *index* is neither int32 nor int64.
- **ValueError** −If rank of any of *self* , *index* and *src* is less than 1.
- **ValueError** −If the rank of *src* is not equal to the rank of *self* .
- **TypeError** −If the data types of *self* and *src* have different dtypes.
- **RuntimeError** −If *index* has negative elements.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> input = Tensor(np.array([[1, 2, 3, 4, 5]]), dtype=ms.float32)
>>> src = Tensor(np.array([[8, 8]]), dtype=ms.float32)
>>> index = Tensor(np.array([[2, 4]]), dtype=ms.int64)
>>> out = input.scatter(axis=1, index=index, src=src)
>>> print(out)
[[1. 2. 8. 4. 8.]]
>>> input = Tensor(np.zeros((5, 5)), dtype=ms.float32)
>>> src = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), dtype=ms.float32)
>>> index = Tensor(np.array([[0, 0, 0], [2, 2, 2], [4, 4, 4]]), dtype=ms.int64)
>>> out = input.scatter(axis=0, index=index, src=src)
>>> print(out)
[[1. 2. 3. 0. 0.]
 [0. 0. 0. 0. 0.]
 [4. 5. 6. 0. 0.]
 [0. 0. 0. 0. 0.]
 [7. 8. 9. 0. 0.]]
>>> input = Tensor(np.zeros((5, 5)), dtype=ms.float32)
```

```

mindspore.Tensor.scatter_

Tensor.**scatter_**(*dim*, *index*, *src*) → *Tensor*

Update the value in *src* to update *self* according to the specified *index*.

Index the dimension *self* selected by *dim* using *index* , traverse the other dimensions in sequence, update the value of *src* to *self* , and return *self* .

This operator is the inverse of the in-place version of *mindspore.Tensor.gather()* .

This operation provides another three overloads to support parameter *reduce* and scalar value.

Here's an example using a 3-dimension tensor.

```
self[index[i][j][k]][j][k] = src[i][j][k]  # if dim == 0

self[i][j][index[i][j][k]] = src[i][j][k]  # if dim == 2
```

Warning:

- If multiple indexes point to the same position in *self* , the final value of this position in *self* is uncertain.
- On Ascend, behavior is unpredictable when the value of *index* is not in the range *[-self.shape[dim], self.shape[dim])* in forward.
- This is an experimental API that is subject to change or deletion.

Note: The inverse gradient from *self* to *src* can be calculated only when the shape of src is the same as that of *index*.

Parameters

- **dim** (*int*) −Which axis to scatter. Accepted range is *[-r, r)* where *r* is the rank of *self* .
- **index** (Tensor) −The index to access *self* on the target axis specified by *dim* whose dtype must be int32 or int64. If it is an empty Tensor, no operations is performed and directly returns *self* . Otherwise, its rank must be the same as *self* and the value range of each element must be *[-s, s)* where *s* is the size of *self* along axis *dim* .
- **src** (Tensor) −The data to doing the update operation with *self* . It should have the same dtype and rank as *self* .

Returns

Tensor, the modified *self* itself.

Raises

- **TypeError** –If type of *self* , *index* or *src* is unsupported.
- **RuntimeError** –If *dim* is out of the range *[-r, r)* .
- **RuntimeError** –If rank of *self* is larger than 8.
- **RuntimeError** –If dtype of tensor *self* , *index* or *src* is unsupported.
- **RuntimeError** –If dtype of *self* is not equal to the dtype of *src* .
- **RuntimeError** –If *self* , *index*, or *src* have different ranks and *index* is not an empty tensor.
- **RuntimeError** –If there is a dimension *d* that makes *index.size(d) > src.size(d)* .
- **RuntimeError** –If there is a dimension *d* that makes *index.size(d) > self.size(d)* .

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor, int64, float32
>>> this_tensor = Tensor([[1, 2], [3, 4]], dtype=float32)
>>> index = Tensor([[1, 0], [1, 0]], dtype=int64)
>>> src = Tensor([[4, 3], [2, 1]], dtype=float32)
>>> this_tensor.scatter_(1, index, src)
>>> print(this_tensor)
[[3., 4.],
 [1., 2.]]
```

`Tensor.`**`scatter_`**(*dim*, *index*, *src*, ***, *reduce*) → *Tensor*

Update the value in *src* to update *self* according to the specified *index*.

Using the operation specified by *reduce* to index the dimension *self* selected by *dim* using *index* , traverse the other dimensions in sequence, accumulate or multiply the value of *src* to *self* , and return *self* .

This operator is the inverse of the in-place version of *mindspore.Tensor.gather()* .

Expect that the replacement operation changes to accumulation or multiplication based on the parameter *reduce*, other operations are the same as the overloaded function that accept *src* without the parameter *reduce* .

Here's an example using a 3-dimension tensor.

```
self[index[i][j][k]][j][k] += src[i][j][k]  # if dim == 0, reduce == "add"

self[i][j][index[i][j][k]] *= src[i][j][k]  # if dim == 2, reduce == "multiply"
```

Warning:

- If multiple indexes point to the same position in *self* , the final value of this position in *self* is uncertain.
- On Ascend, behavior is unpredictable when the value of *index* is not in the range *[-self.shape[dim], self.shape[dim])* in forward.
- This is an experimental API that is subject to change or deletion.

Note: This overload function does not support reverse gradient calculation and will return zeros if calculate gradient.

Parameters

- **dim** (*int*) −Which axis to scatter. Accepted range is *[-r, r)* where *r* is the rank of *self* .
- **index** (Tensor) −The index to access *self* on the target axis specified by *dim* whose dtype must be int32 or int64. If it is an empty Tensor, no operations is performed and directly returns *self* . Otherwise, its rank must be the same as *self* and the value range of each element must be *[-s, s)* where *s* is the size of *self* along axis *dim* .
- **src** (Tensor) −The data to doing the accumulate or multiply operation with *self* . It should have the same dtype and rank as *self* .

Keyword Arguments

reduce (*str*) −Reduce operation, supports `"add"` and `"multiply"` . When *reduce* is `"add"` , *src* is accumulated to *input* base on *index* . When *reduce* is `"multiply"` , *src* is multiplied to *input* base on *index* .

Returns

Tensor, the modified *self* itself.

Raises

- **TypeError** −If type of *self* , *index* or *src* is unsupported.
- **ValueError** −If *reduce* is a str but not `"add"` or `"multiply"` .
- **RuntimeError** −If *dim* is out of the range *[-r, r)* .
- **RuntimeError** −If rank of *self* is larger than 8.
- **RuntimeError** −If dtype of tensor *self* , *index* or *src* is unsupported.
- **RuntimeError** −If dtype of *self* is not equal to the dtype of *src* .
- **RuntimeError** −If *self* , *index*, or *src* have different ranks and *index* is not an empty tensor.
- **RuntimeError** −If there is a dimension *d* that makes *index.size(d)* > *src.size(d)* .
- **RuntimeError** −If there is a dimension *d* that makes *index.size(d)* > *self.size(d)* .

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor, int64, float32
>>> this_tensor = Tensor([[1, 2], [3, 4]], dtype=float32)
>>> index = Tensor([[1, 0], [1, 0]], dtype=int64)
>>> src = Tensor([[4, 3], [2, 1]], dtype=float32)
>>> this_tensor.scatter_(1, index, src, reduce='add')
>>> print(this_tensor)
[[4., 6.],
 [4., 6.]]
```

Tensor.**scatter_**(*dim*, *index*, *value*) → *Tensor*

Update the value *value* to update *self* according to the specified *index*.

Index the dimension *self* selected by *dim* using *index* , traverse the other dimensions in sequence, update the value *value* to *self* , and return *self* .

This operator is the inverse of the in-place version of `mindspore.Tensor.gather()` .

It can be considered that after the value is broadcasted as a Tensor whose shape and dtype are consistent with *self* , other operations are the same as the overloaded function that accept *src* without the parameter *reduce* .

Here's an example using a 3-dimension tensor.

```
self[index[i][j][k]][j][k] = value  # if dim == 0

self[i][j][index[i][j][k]] = value  # if dim == 2
```

Warning:

- If multiple indexes point to the same position in *self* , the final value of this position in *self* is uncertain.
- On Ascend, behavior is unpredictable when the value of *index* is not in the range *[-self.shape[dim], self.shape[dim])* in forward.
- This is an experimental API that is subject to change or deletion.

Parameters

- **dim** (*int*) −Which axis to scatter. Accepted range is *[-r, r)* where *r* is the rank of *self* .
- **index** (Tensor) −The index to access *self* on the target axis specified by *dim* whose dtype must be int32 or int64. If it is an empty Tensor, no operations is performed and directly returns *self* . Otherwise, its rank must be the same as *self* and the value range of each element must be *[-s, s)* where *s* is the size of *self* along axis *dim* .
- **value** (*int, float, bool*) −The data to doing the update operation with *self* . It can be considered as being broadcasted into a Tensor whose shape and dtype are the same as *self* , and then be regarded as *src* for calculation.

Returns

Tensor, the modified *self* itself.

Raises

- **TypeError** −If type of *self* , *index* or *value* is unsupported.
- **RuntimeError** −If *dim* is out of the range *[-r, r)* .
- **RuntimeError** −If rank of *self* is larger than 8.
- **RuntimeError** −If dtype of tensor *self* or *index* is unsupported.
- **RuntimeError** −If *index* is not an empty tensor and its rank is different from the rank of *self* .
- **RuntimeError** −If there is a dimension *d* that makes *index.size(d) > self.size(d)* .

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import Tensor, int64, float32
>>> this_tensor = Tensor([[1, 2], [3, 4]], dtype=float32)
>>> index = Tensor([[0], [1]], dtype=int64)
>>> this_tensor.scatter_(0, index, 10)
>>> print(this_tensor)
[[10., 2.],
 [10., 4.]]
```

Tensor.**scatter_**(*dim*, *index*, *value*, *, *reduce*) → *Tensor*

Update the value *value* to update *self* according to the specified *index*.

Using the operation specified by *reduce* to index the dimension *self* selected by *dim* using *index* , traverse the other dimensions in sequence, accumulate or multiply the value *value* to *self* , and return *self* .

This operator is the inverse of the in-place version of *mindspore.Tensor.gather()* .

Expect that the replacement operation changes to accumulation or multiplication based on the parameter *reduce*, other operations are the same as the overloaded function that accept *value* without the parameter *reduce* .

Here's an example using a 3-dimension tensor.

```
self[i][index[i][j][k]][k] += value  # if dim == 1, reduce == "add"

self[i][j][index[i][j][k]] *= value  # if dim == 2, reduce == "multiply"
```

Warning:

- If multiple indexes point to the same position in *self* , the final value of this position in *self* is uncertain.
- On Ascend, behavior is unpredictable when the value of *index* is not in the range *[-self.shape[dim], self.shape[dim])* in forward.
- This is an experimental API that is subject to change or deletion.

Note: This overload function does not support reverse gradient calculation and will return zeros if calculate gradient.

Parameters

- **dim** (*int*) −Which axis to scatter. Accepted range is *[-r, r)* where *r* is the rank of *self* .
- **index** (Tensor) −The index to access *self* on the target axis specified by *dim* whose dtype must be int32 or int64. If it is an empty Tensor, no operations is performed and directly returns *self* . Otherwise, its rank must be the same as *self* and the value range of each element must be *[-s, s)* where *s* is the size of *self* along axis *dim* .
- **value** (*int, float, bool*) −The data to doing the accumulate or multiply operation with *self* . It can be considered as being broadcasted into a Tensor whose shape and dtype are the same as *self* , and then be regarded as *src* for calculation.

Keyword Arguments

reduce (*str*) −Reduce operation, supports "add" and "multiply" . When *reduce* is "add" , *value* is accumulated to *input* base on *index* . When *reduce* is "multiply" , *value* is multiplied to *input* base on *index* .

Returns

Tensor, the modified *self* itself.

Raises

- **TypeError** –If type of *self* , *index* or *value* is unsupported.
- **ValueError** –If *reduce* is a str but not `"add"` or `"multiply"` .
- **RuntimeError** –If *dim* is out of the range *[-r, r)* .
- **RuntimeError** –If rank of *self* is larger than 8.
- **RuntimeError** –If dtype of tensor *self* or *index* is unsupported.
- **RuntimeError** –If *index* is not an empty tensor and its rank is different from the rank of *self* .
- **RuntimeError** –If there is a dimension *d* that makes *index.size(d)* > *self.size(d)* .

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor, int64, float32
>>> this_tensor = Tensor([[1, 2], [3, 4]], dtype=float32)
>>> index = Tensor([[0], [1]], dtype=int64)
>>> this_tensor.scatter_(0, index, 3, reduce="multiply")
>>> print(this_tensor)
[[3., 2.],
 [9., 4.]]
```

mindspore.Tensor.scatter_add

`Tensor.`**`scatter_add`**(*dim*, *index*, *src*) → *Tensor*

Add all elements in *src* to the index specified by *index* to *self* along dimension specified by *dim*. It takes three inputs *self*, *src* and *index* of the same rank r >= 1.

For a 3-D tensor, the operation updates input as follows:

```
self[index[i][j][k]][j][k] += src[i][j][k]  # if dim == 0

self[i][index[i][j][k]][k] += src[i][j][k]  # if dim == 1

self[i][j][index[i][j][k]] += src[i][j][k]  # if dim == 2
```

Note: The rank of this tensor *self* must be at least 1.

Parameters

- **dim** (*int*) –Which dim to scatter. Accepted range is [-r, r) where r = rank(*self*).
- **index** (Tensor) –The index of *self* to do scatter operation whose data type must be int32 or int64. Same rank as *self*. Except for the dimension specified by *dim*, the size of each dimension of *index* must be less than or equal to the size of the corresponding dimension of *self*.

- **src** (Tensor) −The tensor doing the scatter operation with *self*, has the same type as *self* and the size of each dimension must be greater than or equal to that of *index*.

Returns

Tensor, has the same shape and type as *self*.

Raises

- **TypeError** −If *index* is neither int32 nor int64.
- **ValueError** −If anyone of the rank among *self*, *index* and *src* is less than 1.
- **ValueError** −If the rank of *self*, *index* and *src* is not the same.
- **ValueError** −The size of any dimension of *index* except the dimension specified by *dim* is greater than the size of the corresponding dimension of *self*.
- **ValueError** −If the size of any dimension of *src* is less than that of *index*.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> input = Tensor(np.array([[1, 2, 3, 4, 5]]), dtype=ms.float32)
>>> src = Tensor(np.array([[8, 8]]), dtype=ms.float32)
>>> index = Tensor(np.array([[2, 4]]), dtype=ms.int64)
>>> out = input.scatter_add(dim=1, index=index, src=src)
>>> print(out)
[[1. 2. 11. 4. 13.]]
>>> input = Tensor(np.zeros((5, 5)), dtype=ms.float32)
>>> src = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), dtype=ms.float32)
>>> index = Tensor(np.array([[0, 0, 0], [2, 2, 2], [4, 4, 4]]), dtype=ms.int64)
>>> out = input.scatter_add(dim=0, index=index, src=src)
>>> print(out)
[[1. 2. 3. 0. 0.]
 [0. 0. 0. 0. 0.]
 [4. 5. 6. 0. 0.]
 [0. 0. 0. 0. 0.]
 [7. 8. 9. 0. 0.]]
>>> input = Tensor(np.zeros((5, 5)), dtype=ms.float32)
>>> src = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), dtype=ms.float32)
>>> index = Tensor(np.array([[0, 2, 4], [0, 2, 4], [0, 2, 4]]), dtype=ms.int64)
>>> out = input.scatter_add(dim=1, index=index, src=src)
>>> print(out)
[[1. 0. 2. 0. 3.]
 [4. 0. 5. 0. 6.]
 [7. 0. 8. 0. 9.]
 [0. 0. 0. 0. 0.]
 [0. 0. 0. 0. 0.]]
```

Tensor.**scatter_add**(*indices*, *updates*) → *Tensor*

Creates a new tensor by adding the values from the positions in *self* indicated by *indices*, with values from *updates*. When multiple values are given for the same index, the updated result will be the sum of all values. This operation is almost equivalent to using ScatterNdAdd, except that the updates are applied on output *Tensor* instead of input *Parameter*.

The last axis of *indices* is the depth of each index vectors. For each index vector, there must be a corresponding value in *updates*. The shape of *updates* should be equal to the shape of *self[indices]*. For more details, see Examples.

$$output\left[indices\right] = input\_x + update$$

Note: The dimension of this tensor *self* must be no less than indices.shape[-1].

If some values of the *indices* are out of bound:

- On GPU, if some values of the *indices* are out of bound, instead of raising an index error, the corresponding *updates* will not be updated to self tensor.
- On CPU, if some values of the *indices* are out of bound, raising an index error.
- On Ascend, out of bound checking is not supported, if some values of the *indices* are out of bound, unknown errors may be caused.

Parameters

- **indices** (Tensor) −The index of input tensor whose data type is int32 or int64. The rank must be at least 2.
- **updates** (Tensor) −The tensor to update the input tensor, has the same type as input, and updates. And the shape should be equal to $indices.shape[:-1] + input\_x.shape[indices.shape[-1]:]$.

Returns

Tensor, has the same shape and type as *self*.

Raises

- **TypeError** −If dtype of *indices* is neither int32 nor int64.
- **ValueError** −If length of shape of *self* is less than the last dimension of shape of *indices*.
- **RuntimeError** −If a value of *indices* is not in *self* on CPU backend.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input_x = Tensor(np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]), mindspore.float32)
>>> indices = Tensor(np.array([[0, 0], [0, 0]]), mindspore.int32)
>>> updates = Tensor(np.array([1.0, 2.2]), mindspore.float32)
>>> output = input_x.scatter_add(indices, updates)
>>> print(output)
[[ 3.1  0.3  3.6]
 [ 0.4  0.5 -3.2]]
```

mindspore.Tensor.scatter_add_

Tensor.**scatter_add_**(*dim*, *index*, *src*)

Add all elements in *src* to the index specified by *index* to *self* along dimension specified by *dim*, *scatter_add* is an in-place operation. The ranks of *self*, *index* and *src* must be greater or equal to 1.

For a 3-D tensor, the operation updates *self* as follows:

```
self[index[i][j][k]][j][k] += src[i][j][k]  # if dim == 0

self[i][index[i][j][k]][k] += src[i][j][k]  # if dim == 1

self[i][j][index[i][j][k]] += src[i][j][k]  # if dim == 2
```

Parameters

- **dim** (*int*) −Which dim to scatter. Accepted range is [-r, r) where r = rank(*self*).
- **index** (Tensor) −The index of *self* to do scatter operation whose data type must be int32 or int64. Same rank as *self*. Except for the dimension specified by *dim*, size of each dimension of *index* must be less than or equal to the size of the corresponding dimension of *self*.
- **src** (Tensor) −The tensor doing the scatter operation with *self*, has the same type as *self* and the size of each dimension must be greater than or equal to that of *index*.

Returns

Tensor, has the same shape and type as *self*.

Raises

- **TypeError** −If *index* is neither int32 nor int64.
- **ValueError** −If anyone of the rank among *self*, *index* and *src* is less than 1.
- **ValueError** −If the ranks of *self*, *index* and *src* are not the same.
- **ValueError** −The size of any dimension of *index* except the dimension specified by *dim* is greater than the size of the corresponding dimension of *self*.
- **ValueError** −If the size of any dimension of *src* is less than that of *index*.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> input = Tensor(np.array([[1, 2, 3, 4, 5]]), dtype=ms.float32)
>>> src = Tensor(np.array([[8, 8]]), dtype=ms.float32)
>>> index = Tensor(np.array([[2, 4]]), dtype=ms.int64)
>>> out = input.scatter_add_(1, index, src)
>>> print(out)
[[1. 2. 11. 4. 13.]]
>>> input = Tensor(np.zeros((5, 5)), dtype=ms.float32)
>>> src = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), dtype=ms.float32)
```

(continues on next page)

(continued from previous page)

```
>>> index = Tensor(np.array([[0, 0, 0], [2, 2, 2], [4, 4, 4]]), dtype=ms.int64)
>>> out = input.scatter_add_(0, index, src)
>>> print(out)
[[1. 2. 3. 0. 0.]
[0. 0. 0. 0. 0.]
[4. 5. 6. 0. 0.]
[0. 0. 0. 0. 0.]
[7. 8. 9. 0. 0.]]
>>> input = Tensor(np.zeros((5, 5)), dtype=ms.float32)

mindspore.Tensor.scatter_div

Tensor.**scatter_div**(*indices*, *updates*)
For details, please refer to *mindspore.ops.scatter_div()*.

mindspore.Tensor.scatter_max

Tensor.**scatter_max**(*indices*, *updates*)
For details, please refer to *mindspore.ops.scatter_max()*.

mindspore.Tensor.scatter_min

Tensor.**scatter_min**(*indices*, *updates*)
For details, please refer to *mindspore.ops.scatter_min()*.

mindspore.Tensor.scatter_mul

Tensor.**scatter_mul**(*indices*, *updates*)
For details, please refer to *mindspore.ops.scatter_mul()*.

mindspore.Tensor.scatter_sub

Tensor.**scatter_sub**(*indices*, *updates*)
For details, please refer to *mindspore.ops.tensor_scatter_sub()*.

mindspore.Tensor.searchsorted

Tensor.**searchsorted**(*v*, *side='left'*, *sorter=None*)

For details, please refer to *mindspore.ops.searchsorted()*.

mindspore.Tensor.select

Tensor.**select**(*dim*, *index*) → *Tensor*

Slices the *self* tensor along the selected dimension at the given index.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **dim** (*int*) −the dimension to slice.
- **index** (*int*) −the index to select with.

Returns

Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> input = Tensor([[2, 3, 4, 5], [3, 2, 4, 5]])
>>> y = Tensor.select(input, 0, 0)
>>> print(y)
[2 3 4 5]
```

Tensor.**select**(*condition*, *y*) → *Tensor*

The conditional tensor determines whether the corresponding element in the output must be selected from *self* (if True) or *y* (if False) based on the value of each element.

It can be defined as:

$$out_i = \begin{cases} self_i, & \text{if } condition_i \\ y_i, & \text{otherwise} \end{cases}$$

Parameters

- **condition** (*Tensor[bool]*) −The condition tensor, decides which element is chosen. The shape is $(x_1, x_2, ..., x_N, ..., x_R)$.
- **y** (*Union[Tensor, int, float]*) −The second Tensor to be selected. If *y* is a Tensor, its shape should be or be broadcast to $(x_1, x_2, ..., x_N, ..., x_R)$. If *y* is int or float, it will be casted to int32 or float32, and broadcast to the same shape as *self*. There must be at least one Tensor between *self* and *y*.

Returns

Tensor, has the same shape as *condition*.

Raises

- **TypeError** –If y is not a Tensor, int or float.
- **ValueError** –The shape of inputs cannot be broadcast.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> # Both input are Tensor
>>> cond = Tensor([True, False])
>>> x = Tensor([2,3], mindspore.float32)
>>> y = Tensor([1,2], mindspore.float32)
>>> output = Tensor.select(x, cond, y)
>>> print(output)
[2. 2.]
```

mindspore.Tensor.select_scatter

`Tensor.`**`select_scatter`**(*src*, *axis*, *index*)

For details, please refer to *mindspore.ops.select_scatter()*.

mindspore.Tensor.set_const_arg

`Tensor.`**`set_const_arg`**(*const_arg=True*)

Specify whether the tensor is a constant when it is used for the argument of a network.

Parameters

const_arg (*bool*) –Whether the tensor is a constant when it is used for the argument of a network. Default: `True` .

Returns

Tensor, has been specified whether to be a const network argument.

Raises

TypeError –If *const_arg* is not a bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[1,2,3],[4,5,6]], dtype=np.float32))
>>> x.set_const_arg(True)
```

mindspore.Tensor.sgn

Tensor.**sgn**()

For details, please refer to *mindspore.ops.sgn()*.

mindspore.Tensor.shape

property Tensor.**shape**

For details, please refer to *mindspore.ops.shape()*.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([[1, 2], [3, 4]]))
>>> print(x.shape)
(2, 2)
```

mindspore.Tensor.short

Tensor.**short**()

Return a copy of the tensor, cast to int16 type, equivalent to self.astype(mstype.int16). If the value in tensor is float or half, the decimal will be discarded. For details, please refer to *mindspore.Tensor.astype()*.

Returns

Tensor, converted to the *int16* dtype.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> x = ms.Tensor(np.array([1,2,3,4,5]), ms.int32)
>>> output = x.short()
>>> output
Tensor(shape=[5], dtype=Int16, value= [1, 2, 3, 4, 5])
```

mindspore.Tensor.sigmoid

Tensor.**sigmoid**() → *Tensor*
For details, please refer to *mindspore.ops.sigmoid()*.

mindspore.Tensor.sign

Tensor.**sign**()
For details, please refer to *mindspore.ops.sign()*.

mindspore.Tensor.signbit

Tensor.**signbit**()
For details, please refer to *mindspore.ops.signbit()*.

mindspore.Tensor.sin

Tensor.**sin**() → *Tensor*
For details, please refer to *mindspore.ops.sin()*.

mindspore.Tensor.sinc

Tensor.**sinc**() → *Tensor*
For details, please refer to *mindspore.ops.sinc()*.

mindspore.Tensor.sinh

Tensor.**sinh**() → *Tensor*
For details, please refer to *mindspore.ops.sinh()*.

mindspore.Tensor.size

property Tensor.**size**
For details, please refer to *mindspore.ops.size()*.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([[1, 2], [3, 4]]))
>>> output = x.size
>>> print(output)
4
```

mindspore.Tensor.slice_scatter

Tensor.**slice_scatter**(*src*, *axis=0*, *start=None*, *end=None*, *step=1*)
For details, please refer to *mindspore.ops.slice_scatter()*.

mindspore.Tensor.slogdet

Tensor.**slogdet**()
For details, please refer to *mindspore.ops.slogdet()*.

mindspore.Tensor.softmax

Tensor.**softmax**(*axis*, *dtype=None*)
For details, please refer to *mindspore.ops.softmax()*.

mindspore.Tensor.sort

Tensor.**sort**(*dim=- 1*, *descending=False*)
Sorts the elements of the self tensor along the given dimension in the specified order.

> **Warning:** Currently, the data types of float16, uint8, int8, int16, int32, int64 are well supported. If use float32, it may cause loss of accuracy.

Parameters

- **dim** (*int, optional*) – The dimension to sort along. Default: -1, means the last dimension.
- **descending** (*bool, optional*) – Controls the sort order. If *descending* is True, the elements are sorted in descending order, or else sorted in ascending order. Default: False .

Returns

- y1, a tensor whose values are the sorted values, with the same shape and data type as self.
- y2, a tensor that consists of the indices of the elements in the original self tensor. Data type is int64.

Raises

- **TypeError** – If *dim* is not an int.
- **TypeError** – If *descending* is not a bool.
- **TypeError** – If *self* not in float16, float32, uint8, int8, int16, int32, int64, bfloat16
- **TypeError** – If *stable* is not a bool.
- **ValueError** – If *dim* is not in range of [-len(self.shape), len(self.shape)).

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[8, 2, 1], [5, 9, 3], [4, 6, 7]]), mindspore.float16)
>>> output = x.sort(dim=-1)
>>> # The output below is based on the Ascend platform.
>>> print(output)
(Tensor(shape=[3, 3], dtype=Float16, value=
[[ 1.0000e+00,  2.0000e+00,  8.0000e+00],
[ 3.0000e+00,  5.0000e+00,  9.0000e+00],
[ 4.0000e+00,  6.0000e+00,  7.0000e+00]]), Tensor(shape=[3, 3], dtype=Int64, value=
[[2, 1, 0],
[2, 0, 1],
[0, 1, 2]]))
```

`Tensor.`**`sort`**(*axis=- 1*, *descending=False*)

Sorts the elements of the input tensor along the given dimension in the specified order.

Parameters

- **`axis`** (*int, optional*) – The dimension to sort along. Default: `-1`, means the last dimension. The Ascend backend only supports sorting the last dimension.
- **`descending`** (*bool, optional*) – Controls the sort order. If *descending* is True, the elements are sorted in descending order, or else sorted in ascending order. Default: `False` .

> **Warning:** Currently, the data types of float16, uint8, int8, int16, int32, int64 are well supported. If use float32, it may cause loss of accuracy.

Returns

- y1, a tensor whose values are the sorted values, with the same shape and data type as self.
- y2, a tensor that consists of the indices of the elements in the original self tensor. Data type is int32.

Raises

- **`TypeError`** – If *axis* is not an int.
- **`TypeError`** – If *descending* is not a bool.
- **`TypeError`** – If dtype of *self* is neither float16, float32, uint8, int8, int16, int32, int64.
- **`ValueError`** – If *axis* is not in range of [-len(self.shape), len(self.shape)).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[8, 2, 1], [5, 9, 3], [4, 6, 7]]), mindspore.float16)
>>> output = x.sort(axis=-1)
>>> # The output below is based on the Ascend platform.
>>> print(output)
(Tensor(shape=[3, 3], dtype=Float16, value=
[[ 1.0000e+00,  2.0000e+00,  8.0000e+00],
[ 3.0000e+00,  5.0000e+00,  9.0000e+00],
[ 4.0000e+00,  6.0000e+00,  7.0000e+00]]), Tensor(shape=[3, 3], dtype=Int32, value=
[[2, 1, 0],
[2, 0, 1],
[0, 1, 2]]))
```

mindspore.Tensor.split

Tensor.**split**(*split_size*, *dim=0*)

Splits the Tensor into chunks along the given dim.

Parameters

- **split_size** (*Union[int, tuple(int), list(int)]*) – If *split_size* is an int type, *tensor* will be split into equally sized chunks, each chunk with size *split_size*. Last chunk will be smaller than *split_size* if *tensor.shape[dim]* is not divisible by *split_size*. If *split_size* is a list type, then *tensor* will be split into len(split_size) chunks with sizes *split_size* along the given *dim*.
- **dim** (*int, optional*) – The dim along which to split. Default: `0` .

Returns

A tuple of sub-tensors.

Raises

- **TypeError** – If argument *dim* is not int.
- **ValueError** – If argument *dim* is out of range of $[-tensor.ndim, tensor.ndim)$.
- **TypeError** – If each element in *split_size* is not integer.
- **TypeError** – If argument *split_size* is not int, tuple(int) or list(int).
- **ValueError** – The sum of *split_size* is not equal to x.shape[dim].

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> input_x = np.arange(9).astype("float32")
>>> output = Tensor.split(Tensor(input_x), 3)
>>> print(output)
(Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  1.00000000e+00,  2.
↪00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value= [ 3.00000000e+00,  4.00000000e+00,  5.
↪00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value= [ 6.00000000e+00,  7.00000000e+00,  8.
↪00000000e+00]))
```

`Tensor.`**`split`**(*split_size_or_sections*, *axis=0*)

Splits the Tensor into chunks along the given axis.

Parameters

- **split_size_or_sections** (*Union[int, tuple(int), list(int)]*) –If *split_size_or_sections* is an int type, *tensor* will be split into equally sized chunks, each chunk with size *split_size_or_sections*. Last chunk will be smaller than *split_size_or_sections* if *tensor.shape[axis]* is not divisible by *split_size_or_sections*. If *split_size_or_sections* is a list type, then *tensor* will be split into len(split_size_or_sections) chunks with sizes *split_size_or_sections* along the given *axis*.
- **axis** (*int, optional*) –The axis along which to split. Default: `0` .

Returns

A tuple of sub-tensors.

Raises

- **TypeError** –If argument *axis* is not int.
- **ValueError** –If argument *axis* is out of range of $[-tensor.ndim, tensor.ndim)$.
- **TypeError** –If each element in *split_size_or_sections* is not integer.
- **TypeError** –If argument *split_size_or_sections* is not int, tuple(int) or list(int).
- **ValueError** –The sum of *split_size_or_sections* is not equal to x.shape[axis].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> input_x = np.arange(9).astype("float32")
>>> output = Tensor.split(Tensor(input_x), 3)
>>> print(output)
(Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  1.00000000e+00,  2.
↪00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value= [ 3.00000000e+00,  4.00000000e+00,  5.
↪00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value= [ 6.00000000e+00,  7.00000000e+00,  8.
↪00000000e+00]))
```

(continues on next page)

(continued from previous page)

mindspore.Tensor.sqrt

Tensor.**sqrt**() → *Tensor*
For details, please refer to *mindspore.ops.sqrt()*.

mindspore.Tensor.square

Tensor.**square**() → *Tensor*
For details, please refer to *mindspore.ops.square()*.

mindspore.Tensor.squeeze

Tensor.**squeeze**(*axis=None*)
For details, please refer to *mindspore.ops.squeeze()*.

mindspore.Tensor.std

Tensor.**std**(*axis=None*, *ddof=0*, *keepdims=False*) → *Tensor*
For details, please refer to *mindspore.ops.std()*.

Tensor.**std**(*dim=None*, ***, *correction=1*, *keepdim=False*) → *Tensor*

Calculates the standard deviation over the dimensions specified by *dim*. *dim* can be a single dimension, list of dimensions, or None to reduce over all dimensions.

The standard deviation (σ) is calculated as:

$$\sigma = \sqrt{\frac{1}{N - \delta N} \sum_{j-1}^{N-1} \left(self_{ij} - \overline{x_i}\right)^2}$$

where x is the sample set of elements, $\bar{x}$ is the sample mean, N is the number of samples and δN is the *correction*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

dim (*None, int, tuple(int), optional*) – The dimension or dimensions to reduce. Defaults to None. If None, all dimensions are reduced.

Keyword Arguments

- **correction** (int, *optional*) – The difference between the sample size and sample degrees of freedom. Defaults to Bessel's correction. Defaults to 1.
- **keepdim** (bool, *optional*) – Whether the output tensor has dim retained or not. If True , keep these reduced dimensions and the length is 1. If False, don't keep these dimensions. Defaults to False.

Returns

Tensor, the standard deviation. Suppose the shape of *self* is $(x_0, x_1, ..., x_R)$:

- If *dim* is () and *keepdim* is set to `False` , returns a 0-D Tensor, indicating the standard deviation of all elements in *self*.
- If *dim* is int, e.g. `1` and *keepdim* is set to `False` , then the returned Tensor has shape $(x_0, x_2, ..., x_R)$.
- If *dim* is tuple(int) or list(int), e.g. `(1, 2)` and *keepdim* is set to `False` , then the returned Tensor has shape $(x_0, x_3, ..., x_R)$.

Raises

- **TypeError** –If *self* is not a Tensor.
- **TypeError** –If *self* is not in bfloat16, float16, float32.
- **TypeError** –If *dim* is not one of the followings: None, int, tuple.
- **TypeError** –If *correction* is not an int.
- **TypeError** –If *keepdim* is not a bool.
- **ValueError** –If *dim* is out of range $[-self.ndim, self.ndim)$.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import mint, Tensor
>>> input = Tensor(np.array([[1, 2, 3], [-1, 1, 4]]).astype(np.float32))
>>> output = input.std(dim=1, correction=1, keepdim=False)
>>> print(output)
[1.      2.5166113]
```

mindspore.Tensor.storage_offset

`Tensor.`**`storage_offset`**`()`

Tensor's offset in the underlying storage in terms of the number of storage elements.

Returns

int, tensor's offset in the underlying storage in terms of number of storage elements.

Examples

```
>>> import mindspore as ms
>>> x = ms.Tensor([1, 2, 3, 4, 5], dtype=ms.float32)
>>> ret = x.storage_offset()
>>> print(ret)
0
```

mindspore.Tensor.stride

Tensor.**stride**(*dim=None*)

The stride to jump from one element to the next in the input dim. When no parameters are passed in, a list of stride for all dimensions is returned.

Parameters

dim (*int, optional*) – The dim of stride from one element to the next. Default: None.

Returns

Int, returns the step size necessary to jump from one element to the next in the specified dimension.

Raises

TypeError – *dim* is not an int.

Examples

```
>>> import mindspore as ms
>>> x = ms.Tensor([[1, 2, 3, 4, 5], [6, 7, 8, 9, 10]], dtype=ms.float32)
>>> x.stride()
[5, 1]
```

mindspore.Tensor.strides

property Tensor.**strides**

Return the tuple of bytes to step in each dimension when traversing a tensor.

Examples

```
>>> from mindspore import Tensor
>>> from mindspore import dtype as mstype
>>> import numpy as np
>>> x = Tensor(np.array([[1, 2], [3, 4]]), dtype=mstype.int64)
>>> output = x.strides
>>> print(output)
(16, 8)
```

mindspore.Tensor.sub

Tensor.**sub**(*other*, *, *alpha=1*) → *Tensor*

Subtracts scaled other value from self Tensor.

$$out_i = self_i - alpha \times other_i$$

Note:

- When the two inputs have different shapes, they must be able to broadcast to a common shape.
- The two inputs and alpha comply with the implicit type conversion rules to make the data types consistent.

Parameters

other (*Union[Tensor, number.Number, bool]*) – The second self, is a number.Number or a bool or a tensor whose data type is number or bool_.

Keyword Arguments

alpha (*number.Number, optional*) – A scaling factor applied to *other*, default 1.

Returns

Tensor with a shape that is the same as the broadcasted shape of the self *self* and *other*, and the data type is the one with higher precision or higher digits among the two inputs and alpha.

Raises

- **TypeError** – If the type of *other* or *alpha* is not one of the following: Tensor, number.Number, bool.
- **TypeError** – If *alpha* is of type float but *self* and *other* are not of type float.
- **TypeError** – If *alpha* is of type bool but *self* and *other* are not of type bool.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor(np.array([4, 5, 6]).astype(np.float32))
>>> y = Tensor(1, mindspore.int32)
>>> output = Tensor.sub(x, y, alpha=0.5)
>>> print(output)
[3.5 4.5 5.5]
>>> # the data type of x is float32, the data type of y is int32,
>>> # alpha is a float, and the output is the data format of higher precision float32.
>>> print(output.dtype)
Float32
```

Tensor.**sub**(*y*) → *Tensor*

For details, please refer to *mindspore.ops.sub()* .

mindspore.Tensor.sub_

Tensor.**sub_**(*other*, *, *alpha=1*) → *Tensor*

For details, please refer to *mindspore.mint.sub()*.

mindspore.Tensor.subtract

Tensor.**subtract**(*other*, *, *alpha=1*) → *Tensor*

This interface is deprecated from version 2.4 and will be removed in a future version.

mindspore.Tensor.sum

Tensor.**sum**(*dim=None*, *keepdim=False*, *, *dtype=None*) → *Tensor*

Calculate sum of Tensor elements over a given dim.

Note: The *dim* with tensor type is only used for compatibility with older versions and is not recommended.

Parameters

- **dim** (*Union[None, int, tuple(int), list(int), Tensor], optional*) –Dimensions along which a sum is performed. If `None` , sum all the elements of the self tensor. If the *dim* is a tuple or list of ints, a sum is performed on all the dimensions specified in the tuple. Must be in the range $[-self.ndim, self.ndim)$. Default: `None` .
- **keepdim** (*bool, optional*) –Whether the output tensor has *dim* retained or not. If `True` , keep these reduced dimensions and the length is 1. If `False` , don't keep these dimensions. Default: `False` .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The desired data type of returned Tensor. Default: `None` .

Returns

A Tensor, sum of elements over a given *dim* in *self*.

Raises

- **TypeError** –If *dim* is not an int, tulpe(int), list(int), Tensor or None.
- **ValueError** –If *dim* is not in the range $[-self.ndim, self.ndim)$.
- **TypeError** –If *keepdim* is not a bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import dtype as mstype
>>> x = Tensor(np.array([[[1, 1, 1, 1, 1, 1], [2, 2, 2, 2, 2, 2], [3, 3, 3, 3, 3, 3]],
...                      [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
...                      [[7, 7, 7, 7, 7, 7], [8, 8, 8, 8, 8, 8], [9, 9, 9, 9, 9, 9]]]),␣
↪mstype.float32)
>>> out = Tensor.sum(x)
>>> print(out)
270.0
>>> out = Tensor.sum(x, dim=2)
```

(continues on next page)

(continued from previous page)

```
>>> print(out)
[[ 6. 12. 18.]
[24. 30. 36.]
[42. 48. 54.]]
>>> out = Tensor.sum(x, dim=2, keepdim=True)
>>> print(out)
[[[ 6.]
[12.]
[18.]]
[[24.]
[30.]
[36.]]
[[42.]
[48.]
[54.]]]
```

`Tensor.`**sum**(*axis=None*, *dtype=None*, *keepdims=False*, *initial=None*) → *Tensor*

Return sum of tensor elements over a given axis.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. The *axis* with tensor type is only used for compatibility with older versions and is not recommended.

Parameters

- **axis** (*Union[None, int, tuple(int), list(int), Tensor], optional*) – Axis or axes along which a sum is performed. Default: `None` . If `None` , sum all the elements of the self tensor. If the *axis* is negative, it counts from the last to the first *axis*. If the *axis* is a tuple or list of ints, a sum is performed on all the axes specified in the tuple or list instead of a single *axis* or all the axes as before.
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.
- **keepdims** (*bool, optional*) – If this is set to `True` , the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the self array. If the default value is passed, then *keepdims* will not be passed through to the sum method of sub-classes of ndarray, however any non-default value will be. If the sub-class method does not implement *keepdims* any exceptions will be raised. Default: `False` .
- **initial** (*scalar, optional*) – Starting value for the sum. Default: `None` .

Returns

Tensor. A tensor with the same shape as self, with the specified *axis* removed. If the self tensor is a 0-d array, or if the *axis* is `None` , a scalar is returned.

Raises

- **TypeError** – If self is not array_like, or *axis* is not int, tuple of ints, list of ints or Tensor, or *keepdims* is not integer, or *initial* is not scalar.
- **ValueError** – If any *axis* is out of range or duplicate axes exist.

See also:

- *mindspore.Tensor.cumsum()*: Return the cumulative sum of the elements along a given *axis*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> input_x = Tensor(np.array([-1, 0, 1]).astype(np.float32))
>>> print(input_x.sum())
0.0
>>> input_x = Tensor(np.arange(10).reshape(2, 5).astype(np.float32))
>>> print(input_x.sum(axis=1))
[10. 35.]
```

mindspore.Tensor.sum_to_size

Tensor.**sum_to_size**(**size*)

Sum self Tensor to the *size*. *size* must be expandable to the Tensor size.

Parameters

size (*Union[tuple(int), int]*) – The expected shape of output Tensor.

Returns

Tensor, the sum result of self Tensor according to the *size*.

Raises

ValueError – If *size* is not expandable to the size of self Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor(np.random.randn(3, 3, 3, 3, 3, 3), mindspore.float32)
>>> output = x.sum_to_size((1, 3, 1, 3))
>>> print(output.shape)
(1, 3, 1, 3)
```

mindspore.Tensor.svd

Tensor.**svd**(*full_matrices=False*, *compute_uv=True*)

For details, please refer to *mindspore.ops.svd()*.

mindspore.Tensor.swapaxes

Tensor.**swapaxes**(*axis0*, *axis1*)
For details, please refer to *mindspore.ops.swapaxes()*.

mindspore.Tensor.swapdims

Tensor.**swapdims**(*dim0*, *dim1*)
For details, please refer to *mindspore.ops.swapdims()*.

mindspore.Tensor.T

property Tensor.**T**
Return the transposed tensor.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.array([[1, 2], [3, 4]]))
>>> output = x.T
>>> print(output)
[[1 3]
[2 4]]
```

mindspore.Tensor.take

Tensor.**take**(*indices*, *axis=None*, *mode='clip'*) → *Tensor*
Takes elements from a tensor along an axis.

Parameters

- **indices** (Tensor) –The indices with shape $(Nj...)$ of the values to extract.
- **axis** (*int, optional*) –The axis over which to select values. By default, the flattened input tensor is used. Default: None .
- **mode** (*str, optional*) –Support 'raise', 'wrap', 'clip'.
  - raise: Raises an error;
  - wrap: Wraps around;
  - clip: Clips to the range. 'clip' mode means that all indices that are too large are replaced by the index that addresses the last element along that axis. Note that this disables indexing with negative numbers.

  Default: 'clip' .

Returns

Tensor, the indexed result.

Raises

ValueError –If *axis* is out of range, or *mode* has values other than ('raise', 'wrap', 'clip').

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> a = Tensor(np.array([4, 3, 5, 7, 6, 8]))
>>> indices = Tensor(np.array([0, 1, 4]))
>>> output = a.take(indices)
>>> print(output)
[4 3 6]
```

`Tensor.`**`take`**(*index*) → *Tensor*

Select the self element at the given index.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

index (*LongTensor*) – The index tensor of self tensor.

Returns

Tensor, has the same data type as index tensor.

Raises

TypeError – If the dtype of *index* is not long type.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> input = Tensor([[4, 3, 5],[6, 7, 8]], ms.float32)
>>> index = Tensor([0, 2, 5], ms.int64)
>>> output = input.take(index)
>>> print(output)
[4, 5, 8]
```

mindspore.Tensor.tan

`Tensor.`**`tan`**() → *Tensor*

For details, please refer to *mindspore.ops.tan()*.

mindspore.Tensor.tanh

Tensor.**tanh**() → *Tensor*

For details, please refer to *mindspore.ops.tanh()*.

mindspore.Tensor.tensor_split

Tensor.**tensor_split**(*indices_or_sections*, *axis=0*)

For details, please refer to *mindspore.ops.tensor_split()*.

mindspore.Tensor.tile

Tensor.**tile**(*dims*) → *Tensor*

Replicates an tensor with given dims times.

Note: On Ascend, the number of *dims* should not exceed 8, and currently does not support scenarios where more than 4 dimensions are repeated simultaneously.

Parameters

dims (*tuple[int]*) –The parameter that specifies the number of replications, the parameter type is tuple, and the data type is int, i.e., $(y_1, y_2, ..., y_S)$. Only constant value is allowed.

Returns

Tensor, has the same data type as the *self*. Suppose the length of *dims* is *d*, the dimension of *self* is *self.dim*, and the shape of *self* is $(x_1, x_2, ..., x_S)$.

- If *self.dim* = *d*, then the shape of their corresponding positions can be multiplied, and the shape of Outputs is $(x_1 * y_1, x_2 * y_2, ..., x_S * y_S)$.
- If *self.dim* < *d*, prepend 1 to the shape of *self* until their lengths are consistent. Such as set the shape of *self* as $(1, ..., x_1, x_2, ..., x_S)$, then the shape of their corresponding positions can be multiplied, and the shape of Outputs is $(1 * y_1, ..., x_R * y_R, x_S * y_S)$.
- If *self.dim* > *d*, prepend 1 to *dims* until their lengths are consistent. Such as set the *dims* as $(1, ..., y_1, y_2, ..., y_S)$, then the shape of their corresponding positions can be multiplied, and the shape of Outputs is $(x_1 * 1, ..., x_R * y_R, x_S * y_S)$.

Raises

- **TypeError** –If *dims* is not a tuple or not all elements are int.
- **ValueError** –If not all elements of *dims* are greater than or equal to 0.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.array([[1, 2], [3, 4]]), mindspore.float32)
>>> dims = (2, 3)
>>> output = input.tile(dims)
>>> print(output)
[[1.  2.  1.  2.  1.  2.]
 [3.  4.  3.  4.  3.  4.]
 [1.  2.  1.  2.  1.  2.]
 [3.  4.  3.  4.  3.  4.]]
>>> dims = (2, 3, 2)
>>> output = input.tile(dims)
>>> print(output)
[[[1. 2. 1. 2.]
  [3. 4. 3. 4.]
  [1. 2. 1. 2.]
  [3. 4. 3. 4.]
  [1. 2. 1. 2.]
  [3. 4. 3. 4.]]
 [[1. 2. 1. 2.]
  [3. 4. 3. 4.]
  [1. 2. 1. 2.]
  [3. 4. 3. 4.]
  [1. 2. 1. 2.]
  [3. 4. 3. 4.]]]
```

`Tensor.tile`(*reps*) → *Tensor*

For more details, please refer to *mindspore.ops.tile()*. The parameter *reps* in the current interface and the parameter *dims* in the detail reference interface are actually the same parameter.

mindspore.Tensor.to

`Tensor.to`(*dtype*)

Performs tensor dtype conversion.

Note:

- If the *self* Tensor already has the correct *mindspore.dtype*, then self is returned. Otherwise, the returned tensor is a copy of *self* with the desired mindspore.dtype.
- When converting complex numbers to boolean type, the imaginary part of the complex number is not taken into account. As long as the real part is non-zero, it returns True; otherwise, it returns False.

Parameters

dtype (*dtype.Number*) – The valid data type of the output tensor. Only constant value is allowed.

Returns

Tensor, converted to the specified *dtype*.

Raises

TypeError – If *dtype* is not a Number.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> input_np = np.random.randn(2, 3, 4, 5).astype(np.float32)
>>> input_x = Tensor(input_np)
>>> dtype = mindspore.int32
>>> output = input_x.to(dtype)
>>> print(output.dtype)
Int32
```

mindspore.Tensor.to_coo

`Tensor.to_coo()`

Convert a Tensor to COOTensor.

Note: Only 2-D tensor is supported for now.

Returns

COOTensor, a sparse representation of the original dense tensor, containing the following parts.

- indices (Tensor): 2-D integer tensor, indicates the positions of *values* of the dense tensor.
- values (Tensor): 1-D tensor, indicates the non-zero values of the dense tensor.
- shape (tuple(int)): the shape of the COOTensor, is the same as the original dense tensor.

Raises

ValueError – If input tensor is not 2-D.

Supported Platforms:

`GPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[1,  0], [-5, 0]]), mindspore.float32)
>>> output = x.to_coo()
>>> print(output.indices, output.values, output.shape)
[[0 0]
 [1 0]] [ 1. -5.] (2, 2)
```

mindspore.Tensor.to_csr

Tensor.**to_csr**()

Convert a Tensor to CSRTensor.

Note: Only 2-D tensor is supported for now.

Returns

CSRTensor, a sparse representation of the original dense tensor, containing the following parts.

- indptr (Tensor): 1-D integer tensor, indicates the start and end point for *values* in each row.
- indices (Tensor): 1-D integer tensor, indicates the column positions of all non-zero values of the input.
- values (Tensor): 1-D tensor, indicates the non-zero values of the dense tensor.
- shape (tuple(int)): the shape of the CSRTensor, is the same as the original dense tensor.

Raises

ValueError – If input tensor is not 2-D.

Supported Platforms:

GPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor(np.array([[1,  0], [-5, 0]]), mindspore.float32)
>>> output = x.to_csr()
>>> print(output.indptr, output.indices, output.values, output.shape)
[0 1 2] [0 0] [ 1. -5.] (2, 2)
```

mindspore.Tensor.tolist

Tensor.**tolist**()

Convert a Tensor to List. If the input is Tensor scalar, a Python scalar will be returned.

Returns

List or Python scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> x = ms.Tensor([[1, 2, 3], [4, 5, 6]])
>>> out1 = x.tolist()
>>> print(out1)
[[1, 2, 3], [4, 5, 6]]
>>> out2 = x[0][0].tolist()
>>> print(out2)
1
```

mindspore.Tensor.topk

Tensor.**topk**(*k*, *dim=- 1*, *largest=True*, *sorted=True*)

Finds the *k* largest or smallest element along the given dimension and returns its value and corresponding index.

Warning:

- Due to different memory layout and traversal methods on different platforms, the display order of calculation results may be inconsistent when *sorted* is False.

If the *self* is a one-dimensional Tensor, finds the *k* largest or smallest entries in the Tensor, and outputs its value and index as a Tensor. *values[k]* is the *k* largest item in *self*, and its index is *indices[k]* .

For a multi-dimensional matrix, calculates the first or last *k* entries in a given dimension, therefore:

$$values.shape = indices.shape$$

If the two compared elements are the same, the one with the smaller index value is returned first.

Parameters

- **k** (*int*) –The number of top or bottom elements to be computed along the last dimension.
- **dim** (*int, optional*) –The dimension to sort along. Default: `-1` .
- **largest** (*bool, optional*) –If largest is `False` then the k smallest elements are returned. Default: `True` .
- **sorted** (*bool, optional*) –If `True` , the obtained elements will be sorted by the values in descending order or ascending order according to *largest*. If `False` , the obtained elements will not be sorted. Default: `True` .

Returns

A tuple consisting of *values* and *indices*.

- values (Tensor) - The *k* largest or smallest elements in each slice of the given dimension.
- indices (Tensor) - The indices of values within the last dimension of self.

Raises

- **TypeError** – If *sorted* is not a bool.
- **TypeError** – If *k* is not an int.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> x = ms.Tensor([[0.5368, 0.2447, 0.4302, 0.9673],
...                [0.4388, 0.6525, 0.4685, 0.1868],
...                [0.3563, 0.5152, 0.9675, 0.8230]], dtype=ms.float32)
>>> output = Tensor.topk(x, 2, dim=1)
>>> print(output)
(Tensor(shape=[3, 2], dtype=Float32, value=
[[ 9.67299998e-01,  5.36800027e-01],
 [ 6.52499974e-01,  4.68499988e-01],
 [ 9.67499971e-01,  8.23000014e-01]]), Tensor(shape=[3, 2], dtype=Int32, value=
[[3, 0],
 [1, 2],
 [2, 3]]))
>>> output2 = Tensor.topk(x, 2, dim=1, largest=False)
>>> print(output2)
(Tensor(shape=[3, 2], dtype=Float32, value=
[[ 2.44700000e-01,  4.30200011e-01],
 [ 1.86800003e-01,  4.38800007e-01],
 [ 3.56299996e-01,  5.15200019e-01]]), Tensor(shape=[3, 2], dtype=Int32, value=
[[1, 2],
 [3, 0],
 [0, 1]]))
```

`Tensor.`**`topk`**(*k*, *dim=None*, *largest=True*, *sorted=True*)

For more details, please refer to *mindspore.ops.topk()*.

mindspore.Tensor.trace

`Tensor.`**`trace`**(*offset=0*, *axis1=0*, *axis2=1*, *dtype=None*)

Return the sum along diagonals of the tensor.

Parameters

- **offset** (*int, optional*) – Offset of the diagonal from the main diagonal. Can be positive or negative. Defaults to main diagonal.

- **axis1** (*int, optional*) −Axis to be used as the first axis of the 2-D sub-arrays from which the diagonals should be taken. Defaults to first axis (0).
- **axis2** (*int, optional*) −Axis to be used as the second axis of the 2-D sub-arrays from which the diagonals should be taken. Defaults to second axis.
- **dtype** (*mindspore.dtype*, optional) −defaults to None. Overrides the dtype of the output Tensor.

Returns

Tensor, the sum along diagonals.

Raises

ValueError −If the input tensor has less than two dimensions.

See also:

- *mindspore.Tensor.diagonal()*: Return specified diagonals.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.eye(3, dtype=np.float32))
>>> print(x.trace())
3.0
```

mindspore.Tensor.transpose

`Tensor.`**transpose**(*dim0*, *dim1*) → *Tensor*

Interchange two axes of a tensor.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **dim0** (*int*) −Specifies the first dimension to be transposed.
- **dim1** (*int*) −Specifies the second dimension to be transposed.

Returns

Transposed tensor, has the same data type as *self*.

Raises

- **TypeError** −If *dim0* or *dim1* is not integer.
- **ValueError** −If *dim0* or *dim1* is not in the range of $[-ndim, ndim - 1]$.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.ones((2,3,4), dtype=np.float32))
>>> output = Tensor.transpose(input, 0, 2)
>>> print(output.shape)
(4, 3, 2)
```

`Tensor.`**`transpose`**`(*axes)` → *Tensor*

Permutes the dimensions of the self tensor according to self permutation.

For a 1-D array this has no effect, as a transposed vector is simply the same vector. To convert a 1-D array into a 2D column vector please refer to *mindspore.ops.expand_dims()*. For a 2-D array, this is a standard matrix transpose. For an n-D array, if axes are given, their order indicates how the axes are permuted (see Examples). If axes are not provided and a.shape is $(i[0], i[1], ...i[n-2], i[n-1])$, then a.transpose().shape is $(i[n-1], i[n-2], ...i[1], i[0])$.

Note: On GPU and CPU, if the value of *axes* is negative, its actual value is *axes[i] + rank(self)*.

Parameters

axes (*tuple[int]*) –The permutation to be converted. The elements in *axes* are composed of the indexes of each dimension of *self*. The length of *axes* and the shape of *self* must be the same. Only constant value is allowed. Must be in the range [-rank(self), rank(self)).

Returns

Tensor, the type of output tensor is the same as *self* and the shape of output tensor is decided by the shape of *self* and the value of *axes*.

Raises

- **TypeError** –If *axes* is not a tuple.
- **ValueError** –If length of shape of *self* is not equal to length of shape of *axes*.
- **ValueError** –If the same element exists in *axes*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input = Tensor(np.array([[[1, 2, 3], [4, 5, 6]], [[7, 8, 9], [10, 11, 12]]]), mindspore.
↪float32)
>>> axes = (0, 2, 1)
>>> output = Tensor.transpose(input, axes)
>>> print(output)
[[[ 1.  4.]
  [ 2.  5.]
  [ 3.  6.]]
 [[ 7. 10.]
```

(continues on next page)

(continued from previous page)

```
  [ 8. 11.]
  [ 9. 12.]]]
```

mindspore.Tensor.triangular_solve

Tensor.**triangular_solve**(*A*, *upper=True*, *transpose=False*, *unitriangular=False*)
For details, please refer to *mindspore.mint.triangular_solve()*.

mindspore.Tensor.tril

Tensor.**tril**(*diagonal=0*) → *Tensor*
For details, please refer to *mindspore.ops.tril()*.

mindspore.Tensor.triu

Tensor.**triu**(*diagonal=0*) → *Tensor*
For details, please refer to *mindspore.ops.triu()*.

mindspore.Tensor.true_divide

Tensor.**true_divide**()
Alias for Tensor.div() with $rounding\_mode = None$. For details, please refer to *mindspore.ops.div()*.

mindspore.Tensor.trunc

Tensor.**trunc**() → *Tensor*
For details, please refer to *mindspore.ops.trunc()*.

mindspore.Tensor.type

Tensor.**type**(*dtype=None*)
Change the dtype of the Tensor to the *dtype* . Return the type if *dtype* is None .

Parameters

dtype (mindspore.dtype, *optional*) – The specified dtype of output tensor. Default: None.

Returns

Tensor or str. If *dtype* is None , return a str, which describes the dtype of Tensor. If *dtype* is not None , then return a Tensor, and the dtype of returned Tensor is *dtype* .

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor([[1.2, 2], [3.4, 4]], dtype=mindspore.float32)
>>> print(x.type())
Float32
>>> print(x.type(dtype=mindspore.int32))
[[1 2]
 [3 4]]
```

mindspore.Tensor.type_as

Tensor.**type_as**(*other*)

Returns self tensor cast to the type of the with the input other tensor.

Warning: This is an experimental API that is subject to change or deletion.

Note: When converting complex numbers to boolean type, the imaginary part of the complex number is not taken into account. As long as the real part is non-zero, it returns True; otherwise, it returns False.

Parameters

other (Tensor) – The tensor whose data type is specified. The shape of tensor is $(x_0, x_1, ..., x_R)$.

Returns

Tensor, the shape of tensor is the same as *self*, $(x_0, x_1, ..., x_R)$.

Raises

TypeError – If *other* is not a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> input_np = np.random.randn(2, 3, 4, 5).astype(np.float32)
>>> self = Tensor(input_np)
>>> other_np = np.random.randn(2, 3, 4).astype(np.int32)
>>> other = Tensor(other_np)
>>> output = self.type_as(other)
>>> print(output.dtype)
Int32
>>> print(output.shape)
(2, 3, 4, 5)
```

mindspore.Tensor.unbind

Tensor.**unbind**(*dim=0*) → *Tensor*

For details, please refer to *mindspore.ops.unbind()*.

mindspore.Tensor.unfold

Tensor.**unfold**(*kernel_size*, *dilation=1*, *padding=0*, *stride=1*)

For details, please refer to *mindspore.ops.unfold()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

mindspore.Tensor.uniform

Tensor.**uniform**(*from_=0.*, *to=1.*, *generator=None*)

Generates random numbers that follows a uniform distribution within the half-open interval $[from\_, to)$.

$$P(x) = \frac{1}{to - from\_}$$

Parameters

- **from_** (*number*) –The lower bound of the interval.
- **to** (*number*) –The upper bound of the interval.
- **generator** (*Generator, optional*) –The random seed. Default: None.

Returns

Tensor, with the same shape as tensor.

Raises

TypeError –If *from_* is larger than *to*.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> x = mindspore.ops.ones((4, 2))
>>> generator = mindspore.Generator()
>>> generator.manual_seed(100)
>>> output = x.uniform(1., 2., generator)
>>> print(output.shape)
(4, 2)
```

mindspore.Tensor.uniform_

Tensor.**uniform_**(*from_=0*, *to=1*, ***, *generator=None*)

Update the *self* Tensor in place by generating random numbers sampled from uniform distribution in the half-open interval $[from\_, to)$.

$$P(x) = \frac{1}{to - from\_}$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **from_** (*Union[number.Number, Tensor], optional*) –The lower bound of the uniform distribution, it can be a scalar value or a tensor of any dimension with a single element. Default: 0.
- **to** (*Union[number.Number, Tensor], optional*) –The upper bound of the uniform distribution, it can be a scalar value or a tensor of any dimension with a single element. Default: 1.

Keyword Arguments

generator (*mindspore.Generator*, optional) –a pseudorandom number generator. Default: None, uses the default pseudorandom number generator.

Returns

Return *self* Tensor.

Raises

- **TypeError** –If *from_* or *to* is neither a number nor a Tensor.
- **TypeError** –If dtype of *from* or *to* is not one of: bool, int8, int16, int32, int64, uint8, float32, float64.
- **ValueError** –If *from_* or *to* is Tensor but contains multiple elements.
- **RuntimeError** –If *from_* is larger than *to*.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> x = mindspore.ops.ones((4, 2))
>>> generator = mindspore.Generator()
>>> generator.manual_seed(100)
>>> output = x.uniform_(1., 2., generator=generator)
>>> print(output.shape)
(4, 2)
```

mindspore.Tensor.unique

Tensor.**unique**(*sorted=True*, *return_inverse=False*, *return_counts=False*, *dim=None*)

Returns the unique elements of *self*.

when *return_inverse=True*, also return a tensor containing the index of each value of *self* corresponding to the output unique tensor. when *return_counts=True*, also return a tensor containing the number of occurrences for each unique value or tensor.

Parameters

- **sorted** (*bool, optional*) –Whether to sort the unique elements in ascending order before returning as output. Default: `True` .
- **return_inverse** (*bool, optional*) –Whether to also return the indices for where elements in *self* ended up in the returned unique list. Default: `False` .
- **return_counts** (*bool, optional*) –Whether to also return the counts for each unique element. Default: `False` .
- **dim** (*int, optional*) –the dimension to operate upon. If `None`, the unique of the flattened *self* is returned. Otherwise, each of the tensors indexed by the given dimension is treated as one of the elements to apply the unique operation upon. Default: `None` .

Returns

A tensor or a tuple of tensors containing some of tensor objects (*output*, *inverse_indices*, *counts*).

- **output** (Tensor) - The output tensor including the unique elements of *self*, it has same dtype as *self*.
- **inverse_indices** (Tensor, optional) - Return when `return_inverse` is True. It represents the indices for where elements in *self* map to in the output. When `dim` is `None`, it has same shape as *self*, otherwise, the shape is self.shape[dim].
- **counts** (Tensor, optional) - Return when `return_counts` is True. It represents the number of occurrences for each unique value or tensor. When `dim` is `None`, it has same shape as output, otherwise, the shape is output.shape(dim).

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> x = Tensor(np.array([1, 2, 5, 2]), mindspore.int32)
>>> output = x.unique(return_inverse=True)
>>> print(output)
(Tensor(shape=[3], dtype=Int32, value= [1, 2, 5]), Tensor(shape=[4], dtype=Int64, value= [0,␣
↪1, 2, 1]))
>>> y = output[0]
>>> print(y)
[1 2 5]
>>> idx = output[1]
>>> print(idx)
[0 1 2 1]
```

mindspore.Tensor.unique_consecutive

Tensor.**unique_consecutive**(*return_inverse=False*, *return_counts=False*, *dim=None*)
For details, please refer to *mindspore.ops.unique_consecutive()*.

mindspore.Tensor.unsorted_segment_max

Tensor.**unsorted_segment_max**(*segment_ids*, *num_segments*)
For details, please refer to *mindspore.ops.unsorted_segment_max()*.

mindspore.Tensor.unsorted_segment_min

Tensor.**unsorted_segment_min**(*segment_ids*, *num_segments*)
For details, please refer to *mindspore.ops.unsorted_segment_min()*.

mindspore.Tensor.unsorted_segment_prod

Tensor.**unsorted_segment_prod**(*segment_ids*, *num_segments*)
For details, please refer to *mindspore.ops.unsorted_segment_prod()*.

mindspore.Tensor.unsqueeze

Tensor.**unsqueeze**(*dim*) → *Tensor*
For details, please refer to *mindspore.ops.unsqueeze()*.

mindspore.Tensor.var

Tensor.**var**(*axis=None*, *ddof=0*, *keepdims=False*) → *Tensor*
Compute the variance along the specified axis.

The variance is the average of the squared deviations from the mean, i.e., $var = mean(abs(x - x.mean()) **2)$.

Return the variance, which is computed for the flattened array by default, otherwise over the specified axis.

Note: Numpy arguments *dtype*, *out* and *where* are not supported.

Parameters

- **axis** (*Union[None, int, tuple(int)], optional*) −Axis or axes along which the variance is computed. The default is to compute the variance of the flattened array. Default: `None` .
- **ddof** (*int, optional*) −Means Delta Degrees of Freedom. Default: `0` . The divisor used in calculations is $N - ddof$, where N represents the number of elements.
- **keepdims** (*bool, optional*) −Whether the output Tensor has dim retained or not. If `True` , keep these reduced dimensions and the length is 1. If `False` , don't keep these dimensions. Default: `False` .

Returns

Variance tensor.

Raises

- **TypeError** –If *axis* is not one of the followings: None, int, tuple.
- **TypeError** –If *ddof* is not an int.
- **TypeError** –If *keepdims* is not a bool.
- **ValueError** –If *axis* is out of range $[-self.ndim, self.ndim)$.

See also:

- *mindspore.Tensor.mean()*: Reduce a dimension of a tensor by averaging all elements in the dimension.
- *mindspore.Tensor.std()*: Compute the standard deviation along the specified axis.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> input_x = Tensor(np.array([1., 2., 3., 4.], np.float32))
>>> output = input_x.var()
>>> print(output)
1.25
```

`Tensor.`**var**(*dim=None*, *, *correction=1*, *keepdim=False*) → *Tensor*

Calculates the variance over the dimensions specified by *dim*. *dim* can be a single dimension, list of dimensions, or None to reduce over all dimensions.

The variance (δ^2) is calculated as:

$$\delta^2 = \frac{1}{\max(0, N - \delta N)} \sum_{i=0}^{N-1} (x_i - \bar{x})^2$$

where x is the sample set of elements, $\bar{x}$ is the sample mean, N is the number of samples and δN is the *correction*.

Parameters

dim (*None*, *int*, *tuple(int)*, *optional*) –The dimension or dimensions to reduce. Defaults to `None`. If `None`, all dimensions are reduced.

Keyword Arguments

- **correction** (`int`, *optional*) –The difference between the sample size and sample degrees of freedom. Defaults to Bessel's correction. Defaults to `1`.
- **keepdim** (`bool`, *optional*) –Whether the output tensor has dim retained or not. If `True` , keep these reduced dimensions and the length is 1. If `False`, don't keep these dimensions. Defaults to `False`.

Returns

Tensor, the variance. Suppose the shape of *self* is $(x_0, x_1, ..., x_R)$:

- If *dim* is () and *keepdim* is set to `False` , returns a 0-D Tensor, indicating the variance of all elements in *self*.

- If *dim* is int, e.g. `1` and *keepdim* is set to `False` , then the returned Tensor has shape $(x_0, x_2, ..., x_R)$.
- If *dim* is tuple(int) or list(int), e.g. `(1, 2)` and *keepdim* is set to `False` , then the returned Tensor has shape $(x_0, x_3, ..., x_R)$.

Raises

- **TypeError** –If *dim* is not one of the followings: None, int, list, tuple.
- **TypeError** –If *correction* is not an int.
- **TypeError** –If *keepdim* is not a bool.
- **ValueError** –If *dim* is out of range $[-self.ndim, self.ndim)$.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> input_x = Tensor([[8, 2, 1], [5, 9, 3], [4, 6, 7]], mindspore.float32)
>>> output = input_x.var(dim=0, correction=1, keepdim=True)
>>> print(output)
[[ 4.333333, 12.333333, 9.333333]]
```

mindspore.Tensor.view

`Tensor.`**`view`**`(*shape)`

Reshape the tensor according to the input shape. It's the same as *mindspore.Tensor.reshape()*, implemented by the underlying reshape operator.

Parameters

shape (*Union[tuple(int), int]*) –Dimension of the output tensor.

Returns

Tensor, which dimension is the input shape's value.

Examples

```
>>> from mindspore import Tensor
>>> import numpy as np
>>> a = Tensor(np.array([[1, 2, 3], [2, 3, 4]], dtype=np.float32))
>>> output = a.view((3, 2))
>>> print(output)
[[1. 2.]
[3. 2.]
[3. 4.]]
```

mindspore.Tensor.view_as

Tensor.**view_as**(*other*) → *Tensor*

View *self* Tensor as the same shape as *other* .

Parameters

other (Tensor) –The returned Tensor has the same shape as *other*.

Returns

Tensor, has the same shape as *other*.

Raises

TypeError –If *other* is not a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import Tensor
>>> from mindspore import dtype as mstype
>>> a = Tensor([[1, 2, 3], [2, 3, 4]], mstype.float32)
>>> b = Tensor([1, 1, 1, 1, 1, 1], mstype.float32)
>>> output = a.view_as(b)
>>> print(output)
[1. 2. 3. 2. 3. 4.]
```

mindspore.Tensor.vsplit

Tensor.**vsplit**(*indices_or_sections*)

For details, please refer to *mindspore.ops.vsplit()*.

mindspore.Tensor.where

Tensor.**where**(*condition*, *y*) → *Tensor*

For details, please refer to *mindspore.ops.where()*.

mindspore.Tensor.xdivy

Tensor.**xdivy**(*y*)

For details, please refer to *mindspore.ops.xdivy()*.

mindspore.Tensor.xlogy

Tensor.**xlogy**(*other*) → *Tensor*

For details, please refer to *mindspore.ops.xlogy()*.

mindspore.Tensor.zero_

Tensor.**zero_**()

Return a tensor filled with zeros.

> **Warning:** This is an experimental API that is subject to change or deletion.

Returns

Return a tensor. Fill self tensor with zeros.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> x = Tensor(np.array([2, 2]))
>>> output = x.zero_()
>>> print(output)
[0 0]
```

mindspore.tensor

mindspore.**tensor**(*input_data=None*, *dtype=None*, *shape=None*, *init=None*, *const_arg=False*)

Create a new Tensor in Cell.construct() or function decorated by @jit.

In graph mode, MindSpore would create a new Tensor object at runtime dynamically, based on the *dtype* argument.

Please refer to Creating and Using Tensor .

The difference between it and the Tensor class is that it adds Annotation which can prevent the generation of AnyType compared to the Tensor class.

The arguments and return values are the same as the Tensor class. Also see: *mindspore.Tensor*. internally to indicate the type of the Tensor currently being created,

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import jit, tensor
>>> @jit
... def func(x):
...     return tensor(x.asnumpy(), dtype=ms.float32)
>>> x = tensor([1, 2, 3])
>>> y = func(x)
>>> print(y)
[1. 2. 3.]
```

mindspore.COOTensor

class mindspore.**COOTensor**(*indices=None*, *values=None*, *shape=None*, *coo_tensor=None*)

A sparse representation of a set of nonzero elements from a tensor at given indices, where the indices indicate the position of each non-zero element.

For a tensor dense, its COOTensor(indices, values, shape) has *dense[indices[i]] = values[i]*.

For example, if indices is [[0, 1], [1, 2]], values is [1, 2], shape is (3, 4), then the dense representation of the sparse tensor will be:

```
[[0, 1, 0, 0],
 [0, 0, 2, 0],
 [0, 0, 0, 0]]
```

Common arithmetic operations include: addition (+), subtraction (-), multiplication (*), and division (/). For details about operations supported by *COOTensor*, see operators.

Warning:

- This is an experimental API that is subject to change or deletion.
- If use PyNative mode, set "export MS_PYNATIVE_CONFIG_STATIC_SHAPE=1".
- Currently, duplicate coordinates in the indices will not be coalesced. If the indices contain out-of-bound values, the result will be undefined.

Parameters

- **indices** (Tensor) −A 2-D integer Tensor of shape $(N, ndims)$, where N and $ndims$ are the number of *values* and number of dimensions in the COOTensor, respectively. Currently, $ndims$ must be 2. Default: None . Please make sure that the indices are in range of the given shape.
- **values** (Tensor) −A 1-D tensor of any type and shape (N), which supplies the values for each element in *indices*. Default: None .
- **shape** (*tuple(int)*) −An integer tuple of shape $(ndims)$, which specifies the dense_shape of the sparse tensor. Default: None .
- **coo_tensor** (COOTensor) −A COOTensor object. Default: None .

Returns

COOTensor, composed of *indices*, *values*, and *shape*.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> print(x.values)
[1. 2.]
>>> print(x.indices)
[[0 1]
 [1 2]]
>>> print(x.shape)
(3, 4)
```

abs()

Return absolute value element-wisely.

Returns

COOTensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, COOTensor
>>> indices = Tensor([[0, 1, 2], [1, 0, 2]], dtype=ms.int32)
>>> values = Tensor([1, -5, -4], dtype=ms.float32)
>>> shape = (3, 3)
>>> coo_tensor = COOTensor(indices.transpose(), values, shape)
>>> res = coo_tensor.abs()
>>> print(res.values)
[1. 5. 4.]
```

add(*other:* COOTensor, *thresh:* Tensor)

Return the sum with another COOTensor.

Parameters

- **other** (`COOTensor`) – the second SparseTensor to sum.
- **thresh** (`Tensor`) – A 0-D Tensor, represents the magnitude threshold that determines if an output value/index pair take space, Its dtype should match that of the values if they are real. If output's value is less than the *thresh*, it will vanish.

Returns

COOTensor, representing the sum.

Raises

- **ValueError** – If any input(self/other)'s indices's dim is not equal to 2.
- **ValueError** – If any input(self/other)'s values's dim is not equal to 1.

- **ValueError** –If any input(self/other)'s shape's dim is not equal to 1.
- **ValueError** –If thresh's dim is not equal to 0.
- **TypeError** –If any input(self/other)'s indices's type is not equal to int64.
- **TypeError** –If any input(self/other)'s shape's type is not equal to int64.
- **ValueError** –If any input(self/other)'s indices's length is not equal to its values's length.
- **TypeError** –If any input(self/other)'s values's type is not equal to anf of (int8/int16/int32/int64/float32/float64/complex64/complex128)
- **TypeError** –If thresh's type is not equal to anf of (int8/int16/int32/int64/float32/float64)
- **TypeError** –If self's indices's type is not equal to other's indices's type
- **TypeError** –If self's values's type is not equal to other's values's type
- **TypeError** –If self's shape's type is not equal to other's shape's type
- **TypeError** –If (self/other)'s value's type is not matched with thresh's type

Supported Platforms:

GPU CPU

Examples

```
>>> from mindspore import Tensor, COOTensor
>>> from mindspore import dtype as mstype
>>> indics0 = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values0 = Tensor([1, 2], dtype=mstype.int32)
>>> shape0 = (3, 4)
>>> input0 = COOTensor(indics0, values0, shape0)
>>> indics1 = Tensor([[0, 0], [1, 1]], dtype=mstype.int64)
>>> values1 = Tensor([3, 4], dtype=mstype.int32)
>>> shape1 = (3, 4)
>>> input1 = COOTensor(indics1, values1, shape1)
>>> thres = Tensor(0, dtype=mstype.int32)
>>> out = input0.add(input1, thres)
>>> print(out)
COOTensor(shape=[3, 4], dtype=Int32, indices=Tensor(shape=[4, 2], dtype=Int64, value=
[[0 0]
 [0 1]
 [1 1]
 [1 2]]), values=Tensor(shape=[4], dtype=Int32, value=[3 1 4 2]))
```

astype(*dtype: mstype*)

Return a copy of the COOTensor, cast its values to a specified type.

Parameters

dtype (Union[*mindspore.dtype*, numpy.dtype, str]) –Designated tensor dtype.

Returns

COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (3, 4)
>>> coo_tensor = COOTensor(indices, values, shape)
>>> print(coo_tensor.astype(ms.float64).dtype)
Float64
```

coalesce()

Returns a coalesced copy of an uncoalesced sparse tensor.

Returns

A COOTensor.

Supported Platforms:

GPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, COOTensor
>>> x_indices = Tensor([[0, 0, 1], [1, 1, 2]], dtype=ms.int64)
>>> x_values = Tensor([1, 5, 4], dtype=ms.float32)
>>> x_shape = (3, 3)
>>> coo_tensor = COOTensor(x_indices.transpose(), x_values, x_shape)
>>> res = coo_tensor.coalesce()
>>> print(res)
COOTensor(shape=[3, 3], dtype=Float32, indices=Tensor(shape=[2, 2], dtype=Int64,
    value=[[0 1] [1 2]]), values=Tensor(shape=[2], dtype=Float32, value=[6.00000000e+00␣
↪4.00000000e+00]))
```

property dtype: mstype

Return the dtype of the values of COOTensor (*mindspore.dtype*).

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (3, 4)
>>> coo_tensor = COOTensor(indices, values, shape)
>>> print(coo_tensor.dtype)
Float32
```

property indices: mindspore.common.tensor.Tensor

Return COOTensor's indices.

property itemsize: int

Return the length of one tensor element in bytes.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float64)
>>> shape = (3, 4)
>>> coo_tensor = COOTensor(indices, values, shape)
>>> print(coo_tensor.itemsize)
8
```

property ndim: int
Return the number of tensor dimensions.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> coo_tensor = COOTensor(indices, values, (3, 4))
>>> print(coo_tensor.ndim)
2
```

property shape: Tuple[int, ...]
Return COOTensor's shape.

property size: int
Return the number of non-zero values.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, COOTensor
>>> indices = Tensor([[0, 1, 2], [1, 0, 2]], dtype=ms.int32)
>>> values = Tensor([1, 5, 4], dtype=ms.float32)
>>> shape = (3, 3)
>>> coo_tensor = COOTensor(indices.transpose(), values, shape)
>>> print(coo_tensor.size)
3
```

to_csr()
Converts COOTensor to CSRTensor.

Note: Currently only supports CPU backend with LLVM 12.0.1 installed.

Returns

CSRTensor.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.int32)
>>> shape = (3, 4)
>>> coo_tensor = COOTensor(indices, values, shape)
>>> print(coo_tensor.to_csr())
CSRTensor(shape=[3, 4], dtype=Int32, indptr=Tensor(shape=[4], dtype=Int32, value=[0 1 2␣
↪2]),
    indices=Tensor(shape=[2], dtype=Int32, value=[1 2]), values=Tensor(shape=[2],␣
↪dtype=Int32, value=[1 2]))
```

to_dense()

Converts COOTensor to Dense Tensor.

Returns

Tensor.

Supported Platforms:

GPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, COOTensor
>>> indices = Tensor([[0, 1, 2], [1, 0, 2]], dtype=ms.int32)
>>> values = Tensor([1, 5, 4], dtype=ms.float32)
>>> shape = (3, 3)
>>> coo_tensor = COOTensor(indices.transpose(), values, shape)
>>> print(coo_tensor.to_dense())
[[0. 1. 0.]
 [5. 0. 0.]
 [0. 0. 4.]]
```

to_tuple()

Return indices, values and shape as a tuple.

Returns

Tuple.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (3, 4)
>>> coo_tensor = COOTensor(indices, values, shape)
>>> print(coo_tensor.to_tuple())
(Tensor(shape=[2, 2], dtype=Int32, value=
[[0, 1],
 [1, 2]]), Tensor(shape=[2], dtype=Float32, value= [ 1.00000000e+00,  2.00000000e+00]),␣
↪(3, 4))
```

property values: mindspore.common.tensor.Tensor

Return COOTensor's non-zero values.

mindspore.CSRTensor

class mindspore.**CSRTensor**(*indptr=None*, *indices=None*, *values=None*, *shape=None*, *csr_tensor=None*)

Constructs a sparse tensor in CSR (Compressed Sparse Row) format, with specified values indicated by *values* and row and column positions indicated by *indptr* and *indices*.

For example, if indptr is [0, 2, 5, 6], indices is [0, 3, 1, 2, 4, 2], values is [1., 2., 3., 4., 5., 6.], shape is (3, 5), then the dense representation of the sparse tensor will be:

```
[[1., 0., 0., 2., 0.],
 [0., 3., 4., 0., 5.],
 [0., 0., 6., 0., 0.]]
```

The length of *indptr* should equal to *shape[0]+1*, where the elements should be equal or monotonically increasing and the maximum value should be equal to the number of non-zero values in the tensor. The length of *indices* and *values* should be equal to the number of non-zero values in the tensor. To be concrete, get the query indices of none-zero elements in every line according to *indptr*. Then get the column positions of none-zero elements in every line by looking up query indices in *indices*. Finally, get the actual values of none-zero elements in every line by looking up query indices in *values*.

In the former example, 'indptr' of [0, 2, 5, 6] represents that the indices of 0th row of the tensor origins from [0, 2), the indices of the 1st row of the tensor origins from [2, 5) and the 2nd row of the tensor origins from [5, 6). For example:

- The column positions of the non-zero elements of the 0th row in the tensor are provided by the [0, 2) elements in *indices* (i.e. [0, 3]) and the corresponding values are provided by the [0, 2) elements in *values* (i.e. [1., 2.]).
- The column positions of the non-zero elements of the 1st row in the tensor are provided by the [2, 5) elements in *indices* (i.e. [1, 2, 4]) and the corresponding values are provided by the [2, 5) elements in *values* (i.e. [3., 4., 5.]).
- The column positions of the non-zero elements of the 2nd row in the tensor are provided by the [5, 6) elements in *indices* (i.e. [2]) and the corresponding values are provided by the [5, 6) elements in *values* (i.e. [6.]).

Common arithmetic operations include: addition (+), subtraction (-), multiplication (*), and division (/). For details about operations supported by *CSRTensor*, see operators.

Warning:

- This is an experimental API that is subjected to change.
- If use PyNative mode, set "export MS_PYNATIVE_CONFIG_STATIC_SHAPE=1".

- If the values given by *indptr* or *indices* are invalid, the results may be undefined. Invalid values include when the length of *values* or *indices* exceeds the range indicated by *indptr*, and when the columns indicated by *indices* are repeated on the same row.

Parameters

- **indptr** (Tensor) –1-D Tensor of shape (M), which equals to *shape[0] + 1*, which indicates the start and end point for *values* in each row. Default: None. If provided, must be int16, int32 or int64.
- **indices** (Tensor) –1-D Tensor of shape (N), which has the same length as *values*. *indices* indicates the which column *values* should be placed. Default: None. If provided, must be int16, int32 or int64.
- **values** (Tensor) –Tensor, which has the same length as *indices* (values.shape[0] == indices.shape[0]). *values* stores the data for CSRTensor. Default: None.
- **shape** (*tuple(int)*) –An integer tuple of shape $(ndims)$, and *shape[0]* must equal to *M - 1*, which all equal to number of rows of the CSRTensor. Default: None.
- **csr_tensor** (CSRTensor) –A CSRTensor object. Values' feature dimension should match with CSRTensor's feature dimension ($values.shape[1:] == csr\_tensor.shape[2:]$) . Default: None.

Outputs:

CSRTensor, with shape defined by *shape*, and dtype inferred from *value*.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> # initialize a csr_tensor with indptr, indices, values and shape
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> # access a data member of CSRTensor
>>> print(indptr == csr_tensor.indptr)
[ True  True  True]
```

abs()

Return absolute value element-wisely.

Returns

CSRTensor, with all values being non-negative.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([-1, -2], dtype=ms.float32)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> print(csr_tensor.abs().values)
[1. 2.]
```

add(*b:* CSRTensor, *alpha:* Tensor, *beta:* Tensor)

Addition of two CSR Tensors : C = alpha * A + beta * B

Parameters

- **b** (CSRTensor) –Sparse CSR Tensor.
- **alpha** (Tensor) –Dense Tensor, its shape must be able to broadcast to self.
- **beta** (Tensor) –Dense Tensor, its shape must be able to broadcast to b.

Returns

CSRTensor.

Supported Platforms:

GPU CPU

Examples

```
>>> from mindspore import Tensor, CSRTensor
>>> import mindspore.common.dtype as mstype
>>> indptr = Tensor([0, 1, 2], dtype=mstype.int32)
>>> indices = Tensor([0, 1], dtype=mstype.int32)
>>> values_a = Tensor([2, 1], dtype=mstype.float32)
>>> values_b = Tensor([1, 2], dtype=mstype.float32)
>>> dense_shape = (2, 4)
>>> alpha = Tensor(1, mstype.float32)
>>> beta = Tensor(1, mstype.float32)
>>> a = CSRTensor(indptr, indices, values_a, dense_shape)
>>> b = CSRTensor(indptr, indices, values_b, dense_shape)
>>> print(a.add(b, alpha, beta))
CSRTensor(shape=[2, 4], dtype=Float32,
          indptr=Tensor(shape=[3], dtype=Int32, value=[0 1 2]),
          indices=Tensor(shape=[2], dtype=Int32, value=[0 1]),
          values=Tensor(shape=[2], dtype=Float32, value=[ 3.00000000e+00  3.
↪00000000e+00]))
```

astype(*dtype: mstype*)

Return a copy of the CSRTensor, cast its values to a specified type.

Parameters

dtype (Union[*mindspore.dtype*, numpy.dtype, str]) –Designated tensor dtype.

Returns

CSRTensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> print(csr_tensor.astype(ms.float64).dtype)
Float64
```

property dtype: mstype

Return the dtype of the values of CSRTensor (*mindspore.dtype*).

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> print(csr_tensor.dtype)
Float32
```

property indices: mindspore.common.tensor.Tensor

Return CSRTensor's column indices.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> print(csr_tensor.indices)
[0 1]
```

property indptr: mindspore.common.tensor.Tensor

Return CSRTensor's row indices pointers.

property itemsize: int

Return the length of one tensor element in bytes.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float64)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> print(csr_tensor.itemsize)
8
```

mm(*matrix: Union[*Tensor, CSRTensor*]*)

Return the matrix multiplication result of the right-multiply matrix(dense or CSRTensor) of the CSRTensor. The CSRTensor with shape *[M, N]* needs to adapt the right matrix with shape *[N, K]* to get the dense matrix or CSRTensor with result *[M, K]*.

Note: If right matrix is CSRTensor, currently only supports GPU backend. If right matrix is Tensor, currently supports CPU backend with LLVM no lower than 12.0.1, and GPU backend.

Parameters

matrix (Tensor *or* CSRTensor) – A dense Tensor or CSRTensor, its shape[0] should be equal to csr_tensor.shape[1]

Returns

Tensor or CSRTensor.

Supported Platforms:

GPU CPU

Examples

```
>>> from mindspore import Tensor, CSRTensor
>>> from mindspore import dtype as mstype
>>> indptr = Tensor([0, 1, 2], dtype=mstype.int32)
>>> indices = Tensor([0, 1], dtype=mstype.int32)
>>> values = Tensor([2, 1], dtype=mstype.float32)
>>> dense_shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, dense_shape)
>>> dense_matrix = Tensor([[1., 2.], [1, 2.], [1, 2.], [1., 2.]], dtype=mstype.float32)
>>> print(csr_tensor.mm(dense_matrix))
[[2. 4.]
[1. 2.]]
```

mv(*dense_vector:* Tensor)

Return the matrix multiplication result of the right-multiply dense matrix of the CSRTensor. The CSRTensor with shape *[M, N]* needs to adapt the dense vector with shape *[N, 1]* to get the dense vector with result *[M, 1]*.

Note: Currently only supports CPU backend with LLVM 12.0.1 installed.

Parameters

dense_vector (Tensor) −A dense Tensor, its shape must be (csr_tensor.shape[1], 1)

Returns

Tensor.

Supported Platforms:

GPU CPU

Examples

```
>>> from mindspore import Tensor, CSRTensor
>>> from mindspore import dtype as mstype
>>> indptr = Tensor([0, 1, 2], dtype=mstype.int32)
>>> indices = Tensor([0, 1], dtype=mstype.int32)
>>> values = Tensor([2, 1], dtype=mstype.float32)
>>> dense_shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, dense_shape)
>>> dense = Tensor([[1], [1], [1], [1]], dtype=mstype.float32)
>>> print(csr_tensor.mv(dense))
[[2.]
[1.]]
```

property ndim: int

Return the number of tensor dimensions.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> print(csr_tensor.ndim)
2
```

property shape: Tuple[int, ...]

Return CSRTensor's shape.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> print(csr_tensor.shape)
(2, 4)
```

property size: int
Return the number of non-zero values.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> print(csr_tensor.size)
2
```

sum(*axis: int*)
Reduces a dimension of a CSRTensor by summing all elements in the dimension.

Note: Currently only supports CPU backend with LLVM 12.0.1 installed.

Parameters

axis (*int*) – The dimensions to reduce.

Returns

Tensor, the dtype is the same as *CSRTensor.values*.

Supported Platforms:

GPU CPU

Examples

```
>>> from mindspore import Tensor, CSRTensor
>>> from mindspore import dtype as mstype
>>> indptr = Tensor([0, 1, 2], dtype=mstype.int32)
>>> indices = Tensor([0, 1], dtype=mstype.int32)
>>> values = Tensor([2, 1], dtype=mstype.float32)
>>> dense_shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, dense_shape)
>>> print(csr_tensor.sum(1))
[[2.]
[1.]]
```

to_coo()
Converts CSRTensor to COOTensor.

Note: Currently only supports CPU backend with LLVM 12.0.1 installed.

Returns

COOTensor.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.int32)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> print(csr_tensor.to_coo())
COOTensor(shape=[2, 4], dtype=Int32, indices=Tensor(shape=[2, 2], dtype=Int32, value=
[[0 0]
 [1 1]]), values=Tensor(shape=[2], dtype=Int32, value=[1 2]))
```

to_dense()

Converts CSRTensor to Dense Tensor.

Returns

Tensor.

Supported Platforms:

GPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> print(csr_tensor.to_dense())
[[1. 0. 0. 0.]
 [0. 2. 0. 0.]]
```

to_tuple()

Return indptr, indices, values and shape as a tuple.

Returns

Tuple.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> print(csr_tensor.to_tuple())
(Tensor(shape=[3], dtype=Int32, value= [0, 1, 2]), Tensor(shape=[2], dtype=Int32, value=␣
↪[0, 1]),
    Tensor(shape=[2], dtype=Float32, value= [ 1.00000000e+00,  2.00000000e+00]), (2, 4))
```

property values: mindspore.common.tensor.Tensor

Return CSRTensor's non-zero values.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2], dtype=ms.int32)
>>> indices = Tensor([0, 1], dtype=ms.int32)
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (2, 4)
>>> csr_tensor = CSRTensor(indptr, indices, values, shape)
>>> print(csr_tensor.values)
[1. 2.]
```

mindspore.RowTensor

class mindspore.**RowTensor**(*indices=None*, *values=None*, *shape=None*, *row_tensor=None*)

A sparse representation of a set of tensor slices at given indices.

When the *values* of a RowTensor has a shape of $(d_0, d_1, ..., d_n)$, then this RowTensor is used to represent a subset of a larger dense tensor of shape $(l_0, d_1, ..., d_n)$, where d_i is the size of i-th axis in RowTensor, l_0 is the size of 0-th axis of dense tensor and it satisfies $l_0 > d_0$.

The parameter *indices* is used to specify locations from which the *RowTensor* is sliced in the first dimension of the dense tensor, which means the parameters *indices* and *values* have the following relationship $dense[indices[i], :, :, ...] = values[i, :, :, ...]$.

For example, if indices is [0], values is [[1, 2]], shape is $(3, 2)$, then the dense representation of the row tensor will be:

```
[[1, 2],
 [0, 0],
 [0, 0]]
```

Warning:

- This is an experimental API that is subjected to change or deletion.
- If use PyNative mode, set "export MS_PYNATIVE_CONFIG_STATIC_SHAPE=1".

Parameters

- **indices** (Tensor) −A 1-D integer Tensor of shape (d_0) . Default: None.
- **values** (Tensor) −A Tensor of any dtype of shape $(d_0, d_1, ..., d_n)$. Default: None.
- **shape** (*tuple(int)*) −An integer tuple which contains the shape of the corresponding dense tensor. Default: None.
- **row_tensor** (RowTensor) −A RowTensor object. Default: None.

Returns

RowTensor, composed of *indices*, *values*, and *shape*.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, RowTensor
>>> indices = Tensor([0])
>>> values = Tensor([[1, 2]], dtype=ms.float32)
>>> shape = (3, 2)
>>> x = RowTensor(indices, values, shape)
>>> print(x.values)
[[1. 2.]]
>>> print(x.indices)
[0]
>>> print(x.dense_shape)
(3, 2)
```

mindspore.SparseTensor

class mindspore.**SparseTensor**(*indices*, *values*, *shape*)

A sparse representation of a set of nonzero elements from a tensor at given indices.

SparseTensor can only be used in the *Cell*'s construct method.

For a tensor dense, its SparseTensor(indices, values, dense_shape) has *dense[indices[i]] = values[i]*.

For example, if indices is [[0, 1], [1, 2]], values is [1, 2], dense_shape is (3, 4), then the dense representation of the sparse tensor will be:

```
[[0, 1, 0, 0],
 [0, 0, 2, 0],
 [0, 0, 0, 0]]
```

Note: The interface is deprecated from version 1.7 and will be removed in a future version. Please use *mindspore.COOTensor* instead.

Parameters

- **indices** (Tensor) −A 2-D integer Tensor of shape $(N, ndims)$, where N and ndims are the number of *values* and number of dimensions in the SparseTensor, respectively.
- **values** (Tensor) −A 1-D tensor of any type and shape (N), which supplies the values for each element in *indices*.
- **shape** (*tuple(int)*) −An integer tuple of size $(ndims)$, which specifies the shape of the sparse tensor.

Returns

SparseTensor, composed of *indices*, *values*, and *shape*.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, SparseTensor
>>> indices = Tensor([[0, 1], [1, 2]])
>>> values = Tensor([1, 2], dtype=ms.float32)
>>> shape = (3, 4)
>>> x = SparseTensor(indices, values, shape)
>>> print(x.values)
[1. 2.]
>>> print(x.indices)
[[0 1]
 [1 2]]
>>> print(x.shape)
(3, 4)
```

property indices
Return SparseTensor's indices.

property shape
Return SparseTensor's shape.

property values
Return SparseTensor's non-zero values.

mindspore.is_tensor

mindspore.**is_tensor**(*obj*)
Check whether the input object is *mindspore.Tensor*.

Parameters

obj (*Object*) – input object.

Returns

Bool.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> a = mindspore.tensor([1.9, 2.2, 3.1])
>>> mindspore.ops.is_tensor(a)
True
```

mindspore.from_numpy

mindspore.**from_numpy**(*array*)

Convert numpy array to Tensor. If the data is not C contiguous, the data will be copied to C contiguous, then construct the tensor. Otherwise, the tensor will be constructed using this numpy array without copy.

Parameters

array (*numpy.array*) – The input array.

Returns

Tensor, has the same data type as input array.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = np.array([1, 2])
>>> output = ms.from_numpy(x)
>>> print(output)
[1 2]
```

1.1.2 Parameter

mindspore.Parameter	*Parameter* is a *Tensor* subclass, when they are assigned as Cell attributes they are automatically added to the list of its parameters, and will appear, e.g.
mindspore.ParameterTuple	Inherited from tuple, ParameterTuple is used to save multiple parameter.

mindspore.Parameter

class mindspore.**Parameter**(*default_input*, *name=None*, *requires_grad=True*, *layerwise_parallel=False*, *parallel_optimizer=True*, *storage_format=''*, *device=None*)

Parameter is a *Tensor* subclass, when they are assigned as Cell attributes they are automatically added to the list of its parameters, and will appear, e.g. in *cell.get_parameters()* iterator.

Note:

- When using *AutoParallel(cell)* to enable parallel mode, if init *Parameter* by a *Tensor*, the type of Parameter will be *Tensor*. *Tensor* will save the shape and type info of a tensor with no memory usage.
- The shape can be changed while compiling for auto-parallel. Call *init_data* will return a Tensor Parameter with initialized data.
- If there is an operator in the network that requires part of the inputs to be Parameter, then the Parameters as this part of the inputs are not allowed to be cast.
- Give each *Parameter* a unique name to facilitate subsequent operations and updates. If there are two or more *Parameter* objects with the same name in a network, will be prompted to set a unique name when defining.
- When directly printing a *Parameter*, you cannot view the actual values contained inside it. You need to use the *Parameter.asnumpy()* method to access the actual values.

Parameters

- **default_input** (*Union[Tensor, int, float, numpy.ndarray, list]*) –Parameter data, to initialize the parameter data.
- **name** (*str*) –Name of the parameter. Default: `None` . If two or more *Parameter* objects with the same name exist in a network, you will be prompted to set a unique name when defining them.

  1) If the parameter is not given a name, the default name is its variable name. For example, the name of param_a below is name_a, and the name of param_b is the variable name param_b.

```
self.param_a = Parameter(Tensor([1], ms.float32), name="name_a")
self.param_b = Parameter(Tensor([2], ms.float32))
```

  2) If parameter in list or tuple is not given a name, will give it a unique name. For example, the names of parameters below are **Parameter$1** and **Parameter$2**.

```
self.param_list = [Parameter(Tensor([3], ms.float32)),
                   Parameter(Tensor([4], ms.float32))]
```

  3) If the parameter is given a name, and the same name exists between different parameters, an exception will be thrown. For example, "its name 'name_a' already exists." will be thrown.

```
self.param_a = Parameter(Tensor([1], ms.float32), name="name_a")
self.param_tuple = (Parameter(Tensor([5], ms.float32), name="name_a"),
                    Parameter(Tensor([6], ms.float32)))
```

  4) If a parameter appear multiple times in list or tuple, check the name of the object only once. For example, the following example will not throw an exception.

```
self.param_a = Parameter(Tensor([1], ms.float32), name="name_a")
self.param_tuple = (self.param_a, self.param_a)
```

- **requires_grad** (*bool*) –True if the parameter requires gradient. Default: `True` .
- **layerwise_parallel** (*bool*) –When *layerwise_parallel* is true in data/hybrid parallel mode, broadcast and gradients communication would not be applied to the *Parameter*. Default: `False` .
- **parallel_optimizer** (*bool*) –It is used to filter the weight shard operation in parallel mode. It works only when enable parallel optimizer in *mindspore.parallel.auto_parallel.AutoParallel.hsdp()*. Default: `True` .
- **storage_format** (*str*) –Only Ascend device target is supported. It is used to specify the format of the weight loaded to the device. By default, the format is not changed. The optional values are `"FRACTAL_NZ"` , `"NC1HWC0"` , `"FRACTAL_Z"` , etc. Default: `""` .
- **device** (*str*) –Only Ascend device target is supported. It is used to specify the device which the parameter is stored. By default, the parameter will be stored on NPU while computing. When the device is specified as `"CPU"`, the parameter will be loaded into the device when it needs to be used, and unloaded to the CPU after use. It takes effext only when *memory_offload* is `"ON"`, *jit_level* is not `"O2"` and *memory_optimize_level* is `O0` in *mindspore.set_context()*. Less device memory is needed when device is specified as `"CPU"`.

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Parameter, Tensor, ops, nn
>>>
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.matmul = ops.MatMul()
...         self.weight = Parameter(Tensor(np.ones((1, 2)), mindspore.float32), name="w",␣
↪requires_grad=True)
...
...     def construct(self, x):
...         out = self.matmul(self.weight, x)
...         return out
>>> net = Net()
>>> x = Tensor(np.ones((2, 1)), mindspore.float32)
>>> print(net(x))
[[2.]]
>>> net.weight.set_data(Tensor(np.zeros((1, 2)), mindspore.float32))
>>> print(net(x))
[[0.]]
```

add_pipeline_stage(*stage*)

Add a pipeline stage to the parameter.

Parameters

stage (*int*) – The pipeline stage to be added.

Raises

TypeError – If *stage* is not a positive number or not int type.

property cache_enable

Return whether the parameter is cache enable.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x.cache_enable=True
>>> x.cache_enable
True
```

property cache_shape

Return the cache shape corresponding to the parameter if use cache.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x.cache_enable=True
>>> x.cache_shape=[1, 2]
>>> x.cache_shape
[1, 2]
```

clone(*init='same'*)

Clone the parameter.

Parameters

init (*Union[Tensor, str, numbers.Number]*) – Initialize the shape and dtype of the parameter. If *init* is a *Tensor* or *numbers.Number*, clone a new parameter with the same shape and dtype, and the data of the new parameter will be set according to *init*. If *init* is a *str*, the *init* should be the alias of the class inheriting from *Initializer*. For example, if *init* is `'same'`, clone a new parameter with the same data, shape, and dtype. Default: `'same'`.

Returns

Parameter, a new parameter.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> y = x.clone()
```

property comm_fusion

Get the fusion type (int) for communication operators corresponding to this parameter.

When using *AutoParallel(cell)* to enable parallel mode, some communication operators used for parameters or gradients aggregation are inserted automatically. The value of *comm_fusion* must be greater than or equal to 0. When the value of *comm_fusion* is `0` , operators will not be fused together.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x.comm_fusion = 3
>>> x.comm_fusion
3
```

copy()

Copy the parameter.

Returns

Parameter, a new parameter.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> y = x.copy()
```

property data

Return the parameter object.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([[1, 2], [3, 4]], dtype=np.float32)), name="param")
>>> x.data
Parameter (name=param, shape=(2, 2), dtype=Float32, requires_grad=True)
```

init_data(*layout=None*, *set_sliced=False*)

Initialize the parameter's data.

Parameters

- **layout** (*Union[None, tuple]*) – The parameter's layout info. layout [dev_mat, tensor_map, slice_shape, filed_size, uniform_split, opt_shard_group]. Default: `None`. It's not None only when using *AutoParallel(cell)* to enable parallel mode.
  - dev_mat (list(int)): The parameter's device matrix.
  - tensor_map (list(int)): The parameter's tensor map.
  - slice_shape (list(int)): The parameter's slice shape.
  - filed_size (int): The parameter's filed size.
  - uniform_split (bool): Whether the parameter is split evenly.
  - opt_shard_group (str): The group of the parameter while running optimizer parallel.
- **set_sliced** (*bool*) – True if the parameter is set sliced after initializing the data. Default: `False`.

Returns

Parameter, the *Parameter* after initializing data. If current *Parameter* was already initialized before, returns the same initialized *Parameter*.

Raises

- **RuntimeError** – If it is from Initializer, and parallel mode has changed after the Initializer created.
- **ValueError** – If the length of the layout is less than 6.
- **TypeError** – If *layout* is not tuple.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([[1, 2], [3, 4]], dtype=np.float32)), name="param")
>>> x.init_data()
```

property inited_param

Get the new parameter after call the init_data.

Default is a None, If *self* is a Parameter without data, after call the *init_data* the initialized Parameter with data will be recorded here.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x.inited_param
```

property key

Return the parameter unique key.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x.key = 2
>>> x.key
2
```

property layerwise_parallel

Get the layerwise parallel status(bool) of the parameter.

When *layerwise_parallel* is `True` in *DATA_PARALLEL* and *HYBRID_PARALLEL* parallel mode, broadcast and gradients communication would not be applied to parameters.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x.layerwise_parallel = True
>>> x.layerwise_parallel
True
```

property name

Get the name of the parameter.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x.name = "param1"
>>> x.name
'param1'
```

property parallel_optimizer

Get the optimizer parallel status(bool) of the parameter.

When using *AutoParallel(cell)* to enable parallel mode, it is used to filter the weight shard operation. It works only when enable parallel optimizer in *mindspore.parallel.auto_parallel.AutoParallel.hsdp()*.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x.parallel_optimizer = True
>>> x.parallel_optimizer
True
```

property parallel_optimizer_comm_recompute

Get the communication recompute status(bool) of optimizer parallel for the parameter.

When using *AutoParallel(cell)* to enable parallel mode, and applying parallel optimizer, some *mindspore.ops.AllGather* operators used for parameters gathering are inserted automatically. It is used to control the recompute attr for those *mindspore.ops.AllGather* operators.

Note:

- Only *Graph* mode is supported.
- It is recommended to use cell.recompute(parallel_optimizer_comm_recompute=True/False) to configure the AllGather operators introducing by parallel optimizer rather than using this interface directly.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x.parallel_optimizer_comm_recompute = True
>>> x.parallel_optimizer_comm_recompute
True
```

register_hook(*hook_fn*)

For details, please refer to *mindspore.Tensor.register_hook()*.

property requires_grad

Return whether the parameter requires gradient.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x.requires_grad = True
>>> x.requires_grad
True
```

set_data(*data*, *slice_shape=False*)

Set Parameter's data.

Parameters

- **data** (*Union[Tensor, int, float]*) – New data.
- **slice_shape** (*bool*) – If slice the parameter is set to `True`, the shape consistency will not be checked. Default: `False`. When *slice_shape* is `True`, and the shapes are not consistent, a ValueError will be thrown.

Returns

Parameter, the parameter after set data.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([[1, 2], [3, 4]], dtype=np.float32)), name="param")
>>> x.set_data(Tensor(np.array([[6, 6], [6, 6]], dtype=np.float32)))
Parameter (name=param, shape=(2, 2), dtype=Float32, requires_grad=True)
```

set_param_ps(*init_in_server=False*)

Set whether the trainable parameter is updated by parameter server and whether the trainable parameter is initialized on server.

Note: It only works when a running task is in the parameter server mode. It is supported only in graph mode.

Parameters

init_in_server (*bool*) – Whether trainable parameter updated by parameter server is initialized on server. Default: `False`.

property sliced

Get slice status of the parameter.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x.sliced = True
>>> x.sliced
True
```

property unique
Whether the parameter is already unique or not.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x.unique = True
>>> x.unique
True
```

value()
Return the value of parameter object.

Examples

```
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([1, 2], dtype=np.float32)), name="param")
>>> x_value = x.value()
>>> print(x_value)
[1.  2.]
```

mindspore.ParameterTuple

class mindspore.**ParameterTuple**
Inherited from tuple, ParameterTuple is used to save multiple parameter.

Note: It is used to store the parameters of the network into the parameter tuple collection.

Examples

```
>>> from mindspore import Tensor, Parameter, ParameterTuple
>>> import numpy as np
>>> x = Parameter(Tensor(np.array([[1, 2], [3, 4]], dtype=np.float32)), name="param")
>>> y = Parameter(Tensor(np.array([[5, 6], [7, 8]], dtype=np.float32)), name="param1")
>>> pt = ParameterTuple([x, y])
>>> pt1 = pt.clone(prefix="new")
```

clone(*prefix*, *init='same'*)
Clone the parameters in ParameterTuple element-wisely to generate a new ParameterTuple.

Parameters

- **prefix** (*str*) –Namespace of parameter, the prefix string will be added to the names of parameters in parametertuple.
- **init** (*Union[Tensor, str, numbers.Number]*) –Clone the shape and dtype of Parameters in ParameterTuple and set data according to *init*. Default: `'same'`.
  - If *init* is a *Tensor* , set the new Parameter data to the input Tensor.
  - If *init* is a *str*, data will be set according to the initialization method of the same name in the *Initializer*. When it is `'same'`, the new Parameter will have the same value with the original Parameter.
  - If *init* is *numbers.Number* , set the new Parameter data to the input number.

Returns

Tuple, the new Parameter tuple.

1.1.3 DataType

mindspore.dtype	Data type for MindSpore.
mindspore.dtype_to_nptype	Convert MindSpore dtype to numpy data type.
mindspore.dtype_to_pytype	Convert MindSpore dtype to python data type.
mindspore.pytype_to_dtype	Convert python type to MindSpore type.
mindspore.get_py_obj_dtype	Get the MindSpore data type, which corresponds to python type or variable.
mindspore.QuantDtype	An enum for quant datatype, contains *INT1* ~ *INT16*, *UINT1* ~ *UINT16*.
mindspore.common.np_dtype	Numpy data type for MindSpore.

mindspore.dtype

class mindspore.**dtype**
Data type for MindSpore.

The actual path of `dtype` is `/mindspore/common/dtype.py`. Run the following command to import the package:

```
from mindspore import dtype as mstype
```

Basic Data Type

MindSpore supports the following base data types:

Definition	Description
`mindspore.int8` , `mindspore.byte`	8-bit integer
`mindspore.int16` , `mindspore.short`	16-bit integer
`mindspore.int32` , `mindspore.intc`	32-bit integer
`mindspore.int64` , `mindspore.intp`	64-bit integer
`mindspore.uint8` , `mindspore.ubyte`	unsigned 8-bit integer
`mindspore.uint16` , `mindspore.ushort`	unsigned 16-bit integer
`mindspore.uint32` , `mindspore.uintc`	unsigned 32-bit integer
`mindspore.uint64` , `mindspore.uintp`	unsigned 64-bit integer
`mindspore.float16` , `mindspore.half`	16-bit floating-point number
`mindspore.float32` , `mindspore.single`	32-bit floating-point number
`mindspore.float64` , `mindspore.double`	64-bit floating-point number
`mindspore.bfloat16`	16-bit brain-floating-point number
`mindspore.complex64`	64-bit complex number
`mindspore.complex128`	128-bit complex number

Other Type

For other defined types, see the following table.

Type	Description
`tensor`	MindSpore's `tensor` type. Data format uses NCHW. For details, see tensor.
`bool_`	Boolean `True` or `False`.
`int_`	Integer scalar.
`uint`	Unsigned integer scalar.
`float_`	Floating-point scalar.
`complex`	Complex scalar.
`number`	Number, including `int_` , `uint` , `float_` , `complex` and `bool_` .
`list_`	List constructed by `tensor` , such as `List[T0,T1,...,Tn]` , where the element `Ti` can be of different types.
`tuple_`	Tuple constructed by `tensor` , such as `Tuple[T0,T1,...,Tn]` , where the element `Ti` can be of different types.
`function`	Function. Return in two ways, when function is not None, returns Func directly, the other returns Func(args: List[T0,T1,⋯,Tn], retval: T) when function is None.
`type_type`	Type definition of type.
`type_none`	No matching return type, corresponding to the `type(None)` in Python.
`symbolic_key`	The value of a variable is used as a key of the variable in `env_type` .
`env_type`	Used to store the gradient of the free variable of a function, where the key is the `symbolic_key` of the free variable's node and the value is the gradient.

Type conversion rules

When some inputs of an operator are required to have the same target type, type promotion will be automatically performed according to the type conversion rules. If these inputs have types of different sizes and categories (where `complex > float > int > bool`), they will be promoted a type with sufficient size and category.

For the type conversion rules between Tensor and Tensor, please refer to the following table. The first row and the first column in the table both represent the types of the input `Tensor`, and the corresponding position in the table represents the type of the output `Tensor`. – indicates that no type promotion will be performed.

For convenience of description, `bool_` is used in the table to refer to `mindspore.bool_`, `int8` is used to refer to `mindspore.int8`, and so on.

Tensor and Tensor	**bool_**	**int8**	**int16**	**int32**	**int64**	**uint8**	**uint16**	**uint32**	**uint64**	**float16**	**bfloat16**	**float32**	**float64**	**complex64**	**complex128**
bool_	bool_	int8	int16	int32	int64	uint8	uint16	uint32	uint64	float16	bfloat16	float32	float64	complex64	complex128
int8	int8	int8	int16	int32	int64	int16	–	–	–	float16	bfloat16	float32	float64	complex64	complex128
int16	int16	int16	int16	int32	int64	int16	–	–	–	float16	bfloat16	float32	float64	complex64	complex128
int32	int32	int32	int32	int32	int64	int32	–	–	–	float16	bfloat16	float32	float64	complex64	complex128
int64	int64	int64	int64	int64	int64	int64	–	–	–	float16	bfloat16	float32	float64	complex64	complex128
uint8	uint8	int16	int16	int32	int64	uint8	–	–	–	float16	bfloat16	float32	float64	complex64	complex128
uint16	uint16	–	–	–	–	–	uint16	–	–	–	–	–	–	–	–
uint32	uint32	–	–	–	–	–	–	uint32	–	–	–	–	–	–	–
uint64	uint64	–	–	–	–	–	–	–	uint64	–	–	–	–	–	–
float16	float16	float16	float16	float16	float16	float16	float16	–	–	float16	float32	float32	float64	complex64	complex128
bfloat16	bfloat16	bfloat16	bfloat16	bfloat16	bfloat16	bfloat16	bfloat16	–	–	float32	bfloat16	float32	float64	complex64	complex128
float32	float32	float32	float32	float32	float32	float32	float32	–	–	float32	float32	float32	float64	complex64	complex128
float64	float64	float64	float64	float64	float64	float64	float64	–	–	float64	float64	float64	float64	complex128	complex128
complex64	complex64	complex64	complex64	complex64	complex64	complex64	–	–	–	complex64	complex64	complex64	complex128	complex64	complex128
complex128	complex128	complex128	complex128	complex128	complex128	complex128	–	–	–	complex128	complex128	complex128	complex128	complex128	complex128

For the type conversion rules between Number and Tensor, please refer to the following table. The first row in the table indicates the type of the input `Number`, and the first column indicates the types of input `Tensor`. The corresponding position in the table represents the type of the output `Tensor`. – indicates that no type promotion will be performed.

Number and Tensor	**bool**	**int**	**float**
bool_	bool_	int64	float32
int8	int8	int8	float32
int16	int16	int16	float32
int32	int32	int32	float32
int64	int64	int64	float32
uint8	uint8	uint8	float32
uint16	uint16	-	-
uint32	uint32	-	-
uint64	uint64	-	-
float16	float16	float16	float16
bfloat16	bfloat16	bfloat16	bfloat16
float32	float32	float32	float32
float64	float64	float64	float64
complex64	complex64	complex64	complex64
complex128	complex128	complex128	complex128

mindspore.dtype_to_nptype

mindspore.**dtype_to_nptype**(*type_*)

Convert MindSpore dtype to numpy data type.

Parameters

type_ (*mindspore.dtype*) – MindSpore's dtype.

Returns

The data type of numpy.

Examples

```
>>> import mindspore as ms
>>> ms.dtype_to_nptype(ms.int8)
<class 'numpy.int8'>
```

mindspore.dtype_to_pytype

mindspore.**dtype_to_pytype**(*type_*)

Convert MindSpore dtype to python data type.

Parameters

type_ (*mindspore.dtype*) – MindSpore's dtype.

Returns

Type of python.

Examples

```
>>> import mindspore as ms
>>> out = ms.dtype_to_pytype(ms.bool_)
>>> print(out)
<class 'bool'>
```

mindspore.pytype_to_dtype

mindspore.**pytype_to_dtype**(*obj*)

Convert python type to MindSpore type.

Parameters

obj (*type*) – A python type object.

Returns

Type of MindSpore type.

Raises

NotImplementedError – If the python type cannot be converted to MindSpore type.

Examples

```
>>> import mindspore as ms
>>> out = ms.pytype_to_dtype(bool)
>>> print(out)
Bool
```

mindspore.get_py_obj_dtype

mindspore.**get_py_obj_dtype**(*obj*)

Get the MindSpore data type, which corresponds to python type or variable.

Parameters

obj (*type*) – An object of python type, or a variable of python type.

Returns

Type of MindSpore type.

Examples

```
>>> import mindspore as ms
>>> ms.get_py_obj_dtype(1)
mindspore.int64
```

mindspore.QuantDtype

class mindspore.**QuantDtype**

An enum for quant datatype, contains *INT1 ~ INT16*, *UINT1 ~ UINT16*.

QuantDtype is defined in dtype.py , use command below to import:

```
from mindspore import QuantDtype
```

Tutorial Examples:

- Quantization algorithm in Golden Stick

value()

Return value of *QuantDtype*. This interface is currently used to serialize or deserialize *QuantDtype* primarily.

Returns

An int as value of *QuantDtype*.

Examples

```
>>> from mindspore import QuantDtype
>>> print(QuantDtype.INT8.value())
7
>>> print(QuantDtype.UINT16.value())
115
```

mindspore.common.np_dtype

class mindspore.common.**np_dtype**

Numpy data type for MindSpore.

The actual path of `np_dtype` is `/mindspore/common/np_dtype.py`. Run the following command to import the package:

```
from mindspore.common import np_dtype
```

- **Numeric Type**

Type	Description
`bfloat16`	The `bfloat16` data type under NumPy. This type is only used to construct Tensor of type `bfloat16`, and does not guarantee the full computing power under Numpy. Takes effect only if the version of Numpy at runtime is not less than the version of Numpy at compilation.

1.2 Context

mindspore.set_device	Set device target and device id for running environment.
mindspore.get_current_device	Get device target and device id in the current running environment.
mindspore.set_deterministic	Enables or disables deterministic computing.
mindspore.set_context	Set context for running environment, this interface will be deprecated in future versions, and its parameter-related functionalities will be provided through new APIs.
mindspore.get_context	Get context attribute value according to the input key, this api will be deprecated and removed in future versions, please use *mindspore.get_current_device()* instead.
mindspore.set _auto_parallel_context	Set auto parallel context, this api will be deprecated and removed in future versions, please use the api *mindspore.parallel.auto_parallel.AutoParallel* instead.
mindspore.get _auto_parallel_context	Get auto parallel context attribute value according to the key, this api will be deprecated and removed in future versions.
mindspore.reset _auto_parallel_context	Reset auto parallel context attributes to the default values, this api will be deprecated and removed in future versions, please use the api *mindspore.parallel.auto_parallel.AutoParallel* instead.
mindspore.ParallelMode	Parallel mode options.
mindspore.set_ps_context	Set parameter server training mode context, this api will be deprecated and removed in future versions.
mindspore.get_ps_context	Get parameter server training mode context attribute value according to the key, this api will be deprecated and removed in future versions.
mindspore.reset_ps_context	Reset parameter server training mode context attributes to the default values, this api will be deprecated and removed in future versions.
mindspore.set_algo_parameters	Set parameters in the algorithm for parallel strategy searching.
mindspore.get_algo_parameters	Get the algorithm parameter config attributes.
mindspore.reset_algo_parameters	Reset the algorithm parameter attributes.
mindspore.set_offload_context	Configure heterogeneous training detailed parameters to adjust the offload strategy, this api will be deprecated and removed in future versions.
mindspore.get_offload_context	Gets the offload configuration parameters, this api will be deprecated and removed in future versions.

1.2.1 mindspore.set_device

mindspore.**set_device**(*device_target*, *device_id=None*)

Set device target and device id for running environment.

Note:

- The *device_target* must be set in the ["CPU", "GPU", "Ascend"], there is no default value.
- Suggest setting *device_target* and *device_id* before calling *mindspore.communication.init()*.

Parameters

- **device_target** (*str*) –The target device to run, only support "Ascend", "GPU", and "CPU".
- **device_id** (*int, optional*) –ID of the target device, the value must be in [0, device_num_per_host-1], where device_num_per_host refers to the total number of devices on the host. Default: `None` . The frame will set different default behaviours according to the scenario: if it is a single-card scenario, the frame will be set to 0. In a distributed scenario where msrun is started, the framework will automatically negotiate the available device_id values. In a distributed scenario with other startup methods, the frame is set to 0.

Examples

```
>>> import mindspore as ms
>>> ms.set_device("Ascend", 1)
```

1.2.2 mindspore.get_current_device

mindspore.**get_current_device**()

Get device target and device id in the current running environment.

Examples

```
>>> import mindspore as ms
>>> ms.set_device("Ascend", 1)
>>> ms.get_current_device()
('Ascend', 1)
>>> ms.get_current_device().device_target
'Ascend'
>>> ms.get_current_device().device_id
1
```

1.2.3 mindspore.set_deterministic

mindspore.**set_deterministic**(*deterministic*)

Enables or disables deterministic computing.

When deterministic computing is enabled, the same output is generated if an operator is executed for multiple times with the same hardware and input.This often slows down operator execution. In distributed scenario, we suggest user to set deterministic mode before calling *mindspore.communication.init()* to enable deterministic operation for communication operators in the global communication group.

The framework not enabled deterministic computation by default.

Parameters

deterministic (*bool*) –Whether to enable deterministic computing.

Examples

```
>>> import mindspore as ms
>>> ms.set_deterministic(True)
```

1.2.4 mindspore.set_context

mindspore.**set_context**(***kwargs*)

Set context for running environment, this interface will be deprecated in future versions, and its parameter-related functionalities will be provided through new APIs.

Parameters

- **mode** (*int*) –GRAPH_MODE(0) or PYNATIVE_MODE(1). Default `PYNATIVE_MODE` .
- **device_id** (*int*) –ID of the target device. Default `0` . This parameter will be deprecated and removed in future versions. Please use the api *mindspore.set_device()* instead.
- **device_target** (*str*) –The target device to run, support `"Ascend"`, `"GPU"`, and `"CPU"`. This parameter will be deprecated and removed in future versions. Please use the api *mindspore.set_device()* instead.
- **deterministic** (*str*) –Deterministic computation of operators. Default `"OFF"` . This parameter will be deprecated and removed in future versions. Please use the api *mindspore.set_deterministic()* instead.
- **max_call_depth** (*int*) –The maximum depth of function call. Default `1000` . This parameter will be deprecated and removed in a future version. Please use the api *mindspore.set_recursion_limit()* instead.
- **variable_memory_max_size** (*str*) –This parameter will be deprecated and removed in future versions. Please use the api *mindspore.runtime.set_memory()* instead.
- **mempool_block_size** (*str*) –Set the size of the memory pool block for devices. Default `"1GB"` . This parameter will be deprecated and removed in future versions. Please use the api *mindspore.runtime.set_memory()* instead.
- **memory_optimize_level** (*str*) –The memory optimize level. Default `"O0"`. This parameter will be deprecated and removed in future versions. Please use the api *mindspore.runtime.set_memory()* instead.
- **max_device_memory** (*str*) –Set the maximum memory available for devices. Default `"1024GB"` . This parameter will be deprecated and removed in future versions. Please use the api *mindspore.runtime.set_memory()* instead.
- **pynative_synchronize** (*bool*) –Whether to enable synchronous execution of the device in PyNative mode. Default `False` . This parameter will be deprecated and removed in future versions.Please use the api *mindspore.runtime.launch_blocking()* instead.
- **compile_cache_path** (*str*) –Path to save the compile cache. Default `"."`. This parameter will be deprecated and removed in a future version. Please use the environment variable *MS_COMPILER_CACHE_PATH* instead.
- **inter_op_parallel_num** (*int*) –The thread number of op parallel at the same time. Default `0` . This parameter will be deprecated and removed in future versions. Please use the api *mindspore.runtime.dispatch_threads_num()* instead.
- **memory_offload** (*str*) –Whether to enable the memory offload function. Default `"OFF"` . This parameter will be deprecated and removed in future versions. Please use the api *mindspore.nn.Cell.offload()* instead.
- **disable_format_transform** (*bool*) –Whether to disable the automatic format transform function from NCHW to NHWC. Default `False` . This parameter will be deprecated and removed in future versions. Please use the related parameter of *mindspore.jit()* instead.

- **jit_syntax_level** (*int*) −Set JIT syntax support level. Default `LAX` . This parameter is deprecated and removed in future versions. Please use the related parameter of *mindspore.jit()* instead.
- **jit_config** (*dict*) −Set the global jit config for compile. This parameter is deprecated and removed in future versions. Please use the related parameter of *mindspore.jit()* instead.
- **exec_order** (*str*) −The sorting method for operator execution. This parameter is deprecated and removed in future versions. Please use the related parameter of *mindspore.jit()* instead.
- **op_timeout** (*int*) −Set the maximum duration of executing an operator in seconds. Default `900` . This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.ascend.op_debug.execute_timeout()* instead.
- **aoe_tune_mode** (*str*) −AOE tuning mode. This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.ascend.op_tuning.aoe_tune_mode()* instead.
- **aoe_config** (*dict*) −AOE-specific parameters. This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.ascend.op_tuning.aoe_job_type()* instead.
- **runtime_num_threads** (*int*) −The thread pool number of cpu kernel used in runtime. Default `30` . This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.cpu.op_tuning.threads_num()* instead.
- **save_graphs** (*bool or int*) −Whether to save intermediate compilation graphs. Default `0` . This parameter will be deprecated and removed in a future version. Please use the environment variable *MS_DEV_SAVE_GRAPHS* instead.
- **save_graphs_path** (*str*) −Path to save graphs. Default `"."`. This parameter will be deprecated and removed in a future version. Please use the environment variable *MS_DEV_SAVE_GRAPHS_PATH* instead.
- **precompile_only** (*bool*) −Whether to only precompile the network. Default `False` . This parameter will be deprecated and removed in a future version. Please use the environment variable *MS_DEV_PRECOMPILE_ONLY* instead.
- **enable_compile_cache** (*bool*) −Whether to save or load the compiled cache of the graph. Default `False` . This is an experimental prototype that is subject to change and/or deletion. This parameter will be deprecated and removed in a future version. Please use the environment variable *MS_COMPILER_CACHE_ENABLE* instead.
- **ascend_config** (*dict*) −Set the parameters specific to Ascend hardware platform.
  - precision_mode (str): Mixed precision mode setting. Default `"force_fp16"` . This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.ascend.op_precision.precision_mode()* instead.
  - jit_compile (bool): Whether to select online compilation. This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.ascend.op_tuning.op_compile()* instead.
  - matmul_allow_hf32 (bool): Whether to convert FP32 to HF32 for Matmul operators. Default `False`. This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.ascend.op_precision.matmul_allow_hf32()* instead.
  - conv_allow_hf32 (bool): Whether to convert FP32 to HF32 for Conv operators. Default `True`. This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.ascend.op_precision.conv_allow_hf32()* instead.
  - op_precision_mode (str): Path to config file of op precision mode. This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.ascend.op_precision.op_precision_mode()* instead.
  - op_debug_option (str): Enable debugging options for Ascend operators. This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.ascend.op_debug.debug_option()* instead.

  - ge_options (dict): Set options for CANN. This parameter will be deprecated and removed in future versions. Please use the related parameter of *mindspore.jit()* instead.
  - atomic_clean_policy (int): The policy for cleaning memory occupied by atomic operators in the network. Default `1` represents that memory is not cleaned centrally, `0` represents that memory is cleaned centrally. This parameter will be deprecated and removed in future versions. Please use the related parameter of *mindspore.jit()* instead.
  - exception_dump (str): Enable Ascend operator exception dump. Default `"2"` . This parameter has been deprecated and removed. Please use the api *mindspore.device_context.ascend.op_debug.aclinit_config()* instead.
  - host_scheduling_max_threshold(int): The max threshold to control whether the dynamic shape process is used when run the static graph. Default `0` . This parameter will be deprecated and removed in future versions. Please use the related parameter of *mindspore.jit()* instead.
  - parallel_speed_up_json_path(Union[str, None]): The path to the parallel speed up json file. This parameter will be deprecated and removed in future versions. Please use the api *mindspore.parallel.auto_parallel.AutoParallel.transformer_opt()* instead.
  - hccl_watchdog (bool): Enable a thread to monitor the failure of collective communication. Default `True` .

- **gpu_config** (*dict*) –Set the parameters specific to gpu hardware platform. It is not set by default.
  - conv_fprop_algo (str): Specifies convolution forward algorithm. Default `"normal"` . This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.gpu.op_tuning.conv_fprop_algo()* instead.
  - conv_dgrad_algo (str): Specifies convolution data grad algorithm. Default `"normal"` . This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.gpu.op_tuning.conv_dgrad_algo()* instead.
  - conv_wgrad_algo (str): Specifies convolution filter grad algorithm. Default `"normal"` . This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.gpu.op_tuning.conv_wgrad_algo()* instead.
  - conv_allow_tf32 (bool): Controls to allow Tensor core TF32 computation on CUDNN. Default `True`. This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.gpu.op_precision.conv_allow_tf32()* instead.
  - matmul_allow_tf32 (bool): Controls to allow Tensor core TF32 computation on CUBLAS. Default `False`. This parameter will be deprecated and removed in future versions. Please use the api *mindspore.device_context.gpu.op_precision.matmul_allow_tf32()* instead.
- **print_file_path** (*str*) –This parameter will be deprecated and removed in future versions.
- **env_config_path** (*str*) –This parameter will be deprecated and removed in future versions.
- **debug_level** (*int*) –This parameter will be deprecated and removed in future versions.
- **reserve_class_name_in_scope** (*bool*) –This parameter will be deprecated and removed in future versions.
- **check_bprop** (*bool*) –This parameter will be deprecated and removed in future versions.
- **enable_reduce_precision** (*bool*) –This parameter will be deprecated and removed in a future versions.
- **grad_for_scalar** (*bool*) –This parameter will be deprecated and removed in future versions.
- **support_binary** (*bool*) –Whether to support run .pyc or .so in graph mode.

Examples

```
>>> import mindspore as ms
>>> ms.set_context(mode=ms.PYNATIVE_MODE)
>>> ms.set_context(precompile_only=True)
>>> ms.set_context(device_target="Ascend")
>>> ms.set_context(device_id=0)

1.2.5 mindspore.get_context

mindspore.**get_context**(*attr_key*)

Get context attribute value according to the input key, this api will be deprecated and removed in future versions, please use *mindspore.get_current_device()* instead.

If some attributes are not set, they will be automatically obtained.

Parameters

attr_key (*str*) –The key of the attribute.

Returns

Object, The value of given attribute key.

Raises

ValueError –If input key is not an attribute in context.

Examples

```
>>> import mindspore as ms
>>> ms.get_context("device_target")
>>> ms.get_context("device_id")
```

1.2.6 mindspore.set_auto_parallel_context

mindspore.**set_auto_parallel_context**(***kwargs*)

Set auto parallel context, this api will be deprecated and removed in future versions, please use the api *mindspore.parallel.auto_parallel.AutoParallel* instead.

Note: CPU only support data parallel.

Some configurations are parallel mode specific, see the below table for details:

Common	AUTO_PARALLEL
device_num	gradient_fp32_sync
global_rank	loss_repeated_mean
gradients_mean	search_mode
parallel_mode	parameter_broadcast
all_reduce_fusion_config	strategy_ckpt_load_file
enable_parallel_optimizer	strategy_ckpt_save_file
parallel_optimizer_config	dataset_strategy
enable_alltoall	pipeline_stages
pipeline_config	auto_parallel_search_mode
force_fp32_communication	pipeline_result_broadcast
	comm_fusion
	strategy_ckpt_config
	group_ckpt_save_file
	auto_pipeline
	dump_local_norm
	dump_local_norm_path
	dump_device_local_norm

Parameters

- **device_num** (*int*) –Available device number, the value must be in [1, 4096]. Default: 1 .
- **global_rank** (*int*) –Global rank id, the value must be in [0, 4095]. Default: 0 .

- **gradients_mean** (*bool*) −Whether to perform mean operator after allreduce of gradients. "stand_alone" do not support gradients_mean. Default: `False` .
- **gradient_fp32_sync** (*bool*) −Run allreduce of gradients in fp32. "stand_alone", "data_parallel" and "hybrid_parallel" do not support gradient_fp32_sync. Default: `True` .
- **loss_repeated_mean** (*bool*) −calculation is repeated. Default: `True` .
- **parallel_mode** (*str*) −There are five kinds of parallel modes, `"stand_alone"` , `"data_parallel"` , `"hybrid_parallel"` , `"semi_auto_parallel"` and `"auto_parallel"` . Note the pynative mode only supports the `"stand_alone"` and `"data_parallel"` mode. Default: `"stand_alone"` .
  - stand_alone: Only one processor is working.
  - data_parallel: Distributes the data across different processors.
  - hybrid_parallel: Achieves data parallelism and model parallelism manually.
  - semi_auto_parallel: Achieves data and model parallelism by setting parallel strategies.
  - auto_parallel: Achieving parallelism automatically.
- **search_mode** (*str*) −There are three kinds of shard strategy search modes: `"recursive_programming"` , `"sharding_propagation"` and `"dynamic_programming"` (Not recommended). Only works in `"auto_parallel"` mode. Default: `"recursive_programming"` .
  - recursive_programming: Recursive programming search mode. In order to obtain optimal performance, it is recommended that users set the batch size to be greater than or equal to the product of the number of devices and the number of multi-copy parallelism.
  - sharding_propagation: Propagate shardings from configured ops to non-configured ops. Dynamic shapes are not supported currently.
  - dynamic_programming: Dynamic programming search mode.
- **auto_parallel_search_mode** (*str*) −This is the old version of 'search_mode'. Here, remaining this attribute is for forward compatibility, and this attribute will be deleted in a future MindSpore version.
- **parameter_broadcast** (*bool*) −Whether to broadcast parameters before training. Before training, in order to have the same network initialization parameter values for all devices, broadcast the parameters on device 0 to other devices. Parameter broadcasting in different parallel modes is different, `data_parallel` mode, all parameters are broadcast except for the parameter whose attribute layerwise_parallel is `True` . `Hybrid_parallel` , `semi_auto_parallel` and `auto_parallel mode` , the segmented parameters do not participate in broadcasting. Default: `False` .
- **strategy_ckpt_load_file** (*str*) −The path to load parallel strategy checkpoint. The parameter is not to be recommended currently, it is better using 'strategy_ckpt_config' to replace it. Default: `''`
- **strategy_ckpt_save_file** (*str*) −The path to save parallel strategy checkpoint. The parameter is not to be recommended currently, it is better using 'strategy_ckpt_config' to replace it. Default: `''`
- **full_batch** (*bool*) −If you load whole batch datasets in `auto_parallel` mode, this parameter should be set as `True` . Default: `False` . The interface is not to be recommended currently, it is better using 'dataset_strategy' to replace it.
- **dataset_strategy** (*Union[str, tuple]*) −Dataset sharding strategy. Default: `"data_parallel"` . dataset_strategy="data_parallel" is equal to full_batch=False, dataset_strategy="full_batch" is equal to full_batch=True. For execution mode is 'GRAPH_MODE' and dataset load into net by model parallel strategy likes ds_stra ((1, 8), (1, 8)), it requires using set_auto_parallel_context(dataset_strategy=ds_stra). The dataset sharding strategy is not affected by the currently configured parallel mode. parallel strategy also supports tuple of Layout.
- **enable_parallel_optimizer** (*bool*) −This is a developing feature, which shards the weight update computation for data parallel training in the benefit of time and memory saving. Currently, auto and semi auto parallel mode

support all optimizers in both Ascend and GPU. Data parallel mode only supports *Lamb* and *AdamWeightDecay* in Ascend . Default: `False` .

- **force_fp32_communication** (*bool*) –A switch that determines whether reduce operators (AllReduce, ReduceScatter) are forced to use the fp32 data type for communication during communication. True is the enable switch. Default: `False` .
- **enable_alltoall** (*bool*) –A switch that allows AllToAll operators to be generated during communication. If its value is `False` , there will be a combination of operators such as AllGather, Split and Concat instead of AllToAll. Default: `False` .
- **all_reduce_fusion_config** (*list*) –Set allreduce fusion strategy by parameters indices. Only support ReduceOp.SUM and HCCL_WORLD_GROUP/NCCL_WORLD_GROUP. No Default, if it is not set, the fusion is closed.
- **pipeline_stages** (*int*) –Set the stage information for pipeline parallel. This indicates how the devices are distributed alone in the pipeline. The total devices will be divided into 'pipeline_stags' stages. Default: `1` .
- **pipeline_result_broadcast** (*bool*) –A switch that broadcast the last stage result to all other stage in pipeline parallel inference. Default: `False` .
- **pipeline_config** (*dict*) –A dict contains the keys and values for setting the pipeline parallelism configuration. It supports the following keys:
  - pipeline_interleave(bool): Indicates whether to enable the interleaved execution mode.
  - pipeline_scheduler(str): Indicates the scheduling mode for pipeline parallelism. Only support `gpipe/1f1b/seqpipe/seqvpp/seqsmartvpp`. When applying seqsmartvpp, the pipeline parallel must be an even number.
- **parallel_optimizer_config** (*dict*) –A dict contains the keys and values for setting the parallel optimizer configure. The configure provides more detailed behavior control about parallel training when parallel optimizer is enabled. The configure will be effective when we use mindspore.set_auto_parallel_context(enable_parallel_optimizer=True). It supports the following keys.
  - gradient_accumulation_shard(bool): Please using optimizer_level: `level2` to replace this config. If `true` , the accumulation gradient parameters will be sharded across the data parallel devices. This will introduce additional communication(ReduceScatter) at each step when accumulate the gradients, but saves a lot of device memories, thus can make model be trained with larger batch size. This configure is effective only when the model runs on pipeline training or gradient accumulation with data parallel. Default `False` .
  - parallel_optimizer_threshold(int): Set the threshold of parallel optimizer. When parallel optimizer is enabled, parameters with size smaller than this threshold will not be sharded across the devices. Parameter size is calculated as: shape[0] * ···* shape[n] * size(dtype). Non-negative. Unit: KB. Default: `64` .
  - optimizer_weight_shard_size(int): Set the optimizer weight shard group size, if you want to specific the maximum group size across devices when the parallel optimizer is enabled. The numerical range can be (0, device_num]. If pipeline parallel is enabled, the numerical range is (0, device_num/stage]. If the size of data parallel communication domain of the parameter cannot be divided by *optimizer_weight_shard_size*, then the specified communication group size will not take effect. Default value is `-1` , which means the optimizer weight shard group size will be the size of data parallel group of each parameter.
  - optimizer_level(str, optional): optimizer_level configuration is used to specify the splitting level for optimizer sharding. It is important to note that the implementation of optimizer sharding in static graph is inconsistent with dynamic graph like megatron, but the memory optimization effect is the same. When optimizer_level= `level1` , splitting is performed on weights and optimizer state. When optimizer_level= `level2` , splitting is performed on weights, optimizer state, and gradients. When optimizer_level= `level3` , splitting is performed on weights, optimizer state, gradients, additionally, before the backward pass, the weights are further applied with allgather communication to release the memory used by the forward pass allgather. It must be one of [`level1`, `level2`, `level3`]. Default: `level1`.

- **comm_fusion** (*dict*) −A dict contains the types and configurations for setting the communication fusion. each communication fusion config has two keys: "mode" and "config". It supports following communication fusion types and configurations:
  - openstate: Whether turn on the communication fusion or not. If *openstate* is `True` , turn on the communication fusion, otherwise, turn off the communication fusion. Default: `True` .
  - allreduce: If communication fusion type is *allreduce*. The *mode* contains: *auto*, *size* and *index*. In *auto* mode, AllReduce fusion is configured by gradients size and the default fusion threshold is *64* MB. In 'size' mode, AllReduce fusion is configured by gradients size manually, and the fusion threshold must be larger than *0* MB. In *index* mode, it is same as *all_reduce_fusion_config*.
  - allgather: If communication fusion type is *allgather*. The *mode* contains: *auto*, *size*. In *auto* mode, AllGather fusion is configured by gradients size, and the default fusion threshold is *64* MB. In 'size' mode, AllGather fusion is configured by gradients size manually, and the fusion threshold must be larger than *0* MB.
  - reducescatter: If communication fusion type is *reducescatter*. The *mode* contains: *auto* and *size*. Config is same as *allgather*.
- **strategy_ckpt_config** (*dict*) −A dict contains the configurations for setting the parallel strategy file. This interface contains the functions of parameter *strategy_ckpt_load_file* and *strategy_ckpt_save_file*, it is recommonded to use this parameter to replace those two parameters. It contains following configurations:
  - load_file (str): The path to load parallel strategy checkpoint. If the file name extension is *.json*, the file is loaded in JSON format. Otherwise, the file is loaded in ProtoBuf format. Default: `''`
  - save_file (str): The path to save parallel strategy checkpoint. If the file name extension is *.json*, the file is saved in JSON format. Otherwise, the file is saved in ProtoBuf format. Default: `''`
  - only_trainable_params (bool): Only save/load the strategy information for trainable parameter. Default: `True` .
- **group_ckpt_save_file** (*str*) −The path to save parallel group checkpoint.
- **auto_pipeline** (*bool*) −Set the pipeline stage number to automatic. Its value will be selected between 1 and the parameter *pipeline_stages*. This option requires the *parallel_mode* to be `auto_parallel` and the *search_mode* to be `recursive_programming`. Default: `False` .
- **dump_local_norm** (*bool*) −Whether to dump local_norm value, when the *parallel_mode* is set to `semi_auto_parallel` or `auto_parallel`. Default: `False` .
- **dump_local_norm_path** (*str*) −The path to save dump files of local_norm value. Default: `''` .
- **dump_device_local_norm** (*bool*) −Whether to dump device_local_norm value, when the *parallel_mode* is set to `semi_auto_parallel` or `auto_parallel`. Default: `False` .

Raises

ValueError −If input key is not attribute in auto parallel context.

Examples

```
>>> import mindspore as ms
>>> ms.set_auto_parallel_context(device_num=8)
>>> ms.set_auto_parallel_context(global_rank=0)
>>> ms.set_auto_parallel_context(gradients_mean=True)
>>> ms.set_auto_parallel_context(gradient_fp32_sync=False)
>>> ms.set_auto_parallel_context(parallel_mode="auto_parallel")
>>> ms.set_auto_parallel_context(search_mode="recursive_programming")
>>> ms.set_auto_parallel_context(auto_parallel_search_mode="recursive_programming")
>>> ms.set_auto_parallel_context(parameter_broadcast=False)
```

(continues on next page)

(continued from previous page)

```
>>> ms.set_auto_parallel_context(strategy_ckpt_load_file="./strategy_stage1.ckpt")
>>> ms.set_auto_parallel_context(strategy_ckpt_save_file="./strategy_stage1.ckpt")
>>> ms.set_auto_parallel_context(dataset_strategy=((1, 8), (1, 8)))
>>> ms.set_auto_parallel_context(enable_parallel_optimizer=False)
>>> ms.set_auto_parallel_context(enable_alltoall=False)
>>> ms.set_auto_parallel_context(all_reduce_fusion_config=[8, 160])
>>> ms.set_auto_parallel_context(pipeline_stages=2)
>>> ms.set_auto_parallel_context(pipeline_stages=2, pipeline_result_broadcast=True)
>>> parallel_config = {"gradient_accumulation_shard": True, "parallel_optimizer_threshold":␣
↪24,
...                     "optimizer_weight_shard_size": 2, "optimizer_level": "level3"}
>>> ms.set_auto_parallel_context(parallel_optimizer_config=parallel_config, enable_parallel_
↪optimizer=True)
>>> config = {"allreduce": {"mode": "size", "config": 32}, "allgather": {"mode": "size",
↪"config": 32}}
>>> ms.set_auto_parallel_context(comm_fusion=config)
>>> stra_ckpt_dict = {"load_file": "./stra0.ckpt", "save_file": "./stra1.ckpt", "only_
↪trainable_params": False}
>>> ms.set_auto_parallel_context(strategy_ckpt_config=stra_ckpt_dict)
```

1.2.7 mindspore.get_auto_parallel_context

mindspore.**get_auto_parallel_context**(*attr_key*)

Get auto parallel context attribute value according to the key, this api will be deprecated and removed in future versions.

Parameters

attr_key (*str*) –The key of the attribute.

Returns

Returns attribute value according to the key.

Raises

ValueError –If input key is not attribute in auto parallel context.

Examples

```
>>> import mindspore as ms
>>> parallel_mode = ms.get_auto_parallel_context("parallel_mode")
>>> dataset_strategy = ms.get_auto_parallel_context("dataset_strategy")
```

1.2.8 mindspore.reset_auto_parallel_context

mindspore.**reset_auto_parallel_context**()

Reset auto parallel context attributes to the default values, this api will be deprecated and removed in future versions, please use the api *mindspore.parallel.auto_parallel.AutoParallel* instead.

- device_num: 1.
- global_rank: 0.
- gradients_mean: False.

- gradient_fp32_sync: True.
- parallel_mode: 'stand_alone'.
- search_mode: 'recursive_programming'.
- auto_parallel_search_mode: 'recursive_programming'.
- parameter_broadcast: False.
- strategy_ckpt_load_file: ''.
- strategy_ckpt_save_file: ''.
- full_batch: False.
- enable_parallel_optimizer: False.
- force_fp32_communication: False.
- enable_alltoall: False.
- pipeline_stages: 1.
- pipeline_result_broadcast: False.
- fusion_threshold: 64.
- auto_pipeline: False.
- dump_local_norm: False.
- dump_local_norm_path: ''.
- dump_device_local_norm: False.

Examples

```
>>> import mindspore as ms
>>> ms.reset_auto_parallel_context()
```

1.2.9 mindspore.ParallelMode

class mindspore.**ParallelMode**

Parallel mode options.

There are five kinds of parallel modes, `STAND_ALONE`, `DATA_PARALLEL`, `HYBRID_PARALLEL`, `SEMI_AUTO_PARALLEL` and `AUTO_PARALLEL`. Default: `STAND_ALONE`.

- `STAND_ALONE`: Only one processor is working.
- `DATA_PARALLEL`: Distributes the data across different processors.
- `HYBRID_PARALLEL`: Achieves data parallelism and model parallelism manually.
- `SEMI_AUTO_PARALLEL`: Achieves data parallelism and model parallelism by setting parallel strategies.
- `AUTO_PARALLEL`: Achieves parallelism automatically.

`MODE_LIST`: The list of all supported parallel modes.

1.2.10 mindspore.set_ps_context

mindspore.**set_ps_context**(***kwargs*)

Set parameter server training mode context, this api will be deprecated and removed in future versions.

Note: Parameter server mode is only supported in graph mode. Some other environment variables should also be set for parameter server training mode. These environment variables are listed below:

- MS_SERVER_NUM: Server number
- MS_WORKER_NUM: Worker number
- MS_SCHED_HOST: Scheduler IP address
- MS_SCHED_PORT: Scheduler port
- MS_ROLE: The role of this process:
  - MS_SCHED: represents the scheduler,
  - MS_WORKER: represents the worker,
  - MS_PSERVER/MS_SERVER: represents the Server

Parameters

- **enable_ps** (*bool*) –Whether to enable parameter server training mode. Only after enable_ps is set True, the environment variables will be effective. Default: `False` .
- **config_file_path** (*str*) –Configuration file path used by recovery, parameter server training mode only supports Server disaster recovery currently. Default: `''` .
- **scheduler_manage_port** (*int*) –Scheduler manage port used to scale out/in. Default: `11202` .
- **enable_ssl** (*bool*) –Set PS SSL mode enabled or disabled. Default: `False` .
- **client_password** (*str*) –Password to decrypt the secret key stored in the client certificate. Default: `''` .
- **server_password** (*str*) –Password to decrypt the secret key stored in the server certificate. Default: `''` .

Raises

ValueError –If input key is not the attribute in parameter server training mode context.

Examples

```
>>> import mindspore as ms
>>> ms.set_ps_context(enable_ps=True, enable_ssl=True, client_password='123456', server_
↪password='123456')
```

1.2.11 mindspore.get_ps_context

mindspore.**get_ps_context**(*attr_key*)

Get parameter server training mode context attribute value according to the key, this api will be deprecated and removed in future versions.

Parameters

attr_key (*str*) –The key of the attribute:

- enable_ps (bool, optional): Whether to enable parameter server training mode. Default: `False` .
- config_file_path (str, optional): Configuration file path used by recovery, parameter server training mode only supports Server disaster recovery currently. Default: `''` .
- scheduler_manage_port (int, optional): Scheduler manage port used to scale out/in. Default: `11202` .
- enable_ssl (bool, optional): Set PS SSL mode enabled or disabled. Default: `False` .
- client_password (str, optional): Password to decrypt the secret key stored in the client certificate. Default: `''` .
- server_password (str, optional): Password to decrypt the secret key stored in the server certificate. Default: `''` .

Returns

Returns attribute value according to the key.

Raises

ValueError –If input key is not attribute in auto parallel context.

Examples

```
>>> import mindspore as ms
>>> ms.get_ps_context("enable_ps")
```

1.2.12 mindspore.reset_ps_context

mindspore.**reset_ps_context**()

Reset parameter server training mode context attributes to the default values, this api will be deprecated and removed in future versions.

Meaning of each field and its default value refer to *mindspore.set_ps_context()*.

Examples

```
>>> import mindspore as ms
>>> ms.reset_ps_context()
```

1.2.13 mindspore.set_algo_parameters

mindspore.**set_algo_parameters**(***kwargs*)

Set parameters in the algorithm for parallel strategy searching.

Note: The attribute name is required. This interface works ONLY in AUTO_PARALLEL mode.

Parameters

- **fully_use_devices** (*bool*) −Whether ONLY searching strategies that fully use all available devices. Default: `False` . For example with 8 devices available, if set `True` , strategy (4, 1) will not be included in ReLU's candidate strategies, because strategy (4, 1) only utilizes 4 devices.
- **elementwise_op_strategy_follow** (*bool*) −Whether the elementwise operator has the consistent strategies as its subsequent operators. Elementwise operators refer to operators that operate on input element by element, such as Add, ReLU, etc. Default: `False` . For the example of ReLU followed by Add, if this flag is set `True` , then the searched strategy by the algorithm guarantees that strategies of these two operators are consistent, e.g., ReLU's strategy (8, 1) and Add's strategy ((8, 1), (8, 1)).
- **enable_algo_approxi** (*bool*) −Whether to enable the approximation in the algorithms. Default: `False` . Due to large solution space in searching parallel strategy for large DNN model, the algorithm takes fairly long time in this case. To mitigate it, if this flag is set `True` , an approximation is made to discard some candidate strategies, so that the solution space is shrunken.
- **algo_approxi_epsilon** (*float*) −The epsilon value used in the approximation algorithm. Default: `0.1` . This value describes the extent of approximation. For example, the number of candidate strategies of an operator is S, if 'enable_algo_approxi' is `True` , then the remaining strategies is of size: min{S, 1/epsilon}.
- **tensor_slice_align_enable** (*bool*) −Whether to check the shape of tensor slice of MatMul. Default: `False` . Due to properties of some hardware, MatMul kernel only with large shapes can show advantages. If this flag is `True` , then the slice shape of MatMul is checked to prevent irregular shapes.
- **tensor_slice_align_size** (*int*) −The minimum tensor slice shape of MatMul, the value must be in [1, 1024]. Default: `16` . If 'tensor_slice_align_enable' is set `True` , then the slice size of last dimension of MatMul tensors should be multiple of this value.

Raises

ValueError −If context keyword is not recognized.

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For the Ascend devices, users need to prepare the rank table, set rank_id and device_id. Please see the rank table startup for more details.

For the GPU devices, users need to prepare the host file and mpi, please see the mpirun startup .

For the CPU device, users need to write a dynamic cluster startup script, please see the Dynamic Cluster Startup .

>>> loss_cb = train.LossMonitor()
>>> model = ms.Model(network=net, loss_fn=loss_fn, optimizer=optimizer)
>>> model.train(epoch=2, train_dataset=dataset, callbacks=[loss_cb])
```

1.2.14 mindspore.get_algo_parameters

mindspore.**get_algo_parameters**(*attr_key*)

Get the algorithm parameter config attributes.

Note: The attribute name is required. This interface works ONLY in AUTO_PARALLEL mode.

Parameters

attr_key (*str*) –The key of the attribute. The keys include: "fully_use_devices", "elementwise_op_strategy_follow", "enable_algo_approxi", "algo_approxi_epsilon", "tensor_slice_align_enable","tensor_slice_align_size". See *mindspore.set_algo_parameters()* for more details about the meaning of the attributes.

Returns

Return attribute value according to the key.

Raises

ValueError –If context keyword is not recognized.

Examples

```
>>> import mindspore as ms
>>> ms.get_algo_parameters("fully_use_devices")
False
```

1.2.15 mindspore.reset_algo_parameters

mindspore.**reset_algo_parameters**()

Reset the algorithm parameter attributes.

Note: This interface works ONLY in AUTO_PARALLEL mode.

After reset, the values of the attributes are:

- fully_use_devices: False.
- elementwise_op_strategy_follow: False.
- enable_algo_approxi: False.
- algo_approxi_epsilon: 0.1.

- tensor_slice_align_enable: False.
- tensor_slice_align_size: 16.

Examples

```
>>> import mindspore as ms
>>> ms.reset_algo_parameters()
```

1.2.16 mindspore.set_offload_context

mindspore.**set_offload_context**(*offload_config*)

Configure heterogeneous training detailed parameters to adjust the offload strategy, this api will be deprecated and removed in future versions.

Note: The offload configuration is only used if the memory offload feature is enabled via mindspore.set_context(memory_offload="ON"), and the memory_optimize_level must be set to O0. On the Ascend hardware platform, the graph compilation level must be O0.

Parameters

offload_config (*dict*) – A dict contains the keys and values for setting the offload context configure.It supports the following keys.

- offload_path (str): The path of offload, relative paths are supported. Default: "./offload".
- offload_cpu_size (str): The cpu memory size for offload. The format is "xxGB".
- offload_disk_size (str): The disk size for offload. The format is "xxGB"
- hbm_ratio (float): The ratio that can be used based on the maximum device memory. The range is (0,1], Default: 1.0.
- cpu_ratio (float): The ratio that can be used based on the maximum host memory. The range is (0,1], Default: 1.0.
- enable_pinned_mem (bool): The flag of whether enabling Pinned Memory. Default: True.
- enable_aio (bool): The flag of whether enabling aio. Default: True.
- aio_block_size (str): The size of aio block. The format is "xxGB".
- aio_queue_depth (int): The depth of aio queue.
- offload_param (str): The param for offload destination, cpu or disk, Default: "".
- offload_checkpoint (str): The checkpoint for offload destination, only valid if recompute is turned on, cpu or disk, Default: "".
- auto_offload (bool): The flag of whether auto offload. Default: True.
- host_mem_block_size (str): The memory block size of host memory pool. The format is "xxGB"

Raises

ValueError – If input key is not attribute in auto parallel context.

Examples

```
>>> from mindspore import context
>>> context.set_offload_context(offload_config={"offload_param":"cpu"})
```

1.2.17 mindspore.get_offload_context

mindspore.**get_offload_context**()

Gets the offload configuration parameters, this api will be deprecated and removed in future versions.

Configure through interface mindspore.set_offload_context(). If the user is not set, the default configuration is obtained.

Returns

Dict, heterogeneous training offload detailed configuration parameters.

Examples

```
>>> from mindspore import context
>>> offload_config = context.get_offload_context()
```

1.3 Seed

mindspore.set_seed	Set global seed.
mindspore.get_seed	Get global seed.

1.3.1 mindspore.set_seed

mindspore.**set_seed**(*seed*)

Set global seed.

Note:

- The global seed is used by numpy.random, mindspore.common.Initializer and mindspore.nn.probability.distribution.
- If global seed is not set, these packages will use their own default seed independently, numpy.random and mindspore.common.Initializer will choose a random seed, mindspore.nn.probability.distribution will use zero.
- Seed set by numpy.random.seed() only used by numpy.random, while seed set by this API will also used by numpy.random, so just set all seed by this API is recommended.
- In semi_auto_parallel/auto_parallel mode, when using set_seed, weights with same shape and same sharding strategy in the same device would be initialized to the same result, otherwise, they would be initialized to the different result.

Parameters

seed (*int*) – The seed to be set.

Raises

- **ValueError** – If seed is invalid (< 0).
- **TypeError** – If seed isn't an int.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor, set_seed, Parameter, ops
>>> from mindspore.common.initializer import initializer
>>> # Note: (1) Please make sure the code is running in PYNATIVE MODE;
>>> # (2) Because Composite-level ops need parameters to be Tensors, for below examples,
>>> # when using ops.uniform operator, minval and maxval are initialised as:
>>> minval = Tensor(1.0, ms.float32)
>>> maxval = Tensor(2.0, ms.float32)
>>>
>>> # 1. If global seed is not set, numpy.random and initializer will choose a random seed:
>>> np_1 = np.random.normal(0, 1, [1]).astype(np.float32) # A1
>>> np_1 = np.random.normal(0, 1, [1]).astype(np.float32) # A2
>>> w1 = Parameter(initializer("uniform", [2, 2], ms.float32), name="w1") # W1
>>> w1 = Parameter(initializer("uniform", [2, 2], ms.float32), name="w1") # W2
>>> # Rerun the program will get different results:
>>> np_1 = np.random.normal(0, 1, [1]).astype(np.float32) # A3
>>> np_1 = np.random.normal(0, 1, [1]).astype(np.float32) # A4
>>> w1 = Parameter(initializer("uniform", [2, 2], ms.float32), name="w1") # W3
>>> w1 = Parameter(initializer("uniform", [2, 2], ms.float32), name="w1") # W4
>>>
>>> # 2. If global seed is set, numpy.random and initializer will use it:
>>> set_seed(1234)
>>> np_1 = np.random.normal(0, 1, [1]).astype(np.float32) # A1
>>> np_1 = np.random.normal(0, 1, [1]).astype(np.float32) # A2
>>> w1 = Parameter(initializer("uniform", [2, 2], ms.float32), name="w1") # W1
>>> w1 = Parameter(initializer("uniform", [2, 2], ms.float32), name="w1") # W2
>>> # Rerun the program will get the same results:
>>> set_seed(1234)
>>> np_1 = np.random.normal(0, 1, [1]).astype(np.float32) # A1
>>> np_1 = np.random.normal(0, 1, [1]).astype(np.float32) # A2
>>> w1 = Parameter(initializer("uniform", [2, 2], ms.float32), name="w1") # W1
>>> w1 = Parameter(initializer("uniform", [2, 2], ms.float32), name="w1") # W2
>>>
>>> # 3. If neither global seed nor op seed is set, mindspore.ops.function.random_func and
>>> # mindspore.nn.probability.distribution will choose a random seed:
>>> c1 = ops.uniform((1, 4), minval, maxval) # C1
>>> c2 = ops.uniform((1, 4), minval, maxval) # C2
>>> # Rerun the program will get different results:
>>> c1 = ops.uniform((1, 4), minval, maxval) # C3
>>> c2 = ops.uniform((1, 4), minval, maxval) # C4
>>>
>>> # 4. If global seed is set, but op seed is not set, mindspore.ops.function.random_func␣
 ↪and
>>> # mindspore.nn.probability.distribution will calculate a seed according to global seed␣
 ↪and
>>> # default op seed. Each call will change the default op seed, thus each call get␣
 ↪different
>>> # results.
>>> set_seed(1234)
>>> c1 = ops.uniform((1, 4), minval, maxval) # C1
```

(continues on next page)

(continued from previous page)

```
>>> c2 = ops.uniform((1, 4), minval, maxval) # C2
>>> # Rerun the program will get the same results:
>>> set_seed(1234)
>>> c1 = ops.uniform((1, 4), minval, maxval) # C1
>>> c2 = ops.uniform((1, 4), minval, maxval) # C2
>>>
>>> # 5. If both global seed and op seed are set, mindspore.ops.function.random_func and
>>> # mindspore.nn.probability.distribution will calculate a seed according to global seed␣
 ↪and
>>> # op seed counter. Each call will change the op seed counter, thus each call get␣
 ↪different
>>> # results.
>>> set_seed(1234)
>>> c1 = ops.uniform((1, 4), minval, maxval, seed=2) # C1
>>> c2 = ops.uniform((1, 4), minval, maxval, seed=2) # C2
>>> # Rerun the program will get the same results:
>>> set_seed(1234)
>>> c1 = ops.uniform((1, 4), minval, maxval, seed=2) # C1
>>> c2 = ops.uniform((1, 4), minval, maxval, seed=2) # C2
>>>
>>> # 6. If op seed is set but global seed is not set, 0 will be used as global seed. Then
>>> # mindspore.ops.function.random_func and mindspore.nn.probability.distribution act as in
>>> # condition 5.
>>> c1 = ops.uniform((1, 4), minval, maxval, seed=2) # C1
>>> c2 = ops.uniform((1, 4), minval, maxval, seed=2) # C2
>>> # Rerun the program will get the different results:
>>> c1 = ops.uniform((1, 4), minval, maxval, seed=2) # C1
>>> c2 = ops.uniform((1, 4), minval, maxval, seed=2) # C2
>>>
>>> # 7. Recall set_seed() in the program will reset numpy seed and op seed counter of
>>> # mindspore.ops.function.random_func and mindspore.nn.probability.distribution.
>>> set_seed(1234)
>>> np_1 = np.random.normal(0, 1, [1]).astype(np.float32) # A1
>>> c1 = ops.uniform((1, 4), minval, maxval, seed=2) # C1
>>> set_seed(1234)
>>> np_2 = np.random.normal(0, 1, [1]).astype(np.float32) # still get A1
>>> c2 = ops.uniform((1, 4), minval, maxval, seed=2) # still get C1
```

1.3.2 mindspore.get_seed

mindspore.**get_seed**()

Get global seed.

Returns

Integer. The global seed.

Examples

```
>>> import mindspore as ms
>>> ms.set_seed(1234)
>>> seed = ms.get_seed()
>>> print(seed)
1234
```

1.4 Random Number Generator

mindspore.get_rng_state	Get the state of the default generator.
mindspore.Generator	A generator that manages the state of random numbers and provides seed and offset for random functions.
mindspore.initial_seed	Return the initial seed of the default generator.
mindspore.manual_seed	Set the default generator seed.
mindspore.seed	Seed the default generator with random number.
mindspore.set_rng_state	Set the state of the default generator.

1.4.1 mindspore.get_rng_state

mindspore.**get_rng_state**()

Get the state of the default generator.

Returns

Tensor, generator state.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import get_rng_state
>>> state = get_rng_state()
```

1.4.2 mindspore.Generator

class mindspore.**Generator**

A generator that manages the state of random numbers and provides seed and offset for random functions. When the seed and offset are fixed, the random function generates the same random sequence.

Note: Graph mode does not support the use of multiple generators at the same time for now.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import Generator
>>> generator = Generator()
>>> generator.manual_seed(5)
>>> print(generator.initial_seed())
5
>>> state = generator.get_state()
>>> generator.seed()
>>> generator.set_state(state)
>>> print(generator.initial_seed())
5
```

get_state()
Get the generator state.

Returns

Tensor, generator state.

initial_seed()
Return the initial seed of generator.

Returns

The initial seed of generator.

manual_seed(*seed*)
Set the generator seed.

Parameters

seed (*int*) – Set the generator seed.

Returns

Generator, the generator instance.

seed()
Seed generator with random number.

Returns

Randomly generated seeds, the type is int.

set_state(*state*)
Sets the generator state.

Parameters

state (*tensor*) – target state of the generator.

1.4.3 mindspore.initial_seed

mindspore.**initial_seed**()

Return the initial seed of the default generator.

Returns

The initial seed of the default generator.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import manual_seed, initial_seed
>>> manual_seed(14)
>>> print(initial_seed())
14
```

1.4.4 mindspore.manual_seed

mindspore.**manual_seed**(*seed*)

Set the default generator seed.

Parameters

seed (*int*) – Set the default generator seed.

Returns

Generator, the default generator.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import manual_seed, initial_seed
>>> manual_seed(13)
>>> print(initial_seed())
13
```

1.4.5 mindspore.seed

mindspore.**seed**()

Seed the default generator with random number.

Returns

Randomly generated seeds, the type is int.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import seed
>>> print(seed())
1663920602
```

1.4.6 mindspore.set_rng_state

mindspore.**set_rng_state**(*state*)

Set the state of the default generator.

Parameters

state (Tensor) – the target state

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import set_rng_state, get_rng_state
>>> state = get_rng_state()
>>> set_rng_state(state)
```

1.5 Serialization

mindspore.async _ckpt_thread_status	Get the status of asynchronous save checkpoint thread.
mindspore.check_checkpoint	Check whether the checkpoint is valid.
mindspore.ckpt_to_safetensors	Converts MindSpore checkpoint files into safetensors format and saves them to *save_path*.
mindspore.convert_model	Convert mindir model to other format model.
mindspore.export	Export the MindSpore network into an offline model in the specified format.
mindspore.get _ckpt_path_with_strategy	Find available checkpoint file path from all backup checkpoint files of current rank.

continues on next page

Table 8 – continued from previous page

mindspore.load	Load MindIR.
mindspore.load_checkpoint	Load checkpoint info from a specified file.
mindspore.load_checkpoint_async	Load checkpoint info from a specified file asyncly.
mindspore.load_mindir	load protobuf file.
mindspore.load_param_into_net	Load parameters into network, return parameter list that are not loaded in the network.
mindspore.parse_print	Parse data file generated by *mindspore.ops.Print*.
mindspore.safetensors_to_ckpt	Converts safetensors files into MindSpore checkpoint format and saves them to *save_path*.
mindspore.save_checkpoint	Save checkpoint to a specified file.
mindspore.save_mindir	save protobuf file.

1.5.1 mindspore.async_ckpt_thread_status

mindspore.**async_ckpt_thread_status**()

Get the status of asynchronous save checkpoint thread.

Note: The interface is deprecated from version 2.5 and will be removed in a future version.

When performing asynchronous save checkpoint, you can determine whether the asynchronous thread is completed.

Returns

bool, True, Asynchronous save checkpoint thread is running. False, Asynchronous save checkpoint thread is not executing.

Examples

```
>>> import mindspore as ms
>>> ms.async_ckpt_thread_status()
False
```

1.5.2 mindspore.check_checkpoint

mindspore.**check_checkpoint**(*ckpt_file_name*)

Check whether the checkpoint is valid.

Note: The interface is deprecated from version 2.5 and will be removed in a future version.

Parameters

ckpt_file_name (*str*) – Checkpoint file name.

Returns

bool, whether the checkpoint is valid.

Examples

```
>>> import mindspore as ms
>>> ckpt_file_name = "./checkpoint/LeNet5-1_32.ckpt"
>>> check_result = ms.check_checkpoint(ckpt_file_name)
>>> print(check_result)
True
```

1.5.3 mindspore.ckpt_to_safetensors

mindspore.**ckpt_to_safetensors**(*file_path*, *save_path=None*, *name_map=None*, *file_name_regex=None*, *processes_num=1*)

Converts MindSpore checkpoint files into safetensors format and saves them to *save_path*. Safetensors is a reliable and portable machine learning model storage format introduced by Huggingface, used for securely storing Tensors with fast speed (zero copy).

Note: The number of multiprocess settings is related to the size of the host, and it is not recommended to set it too large, otherwise it may cause freezing. The safetensors format does not support the enc verification function. If ckpt is enabled to save enc verification, an error will be generated when performing the conversion. The safetensors format currently does not support crc verification function. If ckpt contains crc verification information, the crc verification information will be lost after conversion to safetensors.

Parameters

- **file_path** (*str*) –Path to the directory containing checkpoint files or a single checkpoint file (.ckpt).
- **save_path** (*str, optional*) –Directory path where safetensors files will be saved. Defaults: `None`.
- **name_map** (*dict, optional*) –Dictionary mapping original parameter names to new names. Defaults: `None`.
- **file_name_regex** (*str, optional*) –Regular expression used to match the file that needs to be converted. Defaults: `None`.
- **processes_num** (*int, optional*) –Number of processes to use for parallel processing. Defaults: 1.

Raises

ValueError –If the input path is invalid or the save_path is not a directory, or the file_path does not end with '.ckpt'.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore as ms
>>> ms.ckpt_to_safetensors("./ckpt_save_path")
>>> ms.ckpt_to_safetensors("./ckpt_save_path/rank0/checkpoint_0.ckpt")
>>> ms.ckpt_to_safetensors(file_path="./ckpt_save_path/rank0/checkpoint_0.ckpt", save_path="./new_path/")
>>> namemap = {"lin.weight":"new_name"}
>>> ms.ckpt_to_safetensors("./ckpt_save_path/rank0/checkpoint_0.ckpt", "./new_path/", namemap)
```

1.5.4 mindspore.convert_model

mindspore.**convert_model**(*mindir_file*, *convert_file*, *file_format*)

Convert mindir model to other format model. The current version only supports conversion to ONNX models.

Note: The interface is deprecated from version 2.5 and will be removed in a future version.

Parameters

- **mindir_file** (*str*) –MindIR file name.
- **convert_file** (*str*) –Convert model file name.
- **file_format** (*str*) –Convert model's format, current version only supports "ONNX".

Raises

- **TypeError** –If the parameter *mindir_file* is not *str*.
- **TypeError** –If the parameter *convert_file* is not *str*.
- **ValueError** –If the parameter *file_format* is not "ONNX".

Examples

```
>>> import mindspore as ms
>>> ms.convert_model("lenet.mindir", "lenet.onnx", "ONNX")
```

1.5.5 mindspore.export

mindspore.**export**(*net*, **inputs*, *file_name*, *file_format*, ***kwargs*)

Export the MindSpore network into an offline model in the specified format.

Note:

1. When exporting AIR, ONNX format, the size of a single tensor can not exceed 2GB.
2. When *file_name* does not have a suffix, the system will automatically add one according to the *file_format*.
3. Exporting functions decorated with *mindspore.jit()* to mindir format is supported.
4. When exporting a function decorated with *mindspore.jit()*, the function should not involve class properties in calculations.
5. AIR format is deprecated, and will be removed in a future version, please use other format or use MindSpore Lite to do offline inference.

Parameters

- **net** (*Union[Cell, function]*) –MindSpore network.
- **inputs** (*Union[Tensor, Dataset, List, Tuple, Number, Bool]*) –It represents the inputs of the *net*, if the network has multiple inputs, set them together. While its type is Dataset, it represents the preprocess behavior of the *net*, data preprocess operations will be serialized. In second situation, you should adjust batch size of dataset script manually which will impact on the batch size of 'net' input. Only supports parse "image" column from dataset currently.

- **file_name** (*str*) –File name of the model to be exported.
- **file_format** (*str*) –MindSpore currently supports 'AIR', 'ONNX' and 'MINDIR' format for exported model.
  - AIR: Ascend Intermediate Representation. An intermediate representation format of Ascend model.
  - ONNX: Open Neural Network eXchange. An open format built to represent machine learning models.
  - MINDIR: MindSpore Native Intermediate Representation for Anf. An intermediate representation format for MindSpore models. MINDIR does not support operators which have dictionary attribute.
- **kwargs** (*dict*) –Configuration options dictionary.
  - enc_key (byte): Byte-type key used for encryption. The valid length is 16, 24, or 32.
  - enc_mode (Union[str, function]): Specifies the encryption mode, to take effect when enc_key is set.
    - For 'AIR' and 'ONNX' models, only customized encryption is supported.
    - For 'MINDIR', all options are supported. Option: 'AES-GCM', 'AES-CBC', 'SM4-CBC' or Customized encryption. Default: `'AES-GCM'`.
    - For details of using the customized encryption, please check the tutorial.
  - dataset (Dataset): Specifies the preprocessing method of the dataset, which is used to import the preprocessing of the dataset into MindIR.
  - incremental (bool): export MindIR incrementally.
  - custom_func (function): Functions for custom defined export policies. This function will be used to customize the model during network export. Currently only support for files with mindir format. The function only accepts one input representing the proto object of the mindir file. When modifying a model, it is necessary to ensure the correctness of the *custom_func* , otherwise it may lead to model loading failure or functional errors. Default: `None` .

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> input_tensor = Tensor(np.ones([1, 1, 32, 32]).astype(np.float32))
>>> ms.export(net, input_tensor, file_name='lenet', file_format='MINDIR')
>>>
>>> # Export model in MindIR format and modified the model info using custom_func
>>> # The custom_func only support one input representing the Proto object of the model
>>> # And custom_func does not support return value
>>> def _custom_func(mindir_model):
...     mindir_model.producer_name = "test11111"
...     mindir_model.producer_version = "11.0"
...     mindir_model.user_info["version"] = "11.0"
>>> ms.export(net, input_tensor, file_name="lenet", file_format='MINDIR', custom_func=_
↪custom_func)
```

Tutorial Examples:

- Saving and Loading the Model - Saving and Loading MindIR

1.5.6 mindspore.get_ckpt_path_with_strategy

mindspore.**get_ckpt_path_with_strategy**(*cur_ckpt_path*, *cur_strategy_path*)

Find available checkpoint file path from all backup checkpoint files of current rank. It suppose that checkpoint path contains substring 'rank_{rank_id}' which is used to distinguish between different path.If cur_ckpt_path doesn't have 'rank_{rank_id}' substring, will return cur_ckpt_path itself when cur_ckpt_path is exist, otherwise return None.

Note: This API must be called after the communication is initialized because the cluster information needs to be obtained internally.

Parameters

- **cur_ckpt_path** (*str*) –the checkpoint file path which cur rank needs.
- **cur_strategy_path** (*str*) –strategy file path for current rank.

Returns

- new_ckpt_file (str), if found available checkpoint file , return it.
- None, if not found available checkpoint, return None.

Examples

```
>>> import mindspore as ms
>>> from mindspore.communication import init
>>> from mindspore import get_ckpt_path_with_strategy
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> ms.set_auto_parallel_context(parallel_mode=ms.ParallelMode.DATA_PARALLEL, gradients_
↪mean=True)
>>> init()
>>> ckpt_file= "./rank_5/iteration-1_40.ckpt"
>>> strategy_file = "./src_pipeline_strategys/src_strategy_5.ckpt"
>>> ckpt_file_new = get_ckpt_path_with_strategy(ckpt_file, strategy_file)
>>> print(ckpt_file_new)
```

1.5.7 mindspore.load

mindspore.**load**(*file_name*, ***kwargs*)

Load MindIR.

The returned object can be executed by a *GraphCell*, see class *mindspore.nn.GraphCell* for more details.

Parameters

- **file_name** (*str*) –MindIR file name.
- **kwargs** (*dict*) –Configuration options dictionary.
  - dec_key (bytes): Byte-type key used for decryption. The valid length is 16, 24, or 32.
  - dec_mode (Union[str, function], optional): Specifies the decryption mode, to take effect when dec_key is set.
    - Option: 'AES-GCM', 'AES-CBC', 'SM4-CBC' or customized decryption. Default: 'AES-GCM'.
    - For details of using the customized decryption, please check the tutorial.

Returns

GraphCell, a compiled graph that can executed by *GraphCell*.

Raises

- **NotImplementedError** –Dynamic model structure obfuscation is no longer supported.
- **ValueError** –MindIR file does not exist or *file_name* is not a string.
- **RuntimeError** –Failed to parse MindIR file.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> from mindspore import Tensor
>>> from mindspore import context
>>> context.set_context(mode=context.GRAPH_MODE)
>>>
>>> net = nn.Conv2d(1, 1, kernel_size=3, weight_init="ones")
>>> input_tensor = Tensor(np.ones([1, 1, 3, 3]).astype(np.float32))
>>> ms.export(net, input_tensor, file_name="net", file_format="MINDIR")
>>> graph = ms.load("net.mindir")
>>> net = nn.GraphCell(graph)
>>> output = net(input_tensor)
>>> print(output)
[[[[4. 6. 4.]
   [6. 9. 6.]
   [4. 6. 4.]]]]
```

Tutorial Examples:

- Saving and Loading the Model - Saving and Loading MindIR

1.5.8 mindspore.load_checkpoint

mindspore.**load_checkpoint**(*ckpt_file_name*, *net=None*, *strict_load=False*, *filter_prefix=None*, *dec_key=None*, *dec_mode='AES-GCM'*, *specify_prefix=None*, *choice_func=None*, *crc_check=False*, *remove_redundancy=False*, *format='ckpt'*)

Load checkpoint info from a specified file.

Note:

- *specify_prefix* and *filter_prefix* are in the process of being deprecated, *choice_func* is recommended instead. *specify_prefix* and *filter_prefix* do not affect each other. And using either of those two args will override *choice_func* at the same time.
- If none of the parameters are loaded from checkpoint file, it will throw ValueError.
- When loading a checkpoint that has removed redundancy, the network should be compiled.

Parameters

- **ckpt_file_name** (*str*) –Checkpoint file name.
- **net** (*Cell, optional*) –The network where the parameters will be loaded. Default: `None` .

- **strict_load** (*bool, optional*) –Whether to strict load the parameter into net. If `False` , it will load parameter into net when parameter name's suffix in checkpoint file is the same as the parameter in the network. When the types are inconsistent perform type conversion on the parameters of the same type, such as float32 to float16. Default: `False` .
- **filter_prefix** (*Union[str, list[str], tuple[str]], optional*) –Deprecated(see *choice_func*). Parameters starting with the filter_prefix will not be loaded. Default: `None` .
- **dec_key** (*Union[None, bytes], optional*) –Byte type key used for decryption. If the value is `None` , the decryption is not required. Default: `None` .
- **dec_mode** (*str, optional*) –This parameter is valid only when dec_key is not set to `None` . Specifies the decryption mode, currently supports `"AES-GCM"` and `"AES-CBC"` and `"SM4-CBC"` . Default: `"AES-GCM"` .
- **specify_prefix** (*Union[str, list[str], tuple[str]], optional*) –Deprecated(see *choice_func*). Parameters starting with the specify_prefix will be loaded. Default: `None` .
- **choice_func** (*Union[None, function], optional*) –Input value of the function is a Parameter name of type string, and the return value is a bool. If returns `True` , the Parameter that matches the custom condition will be loaded. If returns `False` , the Parameter that matches the custom condition will be removed. Default: `None` .
- **crc_check** (*bool, optional*) –Whether to perform crc32 validation when loading checkpoint. Default: `False` .
- **remove_redundancy** (*bool, optional*) –Whether to enable loading of checkpoint saved with redundancy removal. Redundancy removal refers to eliminating redundant data in data parallelism mode. Default: `False` , means redundant-free loading is not enabled.
- **format** (*str, optional*) –Format of the input file, can be "ckpt" or "safetensors". Default: "ckpt".

Returns

Dict, key is parameter name, value is a Parameter or string. When the *append_dict* parameter of *mindspore.save_checkpoint()* and the *append_info* parameter of *mindspore.train.CheckpointConfig* are used to save the checkpoint, *append_dict* and *append_info* are dict types, and their value are string, then the return value obtained by loading checkpoint is string, and in other cases the return value is Parameter.

Raises

- **ValueError** –Checkpoint file's format is incorrect.
- **ValueError** –Parameter's dict is None after load checkpoint file.
- **TypeError** –The type of *specify_prefix* or *filter_prefix* is incorrect.

Examples

```
>>> import mindspore as ms
>>>
>>> ckpt_file_name = "./checkpoint/LeNet5-1_32.ckpt"
>>> param_dict = ms.load_checkpoint(ckpt_file_name,
...                                 choice_func=lambda x: x.startswith("conv") and not x.
 ↪startswith("conv1"))
>>> print(param_dict["conv2.weight"])
Parameter (name=conv2.weight, shape=(16, 6, 5, 5), dtype=Float32, requires_grad=True)
>>> def func(param_name):
...     whether_load = False
...     if param_name.startswith("conv"):
...         whether_load = True
...     if param_name.startswith("conv1"):
```

(continues on next page)

(continued from previous page)

```
...         whether_load = False
...     return whether_load
>>> param_dict1 = ms.load_checkpoint(ckpt_file_name, choice_func=func)
>>> print(param_dict1["conv2.weight"])
Parameter (name=conv2.weight, shape=(16, 6, 5, 5), dtype=Float32, requires_grad=True)
>>> def func(param_name):
...     whether_load = False
...     if param_name.startswith("conv1"):
...         whether_load = True
...     return whether_load
>>> param_dict2 = ms.load_checkpoint(ckpt_file_name, choice_func=func)
>>> print(param_dict2)
{'conv1.weight': Parameter (name=conv1.weight, shape=(6, 1, 5, 5), dtype=Float32, requires_
↪grad=True)}
```

Tutorial Examples:

1.5.9 mindspore.load_checkpoint_async

mindspore.**load_checkpoint_async**(*ckpt_file_name*, *net=None*, *strict_load=False*, *filter_prefix=None*, *dec_key=None*, *dec_mode='AES-GCM'*, *specify_prefix=None*, *choice_func=None*)

Load checkpoint info from a specified file asyncly.

> **Warning:** This is an experimental API that is subject to change or deletion.

Note:

- *specify_prefix* and *filter_prefix* do not affect each other.
- If none of the parameters are loaded from checkpoint file, it will throw ValueError.
- *specify_prefix* and *filter_prefix* are in the process of being deprecated, *choice_func* is recommended instead. And using either of those two args will override *choice_func* at the same time.

Parameters

- **ckpt_file_name** (*str*) –Checkpoint file name. The file extension must be *ckpt* or *safetensors* .
- **net** (*Cell, optional*) –The network where the parameters will be loaded. Default: `None` .
- **strict_load** (*bool, optional*) –Whether to strict load the parameter into net. If `False` , it will load parameter into net when parameter name's suffix in checkpoint file is the same as the parameter in the network. When the types are inconsistent perform type conversion on the parameters of the same type, such as float32 to float16. Default: `False` .
- **filter_prefix** (*Union[str, list[str], tuple[str]], optional*) –Deprecated(see *choice_func*). Parameters starting with the *filter_prefix* will not be loaded. Default: `None` .
- **dec_key** (*Union[None, bytes], optional*) –Byte type key used for decryption. If the value is `None` , the decryption is not required. Default: `None` .

- **dec_mode** (*str, optional*) –This parameter is valid only when dec_key is not set to `None` . Specifies the decryption mode, currently supports `"AES-GCM"` and `"AES-CBC"` and `"SM4-CBC"` . Default: `"AES-GCM"` .
- **specify_prefix** (*Union[str, list[str], tuple[str]], optional*) –Deprecated(see *choice_func*). Parameters starting with the specify_prefix will be loaded. Default: `None` .
- **choice_func** (*Union[None, function], optional*) –Input value of the function is a Parameter name of type string, and the return value is a bool. If returns `True` , the Parameter that matches the custom condition will be loaded. If returns `False` , the Parameter that matches the custom condition will be removed. Default: `None` .

Returns

A custom inner class, calling its *result* method yields the *mindspore.load_checkpoint()* result.

Raises

- **ValueError** –Checkpoint file's format is incorrect.
- **ValueError** –Parameter's dict is None after load checkpoint file.
- **TypeError** –The type of *specify_prefix* or *filter_prefix* is incorrect.

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.train import Model
>>> from mindspore.amp import FixedLossScaleManager
>>> from mindspore import context
>>> from mindspore import load_checkpoint_async
>>> from mindspore import load_param_into_net
>>> mindspore.set_device(device_target="Ascend")
>>> context.set_context(mode=context.GRAPH_MODE)
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> ckpt_file = "./checkpoint/LeNet5-1_32.ckpt"
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction="mean")
>>> loss_scale_manager = FixedLossScaleManager()
>>> optim = nn.Momentum(params=net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim, metrics=None,
...               loss_scale_manager=loss_scale_manager)
>>> pd_future = load_checkpoint_async(ckpt_file)
>>> model.build(train_dataset=dataset, epoch=2)
>>> param_dict = pd_future.result()
>>> load_param_into_net(net, param_dict)
>>> model.train(2, dataset)
>>> print("param dict len: ", len(param_dict), flush=True)
```

1.5.10 mindspore.load_mindir

mindspore.**load_mindir**(*file_name*)

load protobuf file.

Note: The interface is deprecated from version 2.5 and will be removed in a future version.

Parameters

file_name (*str*) −File name.

Returns

ModelProto, mindir proto object.

Raises

ValueError −The file does not exist or the file name format is incorrect.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> md = ms.load_mindir("test.mindir")
```

1.5.11 mindspore.load_param_into_net

mindspore.**load_param_into_net**(*net*, *parameter_dict*, *strict_load=False*, *remove_redundancy=False*)

Load parameters into network, return parameter list that are not loaded in the network.

Note: When loading a parameter dict that has removed redundancy, the network should be compiled.

Parameters

- **net** (`Cell`) −The network where the parameters will be loaded.
- **parameter_dict** (*dict*) −The dictionary generated by load checkpoint file, it is a dictionary consisting of key: parameters's name, value: parameter.
- **strict_load** (*bool, optional*) −Whether to strict load the parameter into net. If `False` , it will load parameter into net when parameter name's suffix in checkpoint file is the same as the parameter in the network. When the types are inconsistent perform type conversion on the parameters of the same type, such as float32 to float16. Default: `False` .
- **remove_redundancy** (*bool, optional*) −Whether to enable loading of checkpoint saved with redundancy removal. Redundancy removal refers to eliminating redundant data in data parallelism mode. Default: `False` , means redundant-free loading is not enabled.

Returns

- param_not_load (List), the parameter name in model which are not loaded into the network.

- ckpt_not_load (List), the parameter name in checkpoint file which are not loaded into the network.

Raises

TypeError – Argument is not a Cell, or parameter_dict is not a Parameter dictionary.

Examples

```
>>> import mindspore as ms
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> ckpt_file_name = "./checkpoint/LeNet5-1_32.ckpt"
>>> param_dict = ms.load_checkpoint(ckpt_file_name, filter_prefix="conv1")
>>> param_not_load, _ = ms.load_param_into_net(net, param_dict)
>>> print(param_not_load)
['conv1.weight']
```

Tutorial Examples:

- Saving and Loading the Model - Saving and Loading the Model Weight

1.5.12 mindspore.parse_print

mindspore.**parse_print**(*print_file_name*)

Parse data file generated by *mindspore.ops.Print*.

Note: The interface is deprecated from version 2.5 and will be removed in a future version.

Parameters

print_file_name (*str*) – The file name needs to be parsed.

Returns

List, element of list is Tensor.

Raises

- **ValueError** – The print file does not exist or is empty.
- **RuntimeError** – Failed to parse the file.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import nn, Tensor, ops
>>> ms.set_context(mode=ms.GRAPH_MODE, print_file_path='log.data')
>>> class PrintInputTensor(nn.Cell):
...         def __init__(self):
...             super().__init__()
...             self.print = ops.Print()
```

(continues on next page)

(continued from previous page)

```
...
...         def construct(self, input_pra):
...             self.print('print:', input_pra)
...             return input_pra
>>> x = np.array([[1, 2, 3, 4], [5, 6, 7, 8]]).astype(np.float32)
>>> input_pra = Tensor(x)
>>> net = PrintInputTensor()
>>> net(input_pra)
>>>
>>> data = ms.parse_print('./log.data')
>>> print(data)
['print:', Tensor(shape=[2, 4], dtype=Float32, value=
[[ 1.00000000e+00,  2.00000000e+00,  3.00000000e+00,  4.00000000e+00],
[ 5.00000000e+00,  6.00000000e+00,  7.00000000e+00,  8.00000000e+00]])]
```

1.5.13 mindspore.safetensors_to_ckpt

mindspore.**safetensors_to_ckpt**(*file_path*, *save_path=None*, *name_map=None*, *file_name_regex=None*, *processes_num=1*)

Converts safetensors files into MindSpore checkpoint format and saves them to *save_path*. Safetensors is a reliable and portable machine learning model storage format introduced by Huggingface, used for securely storing Tensors with fast speed (zero copy).

Note: The number of multiprocess settings is related to the size of the host, and it is not recommended to set it too large, otherwise it may cause freezing.

Parameters

- **file_path** (*str*) –Path to the directory containing safetensors files or a single safetensors file (.safetensors).
- **save_path** (*str, optional*) –Directory path where checkpoint files will be saved. Defaults: `None`.
- **name_map** (*dict, optional*) –Dictionary mapping original parameter names to new names. Defaults: `None`.
- **file_name_regex** (*str, optional*) –Regular expression used to match the file that needs to be converted. Defaults: `None`.
- **processes_num** (*int, optional*) –Number of processes to use for parallel processing. Defaults: 1.

Raises

ValueError –If the input path is invalid, the save_path is not a directory, or the file_path does not end with '.safetensors'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> ms.safetensors_to_ckpt("./safetensors_save_path")
>>> ms.safetensors_to_ckpt("./safetensors_save_path/rank0/checkpoint_0.safetensors")
>>> ms.safetensors_to_ckpt("./safetensors_save_path/rank0/checkpoint_0.safetensors", "./new_
↪path/")
>>> namemap = {"lin.weight":"new_name"}
>>> ms.safetensors_to_ckpt("./safetensors_save_path/rank0/checkpoint_0.safetensors", "./new_
↪path/", namemap)
```

1.5.14 mindspore.save_checkpoint

mindspore.**save_checkpoint**(*save_obj*, *ckpt_file_name*, *integrated_save=True*, *async_save=False*, *append_dict=None*, *enc_key=None*, *enc_mode='AES-GCM'*, *choice_func=None*, *crc_check=False*, *format='ckpt'*, ***kwargs*)

Save checkpoint to a specified file.

Note: The *enc_mode* and *crc_check* parameters are mutually exclusive and cannot be configured simultaneously.

Parameters

- **save_obj** (*Union[Cell, list, dict]*) –The object to be saved. The data type can be *mindspore.nn.Cell*, list, or dict.
  - If a list, it can be the returned value of *Cell.trainable_params()*, or a list of dict elements(each element is a dictionary, like [{"name": param_name, "data": param_data},···], the type of *param_name* must be string, and the type of *param_data* must be parameter or Tensor).
  - If dict, it can be the returned value of *mindspore.load_checkpoint()*.
- **ckpt_file_name** (*str*) –Checkpoint file name. If the file name already exists, it will be overwritten.
- **integrated_save** (*bool*) –Whether to integrated save in automatic model parallel scene. Default: `True` .
- **async_save** (*Union[bool, str], optional*) –Whether to use asynchronous saving of the checkpoint file or safetensors file, if True, the asynchronous thread is used by default. If the type is string, the method of asynchronous saving, it can be "process" or "thread". Default: `False` .
- **append_dict** (*dict*) –Additional information that needs to be saved. The key of dict must be str, the value of dict must be one of int, float, bool, string, Parameter or Tensor. Default: `None` .
- **enc_key** (*Union[None, bytes]*) –Byte type key used for encryption. If the value is `None` , the encryption is not required. Default: `None` .
- **enc_mode** (*str*) –This parameter is valid only when enc_key is not set to `None` . Specifies the encryption mode, currently supports `"AES-GCM"` and `"AES-CBC"` and `"SM4-CBC"` . Default: `"AES-GCM"` .
- **choice_func** (*function*) –A function for saving custom selected parameters. The input value of *choice_func* is a parameter name in string type, and the returned value is a bool. Default: `None` .
  - If returns `True` , the Parameter that matching the custom condition will be saved.
  - If returns `False` , the Parameter that not matching the custom condition will not be saved.
- **crc_check** (*bool*) –Whether to perform crc32 calculation when saving checkpoint and save the calculation result to the file. Default: `False` .

- **format** (*str*) –Format of the output file, can be "ckpt" or "safetensors". Default: "ckpt".
- **kwargs** (*dict*) –Configuration options dictionary.

Raises

- **TypeError** –If the parameter *save_obj* is not *mindspore.nn.Cell* , list or dict type.
- **TypeError** –If the parameter *integrated_save* is not bool type.
- **TypeError** –If the parameter *ckpt_file_name* is not string type.
- **TypeError** –If the parameter *async_save* is not bool or string type.
- **ValueError** –If the parameter *async_save* is string type but not in ["process", "thread"].

Examples

```
>>> import mindspore as ms
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> ms.save_checkpoint(net, "./lenet.ckpt",
...                    choice_func=lambda x: x.startswith("conv") and not x.startswith("conv1
 ↪"))
>>> param_dict1 = ms.load_checkpoint("./lenet.ckpt")
>>> print(param_dict1)
{'conv2.weight': Parameter (name=conv2.weight, shape=(16, 6, 5, 5), dtype=Float32, requires_
 ↪grad=True)}
>>> params_list = net.trainable_params()
>>> ms.save_checkpoint(params_list, "./lenet_list.ckpt",
...                    choice_func=lambda x: x.startswith("conv") and not x.startswith("conv2
 ↪"))
>>> param_dict2 = ms.load_checkpoint("./lenet_list.ckpt")
>>> print(param_dict2)
{'conv1.weight': Parameter (name=conv1.weight, shape=(6, 1, 5, 5), dtype=Float32, requires_
 ↪grad=True)}
>>> ms.save_checkpoint(param_dict2, "./lenet_dict.ckpt")
>>> param_dict3 = ms.load_checkpoint("./lenet_dict.ckpt")
>>> print(param_dict3)
{'conv1.weight': Parameter (name=conv1.weight, shape=(6, 1, 5, 5), dtype=Float32, requires_
 ↪grad=True)}
```

Tutorial Examples:

- Saving and Loading the Model - Saving and Loading the Model Weight

1.5.15 mindspore.save_mindir

mindspore.**save_mindir**(*model*, *file_name*)

save protobuf file.

Note: The interface is deprecated from version 2.5 and will be removed in a future version.

Parameters

- **model** (*ModelProto*) –mindir model
- **file_name** (*str*) –File name.

Raises

- **TypeError** –The argument *model* is not a ModelProto object.
- **ValueError** –The file path does not exist or the *file_name* format is incorrect.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> md = ms.load_mindir("test.mindir")
>>> md.user_info["version"]="pangu v100"
>>> ms.save_mindir(md,"test_new.mindir")
>>> md_new = ms.load_mindir("test_new.mindir")
>>> md_new.user_info
```

1.6 Automatic Differentiation

mindspore.grad	A wrapper function to generate the gradient function for the input function.
mindspore.value_and_grad	A wrapper function to generate the function to calculate forward output and gradient for the input function.
mindspore.get_grad	When *return_ids* of *mindspore.grad()* or *mindspore.grad()* is set to True , use return value of *mindspore.grad*, or the second return value of *mindspore.grad* as gradients.
mindspore.jacfwd	Compute Jacobian via forward mode, corresponding to forward-mode differentiation.
mindspore.jacrev	Compute Jacobian via reverse mode, corresponding to reverse-mode differentiation.
mindspore.jvp	Compute the jacobian-vector-product of the given network.
mindspore.vjp	Compute the vector-jacobian-product of the given network.

1.6.1 mindspore.grad

mindspore.**grad**(*fn*, *grad_position=0*, *weights=None*, *has_aux=False*, *return_ids=False*)

A wrapper function to generate the gradient function for the input function.

As for gradient, three typical cases are included:

1. gradient with respect to inputs. In this case, *grad_position* is not None while *weights* is None.
2. gradient with respect to weights. In this case, *grad_position* is None while *weights* is not None.
3. gradient with respect to inputs and weights. In this case, *grad_position* and *weights* are not None.

Parameters

- **fn** (*Union[Cell, Function]*) –Function to do GradOperation.
- **grad_position** (*Union[NoneType, int, tuple[int]]*) –Index to specify which inputs to be differentiated. Default: `0` .
  - If int, get the gradient with respect to single input.
  - If tuple, get the gradients with respect to selected inputs. *grad_position* begins with 0.
  - If None, none derivative of any input will be figured out, and in this case, *weights* is required.
- **weights** (*Union[ParameterTuple, Parameter, list[Parameter]]*) –The parameters of the training network that need to calculate the gradient. *weights* can be got through *weights = net.trainable_params()* . Default: `None` .
- **has_aux** (*bool*) –If `True` , only the first output of *fn* contributes the gradient of *fn*, while the other outputs will be returned straightly. It means the *fn* must return more than one outputs in this case. Default: `False` .
- **return_ids** (*bool*) –Whether return the tuple made by gradients and the index to specify which inputs to be differentiated or the name of parameters of the training network that need to calculate the gradient. If `True` , the output gradients will be replaced by the tuples made by gradients and the index to specify which inputs to be differentiated or the name of parameters of the training network. Default: `False` .

Returns

Function, the gradient function to calculate gradient for the input function or cell. For example, as for *out1, out2 = fn(*args)*, when *has_aux* is set `True` , gradient function will return outputs like *(gradient, out2)* and *out2* does not contribute to the differentiation, otherwise *gradient*. When return_ids is set to `True` , the format of the output will be the same with the output of grad when return_ids is set to `False`, but every gradient in the output will be replaced by a tuple of position id or parameter name and its gradient.

Raises

- **ValueError** –If both *grad_position* and *weights* are None.
- **TypeError** –If type of Args does not belong to required ones.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, ops, nn, grad
>>>
>>> # Cell object to be differentiated
>>> class Net(nn.Cell):
...     def construct(self, x, y, z):
...         return x * y * z
>>> x = Tensor([1, 2], mindspore.float32)
>>> y = Tensor([-2, 3], mindspore.float32)
>>> z = Tensor([0, 3], mindspore.float32)
>>> net = Net()
>>> output = grad(net, grad_position=(1, 2))(x, y, z)
>>> print(output)
(Tensor(shape=[2], dtype=Float32, value=[ 0.00000000e+00,  6.00000000e+00]),
 Tensor(shape=[2], dtype=Float32, value=[-2.00000000e+00,  6.00000000e+00]))
>>>
>>> # Function object to be differentiated
>>> def fn(x, y, z):
...     res = x * ops.exp(y) * ops.pow(z, 2)
...     return res, z
>>> x = Tensor([3, 3], mindspore.float32)
>>> y = Tensor([0, 0], mindspore.float32)
>>> z = Tensor([5, 5], mindspore.float32)
>>> gradient, aux = grad(fn, (1, 2), None, True)(x, y, z)
>>> print(gradient)
(Tensor(shape=[2], dtype=Float32, value= [ 7.50000000e+01,  7.50000000e+01]),
 Tensor(shape=[2], dtype=Float32, value= [ 3.00000000e+01,  3.00000000e+01]))
>>> print(aux)
(Tensor(shape=[2], dtype=Float32, value= [ 5.00000000e+00,  5.00000000e+00]),)
>>>
>>> # For given network to be differentiated with both inputs and weights, there are 4 cases.
>>> net = nn.Dense(10, 1)
>>> loss_fn = nn.MSELoss()

...         return x * y * z
>>> x = Tensor([1, 2], mindspore.float32)
>>> y = Tensor([-2, 3], mindspore.float32)
>>> z = Tensor([0, 3], mindspore.float32)
>>> net = Net()
>>> output = grad(net, grad_position=(1, 2), return_ids = True)(x, y, z)
>>> print(output)
((1, Tensor(shape=[2], dtype=Float32, value=[ 0.00000000e+00,  6.00000000e+00])),
 (2, Tensor(shape=[2], dtype=Float32, value=[-2.00000000e+00,  6.00000000e+00])))
```

1.6.2 mindspore.value_and_grad

mindspore.**value_and_grad**(*fn*, *grad_position=0*, *weights=None*, *has_aux=False*, *return_ids=False*)

A wrapper function to generate the function to calculate forward output and gradient for the input function.

As for gradient, three typical cases are included:

1. gradient with respect to inputs. In this case, *grad_position* is not None while *weights* is `None`.
2. gradient with respect to weights. In this case, *grad_position* is None while *weights* is not `None`.
3. gradient with respect to inputs and weights. In this case, *grad_position* and *weights* are not `None`.

Parameters

- **fn** (*Union[Cell, Function]*) – Function to do GradOperation.
- **grad_position** (*Union[NoneType, int, tuple[int]], optional*) – Index to specify which inputs to be differentiated. Default: `0` .
  - If int, get the gradient with respect to single input.
  - If tuple, get the gradients with respect to selected inputs. *grad_position* begins with 0.
  - If None, none derivative of any input will be solved, and in this case, *weights* is required.
- **weights** (*Union[ParameterTuple, Parameter, list[Parameter]], optional*) – The parameters of the training network that need to calculate the gradient. *weights* can be got through *weights = net.trainable_params()* . Default: `None` .

- **has_aux** (*bool, optional*) –If `True` , only the first output of *fn* contributes the gradient of *fn*, while the other outputs will be returned straightly. It means the *fn* must return more than one outputs in this case. Default: `False` .
- **return_ids** (*bool, optional*) –Whether the returned derivation function contains *grad_position* or *weights* information. If `True`, all gradient values in the returned derivation function will be replaced with: [gradient, grad_position] or [gradient, weights]. Default: `False` .

Returns

Function, the derivative function used to compute the gradient of a given function. For example, as for *out1, out2 = fn(*args)* , gradient function will return outputs like *((out1, out2), gradient)* . When *has_aux* is set to `True`, only *out1* contributes to the differentiation. If *return_ids* is `True`, all gradient values in the returned derivation function will be replaced with: [gradient, grad_position] or [gradient, weights].

Raises

- **ValueError** –If both *grad_position* and *weights* are `None`.
- **TypeError** –If type of Args does not belong to required ones.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, ops, nn
>>> from mindspore import value_and_grad
>>>
>>> # Cell object to be differentiated
>>> class Net(nn.Cell):
...     def construct(self, x, y, z):
...         return x * y * z
>>> x = Tensor([1, 2], mindspore.float32)
>>> y = Tensor([-2, 3], mindspore.float32)
>>> z = Tensor([0, 3], mindspore.float32)
>>> net = Net()
>>> grad_fn = value_and_grad(net, grad_position=1)
>>> output, inputs_gradient = grad_fn(x, y, z)
>>> print(output)
[-0. 18.]
>>> print(inputs_gradient)
[0. 6.]
>>>
>>> # Function object to be differentiated
>>> def fn(x, y, z):
...     res = x * ops.exp(y) * ops.pow(z, 2)
...     return res, z
>>> x = Tensor(np.array([3, 3]).astype(np.float32))
>>> y = Tensor(np.array([0, 0]).astype(np.float32))
>>> z = Tensor(np.array([5, 5]).astype(np.float32))
>>> output, inputs_gradient = value_and_grad(fn, grad_position=(1, 2), weights=None, has_
↪aux=True)(x, y, z)
>>> print(output)
(Tensor(shape=[2], dtype=Float32, value= [ 7.50000000e+01,  7.50000000e+01]),
 Tensor(shape=[2], dtype=Float32, value= [ 5.00000000e+00,  5.00000000e+00]))
```

(continues on next page)

(continued from previous page)

(Tensor(shape=[2], dtype=Float32, value= [ 7.50000000e+01,  7.50000000e+01]),
 Tensor(shape=[2], dtype=Float32, value= [ 3.00000000e+01,  3.00000000e+01]))
>>>
>>> # For given network to be differentiated with both inputs and weights, there are 3 cases.
>>> net = nn.Dense(10, 1)
>>> loss_fn = nn.MSELoss()
>>> def forward(inputs, labels):
...     logits = net(inputs)
...     loss = loss_fn(logits, labels)
...     return loss, logits
>>> inputs = Tensor(np.random.randn(16, 10).astype(np.float32))
>>> labels = Tensor(np.random.randn(16, 1).astype(np.float32))
>>> weights = net.trainable_params()
>>>
>>> # Case 1: gradient with respect to inputs.
>>> # For has_aux is set True, only loss contributes to the gradient.
>>> grad_fn = value_and_grad(forward, grad_position=0, weights=None, has_aux=True)
>>> (loss, logits), inputs_gradient = grad_fn(inputs, labels)
>>> print(logits.shape)
(16, 1)
>>> print(inputs.shape, inputs_gradient.shape)
(16, 10) (16, 10)
>>>
>>> # Case 2: gradient with respect to weights.
>>> # For has_aux is set True, only loss contributes to the gradient.
>>> grad_fn = value_and_grad(forward, grad_position=None, weights=weights, has_aux=True)
>>> (loss, logits), params_gradient = grad_fn(inputs, labels)
>>> print(logits.shape)
(16, 1)
>>> print(len(weights), len(params_gradient))
2 2
>>>
>>> # Case 3: gradient with respect to inputs and weights.
>>> # For has_aux is set False, both loss and logits contribute to the gradient.
>>> grad_fn = value_and_grad(forward, grad_position=0, weights=weights, has_aux=False)
>>> (loss, logits), (inputs_gradient, params_gradient) = grad_fn(inputs, labels)
>>> print(logits.shape)
(16, 1)
>>> print(inputs.shape, inputs_gradient.shape)
(16, 10) (16, 10)
>>> print(len(weights), len(params_gradient))
2 2
```

1.6.3 mindspore.get_grad

mindspore.**get_grad**(*gradients*, *identifier*)

When *return_ids* of *mindspore.grad()* or *mindspore.grad()* is set to `True` , use return value of *mindspore.grad*, or the second return value of *mindspore.grad* as gradients. Then find the specific gradient from *gradients* according to *identifier* .

As for gradient, two typical cases are included:

1. *identifier* is the position of the specific tensor to get gradient.
2. *identifier* is a parameter of a network.

Parameters

- **gradients** (*Union[tuple[int, Tensor], tuple[tuple, tuple]]*) –The return value of *mindspore.grad()* when *return_ids* is set to True.
- **identifier** (*Union[int, Parameter]*) –The position number of a tensor, or a parameter that is used in *mindspore.grad()*.

Returns

The Tensor gradient value corresponding to the *identifier*.

Raises

- **RuntimeError** –If gradient value corresponding to the *identifier* is not found.
- **TypeError** –If type of Args does not belong to required ones.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> from mindspore import grad, get_grad
>>>
>>>  # Cell object to be differentiated
>>> class Net(nn.Cell):
...     def construct(self, x, y, z):
...         return x * y * z
>>> x = Tensor([1, 2], mindspore.float32)
>>> y = Tensor([-2, 3], mindspore.float32)
>>> z = Tensor([0, 3], mindspore.float32)
>>> net = Net()
>>> out_grad = grad(net, grad_position=(1, 2), return_ids=True)(x, y, z)
>>> output = get_grad(out_grad, 1)
>>> print(output)
[0. 6.]
```

1.6.4 mindspore.jacfwd

`mindspore.`**jacfwd**(*fn*, *grad_position=0*, *has_aux=False*)

Compute Jacobian via forward mode, corresponding to forward-mode differentiation. When number of outputs is much greater than that of inputs, it's better to calculate Jacobian via forward mode than reverse mode to get better performance.

Parameters

- **fn** (*Union[Cell, Function]*) –Function to do GradOperation.
- **grad_position** (*Union[int, tuple[int]], optional*) –If int, get the gradient with respect to single input. If tuple, get the gradients with respect to selected inputs. 'grad_position' begins with 0. Default: `0` .
- **has_aux** (*bool, optional*) –If `True` , only the first output of *fn* contributes the gradient of *fn*, while the other outputs will be returned straightly. It means the *fn* must return more than one outputs in this case. Default: `False` .

Returns

Function, returns the Jacobian function for the input function or cell. For example, as for *out1, out2 = fn(*args)*, when *has_aux* is set `True` , gradient function will return outputs like *(Jacobian, out2)* and *out2* does not contribute to the differentiation, otherwise *Jacobian* .

Raises

`TypeError` – *grad_position* or *has_aux* does not belong to required types.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore.nn as nn
>>> from mindspore import jacfwd
>>> from mindspore import Tensor
>>> class MultipleInputsMultipleOutputsNet(nn.Cell):
...     def construct(self, x, y, z):
...         return x ** 2 + y ** 2 + z ** 2, x * y * z
>>> x = Tensor(np.array([[1, 2], [3, 4]]).astype(np.float32))
>>> y = Tensor(np.array([[1, 2], [3, 4]]).astype(np.float32))
>>> z = Tensor(np.array([[1, 1], [1, 1]]).astype(np.float32))
>>> net = MultipleInputsMultipleOutputsNet()
>>> jac, aux = jacfwd(net, grad_position=0, has_aux=True)(x, y, z)
>>> print(jac)
[[[[ 2.  0.]
   [ 0.  0.]]
  [[ 0.  4.]
   [ 0.  0.]]]
 [[[ 0.  0.]
   [ 6.  0.]]
  [[ 0.  0.]
   [ 0.  8.]]]]
>>> print(aux)
[[ 1.  4.]
 [ 9. 16.]]
```

1.6.5 mindspore.jacrev

`mindspore.`**`jacrev`**(*fn*, *grad_position=0*, *has_aux=False*)

Compute Jacobian via reverse mode, corresponding to reverse-mode differentiation. When number of inputs is much greater than that of outputs, it's better to calculate Jacobian via reverse mode than forward mode to get better performance.

Parameters

- **`fn`** (*`Union[Cell, Function]`*) – Function to do GradOperation.
- **`grad_position`** (*`Union[int, tuple[int]], optional`*) – If int, get the gradient with respect to single input. If tuple, get the gradients with respect to selected inputs. 'grad_position' begins with 0. Default: `0` .
- **`has_aux`** (*`bool, optional`*) – If `True` , only the first output of *fn* contributes the gradient of *fn*, while the other outputs will be returned straightly. It means the *fn* must return more than one outputs in this case. Default: `False` .

Returns

Function, returns the Jacobian function for the input function or cell. For example, as for *out1, out2 = fn(*args)*, when *has_aux* is set `True` , gradient function will return outputs like *(Jacobian, out2)* and *out2* does not contribute to the differentiation, otherwise *Jacobian* .

Raises

`TypeError` – *grad_position* or *has_aux* does not belong to required types.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore.nn as nn
>>> from mindspore import jacrev
>>> from mindspore import Tensor
>>> class MultipleInputsMultipleOutputsNet(nn.Cell):
...     def construct(self, x, y, z):
...         return x ** 2 + y ** 2 + z ** 2, x * y * z
>>> x = Tensor(np.array([[1, 2], [3, 4]]).astype(np.float32))
>>> y = Tensor(np.array([[1, 2], [3, 4]]).astype(np.float32))
>>> z = Tensor(np.array([[1, 1], [1, 1]]).astype(np.float32))
>>> net = MultipleInputsMultipleOutputsNet()
>>> jac, aux = jacrev(net, grad_position=0, has_aux=True)(x, y, z)
>>> print(jac)
[[[[ 2.  0.]
   [ 0.  0.]]
  [[ 0.  4.]
   [ 0.  0.]]]
 [[[ 0.  0.]
   [ 6.  0.]]
  [[ 0.  0.]
   [ 0.  8.]]]]
>>> print(aux)
[[ 1.  4.]
 [ 9. 16.]]
```

1.6.6 mindspore.jvp

`mindspore.`**`jvp`**(*fn*, *inputs*, *v*, *has_aux=False*)

Compute the jacobian-vector-product of the given network. The calculation procedure of JVP can be found in forward-mode differentiation.

Parameters

- **`fn`** (*`Union[Function, Cell]`*) – The function or net that takes Tensor inputs and returns single Tensor or tuple of Tensors.
- **`inputs`** (*`Union[Tensor, tuple[Tensor], list[Tensor]]`*) – The inputs to *fn* .
- **`v`** (*`Union[Tensor, tuple[Tensor], list[Tensor]]`*) – The vector in jacobian-vector-product. The shape and type of *v* should be the same as *inputs* .
- **`has_aux`** (*`bool`*) – If `True` , only the first output of *fn* contributes the gradient of *fn*, while the other outputs will be returned straightly. It means the *fn* must return more than one outputs in this case. Default: `False` .

Returns

- **net_output** (Union[Tensor, tuple[Tensor]]) - The output of *fn(inputs)* . Specially, when *has_aux* is set `True` , *netout* is the first output of *fn(inputs)* .
- **jvp** (Union[Tensor, tuple[Tensor]]) - The result of jacobian-vector-product.
- **aux_value** (Union[Tensor, tuple[Tensor]], optional) - Only when *has_aux* is `True` , *aux_value* will be returned. It means the second to last outputs of *fn(inputs)* . Specially, *aux_value* does not contribute to gradient.

Raises

TypeError – *inputs* or *v* does not belong to required types.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import jvp
>>> from mindspore import Tensor
>>> import mindspore.nn as nn
>>> class Net(nn.Cell):
...     def construct(self, x, y):
...         return x**3 + y
>>> x = Tensor(np.array([[1, 2], [3, 4]]).astype(np.float32))
>>> y = Tensor(np.array([[1, 2], [3, 4]]).astype(np.float32))
>>> v = Tensor(np.array([[1, 1], [1, 1]]).astype(np.float32))
>>> output = jvp(Net(), (x, y), (v, v))
>>> print(output[0])
[[ 2. 10.]
 [30. 68.]]
>>> print(output[1])
[[ 4. 13.]
 [28. 49.]]
>>>
>>> def fn(x, y):
...     return x ** 3 + y, y
>>> output, jvp_out, aux = jvp(fn, (x, y), (v, v), has_aux=True)
>>> print(output)
[[ 2. 10.]
 [30. 68.]]
>>> print(jvp_out)
[[ 4. 13.]
 [28. 49.]]
>>> print(aux)
[[ 1. 2.]
 [3. 4.]]
```

1.6.7 mindspore.vjp

mindspore.**vjp**(*fn*, **inputs*, *weights=None*, *has_aux=False*)

Compute the vector-jacobian-product of the given network. *vjp* matches reverse-mode differentiation.

Parameters

- **fn** (*Union[Function, Cell]*) – The function or net that takes Tensor inputs and returns single Tensor or tuple of Tensors.
- **inputs** (*Union[Tensor, tuple[Tensor], list[Tensor]]*) – The inputs to *fn* .
- **weights** (*Union[ParameterTuple, Parameter, list[Parameter]], optional*) – The parameters of the training network that need to calculate the gradient. *weights* can be got through *weights = net.trainable_params()* . Default: None .
- **has_aux** (*bool, optional*) – If True, only the first output of *fn* contributes the gradient of *fn*, while the other outputs will be returned straightly. It means the *fn* must return more than one outputs in this case. Default: False.

Returns

Forward outputs and function to calculate vjp.

- **net_output** (Union[Tensor, tuple[Tensor]]) - The output of *fn(inputs)*. Specially, when *has_aux* is set to True, *net_output* is the first output of *fn(inputs)*.
- **vjp_fn** (Function) - To calculate vector-jacobian-product. Its inputs are the vectors whose shape and type should be the same as *net_output* .
- **aux_value** (Union[Tensor, tuple[Tensor]], optional) - When *has_aux* is True, *aux_value* will be returned. It means the second to last outputs of *fn(inputs)*. Specially, *aux_value* does not contribute to gradient.

Raises

TypeError – *inputs* or *v* does not belong to required types.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore.nn as nn
>>> from mindspore import vjp
>>> from mindspore import Tensor
>>> class Net(nn.Cell):
...     def construct(self, x, y):
...         return x**3 + y
>>> x = Tensor(np.array([[1, 2], [3, 4]]).astype(np.float32))
>>> y = Tensor(np.array([[1, 2], [3, 4]]).astype(np.float32))
>>> v = Tensor(np.array([[1, 1], [1, 1]]).astype(np.float32))
>>> outputs, vjp_fn = vjp(Net(), x, y)
>>> print(outputs)
[[ 2. 10.]
 [30. 68.]]
>>> gradient = vjp_fn(v)
>>> print(gradient)
```

```

1.7 Parallel Optimization

1.7.1 Automatic Vectorization

mindspore.vmap	Vectorizing map (vmap) is a kind of higher-order function to map *fn* along the parameter axes.

mindspore.vmap

mindspore.**vmap**(*fn*, *in_axes=0*, *out_axes=0*)

Vectorizing map (vmap) is a kind of higher-order function to map *fn* along the parameter axes.

Vmap is pioneered by Jax and it removes the restriction of batch dimension on the operator, and provides a more convenient and unified operator expression. Moreover, it allows users to composite with other functional modules such as *mindspore.grad()*, to improve the development efficiency. In addition, the vectorizing map does not execute loops outside the function, but sinks loops into the primitive operations of the function for better performance. When combined with *Graph Kernel Fusion*, operational efficiency would be further improved.

Warning: This is an experimental API that is subject to change or deletion.

Note:

- The power of vmap comes from the implementation of VmapRules of primitives. Although we have designed a generalized rule for user custom operators, we can not guarantee that it works well for all operators, unknown exceptions may occur, please be aware the risk of use.
- When calling the random number generation methods within the scope of vmap, the same random number is generated

among vector functions each time. If you expect each vector branch to use different random numbers, you need to generate batch random numbers externally in advance and then transfer them to vmap.

Parameters

- **fn** (*Union[Cell, Function, CellList]*) – Function to be mapped along the parameter axes, which takes at least one argument and returns one or more Tensors or the type of data supported by the MindSpore Tensor. When it is a CellList, the model ensembling scenario, please make sure that the structure of each cell is the same and the number of cells is consistent with the sizes of the mapped axes (*axis_size*).
- **in_axes** (*Union[int, list, tuple]*) – Specifies which dimensions (axes) of the inputs should be mapped over. Default: `0` .
  - If *in_axes* is an integer, all arguments of *fn* are mapped over according to this axis index.
  - If *in_axes* is a tuple or list, which only composed of integers or Nones and the length should equal to the number of positional arguments to *fn*, indicates which axis to map for each corresponding positional argument. Note that, axis integers must be in range $[-ndim, ndim)$ for each argument, where *ndim* is the number of dimensions of the corresponding argument.
  - None means not mapping along any axis. Also the mapping axis index of the *in_axes* must have at least one positional parameter not None. The sizes of the mapped axes (*axis_size*) for all arguments must be equal.
- **out_axes** (*Union[int, list, tuple]*) – Specifies where the mapped dimensions (axes) should appear in the outputs. Default: `0` .
  - If *out_axes* is an integer, all outputs of *fn* are specified according to this axis.
  - If *out_axes* is a tuple or list, which only composed of integers or Nones. And its length also should be equal to the number of outputs of *fn*. Note that, axis integers must be in range $[-ndim, ndim)$ for each output, where *ndim* is the dimension of the output of the *vmap*-mapped function.
  - All outputs with a non-None mapped axis must specify a non-None *out_axes*, and if outputs with None mapped axis specifies a non-None *out_axes*, the result broadcasts across the mapped axis.

Returns

Function, returns the Vectorized/Batched version function of *fn*. The arguments and outputs of this function correspond to those of *fn*, but it adds an extra batch dimension at positions specified by *in_axes* and *out_axes*.

Raises

RuntimeError –

- If base elements in *in_axes* or *out_axes* are not a None or an integer.
- If the all base elements in *in_axes* or *out_axes* are None.
- If *in_axes* is not single integer, and the length of *in_axes* is not equal to the arguments sizes.
- If *out_axes* is not single integer, and the length of *out_axes* is not equal to the outputs sizes.
- If the *axis_size* of each arguments in the scope of *vmap* are not equal.
- If the axis in *in_axes* or *out_axes* is out of bounds.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import vmap
>>> def test_vmap(x, y, z):                                                    # ([a],[a],[a]) ->␣
↪[a]
...     return x + y + z
>>> x = Tensor(np.array([[1, 2], [3, 4], [5, 6]]).astype(np.float32))         # [b, a]
>>> y = Tensor(np.array([[-3, -2, -1], [3, 2, 1]]).astype(np.float32))        # [a, b]
>>> z = Tensor(np.array([0, 3]).astype(np.float32))                           # [a]
>>> output = vmap(test_vmap, in_axes=(0, 1, None), out_axes=1)(x, y, z)       # ([b, a],[a, b],
↪[a]) -> [a, b]
>>> print(output)
[[-2  1  4]
 [ 8  9 10]]
```

1.7.2 Recompute

mindspore.recompute	This function is used to reduce memory, when run block, rather than storing the intermediate activation computed in forward pass, we will recompute it in backward pass.

mindspore.recompute

mindspore.**recompute**(*block*, **args*, ***kwargs*)

This function is used to reduce memory, when run block, rather than storing the intermediate activation computed in forward pass, we will recompute it in backward pass.

Note:

- Recompute function only support block which inherited from Cell object.
- This function interface now only support pynative mode. you can use Cell.recompute interface in graph mode.
- When use recompute function, block object should not decorated by @jit.

Parameters

- **block** (*Cell*) – Block to be recompute.
- **args** (*tuple*) – Inputs for block object to run forward pass.
- **kwargs** (*dict*) – Optional input for recompute function.

Returns

Same as return type of block.

Raises

- **TypeError** – If *block* is not Cell object.
- **AssertionError** – If execute mode is not PYNATIVE_MODE.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> from mindspore import Tensor, recompute
>>> class MyCell(nn.Cell):
...     def __init__(self):
...         super(MyCell, self).__init__(auto_prefix=False)
...         self.conv = nn.Conv2d(2, 2, 2, has_bias=False, weight_init='ones')
...         self.relu = ops.ReLU()
...
...     def construct(self, x):
...         y = recompute(self.conv, x)
...         return self.relu(y)
>>> inputs = Tensor(np.ones([2, 2, 2, 2]).astype(np.float32) * 2)
>>> my_net = MyCell()
>>> grad = ops.grad(my_net)(inputs)
>>> print(grad)

```

1.8 JIT

mindspore.JitConfig	Jit config for compile.
mindspore.jit	Create a callable MindSpore graph from a Python function.
mindspore.jit_class	Class decorator for user-defined classes.
mindspore.ms_memory_recycle	Recycle memory used by MindSpore.
mindspore.mutable	Make a constant value mutable.
mindspore.constexpr	Used to calculate constant in graph copmpiling process and improve compile performance in GRAPH_MODE.
mindspore.lazy_inline	Make the cell to be reusable.
mindspore.no_inline	Make the function to be reusable.
mindspore.set_recursion_limit	Specify the recursion depth limit of function call before compiling graph.

1.8.1 mindspore.JitConfig

class mindspore.**JitConfig**(*jit_level=''*, *exc_mode='auto'*, *jit_syntax_level=''*, *debug_level='RELEASE'*, *infer_boost='off'*, ***kwargs*)

Jit config for compile.

Parameters

- **jit_level** (*str, optional*) –Used to control the compilation optimization level. Supports ["O0", "O1", "O2"]. Default: "" , The framework automatically selects the execution method. Not recommended, it is recommended to use the JIT decorator.
  - "O0": Except for optimizations that may affect functionality, all other optimizations are turned off, adopt KernelByKernel execution mode.
  - "O1": Using commonly used optimizations and automatic operator fusion optimizations, adopt KernelByKernel execution mode.
  - "O2": Ultimate performance optimization, adopt Sink execution mode.
- **exc_mode** (*str, optional*) –Control the execution mode of the model. Supports ["auto", "sink", "no_sink"]. Default: "auto" .
  - "auto": The framework automatically selects the execution method.
  - "sink": Support the network to load and load the entire device at once, and then execute it by input driver, without the need to iterate through each operator to achieve better execution performance. This mode is only supported on the Ascend backend.
  - "no_sink": The network model is executed asynchronously one by one using a single operator.
- **jit_syntax_level** (*str, optional*) –JIT syntax level for graph compiling. The value must be "STRICT" , "LAX" or "" . Default to an empty string, which means that this JitConfig configuration will be ignored and the jit_syntax_level of ms.context will be used. For more details about ms.context, refer to set_context . Default: "" .
  - "STRICT": Only basic syntax is supported, and execution performance is optimal. Can be used for MindIR load and export.
  - "LAX": Compatible with all Python syntax as much as possible. However, execution performance may be affected and not optimal. Cannot be used for MindIR load and export due to some syntax that may not be able to be exported.
- **debug_level** (*str, optional*) –Set debugging level for graph compiling. The value must be "RELEASE" or "DEBUG". Default value: RELEASE.
  - RELEASE: Used for normally running, and some debug information will be discard to get a better compiling performance.
  - DEBUG: Used for debugging when errors occur, more information will be record in compiling process.
- **infer_boost** (*str, optional*) –enable infer boost mode. The value must be "on" , "off". Default to an "off", which means that disable infer boost. when infer boost mode is enabled, MindSpore will use high perf kernel lib, use faster runtime make infer speed is best. Note: current infer boost only support *jit_level* == "O0" and only Atlas A2 series products are supported.
- ****kwargs** (*dict*) –A dictionary of keyword arguments that the class needs.

Examples

```
>>> from mindspore import JitConfig
>>>
>>> jitconfig = JitConfig(jit_level="O1")
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>>
>>> net.set_jit_config(jitconfig)
```

1.8.2 mindspore.jit

mindspore.**jit**(*function: Optional[Callable] = None*, ***, *capture_mode: str = 'ast'*, *jit_level: str = 'O0'*, *dynamic: int = 0*, *fullgraph: bool = False*, *backend: str = ''*, ***options*)

Create a callable MindSpore graph from a Python function.

This allows the MindSpore runtime to apply optimizations based on graph.

Note:

- It is not supported to run a function with decoration @jit(capture_mode="bytecode") in static graph mode, in which case the decoration @jit(capture_mode="bytecode") is considered invalid.
- Calls to functions with decorated @jit(capture_mode="bytecode") inside functions decorated with @jit(capture_mode="ast") are not supported, and the decoration @jit(capture_mode="bytecode") is considered invalid.

Parameters

function (*Function, optional*) – The Python function that will be run as a graph. Default: None.

Keyword Arguments

- **capture_mode** (*str, optional*) – The method to create a callable MindSpore graph. The value of capture_mode should be ast , bytecode or trace . Default: ast .
  - ast : Parse Python ast to build graph.
  - bytecode : Parse Python bytecode to build graph at runtime. This is an experimental prototype that is subject to change and/or deletion.
  - *trace* : Trace the execution of Python code to build graph. This is an experimental prototype that is subject to change and/or deletion.
- **jit_level** (*str, optional*) – Used to control the compilation optimization level. Currently is only effective with default backend. The value of jit_level should be O0 or O1 . Default: O0 .
  - *O0*: Except for optimizations that may affect functionality, all other optimizations are turned off.
  - *O1*: Using commonly used optimizations and automatic operator fusion optimizations. This optimization level is experimental and is being improved.
- **dynamic** (*int, optional*) – Whether dynamic shape compilation should be performed. Default: 0. The value range is as follows:
  - *0*: Do not perform dynamic shape compilation.
  - *1*: Enable dynamic shape compilation and automatically detect shape changes.

- **fullgraph** (bool, optional) – Whether to capture the entire function into graph. If False, jit attempts to be compatible with all Python syntax in the function as much as possible. If True, we require that the entire function can be captured into graph. If this is not possible (that is, if there is Python syntax not supported), then it will raise an exception. This currently only applies when capture_mode is ast. Default: `False`.
- **backend** (str, optional) – The compilation backend to be used. If this parameter is not set, the framework will use `GE` backend for Atlas training series products and `ms_backend` backend for others including Atlas A2 training series products by default.
  - *ms_backend*: Adopt KernelByKernel execution mode.
  - *GE*: Adopt Sink execution mode. The whole model will be sinked to device to execute, only applicable to the top cell of model. And only can be used in Ascend platform.
- ****options** (dict) – A dictionary of options to pass to the compilation backend.

  Some options are device specific, see the below table for details:

Option Parameters	Hardware Platform Support	Backend Support
disable_format_transform	GPU	ms_backend
exec_order	Ascend	ms_backend
ge_options	Ascend	GE
infer_boost	Ascend	ms_backend

  - disable_format_transform (bool, optional): Whether to disable the automatic format transform function from NCHW to NHWC. When the network training performance of fp16 is worse than fp32, *disable_format_transform* can be set to `True` to try to improve training performance. Default: `False` .
  - exec_order (str, optional): Set the sorting method for operator execution, currently only two sorting methods are supported: `bfs` and `dfs` . Default: `bfs` .
    - *bfs*: The default sorting method, breadth priority, good communication masking, relatively good performance.
    - *dfs*: An optional sorting method, depth-first sorting. The performance is relatively worse than that of bfs execution order, but it occupies less memory. It is recommended to try dfs in scenarios where other execution orders run out of memory (OOM).
  - ge_options (dict): Set options for ge backend. The options are divided into two categories: global, and session. This is an experimental prototype that is subject to change and/or deletion. For detailed information, please refer to Ascend community .
    - global (dict): Set global options.
    - session (dict): Set session options.
  - infer_boost (str, optional): Used to control the inference mode. Default: `off`, which means the inference mode is disabled. The range is as follows:
    - *on*: Enable inference mode, get better infer performance.
    - *off*: Disable inference mode, use forward for inference. The performance is poor.

Returns

Function, if *fn* is not None, returns a callable function that will execute the compiled function; If *fn* is None, returns a decorator and when this decorator invokes with a single *fn* argument, the callable function is equal to the case when *fn* is not None.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> from mindspore import jit
...
>>> x = Tensor(np.ones([1, 1, 3, 3]).astype(np.float32))
>>> y = Tensor(np.ones([1, 1, 3, 3]).astype(np.float32))
...
>>> # create a callable MindSpore graph by calling jit
>>> def tensor_add(x, y):
...     z = x + y
...     return z
...
>>> tensor_add_graph = jit(function=tensor_add)
>>> out = tensor_add_graph(x, y)
...
>>> # create a callable MindSpore graph through decorator @jit
>>> @jit
... def tensor_add_with_dec(x, y):
...     z = x + y
...     return z
...
>>> out = tensor_add_with_dec(x, y)
...
>>> # create a callable MindSpore graph and capture the entire function into the graph
>>> @jit(fullgraph=True)
... def tensor_add_fullgraph(x, y):
...     z = x + y
...     return z
...
>>> out = tensor_add_fullgraph(x, y)
```

1.8.3 mindspore.jit_class

mindspore.**jit_class**(*cls*)

Class decorator for user-defined classes.

This allows MindSpore to identify user-defined classes and thus obtain their attributes and methods.

Parameters

cls (*Class*) – User-defined class.

Returns

Class.

Raises

- **TypeError** – If *jit_class* is used for non-class types or nn.Cell.
- **AttributeError** – If the private attributes or magic methods of the class decorated with *jit_class* is called.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.nn as nn
>>> from mindspore import jit_class
...
>>> @jit_class
... class UserDefinedNet:
...     def __init__(self):
...         self.value = 10
...
...     def func(self, x):
...         return 2 * x
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.net = UserDefinedNet()
...
...     def construct(self, x):
...         out = self.net.value + self.net.func(x)
...         return out
...
>>> net = Net()
>>> out = net(5)
>>> print(out)
20
```

1.8.4 mindspore.ms_memory_recycle

mindspore.**ms_memory_recycle**()

Recycle memory used by MindSpore. When train multi Neural network models in one process, memory used by MindSpore is very large, this is because MindSpore cached runtime memory for every model. To recycle these cached memory, users can call this function after training of one model.

Examples

```
>>> import mindspore as ms
>>> ms.ms_memory_recycle()
```

1.8.5 mindspore.mutable

mindspore.**mutable**(*input_data*, *dynamic_len=False*)

Make a constant value mutable.

Currently, all the inputs of Cell except Tensor such as scalar, tuple, list and dict, are regarded as constant values. The constant values are non-differentiable and used to do constant folding in the optimization process.

Besides, currently when the network input is tuple[Tensor], list[Tensor] or dict[Tensor], even without changing the shape and dtype of the Tensors, the network will be re-compiled when calling this network repeatedly because the these inputs are regarded as constant values.

To solve the above problems, we provide api *mutable* to make the constant inputs of Cell 'mutable'. A 'mutable' input means that it is changed to be a variable input just like Tensor and the most important thing is that it will be differentiable.

When the *input_data* is tuple or list and *dynamic_len* is False, *mutable* will return a constant length tuple or list with all mutable elements. If *dynamic_len* is True, the length of the return tuple or list will be dynamic.

When a dynamic-length tuple or list returned by *mutable* is used as input to a network and the network is called repeatedly, and the length of the tuple or list is different for each run, it does not need to be re-compiled.

Parameters

- **input_data** (*Union[Tensor, scalar, tuple, list, dict]*) – The input data to be made mutable. If 'input_data' is list/tuple/dict, the type of each element should also in the valid types.
- **dynamic_len** (*bool, optional*) – Whether to set the whole sequence to be dynamic length. In graph compilation, if *dynamic_len* is `True` , the *input_data* must be list or tuple and the elements of *input_data* must have the same type and shape. Default: `False` .

Warning: This is an experimental API that is subject to change or deletion. *dynamic_len* is an experimental argument. Currently, *dynamic_len* is not supported to be `True` .

Note: Currently this api only works in GRAPH mode.

Returns

The origin input data which has been set mutable.

Raises

- **TypeError** – If *input_data* is not one of Tensor, scalar, tuple, list, dict or their nested structure.
- **TypeError** – If *dynamic_len* is `True` and *input_data* is not tuple or list.
- **ValueError** – If *dynamic_len* is `True` , *input_data* is tuple or list but the elements within *input_data* do not have the same type.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import mutable, nn, ops, Tensor, context
>>> from mindspore import dtype as mstype
>>> context.set_context(mode=context.GRAPH_MODE)
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.matmul = ops.MatMul()
...
...     def construct(self, z):
...         x = z[0]
...         y = z[1]
...         out = self.matmul(x, y)
...         return out
...
>>> class GradNetWrtX(nn.Cell):
...     def __init__(self, net):
```

(continues on next page)

(continued from previous page)

```
...         super(GradNetWrtX, self).__init__()
...         self.net = net
...         self.grad_op = ops.GradOperation()
...
...     def construct(self, z):
...         gradient_function = self.grad_op(self.net)
...         return gradient_function(z)
...
>>> z = mutable((Tensor([[0.5, 0.6, 0.4], [1.2, 1.3, 1.1]], dtype=mstype.float32),
...               Tensor([[0.01, 0.3, 1.1], [0.1, 0.2, 1.3], [2.1, 1.2, 3.3]], dtype=mstype.
↪float32)))
>>> output = GradNetWrtX(Net())(z)
>>> print(output)
(Tensor(shape=[2, 3], dtype=Float32, value=
[[ 1.41000009e+00,  1.60000002e+00,  6.59999943e+00],
 [ 1.41000009e+00,  1.60000002e+00,  6.59999943e+00]]), Tensor(shape=[3, 3], dtype=Float32,␣
↪value=
[[ 1.70000005e+00,  1.70000005e+00,  1.70000005e+00],
 [ 1.89999998e+00,  1.89999998e+00,  1.89999998e+00],
 [ 1.50000000e+00,  1.50000000e+00,  1.50000000e+00]]))
```

1.8.6 mindspore.constexpr

mindspore.**constexpr**(*fn=None*, *get_instance=True*, *name=None*, *reuse_result=True*, *check=True*)

Used to calculate constant in graph copmpiling process and improve compile performance in GRAPH_MODE.

Parameters

- **fn** (*function, optional*) – A *fn* use as the infer_value of the output operator. Default: `None` .
- **get_instance** (*bool, optional*) – If `True` , return the instance of operator, otherwise return the operator class. Default: `True` .
- **name** (*str, optional*) – Defines the operator name. If *name* is `None` , use the function name as op name. Default: `None` .
- **reuse_result** (*bool, optional*) – If `True` , the operator will be executed once and reuse the result next time, otherwise the operator will always be executed. Default: `True` .
- **check** (*bool, optional*) – If `True` , the parameters will be checked and the warning message will raised if the parameter is not const value. Default: `True` .

Examples

```
>>> import mindspore as ms
>>> # define a constant calculate function with for loop inside and use use constexpr to␣
↪accelerate the compile
>>> # process.
>>> @ms.constexpr
... def for_loop_calculate(range_num):
...     out = 0
...     for i in range(range_num):
...         if i %2 == 0 and i % 7 != 0:
...             out = out + i
...     return out // range_num
```

(continues on next page)

(continued from previous page)

```
...
>>> # construct a net and run with GRAPH_MODE.
>>> @ms.jit
... def my_func(x):
...     new_shape = for_loop_calculate(100000)
...     return ms.ops.broadcast_to(x, (new_shape, ))
...
>>> out = my_func(ms.Tensor([1]))
>>> print(out.shape)
>>> (21428, )
```

1.8.7 mindspore.lazy_inline

mindspore.**lazy_inline**(*fn=None*, *attrs=None*, *policy=None*)

Make the cell to be reusable. The corresponding sub graph will not be inline at first and will be inline with the policy. Registering the decorator of the built-in function *__init__* of a cell, the decorator will add the parameters of *__init__* according to the *attrs* as the attributes of this cell.

For a detailed description of the function, see Using the lazy_inline decorator .

Warning: This feature is only supported on Ascend and is not supported on other hardwares. The construct parameters must be positional or key word arguments and have not default values. The cell has not switch sub graph.

Parameters

- **fn** (*function*) – *__init__* function of a cell.
- **attrs** (*Union[list[string], string]*) – The attributes list to add for the cell.
- **policy** (*Union[None, "front"], optional*) – The policy of inline. Default is `None`.
  - `None`: The cell will be compiled to sub graph and will not be inline.
  - `"front"`: The cell will be compiled to sub graph first and will be inline at front end.

Returns

function, original function.

Supported Platforms:

`Ascend`

Examples

```
>>> import os
>>> import numpy as np
>>> from mindspore import Tensor
>>> import mindspore.nn as nn
>>> from mindspore import lazy_inline
>>> from mindspore import context
>>> from mindspore import ops
>>> def conv3x3(in_channels, out_channels, stride=1, padding=1, pad_mode='pad'):
...     return nn.Conv2d(in_channels, out_channels,
```

(continues on next page)

(continued from previous page)

```
...                     kernel_size=3, stride=stride, padding=padding, pad_mode=pad_mode)
...
>>> def conv1x1(in_channels, out_channels, stride=1, padding=0, pad_mode='pad'):
...     return nn.Conv2d(in_channels, out_channels,
...                      kernel_size=1, stride=stride, padding=padding, pad_mode=pad_mode)
...
>>> class Block(nn.Cell):
...     expansion = 4
...
...     @lazy_inline
...     def __init__(self,
...                  in_channels,
...                  out_channels,
...                  stride=1,
...                  down_sample=False):
...         super(Block, self).__init__()
...
...         out_chls = out_channels
...         self.conv1 = conv1x1(in_channels, out_chls, stride=1, padding=0)
...         self.bn1 = nn.BatchNorm2d(out_chls)
...
...         self.conv2 = conv3x3(out_chls, out_chls, stride=stride, padding=1)
...         self.bn2 = nn.BatchNorm2d(out_chls)
...
...         self.conv3 = conv1x1(out_chls, out_channels, stride=1, padding=0)
...         self.bn3 = nn.BatchNorm2d(out_channels)
...
...         self.relu = nn.ReLU()
...         self.downsample = down_sample
...
...         self.conv_down_sample = conv1x1(in_channels, out_channels,
...                                         stride=stride, padding=0)
...         self.bn_down_sample = nn.BatchNorm2d(out_channels)
...         self.add = ops.Add()
...
...     def construct(self, x):
...         identity = x
...
...         out = self.conv1(x)
...         out = self.bn1(out)
...         out = self.relu(out)
...
...         out = self.conv2(out)
...         out = self.bn2(out)
...         out = self.relu(out)
...
...         out = self.conv3(out)
...         out = self.bn3(out)
...
...         if self.downsample:
...             identity = self.conv_down_sample(identity)
...             identity = self.bn_down_sample(identity)
...
...         out = self.add(out, identity)
...         out = self.relu(out)
...
...         return out
```

(continues on next page)

(continued from previous page)

```

...
>>> test_compile()
```

1.8.8 mindspore.no_inline

mindspore.**no_inline**(*fn=None*)

Make the function to be reusable. The corresponding sub graph will not be inline.

Parameters

fn (*function*) – It is the python function. If it is a methon of a cell, please refer to *mindspore.lazy_inline()*.

Returns

function, original function.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import no_inline, Tensor, jit
>>> @no_inline
... def no_inline_fun(val):
...     x = val * 3 + 2
...     return x
>>> @jit
... def call_no_inline_fun(val):
...     for _ in range(100):
...         val = no_inline_fun(val)
...     return val
>>> call_no_inline_fun(Tensor(10))
```

1.8.9 mindspore.set_recursion_limit

mindspore.**set_recursion_limit**(*recursion_limit=1000*)

Specify the recursion depth limit of function call before compiling graph. It needs to be call when the nested function call is too deep or the number of sub graphs is too large. If recursion_limit is set larger than before, the system max stack depth should be set larger too, otherwise a *core dumped* exception may be raised because of system stack overflow.

Parameters

recursion_limit (*int, optional*) – The recursion depth limit. Must be a positive integer. Default: `1000` .

Examples

```
>>> import mindspore as ms
>>> ms.set_recursion_limit(10000)
```

1.9 Tool

1.9.1 Dataset Helper

mindspore.DatasetHelper	DatasetHelper is a class to process the MindData dataset and provides the information of dataset.
mindspore.Symbol	Symbol is a data structure to indicate the symbolic info of shape.
mindspore.connect _network_with_dataset	Connect the *network* with dataset in *dataset_helper*.
mindspore.data_sink	A wrapper function to generate a function for the input function.

mindspore.DatasetHelper

class mindspore.**DatasetHelper**(*dataset*, *dataset_sink_mode=True*, *sink_size=- 1*, *epoch_num=1*)

DatasetHelper is a class to process the MindData dataset and provides the information of dataset.

According to different contexts, change the iterations of dataset and use the same iteration for loop in different contexts.

Note: The iteration of DatasetHelper will provide one epoch data.

Parameters

- **dataset** (*Dataset*) –The dataset iterator. The dataset can be generated by dataset generator API in *mindspore.dataset* module, such as `mindspore.dataset.ImageFolderDataset`.
- **dataset_sink_mode** (*bool*) –If the value is True, GetNext is employed to fetch the data at device through the dataset pipeline, otherwise fetch the data at host by iterating through the dataset. Default: `True`.
- **sink_size** (*int*) –Control the amount of data in each sink. Must be -1 or positive. If sink_size=-1, sink the complete dataset for each epoch. If sink_size>0, sink sink_size data for each epoch. Default: `-1`.
- **epoch_num** (*int*) –The number of passes of the entire dataset to be sent. Default: `1`.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import nn
>>> from mindspore import dataset as ds
>>>
>>> data = {"x": np.float32(np.random.rand(64, 10)), "y": np.random.randint(0, 5, (64,))}
>>> train_dataset = ds.NumpySlicesDataset(data=data).batch(32)
>>> set_helper = ms.DatasetHelper(train_dataset, dataset_sink_mode=False)
>>>
>>> net = nn.Dense(10, 5)
>>> # Object of DatasetHelper is iterable
>>> for next_element in set_helper:
...     # `next_element` includes data and label, using data to run the net
...     data = next_element[0]
...     result = net(data)
```

continue_send()

Continue to send data to device at the beginning of epoch.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import nn
>>> from mindspore import dataset as ds
>>>
>>> data = {"x": np.float32(np.random.rand(64, 10)), "y": np.random.randint(0, 5, (64,))}
>>> train_dataset = ds.NumpySlicesDataset(data=data).batch(32)
>>> dataset_helper = ms.DatasetHelper(train_dataset, dataset_sink_mode=True)
>>> dataset_helper.continue_send()
```

release()
Free up resources about data sink.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import nn
>>> from mindspore import dataset as ds
>>>
>>> data = {"x": np.float32(np.random.rand(64, 10)), "y": np.random.randint(0, 5, (64,))}
>>> train_dataset = ds.NumpySlicesDataset(data=data).batch(32)
>>> dataset_helper = ms.DatasetHelper(train_dataset, dataset_sink_mode=True)
>>> dataset_helper.release()
```

sink_size()
Get sink_size for each iteration.

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>>
>>> # Define a dataset pipeline
>>> def generator():
...     for i in range(5):
...         yield (np.ones((32, 10)),)
>>>
>>> train_dataset = ms.dataset.GeneratorDataset(generator, ["data"])
>>> dataset_helper = ms.DatasetHelper(train_dataset, dataset_sink_mode=True, sink_size=-
 ↪1)
>>>
>>> # if sink_size==-1, then will return the full size of source dataset.
>>> sink_size = dataset_helper.sink_size()
```

stop_send()
Stop send data about data sink.

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> # Define a dataset pipeline
>>> def generator():
...     for i in range(5):
...         yield (np.ones((32, 10)),)
>>> train_dataset = ms.dataset.GeneratorDataset(generator, ["data"])
>>> dataset_helper = ms.DatasetHelper(train_dataset, dataset_sink_mode=True, sink_size=-
↪1)
>>> dataset_helper.stop_send()
```

types_shapes()
Get the types and shapes from dataset on the current configuration.

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>>
>>> # Define a dataset pipeline
>>> def generator():
...     for i in range(5):
...         yield (np.ones((32, 10)),)
>>>
>>> train_dataset = ms.dataset.GeneratorDataset(generator, ["data"])
>>> dataset_helper = ms.DatasetHelper(train_dataset, dataset_sink_mode=True)
>>>
>>> types, shapes = dataset_helper.types_shapes()
```

mindspore.Symbol

class mindspore.**Symbol**(*max=0*, *min=1*, *divisor=1*, *remainder=0*, *unique=False*, ***kawgs*)
Symbol is a data structure to indicate the symbolic info of shape.

For dynamic shape networks, compared with only setting the unknown dimensions (`None`) in *Tensor* , providing more symbolic shape info can help the framework better optimize the computation graph, to improve the performance of network execution.

Parameters

- **max** (*int*) −The maximum length of this dimension, which is valid when it's greater than *min*. Default: `0` .
- **min** (*int*) −The minimum length of this dimension. Default: `1` .
- **divisor** (*int*) −The divisor(d). When *remainder* is 0, it means this dimension can be divided by d . Default: `1` .
- **remainder** (*int*) −The remainder(r) when symbol is represented by $d * N + r, N \geq 1$. Default: `0` .
- **unique** (*bool*) −When the symbol object is used multiple times, if *unique* is `True` , the shape items of this symbol are considered to be same length, otherwise only symbol info is shared by multiple dimensions. Default: `False` .

Outputs:

Symbol.

Raises

- **TypeError** –If *max*, *min*, *divisor*, *remainder* is not an int.
- **TypeError** –If *unique* is not a bool.
- **ValueError** –If *min* is not positive value.
- **ValueError** –If *divisor* is not positive value.
- **ValueError** –If *remainder* is not in the range $[0, d)$.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import nn, Tensor, Symbol
>>>
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.abs = ms.ops.Abs()
...     def construct(self, x):
...         return self.abs(x)
...
>>> net = Net()
>>> s1 = Symbol(divisor=8, remainder=1)
>>> s2 = Symbol(max=32, unique=True)
>>> dyn_t = Tensor(shape=(None, s1, s1, s2, s2), dtype=ms.float32)
>>> net.set_inputs(dyn_t)
>>> # the shape values of last two dimensions must be equal, because "s2" is set to "unique"
>>> net(Tensor(np.random.randn(1, 9, 17, 32, 32), dtype=ms.float32)).shape
(1, 9, 17, 32, 32)
>>> net(Tensor(np.random.randn(8, 25, 9, 30, 30), dtype=ms.float32)).shape
(8, 25, 9, 30, 30)
```

mindspore.connect_network_with_dataset

mindspore.**connect_network_with_dataset**(*network*, *dataset_helper*)

Connect the *network* with dataset in *dataset_helper*. Only supported in sink mode, (dataset_sink_mode=True).

Parameters

- **network** (Cell) –The training network for dataset.
- **dataset_helper** (DatasetHelper) –A class to process the MindData dataset, it provides the type, shape and queue name of the dataset.

Returns

Cell, a new network containing the type, shape and queue name of the dataset info.

Raises

RuntimeError –If the API was not called in dataset sink mode.

Supported Platforms:

Ascend GPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import nn
>>> from mindspore import dataset as ds
>>>
>>> data = {"x": np.float32(np.random.rand(64, 10)), "y": np.random.randint(0, 5, (64,))}
>>> train_dataset = ds.NumpySlicesDataset(data=data).batch(32)
>>> dataset_helper = ms.DatasetHelper(train_dataset, dataset_sink_mode=True)
>>> net = nn.Dense(10, 5)
>>> net_with_dataset = ms.connect_network_with_dataset(net, dataset_helper)
```

mindspore.data_sink

mindspore.**data_sink**(*fn*, *dataset*, *sink_size=1*, *jit_config=None*, *input_signature=None*)

A wrapper function to generate a function for the input function.

Note: When using data sinking, the dataset will be automatically looped to the device. The device side can cache up to 100 batches of data and occupy no more than 2GB of memory. At this time, only the number of steps for each sinking *sink_size* needs to be considered. *sink_size* defaults to 1, indicating that each epoch only takes one batch of data from the cache for training and outputs a loss. If *sink_size* is greater than 1, each epoch takes out *sink_size* batches of data from the cache for training and outputs a loss.

Parameters

- **fn** (*Function*) –The Python function that will be run with dataset.
- **dataset** (*Dataset*) –The dataset iterator. The dataset can be generated by dataset generator API in mindspore.dataset, such as mindspore.dataset.ImageFolderDataset.
- **sink_size** (*int*) –Control the amount of data in each sink. *sink_size* must be positive integer. Default: 1 .
- **jit_config** (JitConfig) –Controls the execution mode(Graph mode/PyNative mode) of the generated function, and Jit config for compile. Default: None , means running in PyNative mode.
- **input_signature** (*Union[Tensor, List or Tuple of Tensors]*) –The Tensor which describes the input arguments. The shape and dtype of the Tensor will be supplied to this function. If input_signature is specified, each input to *fn* must be a *Tensor*. And the input parameters of *fn* cannot accept ***kwargs*. The shape and dtype of actual inputs should keep the same as *input_signature*. Otherwise, TypeError will be raised. Default: None .

Returns

Function, the generated function will be executed in data sinking mode.

Raises

ValueError –If *sink_size* is not positive integer.

Supported Platforms:

Ascend GPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import dataset as ds
>>>
>>> data = {"x": np.ones((1,), dtype=np.int32), "y": np.ones((1,), dtype=np.int32)}
>>> dataset = ds.NumpySlicesDataset(data=data)
>>>
>>> def func_net(x, y):
...     out = x + y
...     return out
>>>
>>> sink_process = ms.data_sink(func_net, dataset, sink_size=1)
>>> for _ in range(2):
...     out = sink_process()
...     print(out)
2
2
```

1.9.2 Debugging and Tuning

mindspore.profiler.profile	This class to enable the profiling of MindSpore neural networks.
mindspore.profiler._ExperimentalConfig	The purpose of this class is to configure scalable parameters when using profiles for model performance data acquisition.
mindspore.profiler.mstx	Mstx class provides profiling tools for marking and tracing on NPU.
mindspore.profiler.DynamicProfilerMonitor	This class to enable the dynamic profile monitoring of MindSpore neural networks.
mindspore.profiler.schedule	This class use to get the actions of each step.
mindspore.profiler.tensorboard_trace_handler	For each step in dynamic graph mode, call this method for online analyse.
mindspore.profiler.profiler.analyse	Analyze training performance data offline, which is invoked after performance data collection is completed.
mindspore.SummaryCollector	SummaryCollector can help you to collect some common information, such as loss, learning late, computational graph and so on.
mindspore.SummaryLandscape	SummaryLandscape can help you to collect loss landscape information.
mindspore.SummaryRecord	SummaryRecord is used to record the summary data and lineage data.
mindspore.set_dump	Enable or disable dump for the *target* and its contents.
mindspore.Profiler	The current interface is deprecated, please use: *mindspore.profiler.profile* instead.

mindspore.profiler.profile

class mindspore.profiler.**profile**(*activities: list = None*, *with_stack: bool = False*, *profile_memory: bool = False*, *data_process: bool = False*, *parallel_strategy: bool = False*, *start_profile: bool = True*, *hbm_ddr: bool = False*, *pcie: bool = False*, *sync_enable: bool = True*, *schedule: Schedule = None*, *on_trace_ready: Optional[Callable[..., Any]] = None*, *experimental_config: Optional[_ExperimentalConfig] = None*)

This class to enable the profiling of MindSpore neural networks. MindSpore users can import the mindspore.profiler.profile, initialize the profile object to start profiling, Use profile.start() to start the analysis, and use profile.stop() to stop collecting and analyzing the results. Users can visualize the results using the MindStudio Insight tool. Now, profile supports AICORE operator, AICPU operator, HostCPU operator, memory, correspondence, cluster, etc data analysis.

Parameters

- **start_profile** (*bool, optional*) –The start_profile parameter controls whether to enable or disable performance data collection based on conditions. Default: `True` .
- **activities** (*list, optional*) –The activities to collect. Default: `[ProfilerActivity.CPU, ProfilerActivity.NPU]`.
  - ProfilerActivity.CPU: Collect MindSpore framework data.
  - ProfilerActivity.NPU: Collect CANN software stack and NPU data.
  - ProfilerActivity.GPU: Collect GPU data.
- **schedule** (*schedule, optional*) –Sets the action strategy for the capture, defined by the schedule class, to be used with the step interface. Default: `None`. Performance data of all steps is collected. For details, see *mindspore.profiler.schedule* .
- **on_trace_ready** (*Callable, optional*) –Sets the callback function to be executed when the performance data is collected. Default: `None`. It indicates that only performance data is collected, but not resolved. For details, see *mindspore.profiler.tensorboard _trace_handler()* .
- **profile_memory** (*bool, optional*) –(Ascend only) Whether to collect tensor memory data, collect when `True` . When using this parameter, *activities* must set to `[ProfilerActivity.CPU, ProfilerActivity.NPU]`. Collecting operator memory data when the graph compilation level is O2 requires collecting from the first step. Default: `False` . The operator name currently collected by this parameter is incomplete. This issue will be resolved in later versions. It is recommended to use the environment variable `MS_ALLOC_CONF` instead.
- **with_stack** (*bool, optional*) –(Ascend only) Whether to collect frame host call stack data on the Python side. This data is presented in the form of a flame graph in the timeline. When using this parameter, *activities* must include `ProfilerActivity.CPU`. Default value: `False` .
- **hbm_ddr** (*bool, optional*) –(Ascend only) Whether to collect On-Chip Memory/DDR read and write rate data, collect when True. Default: `False` .
- **pcie** (*bool, optional*) –(Ascend only) Whether to collect PCIe bandwidth data, collect when True. Default: `False` .
- **data_process** (*bool, optional*) –(Ascend/GPU) Whether to collect data to prepare performance data. Default value: `False` .
- **parallel_strategy** (*bool, optional*) –(Ascend only) Whether to collect parallel policy performance data. Default value: `False` .
- **sync_enable** (*bool, optional*) –(GPU only) Whether the profiler collects operators in a synchronous way. Default: `True` .
  - True: The synchronous way. Before sending the operator to the GPU, the CPU records the start timestamp. Then the operator is returned to the CPU after execution, and the end timestamp is recorded, The duration of the operator is the difference between the two timestamps.

  - False: The asynchronous way. The duration of the operator is that of sending from the CPU to the GPU. This method can reduce the impact of adding profiler on overall training time.

- **experimental_config** (*_ExperimentalConfig, optional*) – expandable parameters can be configured in this configuration item. For details, see *mindspore.profiler._ExperimentalConfig*.

Raises

RuntimeError – When the version of CANN does not match the version of MindSpore, MindSpore cannot parse the generated ascend_job_id directory structure.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import nn, context
>>> import mindspore.dataset as ds
>>> from mindspore.profiler import ProfilerLevel, ProfilerActivity, AicoreMetrics, ExportType
>>>
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.fc = nn.Dense(2,2)
...     def construct(self, x):
...         return self.fc(x)
>>>
>>> def generator():
...     for i in range(2):
...         yield np.ones([2, 2]).astype(np.float32), np.ones([2]).astype(np.int32)
>>>
>>> def train(net):
...     optimizer = nn.Momentum(net.trainable_params(), 1, 0.9)
...     loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
...     data = ds.GeneratorDataset(generator, ["data", "label"])
...     model = mindspore.train.Model(net, loss, optimizer)
...     model.train(1, data)
>>>
>>> if __name__ == '__main__':
...     # If the device_target is GPU, set the device_target to "GPU"
...     context.set_context(mode=mindspore.GRAPH_MODE)
...     mindspore.set_device("Ascend")
...
...     # Init Profiler
...     experimental_config = mindspore.profiler._ExperimentalConfig(
...                                 profiler_level=ProfilerLevel.Level0,
...                                 aic_metrics=AicoreMetrics.AiCoreNone,
...                                 l2_cache=False,
...                                 mstx=False,
...                                 data_simplification=False,
...                                 export_type=[ExportType.Text])
...     steps = 10
...     net = Net()
...     # Note that the Profiler should be initialized before model.train
```

(continues on next page)

(continued from previous page)

```
...     with mindspore.profiler.profile(activities=[ProfilerActivity.CPU, ProfilerActivity.
↪NPU],
...                                     schedule=mindspore.profiler.schedule(wait=1,␣
↪warmup=1, active=2,
...                                          repeat=1, skip_first=2),
...                                     on_trace_ready=mindspore.profiler.
...                                          tensorboard_trace_handler("./data"),
...                                     profile_memory=False,
...                                     experimental_config=experimental_config) as prof:
...
...         # Train Model
...         for step in range(steps):
...             train(net)
...             prof.step()
```

add_metadata(*key: str*, *value: str*)

Report custom metadata key-value pair data.

Parameters

- **key** (*str*) –The key to the metadata.
- **value** (*str*) –The value to the metadata.

Examples

```
>>> import mindspore
>>> # Profiler init.
>>> with mindspore.profiler.profile() as prof:
...     # Call Profiler add_metadata
...     prof.add_metadata("test_key", "test_value")
```

add_metadata_json(*key: str*, *value: str*)

Report custom metadata key-value pair data with the value as a JSON string data.

Parameters

- **key** (*str*) –The key to the metadata.
- **value** (*str*) –The json str format value to the metadata.

Examples

```
>>> import json
>>> import mindspore
>>> # Profiler init.
>>> with mindspore.profiler.profile() as prof:
...     # Call Profiler add_metadata_json
...     prof.add_metadata_json("test_key", json.dumps({"key1": 1, "key2": 2}))
```

start()

Turn on profile data collection. profile can be turned on by condition.

Raises

- **RuntimeError** –If the profile has already started.

- **RuntimeError** – If the *start_profile* parameter is not set or is set to `True`.

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import nn, context
>>> import mindspore.dataset as ds
>>> from mindspore.profiler import ProfilerLevel, ProfilerActivity, AicoreMetrics,␣
↪ExportType
>>>
>>> class Net(nn.Cell):

...     optimizer = nn.Momentum(net.trainable_params(), 1, 0.9)
...     loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
...     data = ds.GeneratorDataset(generator, ["data", "label"])
...     model = mindspore.train.Model(net, loss, optimizer)
...     model.train(1, data)
>>>
>>> if __name__ == '__main__':
...     # If the device_target is GPU, set the device_target to "GPU"
...     context.set_context(mode=mindspore.GRAPH_MODE)
...     mindspore.set_device("Ascend")
...
...     # Init Profiler
...     experimental_config = mindspore.profiler._ExperimentalConfig(
...                                 profiler_level=ProfilerLevel.Level0,
...                                 aic_metrics=AicoreMetrics.AiCoreNone,
...                                 l2_cache=False,
...                                 mstx=False,
...                                 data_simplification=False,
...                                 export_type=[ExportType.Text])
...     steps = 10
...     net = Net()
...     # Note that the Profiler should be initialized before model.train
...     prof = mindspore.profiler.profile(activities=[ProfilerActivity.CPU,␣
↪ProfilerActivity.NPU],
...                                       schedule=mindspore.profiler.schedule(wait=1,␣
↪warmup=1, active=2,
...                                           repeat=1, skip_first=2),
...                                       on_trace_ready=mindspore.profiler.
...                                           tensorboard_trace_handler("./data"),
...                                       profile_memory=False,
...                                       experimental_config=experimental_config)
...     prof.start()
...     # Train Model
```

(continues on next page)

(continued from previous page)

```
...     for step in range(steps):
...         train(net)
...         prof.step()
...     prof.stop()
```

step()

Used for Ascend, distinguish step collection and parsing performance data through schedule and on_trace_ready.

Raises

- **RuntimeError** – If the *start_profile* parameter is not set or the Profiler is not started.
- **RuntimeError** – If the *schedule* parameter is not set.

Examples: >>> import numpy as np >>> import mindspore >>> from mindspore import nn, context >>> import mindspore.dataset as ds >>> from mindspore.profiler import ProfilerLevel, ProfilerActivity, AicoreMetrics, ExportType >>> >>> class Net(nn.Cell): ···def __init__(self): ···super(Net, self).__init__() ···self.fc = nn.Dense(2,2) ···def construct(self, x): ···return self.fc(x) >>> >>> def generator(): ···for i in range(2): ···yield np.ones([2, 2]).astype(np.float32), np.ones([2]).astype(np.int32) >>> >>> def train(net): ···optimizer = nn.Momentum(net.trainable_params(), 1, 0.9) ··· loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True) ···data = ds.GeneratorDataset(generator, ["data", "label"]) ··· model = mindspore.train.Model(net, loss, optimizer) ···model.train(1, data) >>> >>> if __name__ == '__main__': ···# If the device_target is GPU, set the device_target to "GPU" ···context.set_context(mode=mindspore.GRAPH_MODE) ···mindspore.set_device("Ascend") ·····# Init Profiler ···experimental_config = mindspore.profiler._ExperimentalConfig(···profiler_level=ProfilerLevel.Level0, ···aic_metrics=AicoreMetrics.AiCoreNone, ···l2_cache=False, ···mstx=False, ···data_simplification=False, ···export_type=[ExportType.Text]) ···steps = 10 ···net = Net() ···# Note that the Profiler should be initialized before model.train ···with mindspore.profiler.profile(activities=[ProfilerActivity.CPU, ProfilerActivity.NPU], ···schedule=mindspore.profiler.schedule(wait=1, warmup=1, active=2, ···repeat=1, skip_first=2), ···on_trace_ready=mindspore.profiler.tensorboard_trace_handler("./data"), ···profile_memory=False, ···experimental_config=experimental_config) as prof: ·····# Train Model ···for step in range(steps): ···train(net) ···prof.step()

stop()

Turn off profile data collection. profile can be turned off by condition.

Raises

RuntimeError – If the profile has not started, this function is disabled.

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import nn, context
>>> import mindspore.dataset as ds
>>> from mindspore.profiler import ProfilerLevel, ProfilerActivity, AicoreMetrics,␣
↪ExportType

mindspore.profiler._ExperimentalConfig

class mindspore.profiler.**_ExperimentalConfig**(*profiler_level: ProfilerLevel = ProfilerLevel.Level0*, *aic_metrics: AicoreMetrics = AicoreMetrics.AiCoreNone*, *l2_cache: bool = False*, *mstx: bool = False*, *data_simplification: bool = True*, *export_type: list = None*)

The purpose of this class is to configure scalable parameters when using profiles for model performance data acquisition.

Parameters

- **profiler_level** (*ProfilerLevel, optional*) –(Ascend only) The level of profiling. Default: `ProfilerLevel.Level0`.
  - ProfilerLevel.LevelNone: This setting takes effect only when mstx is enabled, indicating that no operator data is collected on the device side.

  - ProfilerLevel.Level0: Leanest level of profiling data collection, collects information about the elapsed time of the computational operators on the NPU and communication large operator information.
  - ProfilerLevel.Level1: Collect more CANN layer AscendCL data and AICore performance metrics and communication mini operator information based on Level0.
  - ProfilerLevel.Level2: Collect GE and Runtime information in CANN layer on top of Level1

- **aic_metrics** (*AicoreMetrics, optional*) –(Ascend only) Types of AICORE performance data collected, when using this parameter, *activities* must include `ProfilerActivity.NPU` , and the value must be a member of AicoreMetrics. When profiler_level is Level0, the default value is `AicoreMetrics.AiCoreNone`; Profiler_level is a Level1 or Level2 stores, the default value is: `AicoreMetrics. PipeUtilization`.The data items contained in each metric are as follows:
  - AicoreMetrics.AiCoreNone: Does not collect AICORE data.
  - AicoreMetrics.ArithmeticUtilization: ArithmeticUtilization contains mac_fp16/int8_ratio, vec_fp32/fp16/int32_ratio, vec_misc_ratio etc.
  - AicoreMetrics.PipeUtilization: PipeUtilization contains vec_ratio, mac_ratio, scalar_ratio, mte1/mte2/mte3_ratio, icache_miss_rate etc.
  - AicoreMetrics.Memory: Memory contains ub_read/write_bw, l1_read/write_bw, l2_read/write_bw, main_mem_read/write_bw etc.
  - AicoreMetrics.MemoryL0: MemoryL0 contains l0a_read/write_bw, l0b_read/write_bw, l0c_read/write_bw etc.
  - AicoreMetrics.ResourceConflictRatio: ResourceConflictRatio contains vec_bankgroup/bank/resc_cflt_ratio etc.
  - AicoreMetrics.MemoryUB: MemoryUB contains ub_read/write_bw_mte, ub_read/write_bw_vector, ub_read/write_bw_scalar etc.
  - AicoreMetrics.L2Cache: L2Cache contains write_cache_hit, write_cache_miss_allocate, r0_read_cache_hit, r1_read_cache_hit etc. This function only supports Atlas A2 training series products.
  - AicoreMetrics.MemoryAccess: Statistics on storage access bandwidth and storage capacity of main storage and l2 cache etc.
- **l2_cache** (*bool, optional*) –(Ascend only) Whether to collect l2 cache data, collect when True. Default: `False` . The l2_cache.csv file is generated in the ASCEND_PROFILER_OUTPUT folder.In O2 mode, only wait and skip_first parameters in schedule configuration can be set to 0.
- **mstx** (*bool, optional*) –(Ascend only) Whether to collect light weight profiling data, collect when True. Default: `False` .
- **data_simplification** (*bool, optional*) –(Ascend only) Whether to remove FRAMEWORK data and other redundant data. If set to True, only the profiler deliverables and raw performance data under the PROF_XXX directory are kept to save space. Default value: `True` .
- **export_type** (*list, optional*) –(Ascend only) The data type to export. The db and text formats can be exported at the same time. The default value is `None`, indicating that data of the text type is exported.
  - ExportType.Text: Export text type data.
  - ExportType.Db: Export db type data.

Raises

RuntimeError –When the version of CANN does not match the version of MindSpore, MindSpore cannot parse the generated ascend_job_id directory structure.

Supported Platforms:

`Ascend` `GPU`

```

mindspore.profiler.mstx

class mindspore.profiler.**mstx**

Mstx class provides profiling tools for marking and tracing on NPU. This class provides three static methods: mark, range_start and range_end for adding marker points and ranges in profiling.

static mark (*message: str*, *stream:* mindspore.runtime.Stream = *None*)

Add a marker point in profiling.

Parameters

- **message** (*str*) – Description for the marker.
- **stream** (*Stream*, optional) – NPU stream for async execution, expected type: mindspore.runtime.Stream. Default: None, which means only marking on host side without marking on device stream.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore
>>> from mindspore import nn
>>> import mindspore.dataset as ds
>>> from mindspore import Profiler
>>> from mindspore.profiler import ProfilerLevel, ProfilerActivity, schedule,␣
↪tensorboard_trace_handler
>>> from mindspore.profiler import mstx
>>>
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.fc = nn.Dense(2,2)
...     def construct(self, x):
...         return self.fc(x)
>>>
>>> def generator():
...     for i in range(2):
...         yield (np.ones([2, 2]).astype(np.float32), np.ones([2]).astype(np.int32))
>>>
>>> def train(net):
...     stream = ms.runtime.current_stream()
...     optimizer = nn.Momentum(net.trainable_params(), 1, 0.9)
...     loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
...     data = ds.GeneratorDataset(generator, ["data", "label"])
...     model = ms.train.Model(net, loss, optimizer)
...     # Add marker before training
...     mstx.mark("train start", stream)
...     model.train(1, data)
...     # Add marker after training
...     mstx.mark("train end", stream)
>>>
>>> if __name__ == '__main__':
...     # Note: mstx only supports Ascend device and cannot be used in mindspore.nn.Cell.
↪construct
...     # when in mindspore.GRAPH_MODE
...     ms.set_context(mode=ms.PYNATIVE_MODE)
...     ms.set_device(device_target="Ascend", device_id=0)
```

(continues on next page)

(continued from previous page)

```
...     # Init Profiler
...     experimental_config = mindspore.profiler._ExperimentalConfig(
...                               profiler_level=ProfilerLevel.LevelNone,
...                               mstx=True)
...     # Note that the Profiler should be initialized before model.train
...     with mindspore.profiler.profile(
...         activities=[ProfilerActivity.CPU, ProfilerActivity.NPU],
...         schedule=schedule(wait=0, warmup=0, active=3, repeat=1, skip_first=0),
...         on_trace_ready=mindspore.profiler.tensorboard_trace_handler("./data"),
...         experimental_config=experimental_config

...         for i in range(5):
...             train(net)
...             profiler.step()
```

static range_end(*range_id: int*)

End a profiling range.

Parameters

range_id (*int*) –Range ID from range_start.

Examples

```
>>> # Please refer to the example in range_start
>>> # range_id = mstx.range_start("training process", stream)
>>> # model.train(1, data)
>>> # mstx.range_end(range_id)
```

static range_start(*message: str*, *stream:* mindspore.runtime.Stream = *None*)

Start a profiling range.

Parameters

- **message** (*str*) –Description for the range.
- **stream** (*Stream*, optional) –NPU stream for async execution, expected type: mindspore.runtime.Stream. Default: `None`, which means only starting mstx range on host side without starting on device stream.

Returns

int, range ID for range_end.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore
>>> from mindspore import nn
>>> import mindspore.dataset as ds
>>> from mindspore import Profiler
>>> from mindspore.profiler import ProfilerLevel, ProfilerActivity, schedule,␣

```

mindspore.profiler.DynamicProfilerMonitor

class mindspore.profiler.**DynamicProfilerMonitor**(*cfg_path*, *output_path='./dyn_profile_data'*, *poll_interval=2*, ***kwargs*)

This class to enable the dynamic profile monitoring of MindSpore neural networks.

Parameters

- **cfg_path** (*str*) –(Ascend only) Dynamic profile json config file directory. The requirement is a shared path that can be accessed by all nodes. The parameters of the json configuration file are as follows:
  - start_step (int, required) - Sets the step number at which the Profiler starts collecting data. It is a relative value,

with the first step of training being 1. The default value is -1, indicating that data collection will not start during the entire training process.

- stop_step (int, required) - Sets the step number at which the Profiler stops collecting data. It is a relative value, with the first step of training being 1. The stop_step must be greater than or equal to start_step. The default value is -1, indicating that data collection will not start during the entire training process.
- aic_metrics (int, optional) - The range of values corresponds to the Profiler. The default value -1 indicates that AI Core utilization is not collected, and 0 indicates PipeUtilization, 1 indicates ArithmeticUtilization, 2 stands for Memory, 3 stands for MemoryL0, 4 stands for MemoryUB, 5 indicates ResourceConflictRatio, 6 indicates L2Cache, 7 indicates MemoryAccess.
- profiler_level (int, optional) - Sets the level of performance data collection, where -1 represents ProfilerLevel.LevelNone, 0 represents ProfilerLevel.Level0, 1 represents ProfilerLevel.Level1, and 2 represents ProfilerLevel.Level2. The default value is 0, indicating the ProfilerLevel.Level0 collection level.
- activities (int, optional) - Sets the devices for performance data collection, where 0 represents CPU+NPU, 1 represents CPU, and 2 represents NPU. The default value is 0, indicating the collection of CPU+NPU performance data.
- export_type (int, optional) - Sets the data type to export, where 0 represents text, 1 represents db, and 2 represents text and db. The default value is 0, indicating only export text type data.
- profile_memory (bool, optional) - Set whether to collect memory performance data, true indicates that memory performance data is collected, false indicates that memory performance data is not collected. The default value is false, indicating that memory performance data is not collected.
- mstx (bool, optional) - Set whether to enable mstx, true indicates that mstx is enabled, false indicates that mstx is disabled. The default value is false, indicating that mstx is not enabled.
- analyse_mode (int, optional) - Sets the mode for online analysis, corresponding to the analyse_mode parameter of the mindspore.Profiler.analyse interface, where 0 represents "sync" and 1 represents "async". The default value is -1, indicating that online analysis is not used.
- parallel_strategy (bool, optional) - Sets whether to collect parallel strategy performance data, where true means to collect and false means not to collect. The default value is false, indicating that parallel strategy performance data is not collected.
- with_stack (bool, optional) - Sets whether to collect call stack information, where true means to collect and false means not to collect. The default value is false, indicating that call stack information is not collected.
- data_simplification (bool, optional) - Sets whether to enable data simplification, where true means to enable and false means not to enable. The default value is true, indicating that data simplification is enabled.

- **output_path** (*str, optional*) –(Ascend only) Output data path. Default: `"./dyn_profile_data"` .
- **poll_interval** (*int, optional*) –(Ascend only) The polling period of the monitoring process, in seconds. Default value: `2`.

Raises

RuntimeError –When create shared memory times exceeds max times.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import nn
>>> import mindspore.dataset as ds
>>> from mindspore.profiler import DynamicProfilerMonitor
>>>
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.fc = nn.Dense(2,2)
...     def construct(self, x):
...         return self.fc(x)
>>>
>>> def generator():
...     for i in range(2):
...         yield (np.ones([2, 2]).astype(np.float32), np.ones([2]).astype(np.int32))
>>>
>>> def train(net):
...     optimizer = nn.Momentum(net.trainable_params(), 1, 0.9)
...     loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
...     data = ds.GeneratorDataset(generator, ["data", "label"])
...     dynprof_cb = DynamicProfilerMonitor(cfg_path="./dyn_cfg", output_path="./dyn_prof_
↪data")
...     model = ms.train.Model(net, loss, optimizer)
...     # register DynamicProfilerMonitor to model.train()
...     model.train(10, data, callbacks=[dynprof_cb])
```

step()

Used for Ascend, distinguish step collection and parsing performance data by dynamic profiler.

Raises

RuntimeError – If the 'start_step' parameter setting is greater than the 'stop_step' parameter setting.

Examples

```
>>> import json
>>> import os
>>> import numpy as np
>>>
>>> import mindspore
>>> import mindspore.dataset as ds
>>> from mindspore import context, nn
>>> from mindspore.profiler import DynamicProfilerMonitor
>>>
>>>

(continued from previous page)

```
...             # Modify parameters in the JSON file
...             change_cfg_json(os.path.join(output_path, "profiler_config.json"))
...         # Call step collection
...         dp.step()
```

mindspore.profiler.schedule

class mindspore.profiler.**schedule**(*, *wait: int*, *active: int*, *warmup: int = 0*, *repeat: int = 0*, *skip_first: int = 0*)

This class use to get the actions of each step. The schedule is as follows:

```
(NONE)         (NONE)           (NONE)        (WARM_UP)        (RECORD)       (RECORD)     ␣
↪(RECORD_AND_SAVE)     None
START-------->skip_first------->wait--------->warmup-------->active........active.........
↪active----------->stop
                               |                                                           |
                               |                            repeat_1                       |
                               -------------------------------------------------------------
```

The profiler will skip the first `skip_first` steps, then wait for `wait` steps, then do the warmup for the next `warmup` steps, then do the active recording for the next `active` steps and then repeat the cycle starting with `wait` steps. The optional number of cycles is specified with the `repeat` parameter, the zero value means that the cycles will continue until the profiling is finished.

Keyword Arguments

- **wait** (`int`) – The number of steps to wait before starting the warm-up phase. must be greater than or equal to 0. If the wait parameter is not set externally, it is set to `0` when the schedule class is initialized.
- **active** (`int`) – The number of steps to record data during the active phase. must be greater than or equal to 1. If the active parameter is not set externally, it is set to `1` when the schedule class is initialized.
- **warmup** (`int, optional`) – The number of steps to perform the warm-up phase. must be greater than or equal to 0. Default value: `0`.
- **repeat** (`int, optional`) – The number of times to repeat the cycle. If repeat is set to 0, the Profiler will determine the repeat value based on the number of times the model is trained, which will generate one more performance data with incomplete collection. The data in the last step is abnormal data that users do not need to pay attention to. Default value: `0`.
- **skip_first** (`int, optional`) – The number of steps to skip at the beginning. Must be greater than or equal to 0. Default value: `0`

Raises

ValueError – When the parameter step is less than 0.

Supported Platforms:

`Ascend`

Examples

```

↪handler("./data"),
...                                     profile_memory=False,
...                                     experimental_config=experimental_config) as prof:
...
...         # Train Model
...         for step in range(steps):
...             train(net)
...             prof.step()
```

to_dict()
Convert schedule to a dict.

Returns

dict, the parameters of schedule and their values.

mindspore.profiler.tensorboard_trace_handler

mindspore.profiler.**tensorboard_trace_handler**(*dir_name: str = None*, *worker_name: str = None*, *analyse_flag: bool = True*, *async_mode: bool = False*)

For each step in dynamic graph mode, call this method for online analyse.

Parameters

- **dir_name** (*str, optional*) –Specifies the directory path to save the analysis results. The default is `None`. The default save path is `"./data"`.
- **worker_name** (*str, optional*) –Specifies the system version name. The default is `None`. The default project thread name is `"Name of the current operating system + process ID"`.
- **analyse_flag** (*bool, optional*) –Whether to enable online analysis. The default value is `True`. Indicates online analysis.
- **async_mode** (*bool, optional*) –Whether to use asynchronous parsing mode. The default value is `False`. Indicates the use of synchronous parsing mode.

Examples

```
>>> import numpy as np
>>> import mindspore
>>> import mindspore.dataset as ds
>>> from mindspore import context, nn
>>> from mindspore.profiler import ProfilerLevel, AicoreMetrics, ExportType, ProfilerActivity
>>>
>>> class Net(nn.Cell):
...     def __init__(self):

```

mindspore.profiler.profiler.analyse

mindspore.profiler.profiler.**analyse**(*profiler_path: str*, *max_process_number: int = os.cpu_count() // 2*, *pretty=False*, *step_list=None*, *data_simplification=True*)

Analyze training performance data offline, which is invoked after performance data collection is completed.

Parameters

- **profiler_path** (*str*) –The path to profiling data that needs to be analyzed offline, specified to the upper directory `*_ascend_ms`.
- **max_process_number** (*int, optional*) –Maximum number of processes. The default value is `os.cpu_count() // 2`.
- **pretty** (*bool, optional*) –Format the JSON file. Default: `False`, indicating that the formatting is not performed.
- **step_list** (*list, optional*) –Only the performance data of the specified step is parsed. The specified step must be a consecutive integer. It supports CallBack collection only in GRAPH mode, and can only slice the CANN layer and the following information. Default value: `None`, that is, full resolution.
- **data_simplification** (*bool, optional*) –Whether to enable data simplification. Default: `True`, indicating the data simplification is enabled.

Examples

```
>>> from mindspore.profiler.profiler import analyse
>>> analyse(profiler_path="./profiling_path")
```

mindspore.SummaryCollector

class mindspore.**SummaryCollector**(*summary_dir*, *collect_freq=10*, *num_process=32*, *collect_specified_data=None*, *keep_default_action=True*, *custom_lineage_data=None*, *collect_tensor_freq=None*, *max_file_size=None*, *export_options=None*)

SummaryCollector can help you to collect some common information, such as loss, learning late, computational graph and so on.

SummaryCollector also enables the summary operator to collect data to summary files.

Note:

1. Multiple SummaryCollector instances in callback list are not allowed.
2. Not all information is collected at the training phase or at the eval phase.
3. SummaryCollector always record the data collected by the summary operator.
4. SummaryCollector only supports Linux systems.
5. The Summary is not supported when compile source with *-s on* option.

Parameters

- **summary_dir** (*str*) –The collected data will be persisted to this directory. If the directory does not exist, it will be created automatically.
- **collect_freq** (*int*) –Set the frequency of data collection, it should be greater than zero, and the unit is *step*. If a frequency is set, we will collect data when (current steps % freq) equals to 0, and the first step will be collected at any time. It is important to note that if the data sink mode is used, the unit will become the *epoch*. It is not recommended to collect data too frequently, which can affect performance. Default: `10` .
- **num_process** (*int*) –Number of processes saving summary data. The more processes there are, the better the performance, but there may be host memory overflow issues. Default: `32` .
- **collect_specified_data** (*Union[None, dict]*) –Perform custom operations on the collected data. By default, if set to None, all data is collected as the default behavior. You can customize the collected data with a dictionary. For example, you can set {'collect_metric': False} to control not collecting metrics. The data that supports control is shown below. Default: `None` .
  - collect_metric (bool): Whether to collect training metrics, currently only the loss is collected. The first output will be treated as the loss and it will be averaged. Default: `True` .
  - collect_graph (bool): Whether to collect the computational graph. Currently, only training computational graph is collected. Default: `True` .
  - collect_train_lineage (bool): Whether to collect lineage data for the training phase. Default: `True` .
  - collect_eval_lineage (bool): Whether to collect lineage data for the evaluation phase. Default: `True` .
  - collect_input_data (bool): Whether to collect dataset for each training. Currently only image data is supported. If there are multiple columns of data in the dataset, the first column should be image data. Default: `True` .
  - collect_dataset_graph (bool): Whether to collect dataset graph for the training phase. Default: `True` .

- histogram_regular (Union[str, None]): Collect weight and bias for parameter distribution page. This field allows regular strings to control which parameters to collect. It is not recommended to collect too many parameters at once, as it can affect performance. Note that if you collect too many parameters and run out of memory, the training will fail. Default: `None` , it means only the first five parameters are collected.
- collect_landscape (Union[dict,None]): Whether to collect the parameters needed to create the loss landscape. If set to None, collect_landscape parameters will not be collected. All parameter information is collected by default and stored in file *{summary_dir}/ckpt_dir/train_metadata.json*.
  - landscape_size (int): Specify the image resolution of the generated loss landscape. For example, if it is set to `128` , the resolution of the landscape is 128 * 128. The calculation time increases with the increase of resolution. Default: `40` . Optional values: between 3 and 256.
  - unit (str): Specify the interval strength of the training process. Default: `"step"` . Optional: epoch/step.
  - create_landscape (dict): Select how to create loss landscape. Training process loss landscape(train) and training result loss landscape(result). Default: `{"train": True, "result": True}`. Optional: `True` / `False` .
  - num_samples (int): The size of the dataset used to create the loss landscape. For example, in image dataset, You can set num_samples is 128, which means that 128 images are used to create loss landscape. Default: `128` .
  - intervals (List[List[int]]): Specifies the interval in which the loss landscape. For example: If the user wants to create loss landscape of two training processes, they are 1-5 epoch and 6-10 epoch respectively. They anc set [[1, 2, 3, 4, 5], [6, 7, 8, 9, 10]]. Note: Each interval have at least three epochs.

- **keep_default_action** (*bool*) – This field affects the collection behavior of the 'collect_specified_data' field. True: it means that after specified data is set, non-specified data is collected as the default behavior. False: it means that after specified data is set, only the specified data is collected, and the others are not collected. Default: `True` .
- **custom_lineage_data** (*Union[dict, None]*) – Allows you to customize the data. In the custom data, the type of the key supports str, and the type of value supports str, int and float. Default: `None` , it means there is no custom data.
- **collect_tensor_freq** (*Optional[int]*) – The same semantics as the *collect_freq*, but controls TensorSummary only. Because TensorSummary data is too large to be compared with other summary data, this parameter is used to reduce its collection. By default, The maximum number of steps for collecting TensorSummary data is 20, but it will not exceed the number of steps for collecting other summary data. For example, given *collect_freq=10*, when the total steps is 600, TensorSummary will be collected 20 steps, while other summary data 61 steps, but when the total steps is 20, both TensorSummary and other summary will be collected 3 steps. Also note that when in parallel mode, the total steps will be split evenly, which will affect the number of steps TensorSummary will be collected. Default: `None` , which means to follow the behavior as described above.
- **max_file_size** (*Optional[int]*) – The maximum size in bytes of each file that can be written to the disk. For example, to write not larger than 4GB, specify *max_file_size=4*1024*3*. Default: `None` , which means no limit.
- **export_options** (*Union[None, dict]*) – Perform custom operations on the export data. Note that the size of export files is not limited by the max_file_size. You can customize the export data with a dictionary. For example, you can set {'tensor_format': 'npy'} to export tensor as npy file. The data that supports control is shown below. Default: `None` , it means that the data is not exported.
  - tensor_format (Union[str, None]): Customize the export tensor format. Supports ["npy", None]. Default: `None` , it means that the tensor is not exported.
    - npy: export tensor as npy file.

Raises

ValueError – The Summary is not supported, please without *-s on* and recompile source.

```

mindspore.SummaryLandscape

class mindspore.**SummaryLandscape**(*summary_dir*)

SummaryLandscape can help you to collect loss landscape information. It can create landscape in PCA direction or random direction by calculating loss.

Note: SummaryLandscape only supports Linux systems.

Parameters

summary_dir (*str*) – The path of summary is used to save the model weight, metadata and other data required to create landscape.

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> from mindspore.train import Model, Accuracy, Loss
>>> from mindspore import SummaryCollector, SummaryLandscape
>>>
>>> if __name__ == '__main__':
...     # If the device_target is Ascend, set the device_target to "Ascend"
...     ms.set_context(mode=ms.GRAPH_MODE, device_target="GPU")

...                                                                                                 ␣
↪  "result":False},
...                                                                                  "num_samples":␣
↪2048,
...                                                                                  "intervals":␣
↪[interval_1]},
...                                                                 device_ids=[1])
```

clean_ckpt()
Clean the checkpoint.

gen_landscapes_with_multi_process(*callback_fn*, *collect_landscape=None*, *device_ids=None*, *output=None*)
Use the multi process to generate landscape.

Parameters

- **callback_fn** (*python function*) –A python function object. User needs to write a function, it has no input, and the return requirements are as follows.
  - mindspore.train.Model: User's model object.
  - mindspore.nn.Cell: User's network object.
  - mindspore.dataset: User's dataset object for create loss landscape.
  - mindspore.train.Metrics: User's metrics object.
- **collect_landscape** (*Union[dict, None]*) –The meaning of the parameters when creating loss landscape is consistent with the fields with the same name in SummaryCollector. The purpose of setting here is to allow users to freely modify creating parameters. Default: `None` .
  - landscape_size (int): Specify the image resolution of the generated loss landscape. For example, if it is set to `128` , the resolution of the landscape is 128 * 128. The calculation time increases with the increase of resolution. Default: `40` . Optional values: between 3 and 256.
  - create_landscape (dict): Select how to create loss landscape. Training process loss landscape(train) and training result loss landscape(result). Default: `{"train": True, "result": True}`. Optional: `True` / `False` .
  - num_samples (int): The size of the dataset used to create the loss landscape. For example, in image dataset, You can set num_samples is 2048, which means that 2048 images are used to create loss landscape. Default: `2048` .
  - intervals (List[List[int]]): Specifies the interval in which the loss landscape. For example: If the user wants to create loss landscape of two training processes, they are 1-5 epoch and 6-10 epoch respectively. They can set [[1, 2, 3, 4, 5], [6, 7, 8, 9, 10]]. Note: Each interval have at least three epochs.
- **device_ids** (*List(int)*) –Specifies which devices are used to create loss landscape. For example: [0, 1] refers to creating loss landscape with device 0 and device 1. Default: `None` .
- **output** (*str*) –Specifies the path to save the loss landscape. Default: `None` . The default save path is the same as the summary file.

mindspore.SummaryRecord

class mindspore.**SummaryRecord**(*log_dir*, *file_prefix='events'*, *file_suffix='_MS'*, *num_process=32*, *network=None*, *max_file_size=None*, *raise_exception=False*, *export_options=None*)

SummaryRecord is used to record the summary data and lineage data.

The API will create a summary file and lineage files lazily in a given directory and writes data to them. It writes the data to files by executing the *record* method. In addition to recording the data bubbled up from the network by defining the summary operators, SummaryRecord also supports to record extra data which can be added by calling add_value.

Note:

1. Make sure to close the SummaryRecord at the end, otherwise the process will not exit. Please see the Example section below to learn how to close properly in two ways.
2. Only one SummaryRecord instance is allowed at a time, otherwise it will cause data writing problems.
3. SummaryRecord only supports Linux systems.
4. The Summary is not supported when compile source with *-s on* option.

Parameters

- **log_dir** (*str*) –The log_dir is a directory location to save the summary.
- **file_prefix** (*str*) –The prefix of file. Default: `"events"` .
- **file_suffix** (*str*) –The suffix of file. Default: `"_MS"` .
- **num_process** (*int*) –Number of processes saving summary data. The more processes there are, the better the performance, but there may be host memory overflow issues. Default: `32` .
- **network** (`Cell`) –Obtain a pipeline through network for saving graph summary. Default: `None` .
- **max_file_size** (*int, optional*) –The maximum size of each file that can be written to disk (in bytes). For example, to write not larger than 4GB, specify *max_file_size=4*1024**3*. Default: `None` , which means no limit.
- **raise_exception** (*bool, optional*) –Sets whether to throw an exception when a RuntimeError or OSError exception occurs in recording data. Default: `False` , this means that error logs are printed and no exception is thrown.
- **export_options** (*Union[None, dict]*) –Perform custom operations on the export data. Note that the size of export files is not limited by the max_file_size. You can customize the export data with a dictionary. For example, you can set {'tensor_format': 'npy'} to export tensor as npy file. The data that supports control is shown below. Default: `None` , it means that the data is not exported.
  - tensor_format (Union[str, None]): Customize the export tensor format. Supports ["npy", None]. Default: `None` , it means that the tensor is not exported.
    - npy: export tensor as npy file.

Raises

- **TypeError** –*max_file_size* is not int or *file_prefix* and *file_suffix* is not string.
- **ValueError** –The Summary is not supported, please without *-s on* and recompile source.

Examples

```
>>> import mindspore as ms
>>> if __name__ == '__main__':
...     # use in with statement to auto close
...     with ms.SummaryRecord(log_dir="./summary_dir") as summary_record:
...         pass
...
...     # use in try .. finally .. to ensure closing
...     try:
...         summary_record = ms.SummaryRecord(log_dir="./summary_dir")
...     finally:
...         summary_record.close()
```

add_value (*plugin*, *name*, *value*)

Add value to be recorded later.

Parameters

- **plugin** (*str*) – The plugin of the value.
  - graph: the value is a computational graph.
  - scalar: the value is a scalar.
  - image: the value is an image.
  - tensor: the value is a tensor.
  - histogram: the value is a histogram.
  - train_lineage: the value is a lineage data for the training phase.
  - eval_lineage: the value is a lineage data for the evaluation phase.
  - dataset_graph: the value is a dataset graph.
  - custom_lineage_data: the value is a customized lineage data.
  - LANDSCAPE: the value is a landscape.
- **name** (*str*) – The value of the name.
- **value** (*Union[Tensor, GraphProto, TrainLineage, EvaluationLineage, DatasetGraph, UserDefinedInfo, LossLandscape]*) – The value to store.
  - The data type of value should be 'GraphProto' (see mindspore/ccsrc/anf_ir.proto) object when the plugin is 'graph'.
  - The data type of value should be 'Tensor' object when the plugin is 'scalar', 'image', 'tensor' or 'histogram'.
  - The data type of value should be a 'TrainLineage' object when the plugin is 'train_lineage', see mindspore/ccsrc/lineage.proto.
  - The data type of value should be a 'EvaluationLineage' object when the plugin is 'eval_lineage', see mindspore/ccsrc/lineage.proto.
  - The data type of value should be a 'DatasetGraph' object when the plugin is 'dataset_graph', see mindspore/ccsrc/lineage.proto.
  - The data type of value should be a 'UserDefinedInfo' object when the plugin is 'custom_lineage_data', see mindspore/ccsrc/lineage.proto.
  - The data type of value should be a 'LossLandscape' object when the plugin is 'LANDSCAPE', see mindspore/ccsrc/summary.proto.

Raises

- **ValueError** – *plugin* is not in the optional value.
- **TypeError** – *name* is not non-empty string, or the data type of value is not 'Tensor' object when the plugin is 'scalar', 'image', 'tensor' or 'histogram'.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> if __name__ == '__main__':
...     with ms.SummaryRecord(log_dir="./summary_dir", file_prefix="xx_", file_suffix="_
↪yy") \
...             as summary_record:
...         summary_record.add_value('scalar', 'loss', Tensor(0.1))
```

close()

Flush the buffer and write files to disk and close summary records. Please use the statement to autoclose.

Examples

```
>>> import mindspore as ms
>>> if __name__ == '__main__':
...     try:
...         summary_record = ms.SummaryRecord(log_dir="./summary_dir")
...     finally:
...         summary_record.close()
```

flush()

Flush the buffer and write buffer data to disk.

Call it to make sure that all pending events have been written to disk.

Examples

```
>>> import mindspore as ms
>>> if __name__ == '__main__':
...     with ms.SummaryRecord(log_dir="./summary_dir", file_prefix="xx_", file_suffix="_
↪yy") \
...             as summary_record:
...         summary_record.flush()
```

property log_dir

Get the full path of the log file.

Returns

str, the full path of log file.

Examples

```
>>> import mindspore as ms
>>> if __name__ == '__main__':
...     with ms.SummaryRecord(log_dir="./summary_dir", file_prefix="xx_", file_suffix="_
↪yy") \
...             as summary_record:
...         log_dir = summary_record.log_dir
```

record(*step*, *train_network=None*, *plugin_filter=None*)

Record the summary.

Parameters

- **step** (*int*) –Represents training step number.
- **train_network** (Cell) –The spare network for saving graph. Default: None, it means just do not save the graph summary when the original network graph is None.
- **plugin_filter** (*Callable[[str], bool], optional*) –The filter function, which is used to filter out which plugin should be written. Default: None.

Returns

bool, whether the record process is successful or not.

Raises

TypeError –*step* is not int, or *train_network* is not *mindspore.nn.Cell*.

Examples

```
>>> import mindspore as ms
>>> if __name__ == '__main__':
...     with ms.SummaryRecord(log_dir="./summary_dir", file_prefix="xx_", file_suffix="_
↪yy") \
...             as summary_record:
...         result = summary_record.record(step=2)
```

set_mode(*mode*)

Set the model running phase. Different phases affect data recording.

Parameters

mode (*str*) –The mode to be set, which should be 'train' or 'eval'. When the mode is 'eval', summary_record will not record the data of summary operators.

- train: the model running phase is train mode.
- eval: the model running phase is eval mode, When the mode is 'eval', summary_record will not record the data of summary operators.

Raises

ValueError –*mode* is not in the optional value.

Examples

```
>>> import mindspore as ms
>>> if __name__ == '__main__':
...     with ms.SummaryRecord(log_dir="./summary_dir", file_prefix="xx_", file_suffix="_
↪yy") \
...             as summary_record:
...         summary_record.set_mode('eval')
```

mindspore.set_dump

mindspore.**set_dump**(*target*, *enabled=True*)

Enable or disable dump for the *target* and its contents.

target should be an instance of *mindspore.nn.Cell* or *mindspore.ops.Primitive* . Please note that this API takes effect only when Synchronous Dump is enabled and the *dump_mode* field in dump config file is "2" . See the dump document for details. The default enabled status for a *mindspore.nn.Cell* or *mindspore.ops.Primitive* is False.

Note:

1. This API is only effective for GRAPH_MODE whose graph compilation level is O0/O1 with Ascend backend, and can not work for fusion Primitive operators.
2. This API only supports being called before training starts. If you call this API during training, it may not be effective.
3. After using *set_dump(Cell, True)* , operators in forward and backward computation (computation generated by the grad operations) of the cell will be dumped.
4. For *mindspore.nn.SoftmaxCrossEntropyWithLogits* layer, the forward computation and backward computation use the same set of operators. So you can only see dump data from backward computation. Please note that *mindspore.nn.SoftmaxCrossEntropyWithLogits* layer will also use the above operators internally when initialized with *sparse=True* and *reduction="mean"* .

Parameters

- **target** (*Union[Cell, Primitive]*) – The Cell instance or Primitive instance to which the dump flag is set.
- **enabled** (*bool, optional*) – True means enable dump, False means disable dump. Default: True .

Supported Platforms:

Ascend

Examples

Note: Please set environment variable *MINDSPORE_DUMP_CONFIG* to the dump config file and set *dump_mode* field in dump config file to 2 before running this example. See dump document for details.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> from mindspore import Tensor, set_dump
```

(continues on next page)

(continued from previous page)

```
>>>
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> ms.set_device(device_target="Ascend")
>>>
>>> class MyNet(nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.conv1 = nn.Conv2d(5, 6, 5, pad_mode='valid')
...         self.relu1 = nn.ReLU()
...
...     def construct(self, x):
...         x = self.conv1(x)
...         x = self.relu1(x)
...         return x
>>>
>>> if __name__ == "__main__":
...     net = MyNet()
...     set_dump(net.conv1)
...     input_tensor = Tensor(np.ones([1, 5, 10, 10], dtype=np.float32))
...     output = net(input_tensor)
```

mindspore.Profiler

class mindspore.**Profiler**(***kwargs*)

The current interface is deprecated, please use: *mindspore.profiler.profile* instead. This class to enable the profiling of MindSpore neural networks. MindSpore users can import the mindspore.Profiler, initialize the Profiler object to start profiling, and use Profiler.analyse() to stop profiling and analyse the results. Users can visualize the results using the MindStudio Insight tool. Now, Profiler supports AICORE operator, AICPU operator, HostCPU operator, memory, correspondence, cluster, etc data analysis.

Parameters

- **start_profile** (*bool, optional*) –The start_profile parameter controls whether to enable or disable performance data collection based on conditions. Default: `True` .
- **output_path** (*str, optional*) –Output data path. Default: `"./data"` .
- **profiler_level** (*ProfilerLevel, optional*) –(Ascend only) The level of profiling. Default: `ProfilerLevel.Level0`.
  - ProfilerLevel.LevelNone: This setting takes effect only when mstx is enabled, indicating that no operator data is collected on the device side.
  - ProfilerLevel.Level0: Leanest level of profiling data collection, collects information about the elapsed time of the computational operators on the NPU and communication large operator information.
  - ProfilerLevel.Level1: Collect more CANN layer AscendCL data and AICore performance metrics and communication mini operator information based on Level0.
  - ProfilerLevel.Level2: Collect GE and Runtime information in CANN layer on top of Level1
- **activities** (*list, optional*) –The activities to collect. Default: `[ProfilerActivity.CPU, ProfilerActivity.NPU]`.
  - ProfilerActivity.CPU: Collect MindSpore framework data.
  - ProfilerActivity.NPU: Collect CANN software stack and NPU data.
  - ProfilerActivity.GPU: Collect GPU data.

- **schedule** (schedule, *optional*) –Sets the action strategy for the capture, defined by the schedule class, to be used with the step interface. Default: None. Performance data of all steps is collected. For details, see *mindspore.profiler.schedule* .
- **on_trace_ready** (*Callable, optional*) –Sets the callback function to be executed when the performance data is collected. Default: None. It indicates that only performance data is collected, but not resolved. For details, see *mindspore.profiler.tensorboard _trace_handler()* .
- **profile_memory** (*bool, optional*) –(Ascend only) Whether to collect tensor memory data, collect when True . When using this parameter, *activities* must set to [ProfilerActivity.CPU, ProfilerActivity.NPU]. Collecting operator memory data when the graph compilation level is O2 requires collecting from the first step. Default: False . The operator name currently collected by this parameter is incomplete. This issue will be resolved in later versions. It is recommended to use the environment variable MS_ALLOC_CONF instead.
- **aic_metrics** (*AicoreMetrics, optional*) –(Ascend only) Types of AICORE performance data collected, when using this parameter, *activities* must include ProfilerActivity.NPU , and the value must be a member of AicoreMetrics. When *profiler_level* is ProfilerLevel.Level0, the default value is AicoreMetrics.AiCoreNone; when *profiler_level* is ProfilerLevel.Level1 or ProfilerLevel.Level2, the default value is AicoreMetrics.PipeUtilization.

  The data items contained in each metric are as follows:

  - AicoreMetrics.AiCoreNone: Does not collect AICORE data.
  - AicoreMetrics.ArithmeticUtilization: ArithmeticUtilization contains mac_fp16/int8_ratio, vec_fp32/fp16/int32_ratio, vec_misc_ratio etc.
  - AicoreMetrics.PipeUtilization: PipeUtilization contains vec_ratio, mac_ratio, scalar_ratio, mte1/mte2/mte3_ratio, icache_miss_rate etc.
  - AicoreMetrics.Memory: Memory contains ub_read/write_bw, l1_read/write_bw, l2_read/write_bw, main_mem_read/write_bw etc.
  - AicoreMetrics.MemoryL0: MemoryL0 contains l0a_read/write_bw, l0b_read/write_bw, l0c_read/write_bw etc.
  - AicoreMetrics.ResourceConflictRatio: ResourceConflictRatio contains vec_bankgroup/bank/resc_cflt_ratio etc.
  - AicoreMetrics.MemoryUB: MemoryUB contains ub_read/write_bw_mte, ub_read/write_bw_vector, ub_/write_bw_scalar etc.
  - AicoreMetrics.L2Cache: L2Cache contains write_cache_hit, write_cache_miss_allocate, r0_read_cache_hit, r1_read_cache_hit etc. This function only support Atlas A2 training series products.
  - AicoreMetrics.MemoryAccess: Statistics on storage access bandwidth and storage capacity of main storage and l2 cache etc.
- **with_stack** (*bool, optional*) –(Ascend only) Whether to collect frame host call stack data on the Python side. This data is presented in the form of a flame graph in the timeline. When using this parameter, *activities* must include ProfilerActivity.CPU. Default value: False .
- **data_simplification** (*bool, optional*) –(Ascend only) Whether to remove FRAMEWORK data and other redundant data. If set to True, only the profiler deliverables and raw performance data under the PROF_XXX directory are kept to save space. Default value: True .
- **l2_cache** (*bool, optional*) –(Ascend only) Whether to collect l2 cache data, collect when True. Default: False . The l2_cache.csv file is generated in the ASCEND_PROFILER_OUTPUT folder.In O2 mode, only wait and skip_first parameters in schedule configuration can be set to 0.
- **hbm_ddr** (*bool, optional*) –(Ascend only) Whether to collect On-Chip Memory/DDR read and write rate data, collect when True. Default: False .
- **pcie** (*bool, optional*) –(Ascend only) Whether to collect PCIe bandwidth data, collect when True. Default: False .

- **data_process** (*bool, optional*) –(Ascend/GPU) Whether to collect data to prepare performance data. Default value: `False` .
- **parallel_strategy** (*bool, optional*) –(Ascend only) Whether to collect parallel policy performance data. Default value: `False` .
- **sync_enable** (*bool, optional*) –(GPU only) Whether the profiler collects operators in a synchronous way. Default: `True` .
  - True: The synchronous way. Before sending the operator to the GPU, the CPU records the start timestamp. Then the operator is returned to the CPU after execution, and the end timestamp is recorded, The duration of the operator is the difference between the two timestamps.
  - False: The asynchronous way. The duration of the operator is that of sending from the CPU to the GPU. This method can reduce the impact of adding profiler on overall training time.

Raises

RuntimeError –When the version of CANN does not match the version of MindSpore, MindSpore cannot parse the generated ascend_job_id directory structure.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import nn
>>> import mindspore.dataset as ds
>>> from mindspore import Profiler
>>> from mindspore.profiler import ProfilerLevel, ProfilerActivity, AicoreMetrics
>>>
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.fc = nn.Dense(2,2)
...     def construct(self, x):
...         return self.fc(x)
>>>
>>> def generator():
...     for i in range(2):
...         yield (np.ones([2, 2]).astype(np.float32), np.ones([2]).astype(np.int32))
>>>
>>> def train(net):
...     optimizer = nn.Momentum(net.trainable_params(), 1, 0.9)
...     loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
...     data = ds.GeneratorDataset(generator, ["data", "label"])
...     model = ms.train.Model(net, loss, optimizer)
...     model.train(1, data)
>>>
>>> if __name__ == '__main__':
...     # If the device_target is GPU, set the device_target to "GPU"
...     ms.set_context(mode=ms.GRAPH_MODE, device_target="Ascend")
...
...     # Init Profiler
...     # Note that the Profiler should be initialized before model.train
```

(continues on next page)

(continued from previous page)

```
...     profiler = Profiler(profiler_level=ProfilerLevel.Level0,
...                         activities=[ProfilerActivity.CPU, ProfilerActivity.NPU],
...                         aic_metrics=AicoreMetrics.AiCoreNone)
...
...     # Train Model
...     net = Net()
...     train(net)
...
...     # Profiler end
...     profiler.analyse()
```

add_metadata(*key: str*, *value: str*)

Report custom metadata key-value pair data.

Parameters

- **key** (*str*) – The key to the metadata.
- **value** (*str*) – The value to the metadata.

Examples

```
>>> from mindspore import Profiler
>>> # Profiler init.
>>> profiler = Profiler()
>>> # Call Profiler add_metadata
>>> profiler.add_metadata("test_key", "test_value")
>>> # Profiler end
>>> profiler.stop()
```

add_metadata_json(*key: str*, *value: str*)

Report custom metadata key-value pair data with the value as a JSON string data.

Parameters

- **key** (*str*) – The key to the metadata.
- **value** (*str*) – The json str format value to the metadata.

Examples

```
>>> import json
>>> from mindspore import Profiler
>>> # Profiler init.
>>> profiler = Profiler()
>>> # Call Profiler add_metadata_json
>>> profiler.add_metadata_json("test_key", json.dumps({"key1": 1, "key2": 2}))
>>> # Profiler end, metadata will be saved in profiler_metadata.json
>>> profiler.stop()
```

analyse(*offline_path=None*, *pretty=False*, *step_list=None*, *mode='sync'*)

Collect and analyze training performance data, support calls during and after training. The example shows above.

Parameters

- **offline_path** (*Union[str, None], optional*) –The data path which need to be analyzed with offline mode. Offline mode isused in abnormal exit scenario. This parameter should be set to `None` for online mode. Default: `None`.
- **pretty** (*bool, optional*) –Whether to pretty json files. Default: `False`.
- **step_list** (*list, optional*) –A list of steps that need to be analyzed, the steps must be consecutive integers. Default: `None`. By default, all steps will be analyzed.
- **mode** (*str, optional*) –Analysis mode, it must be one of ["sync", "async"]. Default: `sync`.
  - sync: analyse data in current process, it will block the current process.
  - async: analyse data in subprocess, it will not block the current process. Since the parsing process will take up extra CPU resources, please enable this mode according to the actual resource situation.

Examples

```
>>> from mindspore.train import Callback
>>> from mindspore import Profiler
>>> class StopAtStep(Callback):
...     def __init__(self, start_step=1, stop_step=5):
...         super(StopAtStep, self).__init__()
...         self.start_step = start_step
...         self.stop_step = stop_step
...         self.profiler = Profiler(start_profile=False)
...
...     def step_begin(self, run_context):
...         cb_params = run_context.original_args()
...         step_num = cb_params.cur_step_num
...         if step_num == self.start_step:
...             self.profiler.start()
...
...     def step_end(self, run_context):
...         cb_params = run_context.original_args()
...         step_num = cb_params.cur_step_num
...         if step_num == self.stop_step:
...             self.profiler.stop()
...
...     def end(self, run_context):
...         self.profiler.analyse(step_list=[2,3,4], mode="sync")
```

classmethod offline_analyse(*path: str*, *pretty=False*, *step_list=None*, *data_simplification=True*)

Analyze training performance data offline, which is invoked after performance data collection is completed.

Parameters

- **path** (*str*) –The profiling data path which needs to be analyzed offline. There needs to be a profiler directory in this path.
- **pretty** (*bool, optional*) –Whether to pretty json files. Default: `False`.
- **step_list** (*list, optional*) –A list of steps that need to be analyzed, the steps must be consecutive integers. Default: `None`. By default, all steps will be analyzed.
- **data_simplification** (*bool, optional*) –Whether to enable data simplification. Default: `True`.

Examples

```
>>> from mindspore import Profiler
>>> Profiler.offline_analyse("./profiling_path")
```

op_analyse(*op_name*, *device_id=None*)

Profiler users can use this interface to obtain operator performance data.

Parameters

- **op_name** (*str or list*) –The primitive operator name to query.
- **device_id** (*int, optional*) –ID of the target device. This parameter is optional during network training or inference, and users can use device_id parameter to specify which card operator performance data to parse. If this interface is used for offline data parsing, the default value is `None` .

Raises

- **TypeError** –If the *op_name* parameter type is incorrect.
- **TypeError** –If the *device_id* parameter type is incorrect.
- **RuntimeError** –If MindSpore runs on Ascend, this interface cannot be used.

Supported Platforms:

GPU CPU

Examples

```
>>> from mindspore import Profiler
>>> from mindspore import nn
>>> from mindspore import Model
>>> # Profiler init.
>>> profiler = Profiler()
>>> # Train Model or eval Model, taking LeNet5 as an example.
>>> # Refer to https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> optimizer = nn.Momentum(net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> # Create the dataset taking MNIST as an example.
>>> # Refer to https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataloader = create_dataset()
>>> model = Model(net, loss, optimizer)
>>> model.train(5, dataloader, dataset_sink_mode=False)
>>>
>>> # Profiler end
>>> profiler.analyse()
>>>
>>> profiler.op_analyse(op_name=["BiasAdd", "Conv2D"])
```

start()

Turn on Profiler data collection. Profiler can be turned on by condition.

Raises

- **RuntimeError** –If the profiler has already started.
- **RuntimeError** –If the *start_profile* parameter is not set or is set to `True`.

Examples

```
>>> from mindspore.train import Callback
>>> from mindspore import Profiler
>>> class StopAtStep(Callback):
...     def __init__(self, start_step, stop_step):
...         super(StopAtStep, self).__init__()
...         self.start_step = start_step
...         self.stop_step = stop_step
...         self.profiler = Profiler(start_profile=False)
...
...     def step_begin(self, run_context):
...         cb_params = run_context.original_args()
...         step_num = cb_params.cur_step_num
...         if step_num == self.start_step:
...             self.profiler.start()
...
...     def step_end(self, run_context):
...         cb_params = run_context.original_args()
...         step_num = cb_params.cur_step_num
...         if step_num == self.stop_step:
...             self.profiler.stop()
...
...     def end(self, run_context):
...         self.profiler.analyse()
```

step()

Used for Ascend, distinguish step collection and parsing performance data through schedule and on_trace_ready.

Raises

- **RuntimeError** – If the *start_profile* parameter is not set or the Profiler is not started.
- **RuntimeError** – If the *schedule* parameter is not set.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.dataset as ds
>>> from mindspore import context, nn, Profiler
>>> from mindspore.profiler import schedule, tensorboard_trace_handler, ProfilerLevel,␣
↪AicoreMetrics,
>>> ExportType, ProfilerActivity
>>>
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.fc = nn.Dense(2, 2)
...
...     def construct(self, x):
...         return self.fc(x)
>>>
>>> def generator_net():
...     for _ in range(2):
...         yield np.ones([2, 2]).astype(np.float32), np.ones([2]).astype(np.int32)
>>>
```

(continues on next page)

(continued from previous page)

```
>>> def train(test_net):
...     optimizer = nn.Momentum(test_net.trainable_params(), 1, 0.9)
...     loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
...     data = ds.GeneratorDataset(generator_net(), ["data", "label"])
...     model = ms.train.Model(test_net, loss, optimizer)
...     model.train(1, data)
>>>
>>> if __name__ == '__main__':
...     context.set_context(mode=ms.PYNATIVE_MODE, device_target="Ascend")
...
...     net = Net()
...     STEP_NUM = 15
...
...     with Profiler(schedule=schedule(wait=1, warmup=1, active=2, repeat=1, skip_
↪first=2),
...                   on_trace_ready=tensorboard_trace_handler) as prof:
...         for _ in range(STEP_NUM):
...             train(net)
...             prof.step()
```

stop()

Turn off Profiler data collection. Profiler can be turned off by condition.

Raises

RuntimeError – If the profiler has not started, this function is disabled.

Examples

```
>>> from mindspore.train import Callback
>>> from mindspore import Profiler
>>> class StopAtEpoch(Callback):
...     def __init__(self, start_epoch, stop_epoch):
...         super(StopAtEpoch, self).__init__()
...         self.start_epoch = start_epoch
...         self.stop_epoch = stop_epoch
...         self.profiler = Profiler(start_profile=False)
...
...     def epoch_begin(self, run_context):
...         cb_params = run_context.original_args()
...         epoch_num = cb_params.cur_epoch_num
...         if epoch_num == self.start_epoch:
...             self.profiler.start()
...
...     def epoch_end(self, run_context):
...         cb_params = run_context.original_args()
...         epoch_num = cb_params.cur_epoch_num
...         if epoch_num == self.stop_epoch:
...             self.profiler.stop()
...
...     def end(self, run_context):
...         self.profiler.analyse()
```

1.9.3 Log

mindspore.get_level	Get the logger level.
mindspore.get_log_config	Get logger configurations.

mindspore.get_level

mindspore.**get_level**()

Get the logger level.

Returns

str, the Log level includes 4(CRITICAL), 3(ERROR), 2(WARNING), 1(INFO), 0(DEBUG).

Examples

```
>>> import os
>>> os.environ['GLOG_v'] = '3'
>>> import mindspore as ms
>>> level = ms.get_level()
>>> print(level)
'3'
```

mindspore.get_log_config

mindspore.**get_log_config**()

Get logger configurations.

Returns

Dict, the dictionary of logger configurations.

Examples

```
>>> import os
>>> import mindspore as ms
>>> os.environ['GLOG_v'] = '1'
>>> os.environ['GLOG_logtostderr'] = '0'
>>> os.environ['GLOG_log_dir'] = '/var/log'
>>> os.environ['logger_maxBytes'] = '5242880'
>>> os.environ['logger_backupCount'] = '10'
>>> os.environ['GLOG_stderrthreshold'] = '2'
>>> config = ms.get_log_config()
>>> print(config)
{'GLOG_v': '1', 'GLOG_logtostderr': '0', 'GLOG_log_dir': '/var/log',
 'logger_maxBytes': '5242880', 'logger_backupCount': '10', 'GLOG_stderrthreshold': '2'}
```

1.9.4 Installation Verification

mindspore.run_check	Provide a convenient API to check if the installation is successful or failed.

mindspore.run_check

mindspore.**run_check**()

Provide a convenient API to check if the installation is successful or failed. If the version in the check result is not as expected, use *mindspore.set_context()* to set device_target before run_check().

Examples

```
>>> import mindspore
>>> mindspore.run_check()
MindSpore version: xxx
The result of multiplication calculation is correct, MindSpore has been installed on␣
↪platform [XX] successfully!
```

1.9.5 Security

mindspore.obfuscate_ckpt	Obfuscate the plaintext checkpoint files according to the obfuscation config.
mindspore.load _obf_params_into_net	Modify model structure according to obfuscation config and load obfuscated checkpoint into obfuscated network.

mindspore.obfuscate_ckpt

mindspore.**obfuscate_ckpt**(*network*, *ckpt_files*, *target_modules=None*, *obf_config=None*, *saved_path='./'*, *obfuscate_scale=100*)

Obfuscate the plaintext checkpoint files according to the obfuscation config.

Parameters

- **network** (nn.Cell) –The original network that need to be obfuscated.
- **ckpt_files** (*str*) –The directory path of original ckpt files.
- **target_modules** (*list[str], optional*) –The target ops that need to be obfuscated in the network. The first string represents the network path of the target ops in the original network, which should be in form of "A/B/C". The second string represents the names of multiple target ops in the same path, which should be in form of "D|E|F". For example, the target_modules of GPT2 can be ['backbone/blocks /attention', 'dense1|dense2|dense3']. If target_modules has the third value, it should be in the format of 'obfuscate_layers:all' or 'obfuscate_layers:int', which represents the number of layers need to be obfuscated of duplicate layers (such as transformer layers or resnet blocks). Default: None.
- **obf_config** (*dict, optional*) –The configuration of model obfuscation polices. Default: None.
- **saved_path** (*str, optional*) –The directory path for saving obfuscated ckpt files. Default: './'.

- **obfuscate_scale** (*Union[float, int], optional*) –Obfuscate scale of weights. The generated random obf_ratios will be in range of (1 / obfuscate_scale, obfuscate_scale). Default: `100`.

Returns

dict[str], obf_metadata, which is the necessary data that needs to be load when running obfuscated network.

Raises

- **TypeError** –If *network* is not nn.Cell.
- **TypeError** –If *ckpt_files* is not string or *saved_path* is not string.
- **TypeError** –If *target_modules* is not list.
- **TypeError** –If target_modules's elements are not string.
- **TypeError** –If obf_config is not dict.
- **ValueError** –If *ckpt_files* is not exist or *saved_path* is not exist.
- **ValueError** –If the number of elements of *target_modules* is less than `2`.
- **ValueError** –If the first string of *target_modules* contains characters other than uppercase and lowercase letters, numbers, `'_'` and `'/'`.
- **ValueError** –If the second string of *target_modules* is empty or contains characters other than uppercase and lowercase letters, numbers, `'_'` and `'|'`.
- **ValueError** –If the third string of *target_modules* is not in the format of 'obfuscate_layers:all' or 'obfuscate_layers:int'.

Examples

```
>>> from mindspore import obfuscate_ckpt, save_checkpoint
>>> # Refer to https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> save_checkpoint(net, './test_net.ckpt')
>>> target_modules = ['', 'fc1|fc2']
>>> obfuscate_ckpt(net, './', target_modules=target_modules, saved_path='./')
```

mindspore.load_obf_params_into_net

mindspore.**load_obf_params_into_net**(*network*, *target_modules=None*, *obf_ratios=None*, *obf_config=None*, *data_parallel_num=1*, ***kwargs*)

Modify model structure according to obfuscation config and load obfuscated checkpoint into obfuscated network.

Parameters

- **network** (`nn.Cell`) –The original network that need to be obfuscated.
- **target_modules** (*list[str], optional*) –The target ops that need to be obfuscated in the network. The first string represents the network path of the target ops in the original network, which should be in form of `"A/B/C"`. The second string represents the names of multiple target ops in the same path, which should be in form of `"D|E|F"`. For example, thr target_modules of GPT2 can be `['backbone /blocks/attention', 'dense1|dense2|dense3']`. If target_modules has the third value, it should be in the format of 'obfuscate_layers:all' or 'obfuscate_layers:int', which represents the number of layers need to be obfuscated of duplicate layers (such as transformer layers or resnet blocks). Default: `None`.
- **obf_ratios** (`Tensor`, *optional*) –The obf ratios generated when execute *mindspore.obfuscate_ckpt()*. Default: `None`.

- **obf_config** (*dict, optional*) –The configuration of model obfuscation polices. Default: None.
- **data_parallel_num** (*int, optional*) –The data parallel number of parallel training. Default: 1.
- **kwargs** (*dict*) –Configuration options dictionary.
  - ignored_func_decorators (list[str]): The name list of function decorators in network's python code.
  - ignored_class_decorators (list[str]): The name list of class decorators in network's python code.

Returns

nn.Cell, new_net, which is the obfuscated network.

Raises

- **TypeError** –If *network* is not nn.Cell.
- **TypeError** –If *obf_ratios* is not Tensor.
- **TypeError** –If *target_modules* is not list.
- **TypeError** –If *obf_config* is not dict.
- **TypeError** –If target_modules's elements are not string.
- **ValueError** –If the number of elements of *target_modules* is less than 2.
- **ValueError** –If *obf_ratios* is empty Tensor.
- **ValueError** –If the first string of *target_modules* contains characters other than uppercase and lowercase letters, numbers, '_' and '/'.
- **ValueError** –If the second string of *target_modules* is empty or contains characters other than uppercase and lowercase letters, numbers, '_' and '|'.
- **ValueError** –If the third string of *target_modules* is not in the format of 'obfuscate_layers:all' or 'obfuscate_layers:int'.
- **TypeError** –If *ignored_func_decorators* is not list[str] or *ignored_class_decorators* is not list[str].

Examples

```
>>> from mindspore import obfuscate_ckpt, save_checkpoint, load_checkpoint, Tensor
>>> import mindspore.common.dtype as mstype
>>> import numpy as np
>>> # Refer to https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> save_checkpoint(net, './test_net.ckpt')
>>> target_modules = ['', 'fc1|fc2']
>>> # obfuscate ckpt files
>>> obfuscate_ckpt(net, './', target_modules=target_modules, saved_path='./')
>>> # load obf ckpt into network
>>> new_net = LeNet5()
>>> load_checkpoint('./test_net_obf.ckpt', new_net)
>>> obf_net = load_obf_params_into_net(new_net, target_modules)
```

CHAPTER

TWO

MINDSPORE.OPS

mindspore.ops provides a large number of function interfaces, including neural network functions, mathematical operation functions, Tensor operation functions, Parameter operation functions, differential functions and so on.

For more information about dynamic shape support status, please refer to Dynamic Shape Support Status of ops Interface .

The module import method is as follows:

```
from mindspore import ops
```

Compared with the previous version, the added, deleted and supported platforms change information of *mindspore.ops* operators in MindSpore, please refer to the link mindspore.ops API Interface Change.

2.1 Tensor Operation Functions

2.1.1 Tensor Creation

API Name	Description	Supported Platforms
mindspore.ops.eps	Create a tensor with the same data type and shape as input, and the element value is the minimum value that the corresponding data type can express.	Ascend GPU CPU
mindspore.ops.eye	Returns a tensor with ones on the diagonal and zeros in the rest.	Ascend GPU CPU
mindspore.ops.fill	Create a tensor filled with a specified value.	Ascend GPU CPU
mindspore.ops.full	Create a tensor filled with a specified value.	Ascend GPU CPU
mindspore.ops.full_like	Return a tensor of the same shape as *input* and filled with a specified value.	Ascend GPU CPU
mindspore.ops.linspace	Generate a one-dimensional tensor with *steps* elements, evenly distributed in the interval [start, end].	Ascend GPU CPU
mindspore.ops.logspace	Return a tensor with *steps* elements, evenly distributed in the interval [$base^{start}$, $base^{end}$].	Ascend GPU CPU
mindspore.ops.move_to	Copy tensor to target device synchronously or asynchronously, default synchronously.	Ascend CPU
mindspore.ops.one_hot	Generate a new tensor, where the positions specified by *indices* are assigned *on_value*, and all other positions are assigned *off_value*.	Ascend GPU CPU
mindspore.ops.ones	Creates a tensor filled with value ones.	Ascend GPU CPU
mindspore.ops.ones_like	Return a tensor filled with 1, with the same size as *input*.	Ascend GPU CPU

continues on next page

Table 1 – continued from previous page

mindspore.ops.arange	Returns a tensor with a step length of *step* in the interval [*start* , *end*).	Ascend GPU CPU
mindspore.ops.range	Returns a tensor with a step length of *step* in the interval [*start* , *end*).	GPU CPU
mindspore.ops.zeros	Creates a tensor filled with value zeros.	Ascend GPU CPU
mindspore.ops.zeros_like	Return a tensor filled with 0, with the same size as *input* .	Ascend GPU CPU
mindspore.ops.heaviside	Perform Heaviside step function element-wise.	Ascend GPU CPU

mindspore.ops.eps

mindspore.ops.**eps**(*x*)

Create a tensor with the same data type and shape as input, and the element value is the minimum value that the corresponding data type can express.

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([4, 1, 2, 3], mindspore.float32)
>>> mindspore.ops.eps(x)
Tensor(shape=[4], dtype=Float32, value= [ 1.19209290e-07,  1.19209290e-07,  1.19209290e-07,
↪1.19209290e-07])
```

mindspore.ops.eye

mindspore.ops.**eye**(*n*, *m=None*, *dtype=None*)

Returns a tensor with ones on the diagonal and zeros in the rest.

Parameters

- **n** (*int*) – The number of rows returned.
- **m** (*int, optional*) – The number of columns returned. If None , the number of columns is as the same as n.
- **dtype** (mindspore.dtype, *optional*) – The data type returned.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.eye(3)
>>> print(output)
[[1. 0. 0.]
 [0. 1. 0.]
 [0. 0. 1.]]
>>>
>>> output = mindspore.ops.eye(3, 4)
>>> print(output)
[[1. 0. 0. 0.]
 [0. 1. 0. 0.]
 [0. 0. 1. 0.]]
```

mindspore.ops.fill

mindspore.ops.**fill**(*type*, *shape*, *value*)

Create a tensor filled with a specified value.

Parameters

- **type** (mindspore.dtype) – The data type specified.
- **shape** (*Union(Tensor, tuple[int])*) – The shape specified.
- **value** (*Union(Tensor, number.Number, bool)*) – The value specified.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> mindspore.ops.fill(mindspore.float32, (2, 3),  1.2)
Tensor(shape=[2, 3], dtype=Float32, value=
[[ 1.20000005e+00,  1.20000005e+00,  1.20000005e+00],
 [ 1.20000005e+00,  1.20000005e+00,  1.20000005e+00]])
```

mindspore.ops.full

mindspore.ops.**full**(*size*, *fill_value*, *, *dtype=None*)

Create a tensor filled with a specified value.

Note: *fill_value* 's data type not support complex numbers.

Parameters

- **size** (*Union(tuple[int], list[int])*) – The shape specified.

- **fill_value** (*number.Number*) –The value specified.

Keyword Arguments

dtype (mindspore.dtype) –The data type specified. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> mindspore.ops.full((2, 3), 1.2)
Tensor(shape=[2, 3], dtype=Int64, value=
[[1, 1, 1],
 [1, 1, 1]])
>>> mindspore.ops.full((2, 3), 1.2, dtype=mindspore.float32)
Tensor(shape=[2, 3], dtype=Float32, value=
[[ 1.20000005e+00,  1.20000005e+00,  1.20000005e+00],
 [ 1.20000005e+00,  1.20000005e+00,  1.20000005e+00]])
```

mindspore.ops.full_like

mindspore.ops.**full_like**(*input*, *fill_value*, *, *dtype=None*)

Return a tensor of the same shape as *input* and filled with a specified value.

Note: *fill_value* 's data type not support complex numbers.

Parameters

- **input** (Tensor) –The input tensor.
- **fill_value** (*Number*) –The specified value.

Keyword Arguments

dtype (mindspore.dtype, *optional*) –The data type specified. Default: None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.ops.arange(4)
>>> mindspore.ops.full_like(input, 1.2)
Tensor(shape=[4], dtype=Int64, value= [1, 1, 1, 1])
>>> mindspore.ops.full_like(input, 1.2, dtype=mindspore.float32)
Tensor(shape=[4], dtype=Float32, value= [ 1.20000005e+00,  1.20000005e+00,  1.20000005e+00,
↪1.20000005e+00])
```

mindspore.ops.linspace

mindspore.ops.**linspace**(*start*, *end*, *steps*)

Generate a one-dimensional tensor with *steps* elements, evenly distributed in the interval [start, end].

$$step = (end - start)/(steps - 1)$$
$$output = [start, start + step, start + 2 * step, ..., end]$$

Parameters

- **start** (*Union[Tensor, int, float]*) – Start value of interval.
- **end** (*Union[Tensor, int, float]*) – Last value of interval.
- **steps** (*Union[Tensor, int]*) – Number of elements.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.linspace(3, 10, 5)
>>> print(output)
[ 3.    4.75  6.5   8.25 10.  ]
>>> output = mindspore.ops.linspace(-10, 10, 5)
>>> print(output)
[-10.  -5.   0.   5.  10.]
>>> output = mindspore.ops.linspace(-10, 10, 1)
>>> print(output)
[-10.]
```

mindspore.ops.logspace

mindspore.ops.**logspace**(*start*, *end*, *steps*, *base=10*, ***, *dtype=mstype.float32*)

Return a tensor with *steps* elements, evenly distributed in the interval [$base^{start}$, $base^{end}$].

$$step = (end - start)/(steps - 1)$$
$$output = [base^{start}, base^{start+1*step}, ..., base^{start+(steps-2)*step}, base^{end}]$$

Parameters

- **start** (*Union[float, Tensor]*) –Start value of interval.
- **end** (*Union[float, Tensor]*) –Last value of interval.
- **steps** (*int*) –Number of elements.
- **base** (*int, optional*) –Base of the logarithm function. Default `10` .

Keyword Arguments

dtype (`mindspore.dtype`, *optional*) –The data type specified. Default `mstype.float32` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> output = mindspore.ops.logspace(1., 10., steps = 10, base = 10)
>>> print(output)
[1.e+01 1.e+02 1.e+03 1.e+04 1.e+05 1.e+06 1.e+07 1.e+08 1.e+09 1.e+10]
```

mindspore.ops.move_to

mindspore.ops.**move_to**(*input*, *to='CPU'*, *blocking=True*)

Copy tensor to target device synchronously or asynchronously, default synchronously.

Note: This interface currently only supports Graph mode with jit_level of O0 or O1.

Parameters

- **input** (*Union[Tensor, list[int], tuple[int]]*) –The input tensor. When the input is list and tuple, it will be converted to tensor before copying.
- **to** (*str, optional*) –Specify the target device, with optional values of `"Ascend"` and `"CPU"`. Default `"CPU"` .
- **blocking** (*bool, optional*) –Whether use synchronous copying. Default `True`.

Returns

A new tensor on target device.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn, ops, Tensor
>>> mindspore.set_context(mode=mindspore.GRAPH_MODE)
>>> class MoveToNet(nn.Cell):
...     def __init__(self):
...         super().__init__()
...
...     def construct(self, x):
...         cpu_x = ops.move_to(x, "CPU")
...         npu_x = ops.move_to(cpu_x, "Ascend")
...         return npu_x
...
>>> net = MoveToNet()
>>> x = Tensor([1, 2, 3], mindspore.int64)
>>> y = net(x)
>>> print(y)
[1 2 3]
```

mindspore.ops.one_hot

`mindspore.ops.`**`one_hot`**(*indices*, *depth*, *on_value=1*, *off_value=0*, *axis=- 1*)

Generate a new tensor, where the positions specified by *indices* are assigned *on_value*, and all other positions are assigned *off_value*.

Note: If the input *indices* has rank *N*, the output will have rank *N+1*. The new axis is created at dimension *axis*. On Ascend, if *on_value* is int64 dtype, *indices* must be int64 dtype, and the value for *on_value* and *off_value* can only be 1 and 0.

Parameters

- **`indices`** (`Tensor`) –The input tensor of indices.
- **`depth`** (*`int`*) –The depth of the one-hot.
- **`on_value`** (*`Union[Tensor, int, float], optional`*) –The value used to fill indexed positions. Default `1` .
- **`off_value`** (*`Union[Tensor, int, float], optional`*) –The value used to fill non-indexed positions. Default `0` .
- **`axis`** (*`int, optional`*) –Specify the axis for computation. Default `-1` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> indices = mindspore.tensor([0, 1, 2, 4])
>>> mindspore.ops.one_hot(indices, depth=5)
Tensor(shape=[4, 5], dtype=Int64, value=
[[1, 0, 0, 0, 0],
 [0, 1, 0, 0, 0],
 [0, 0, 1, 0, 0],
 [0, 0, 0, 0, 1]])
>>>
>>> mindspore.ops.one_hot(indices, depth=3)

  [10,  4]],
 [[ 4, 10],
  [ 4,  4]]])
```

mindspore.ops.ones

mindspore.ops.**ones**(*shape*, *dtype=None*)

Creates a tensor filled with value ones.

> **Warning:** For argument *shape*, Tensor type input will be deprecated in the future version.

Parameters

- **shape** (*Union[tuple[int], list[int], int, Tensor]*) – The shape specified.
- **dtype** (*mindspore.dtype*) – The data type specified. Default `None` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> mindspore.ops.ones(4)
Tensor(shape=[4], dtype=Float32, value= [ 1.00000000e+00,  1.00000000e+00,  1.00000000e+00, ␣
↪1.00000000e+00])
>>> mindspore.ops.ones((2, 3))
Tensor(shape=[2, 3], dtype=Float32, value=
[[ 1.00000000e+00,  1.00000000e+00,  1.00000000e+00],
 [ 1.00000000e+00,  1.00000000e+00,  1.00000000e+00]])
>>> mindspore.ops.ones(mindspore.tensor([1, 2, 3]))
Tensor(shape=[1, 2, 3], dtype=Float32, value=
[[[ 1.00000000e+00,  1.00000000e+00,  1.00000000e+00],
  [ 1.00000000e+00,  1.00000000e+00,  1.00000000e+00]]])
```

mindspore.ops.ones_like

mindspore.ops.**ones_like**(*input*, *, *dtype=None*)

Return a tensor filled with 1, with the same size as *input*.

Parameters

input (Tensor) –The input tensor.

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The data type specified. Default None represents the same data type as the input.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.ops.arange(4)
>>> mindspore.ops.ones_like(input)
Tensor(shape=[4], dtype=Int64, value= [1, 1, 1, 1])
```

mindspore.ops.arange

mindspore.ops.**arange**(*start=0*, *end=None*, *step=1*, *, *dtype=None*)

Returns a tensor with a step length of *step* in the interval [*start* , *end*).

Parameters

- **start** (*Union[float, int, Tensor], optional*) –The start value of the interval. Default 0 .
- **end** (*Union[float, int, Tensor], optional*) –The end value of the interval. Default None represents to the value of *start* , and *0* is used as the start value.
- **step** (*Union[float, int, Tensor], optional*) –The interval between each value. Default 1 .

Keyword Arguments

dtype (*mindspore.dtype, optional*) –The data type specified. Default `None` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> mindspore.ops.arange(4)
Tensor(shape=[4], dtype=Int64, value= [0, 1, 2, 3])
>>> mindspore.ops.arange(1, 6)
Tensor(shape=[5], dtype=Int64, value= [1, 2, 3, 4, 5])
>>> mindspore.ops.arange(0, 2, 0.5)
Tensor(shape=[4], dtype=Float32, value= [ 0.00000000e+00,  5.00000000e-01,  1.00000000e+00,
 ↪1.50000000e+00])
```

mindspore.ops.range

`mindspore.ops.`**`range`**(*start*, *end*, *step*, *maxlen=1000000*)

Returns a tensor with a step length of *step* in the interval [*start* , *end*).

Note: The types of all 3 inputs must be all integers or floating-point numbers.

Parameters

- **start** (*number*) –The start value of the interval.
- **end** (*number*) –The end value of the interval.
- **step** (*number*) –The interval between each value.
- **maxlen** (*int, optional*) –Memory that can fit *maxlen* many elements will be allocated for the output. Optional, must be positive. Default: 1000000. If the output has more than *maxlen* elements, a runtime error will occur.

Returns

Tensor

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import mindspore
>>> mindspore.ops.range(0, 6, 2)
Tensor(shape=[3], dtype=Int64, value= [0, 2, 4])
```

mindspore.ops.zeros

mindspore.ops.**zeros**(*size*, *dtype=None*)

Creates a tensor filled with value zeros.

> **Warning:** For argument *size*, Tensor type input will be deprecated in the future version.

Parameters

- **size** (*Union[tuple[int], list[int], int, Tensor]*) −The shape specified.
- **dtype** (*mindspore.dtype*, optional) −The data type specified. Default: None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> mindspore.ops.zeros(4)
Tensor(shape=[4], dtype=Float32, value= [ 0.00000000e+00,  0.00000000e+00,  0.00000000e+00, ␣
↪0.00000000e+00])
>>> mindspore.ops.zeros((2, 3))
Tensor(shape=[2, 3], dtype=Float32, value=
[[ 0.00000000e+00,  0.00000000e+00,  0.00000000e+00],
 [ 0.00000000e+00,  0.00000000e+00,  0.00000000e+00]])
>>> mindspore.ops.zeros(mindspore.tensor([1, 2, 3]))
Tensor(shape=[1, 2, 3], dtype=Float32, value=
[[[ 0.00000000e+00,  0.00000000e+00,  0.00000000e+00],
  [ 0.00000000e+00,  0.00000000e+00,  0.00000000e+00]]])
```

mindspore.ops.zeros_like

mindspore.ops.**zeros_like**(*input*, *, *dtype=None*)

Return a tensor filled with 0, with the same size as *input* .

Parameters

input (Tensor) −The input tensor.

Keyword Arguments

dtype (*mindspore.dtype*, optional) −The data type specified. Default None represents the same data type as the input.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.ops.arange(4)
>>> mindspore.ops.zeros_like(input)
Tensor(shape=[4], dtype=Int64, value= [0, 0, 0, 0])
```

mindspore.ops.heaviside

`mindspore.ops.`**`heaviside`**(*input*, *values*)

Perform Heaviside step function element-wise.

Support broadcasting.

$$\text{heaviside}(\text{input}, \text{values}) = \begin{cases} 0, & \text{if input} < 0 \\ \text{values}, & \text{if input} = 0 \\ 1, & \text{if input} > 0 \end{cases}$$

Parameters

- **`input`** (`Tensor`) –The input tensor.
- **`values`** (`Tensor`) –The value to fill when the element in *input* is 0.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[-2., 0, 3],
...                           [5, -1, 0],
...                           [0, 7, -3]])
>>> values = mindspore.tensor([2, 0.5, 1])
>>> output = mindspore.ops.heaviside(input, values)
>>> print(output)
[[0.  0.5 1. ]
 [1.  0.  1. ]
 [2.  1.  0. ]]
>>> output = mindspore.ops.heaviside(input, mindspore.tensor(0.5))
>>> print(output)
[[0.  0.5 1. ]
 [1.  0.  0.5]
```

(continues on next page)

(continued from previous page)

```
 [0.5 1.  0. ]]
>>> output = mindspore.ops.heaviside(mindspore.tensor(-3.), values)
>>> print(output)
[0. 0. 0.]
```

2.1.2 Randomly Generating Functions

API Name	Description	Supported Platforms
mindspore.ops.bernoulli	Generates Bernoulli random values (0 or 1).	GPU CPU
mindspore.ops.gamma	Generates random numbers according to the Gamma random number distribution.	Ascend
mindspore.ops.laplace	Generates random numbers according to the Laplace random number distribution.	Ascend GPU CPU
mindspore.ops.multinomial	Generate a tensor from a multinomial distribution.	Ascend GPU CPU
mindspore.ops.multinomial_with_replacement	Generate a tensor from a multinomial distribution.	CPU
mindspore.ops.rand	Return a new tensor that fills numbers from the uniform distribution over an interval $[0, 1)$ based on the given *size* and *dtype*.	Ascend GPU CPU
mindspore.ops.rand_like	Return a tensor with the same shape as *input* that is filled with random numbers from a uniform distribution on the interval $[0, 1)$.	Ascend GPU CPU
mindspore.ops.randint	Return a tensor whose elements are random integers in the range of [*low* , *high*) .	Ascend GPU CPU
mindspore.ops.randint_like	Returns a tensor with the same shape as *input* whose elements are random integers in the range of [*low* , *high*) .	Ascend GPU CPU
mindspore.ops.randn	Return a new tensor with given shape and dtype, filled with random numbers from the standard normal distribution.	Ascend GPU CPU
mindspore.ops.randn_like	Return a tensor with the same shape as *input*, filled with random numbers from the standard normal distribution.	Ascend GPU CPU
mindspore.ops.random_gamma	Generate random numbers from the Gamma distribution(s).	CPU
mindspore.ops.random_poisson	Generate random number Tensor with *shape* according to a Poisson distribution with mean *rate*.	GPU CPU
mindspore.ops.randperm	Generates random permutation of integers from 0 to n-1.	CPU
mindspore.ops.standard_laplace	Generates random numbers according to the Laplace random number distribution (mean=0, lambda=1).	Ascend GPU CPU
mindspore.ops.standard_normal	Generates random numbers according to the standard Normal (or Gaussian) random number distribution.	Ascend GPU CPU
mindspore.ops.uniform	Generates random numbers according to the Uniform random number distribution.	GPU CPU

mindspore.ops.bernoulli

mindspore.ops.**bernoulli**(*input*, *p=0.5*, *seed=None*)

Generates Bernoulli random values (0 or 1).

$$out_i \sim Bernoulli(p_i)$$

Parameters

- **input** (Tensor) –The input Tensor.
- **p** (*Union[Tensor, float], optional*) –The probability of setting 1 for the corresponding position of the returned tensor. The value of *p* must be in the range *[0, 1]*. Default 0.5 .
- **seed** (*Union[int, None], optional*) –The random seed. Default None means using the current timestamp.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 2, 3])
>>> mindspore.ops.bernoulli(input, p=1.0)
Tensor(shape=[3], dtype=Int64, value= [1, 1, 1])
>>> p = mindspore.tensor([0.0, 1.0, 1.0])
>>> mindspore.ops.bernoulli(input, p)
Tensor(shape=[3], dtype=Int64, value= [0, 1, 1])
```

mindspore.ops.gamma

mindspore.ops.**gamma**(*shape*, *alpha*, *beta*, *seed=None*)

Generates random numbers according to the Gamma random number distribution.

Support broadcasting.

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **shape** (*tuple*) –The shape specified.
- **alpha** (Tensor) –The shape parameter.
- **beta** (Tensor) –The inverse scale parameter.
- **seed** (*int, optional*) –The random seed, Default None .

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> # case 1: alpha_shape is (2, 2)
>>> shape = (3, 1, 2)
>>> alpha = mindspore.tensor([[3, 4], [5, 6]], mindspore.float32)
>>> beta = mindspore.tensor([1.0], mindspore.float32)
>>> output = mindspore.ops.gamma(shape, alpha, beta, seed=5)
>>> result = output.shape
>>> print(result)
(3, 2, 2)
>>> # case 2: alpha_shape is (2, 3), so shape is (3, 1, 3)
>>> shape = (3, 1, 3)
>>> alpha = mindspore.tensor([[1, 3, 4], [2, 5, 6]]), mindspore.float32)
>>> beta = mindspore.tensor([1.0], mindspore.float32)
>>> output = mindspore.ops.gamma(shape, alpha, beta, seed=5)
>>> result = output.shape
>>> print(result)
(3, 2, 3)
>>> # case 3: beta_shape is (1, 2), the output is different.
>>> shape = (3, 1, 2)
>>> alpha = mindspore.tensor([[3, 4], [5, 6]], mindspore.float32)
>>> beta = mindspore.tensor([1.0, 2], mindspore.float32)
>>> output = mindspore.ops.gamma(shape, alpha, beta, seed=5)
>>> print(output)
[[[ 2.2132034  5.8855834]
  [ 3.8825176  8.6066265]]
 [[ 3.3981476  7.5805717]
  [ 3.7190282 19.941492 ]]
 [[ 2.9512358  2.5969937]
  [ 3.786061   5.160872 ]]]
>>> # case 4: beta_shape is (2, 1), the output is different.
>>> shape = (3, 1, 2)
>>> alpha = mindspore.tensor([[3, 4], [5, 6]], mindspore.float32)
>>> beta = mindspore.tensor([[1.0], [2.0]], mindspore.float32)
>>> output = mindspore.ops.gamma(shape, alpha, beta, seed=5)
>>> print(output)
[[[ 5.6085486  7.8280783]
  [ 15.97684  16.116285]]
[[ 1.8347423  1.713663]
  [ 3.2434065 15.667398]]
[[ 4.2922077  7.3365674]
  [ 5.3876944  13.159832 ]]]
```

mindspore.ops.laplace

mindspore.ops.**laplace**(*shape*, *mean*, *lambda_param*, *seed=None*)

Generates random numbers according to the Laplace random number distribution.

Support broadcasting.

$$\mathrm{f}(x;,) = \frac{1}{2}\exp(-\frac{|x-|}{}),$$

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **shape** (*tuple*) –The shape specified.
- **mean** (Tensor) –The mean of distribution.
- **lambda_param** (Tensor) –Control the variance of distribution. The variance of Laplace distribution is equal to twice the square of *lambda_param* .
- **seed** (*int, optional*) –Random seed. Default None represents 0.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> shape = (2, 3)
>>> mean = mindspore.tensor(1.0, mindspore.float32)
>>> lambda_param = mindspore.tensor(1.0, mindspore.float32)
>>> output = mindspore.ops.laplace(shape, mean, lambda_param, seed=5)
>>> print(output.shape)
(2, 3)
```

mindspore.ops.multinomial

mindspore.ops.**multinomial**(*input*, *num_samples*, *replacement=True*, *seed=None*)

Generate a tensor from a multinomial distribution.

The polynomial distribution is a probability distribution that generalizes the binomial distribution formula to multiple states. In the polynomial distribution, each event has a fixed probability, and the sum of these probabilities is 1.

The purpose of this interface is to perform *num_samples* sampling on the input *input*, and the output tensor is the index of the input tensor for each sampling. The values in *input* represent the probability of selecting the corresponding index for each sampling.

Here is an extreme example for better understanding. Suppose we have an input probability tensor with values *[90 / 100, 10 / 100, 0]*, which means we can sample three indices, namely index 0, index 1, and index 2, with probabilities of 90%, 10%, and 0%, respectively. We perform n samplings, and the resulting sequence is the calculation result of the polynomial distribution, with a length equal to the number of samplings.

In case 1 of the sample code, we perform two non-replacement samplings (*replacement* is *False*). Since the probability of selecting index 0 is 90% for each sampling, the first result is most likely to be index 0. Since the probability of selecting index 2 is 0, index 2 cannot appear in the sampling result. Therefore, the second result must be index 1, and the resulting sequence is *[0, 1]*.

In case 2 of the sample code, we perform 10 replacement samplings (*replacement* is *True*). As expected, about 90% of the sampling results are index 0.

In case 3 of the sample code, we extend the input to 2 dimensions, and the sampling results in each dimension also match our sampling expectations.

Note: The rows of input do not need to sum to one (in which case we use the values as weights), but must be non-negative, finite and have a non-zero sum. When using values as weights, it can be understood as normalizing the input along the last dimension.

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **input** (Tensor) –The input tensor containing probabilities.
- **num_samples** (*int*) –Number of samples to draw.
- **replacement** (*bool, optional*) –Whether to draw with replacement or not. Default `True` .
- **seed** (*int, optional*) –Random seed. Default `None` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: The output is random, and the length of the output is the same as num_sample.
>>> # replacement is False.
>>> input1 = mindspore.tensor([90 / 100, 10 / 100, 0])
>>> input2 = mindspore.tensor([90, 10, 0])
>>> # input1 and input2 have the same meaning.
>>> mindspore.ops.multinomial(input1, 2, replacement=False)
Tensor(shape=[2], dtype=Int32, value= [0, 1])
>>> mindspore.ops.multinomial(input2, 2, replacement=False)
Tensor(shape=[2], dtype=Int32, value= [1, 0])
>>>
>>> # case 2: The output is random, and the length of the output is the same as num_sample.
>>> # replacement is True.
>>> mindspore.ops.multinomial(input1, 10)
Tensor(shape=[10], dtype=Int32, value= [0, 0, 1, 0, 0, 0, 0, 0, 0, 0])
>>>
>>> # case 3: The output is random, and the length of the output is the same as num_sample.
>>> # replacement is True.
>>> # rank is 2
>>> input3 = mindspore.tensor([[90, 10, 0], [10, 90, 0]], mindspore.float32)
```

(continues on next page)

(continued from previous page)

```
>>> output = mindspore.ops.multinomial(input3, 10)
>>> print(output)
[[0 0 0 0 0 0 0 0 0 0]
 [1 0 1 1 1 1 1 1 1 1]]
```

mindspore.ops.multinomial_with_replacement

mindspore.ops.**multinomial_with_replacement**(*x*, *seed*, *offset*, *numsamples*, *replacement=False*)

Generate a tensor from a multinomial distribution.

Note:

- The rows of input do not need to sum to one (in which case we use the values as weights), but must be non-negative, finite and have a non-zero sum.
- If *seed* is set to be `-1` , and *offset* is set to be `0`, the random number generator is seeded by a random seed.

Parameters

- **x** (*Tensor*) – The 1-D or 2-D input tensor containing probabilities.
- **seed** (*int*) – Random seed.
- **offset** (*int*) – Offset.
- **numsamples** (*int*) – The number of samples to draw.
- **replacement** (*bool, optional*) – Whether to draw with replacement or not. Default `False` .

Returns

Tensor

Supported Platforms:

`CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[0., 9., 4., 0.]], mindspore.float32)
>>> mindspore.ops.multinomial_with_replacement(x, 2, 5, 2, True)
Tensor(shape=[1, 2], dtype=Int64, value=
[[1, 1]])
```

mindspore.ops.rand

mindspore.ops.**rand**(**size*, *dtype=None*, *seed=None*)

Return a new tensor that fills numbers from the uniform distribution over an interval $[0, 1)$ based on the given *size* and *dtype*.

> **Warning:** The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

size (*Union[int, tuple(int), list(int)]*) – The shape of the output tensor.

Keyword Arguments

- **dtype** (*mindspore.dtype*, optional) – The data type returned. Default `None` .
- **seed** (*int, optional*) – Random seed, must be greater or equal to 0. Default `None` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> print(mindspore.ops.rand((2,3)))
[[4.1702199e-01 9.9718481e-01 7.2032452e-01]
 [9.3255734e-01 1.1438108e-04 1.2812445e-01]]
```

mindspore.ops.rand_like

mindspore.ops.**rand_like**(*input*, *seed=None*, ***, *dtype=None*)

Return a tensor with the same shape as *input* that is filled with random numbers from a uniform distribution on the interval $[0, 1)$.

> **Warning:** The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **input** (`Tensor`) – The input tensor.
- **seed** (*int, optional*) – Random seed, must be greater or equal to 0. Default `None` .

Keyword Arguments

dtype (*mindspore.dtype*, optional) – The data type returned. Default `None` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> a = mindspore.tensor([[2, 3, 4], [1, 2, 3]])
>>> print(mindspore.ops.rand_like(a, dtype=mindspore.float32))
[[4.1702199e-01 9.9718481e-01 7.2032452e-01]
 [9.3255734e-01 1.1438108e-04 1.2812445e-01]]
```

mindspore.ops.randint

mindspore.ops.**randint**(*low*, *high*, *size*, *seed=None*, ***, *dtype=None*)

Return a tensor whose elements are random integers in the range of [*low* , *high*) .

> **Warning:** The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **low** (*int*) –Start value of interval.
- **high** (*int*) –End value of interval.
- **size** (*tuple*) –Shape of the output tensor.
- **seed** (*int, optional*) –Random seed, must be non-negative. Default `None` .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The data type returned. Default `None` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> print(mindspore.ops.randint(1, 10, (2,3)))
[[4 9 7]
 [9 1 2]]
```

mindspore.ops.randint_like

mindspore.ops.**randint_like**(*input*, *low*, *high*, *seed=None*, ***, *dtype=None*)

Returns a tensor with the same shape as *input* whose elements are random integers in the range of [*low* , *high*) .

> **Warning:** The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **input** (Tensor) –The input tensor.
- **low** (*int*) –Start value of interval.
- **high** (*int*) –End value of interval.
- **seed** (*int, optional*) –Random seed, must be non-negative. Default None .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The data type returned. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> a = mindspore.tensor([[1, 2, 3], [3, 2, 1]])
>>> print(mindspore.ops.randint_like(a, 1, 10))
[[4 9 7]
 [9 1 2]]
```

mindspore.ops.randn

mindspore.ops.**randn**(**size*, *dtype=None*, *seed=None*)

Return a new tensor with given shape and dtype, filled with random numbers from the standard normal distribution.

> **Warning:** The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

size (*Union[int, tuple(int), list(int)]*) –Shape of the output tensor.

Keyword Arguments

- **dtype** (*mindspore.dtype*, optional) –The data type returned. Default None .
- **seed** (*int, optional*) –Random seed, must be non-negative. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> print(mindspore.ops.randn((2, 2)))
[[ 0.30639967 -0.42438635]
 [-0.4287376   1.3054721 ]]
```

mindspore.ops.randn_like

mindspore.ops.**randn_like**(*input*, *seed=None*, *, *dtype=None*)

Return a tensor with the same shape as *input*, filled with random numbers from the standard normal distribution.

> **Warning:** The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **input** (Tensor) –The input tensor.
- **seed** (*int, optional*) –Random seed, must be non-negative. Default None .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The data type returned. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> a = mindspore.tensor([[1, 2, 3], [4, 5, 6]])
>>> print(mindspore.ops.randn_like(a, dtype=mindspore.float32))
[[ 0.30639967 -0.42438635 -0.20454668]
 [-0.4287376   1.3054721   0.64747655]]
```

mindspore.ops.random_gamma

mindspore.ops.**random_gamma**(*shape*, *alpha*, *seed=None*)

Generate random numbers from the Gamma distribution(s).

Parameters

- **shape** (Tensor) –The shape of random tensor to be generated.
- **alpha** (Tensor) –The α distribution parameter.
- **seed** (*int, optional*) –Random seed, must be non-negative. Default None .

Returns

Tensor, the shape is *mindspore.ops.concat([shape, rate.shape], axis=0)*. The data type is the same as *alpha*.

Supported Platforms:

CPU

Examples

```
>>> import mindspore
>>> shape = mindspore.tensor([7, 5], mindspore.int32)
>>> alpha = mindspore.tensor([0.5, 1.5], mindspore.float32)
>>> output = mindspore.ops.random_gamma(shape, alpha, seed=5)
>>> print(output.shape, output.dtype)
(7, 5, 2) Float32
```

mindspore.ops.random_poisson

mindspore.ops.**random_poisson**(*shape*, *rate*, *seed=None*, *dtype=mstype.float32*)

Generate random number Tensor with *shape* according to a Poisson distribution with mean *rate*.

$$\mathrm{P}(i|) = \frac{\exp(-)^i}{i!}$$

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **shape** (Tensor) –The shape of random tensor to be sampled from each poisson distribution, 1-D integer tensor.
- **rate** (Tensor) –The parameter the distribution is constructed with. It represents the mean of poisson distribution and also the variance of the distribution.
- **seed** (*int, optional*) –Random seed, must be non-negative. Default None .
- **dtype** (mindspore.dtype) –The data type returned. Default mstype.float32.

Returns

Tensor, the shape is *mindspore.ops.concat([shape, rate.shape], axis=0)*.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: 1-D shape, 2-D rate, float64 output
>>> shape = mindspore.tensor([2, 2], mindspore.int64)
>>> rate = mindspore.tensor([[5.0, 10.0], [5.0, 1.0]], mindspore.float32)
>>> output = mindspore.ops.random_poisson(shape, rate, seed=5, dtype=mindspore.float64)
>>> print(output.shape, output.dtype)
(2, 2, 2, 2) Float64
>>> # case 2: 1-D shape, scalar rate, int64 output
>>> shape = mindspore.tensor([2, 2], mindspore.int64)
```

(continues on next page)

(continued from previous page)

```
>>> rate = mindspore.tensor(5.0, mindspore.float64)
>>> output = mindspore.ops.random_poisson(shape, rate, seed=5, dtype=mindspore.int64)
>>> print(output.shape, output.dtype)
(2, 2) Int64
```

mindspore.ops.randperm

mindspore.ops.**randperm**(*n*, *seed=0*, *offset=0*, *dtype=mstype.int64*)

Generates random permutation of integers from 0 to n-1.

Warning:

- This is an experimental API that is subject to change or deletion.
- The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **n** (*Union[Tensor, int]*) – The upper bound (exclusive).
- **seed** (*int, optional*) – Random seed. Default `0` . When seed is -1, offset is 0, it's determined by time.
- **offset** (*int, optional*) – Offset to generate random numbers. Priority is higher than random seed. Default `0` . It must be non-negative.
- **dtype** (mindspore.dtype, *optional*) – The data type returned. Default `mstype.int64`.

Returns

Tensor. Its shape is specified by the required args *n*.

Supported Platforms:

`CPU`

Examples

```
>>> import mindspore
>>> n, seed, offset = 4, 0, 0
>>> output = mindspore.ops.randperm(n, seed, offset, dtype=mindspore.int64)
>>> print(output)
[0 2 1 3]
```

mindspore.ops.standard_laplace

mindspore.ops.**standard_laplace**(*shape*, *seed=None*)

Generates random numbers according to the Laplace random number distribution (mean=0, lambda=1).

$$\mathrm{f}(x) = \frac{1}{2}\exp(-|x|)$$

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **shape** (*Union[tuple, Tensor]*) –The shape of returned tensor.
- **seed** (*int, optional*) –Random number seed. Default `None` .

Returns

Tensor

Raises

- **ValueError** –If shape is a tuple containing non-positive items.
- **ValueError** –If shape is a Tensor, and the rank of the Tensor is not equal to 1.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> shape = (4, 4)
>>> output = mindspore.ops.standard_laplace(shape, seed=5)
>>> print(f'output shape is {output.shape}')
output shape is (4, 4)
```

mindspore.ops.standard_normal

`mindspore.ops.`**`standard_normal`**(*shape*, *seed=None*)

Generates random numbers according to the standard Normal (or Gaussian) random number distribution.

$$f(x) = \frac{1}{\sqrt{2\pi}} e^{\left(-\frac{x^2}{2}\right)}$$

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **shape** (*Union[tuple, Tensor]*) –The shape of returned tensor.
- **seed** (*int, optional*) –Random number Seed. Default `None` .

Returns

Tensor

Raises

- **ValueError** –If *shape* is a tuple containing non-positive items.
- **ValueError** –If shape is a Tensor, and the rank of the Tensor is not equal to 1.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> shape = (4, 4)
>>> output = mindspore.ops.standard_normal(shape, seed=5)
>>> print(f'output shape is {output.shape}')
output shape is (4, 4)
```

mindspore.ops.uniform

mindspore.ops.**uniform**(*shape*, *minval*, *maxval*, *seed=None*, *dtype=mstype.float32*)

Generates random numbers according to the Uniform random number distribution.

Note: The number in tensor minval should be strictly less than maxval at any position after broadcasting.

Parameters

- **shape** (*Union[tuple, Tensor]*) –The shape of returned tensor.
- **minval** (Tensor) –Defines the minimum possible generated value.
- **maxval** (Tensor) –Defines the maximum possible generated value.
- **seed** (*int*) –Random number seed. Default None .
- **dtype** (mindspore.dtype) –Type of the returned tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> # For discrete uniform distribution, only one number is allowed for both minval and␣
↪maxval:
>>> shape = (4, 2)
>>> minval = mindspore.tensor(1, mindspore.int32)
>>> maxval = mindspore.tensor(2, mindspore.int32)
>>> output = mindspore.ops.uniform(shape, minval, maxval, seed=5, dtype=mindspore.int32)
>>>
>>> # For continuous uniform distribution, minval and maxval can be multi-dimentional:
>>> shape = (3, 1, 2)
>>> minval = mindspore.tensor([[3, 4], [5, 6]], mindspore.float32)
>>> maxval = mindspore.tensor([8.0, 10.0], mindspore.float32)
>>> output = mindspore.ops.uniform(shape, minval, maxval, seed=5)
```

(continues on next page)

(continued from previous page)

```
>>> result = output.shape
>>> print(result)
(3, 2, 2)
```

2.1.3 Array Operation

API Name	Description	Supported Platforms
mindspore.ops.argwhere	Return a tensor of containing the positions of all non-zero elements in the input tensor.	Ascend GPU CPU
mindspore.ops.batch_to_space_nd	Divides batch dimension with blocks and interleaves these blocks back into spatial dimensions.	Ascend GPU CPU
mindspore.ops.bincount	Count the frequency of each value in the input tensor of non-negative ints.	Ascend GPU CPU
mindspore.ops.block_diag	Creates a block diagonal matrix from the provided tensor.	Ascend GPU CPU
mindspore.ops.broadcast_to	Broadcasts input tensor to a given shape.	Ascend GPU CPU
mindspore.ops.cat	Connect input tensors along with the given axis.	Ascend GPU CPU
mindspore.ops.channel_shuffle	Divide the channels in a tensor of shape $(*, C, H, W)$ into g groups and rearrange them as $(*, \frac{C}{g}, g, H*W)$, while retaining the original tensor shape in the final output.	Ascend CPU
mindspore.ops.chunk	Split the input tensor into multiple sub-tensors along the specified axis.	Ascend GPU CPU
mindspore.ops.column_stack	Creates a new tensor by horizontally stacking the tensors in *tensors*.	Ascend GPU CPU
mindspore.ops.concat	Alias for mindspore.ops.cat().	
mindspore.ops.conj	Returns a tensor of complex numbers that are the complex conjugate of each element in input.	Ascend GPU CPU
mindspore.ops.count_nonzero	Counts the number of non-zero values in the input tensor along the given axis.	Ascend GPU CPU
mindspore.ops.deepcopy	Return a deepcopy of input tensor.	Ascend GPU CPU
mindspore.ops.diag	Return a tensor with the *input* as its diagonal elements and 0 elsewhere.	Ascend GPU CPU
mindspore.ops.diagflat	If *input* is a vector (1-D tensor), then returns a 2-D square tensor with the elements of *input* as the diagonal, If *input* is a tensor with more than one dimension, then returns a 2-D tensor with diagonal elements equal to a flattened *input*.	Ascend GPU CPU
mindspore.ops.diagonal	Returns diagonals of the input tensor along specified dimension.	Ascend GPU CPU
mindspore.ops.diagonal_scatter	Embeds the values of the *src* tensor into *input* along the diagonal elements of input, with respect to *dim1* and *dim2* .	Ascend GPU CPU
mindspore.ops.diag_embed	Create a tensor whose diagonals of certain 2D planes (specified by *dim1* and *dim2*) are filled by *input*, and all other positions are set to 0.	Ascend GPU CPU
mindspore.ops.dyn_shape	Returns the shape of the input tensor.	Ascend GPU CPU
mindspore.ops.dsplit	Splits a tensor along the 3rd axis.	Ascend GPU CPU

continues on next page

Table 3 – continued from previous page

mindspore.ops.dstack	Stacks tensors along the third axis.	Ascend GPU CPU
mindspore.ops.einsum	According to the Einstein summation Convention (Einsum), the product of the input tensor elements is summed along the specified dimension.	GPU
mindspore.ops.expand_dims	Adds an additional axis to input tensor.	Ascend GPU CPU
mindspore.ops.flip	Reverses elements in a tensor along the given dims.	Ascend GPU CPU
mindspore.ops.fliplr	Flip the input tensor in left/right direction.	Ascend GPU CPU
mindspore.ops.flipud	Flip the input tensor in up/down direction.	Ascend GPU CPU
mindspore.ops.gather	Returns the slice of the input tensor corresponding to the elements of *input_indices* on the specified *axis*.	Ascend GPU CPU
mindspore.ops.gather_d	Gathers elements along an axis specified by dim.	Ascend GPU CPU
mindspore.ops.gather_elements	Gathers elements along the specified dim and indices.	Ascend GPU CPU
mindspore.ops.gather_nd	Gathers slices from the input tensor by specified indices.	Ascend GPU CPU
mindspore.ops.hstack	Stacks tensors in sequence horizontally.	Ascend GPU CPU
mindspore.ops.hsplit	Splits a tensor into multiple sub-tensors horizontally.	Ascend GPU CPU
mindspore.ops.index_add	Add the elements of input *y* into input *x* along the given axis and indices.	Ascend GPU CPU
mindspore.ops.index_fill	Fills the elements of the input *x* with *value* along the given axis and indices.	Ascend GPU CPU
mindspore.ops.index_select	Select the input tensor according to the specified axis and index and return a new tensor.	Ascend GPU CPU
mindspore.ops.inplace_add	Add *x* to *v* according to the indices.	Ascend GPU CPU
mindspore.ops.inplace_index_add	Add *updates* to *var* according to the indices and axis.	Ascend CPU
mindspore.ops.inplace_sub	Subtract *v* in *x* according to the indices.	Ascend GPU CPU
mindspore.ops.inplace_update	Updates *x* to *v* according to the indices.	GPU CPU
mindspore.ops.is_nonzero	Determine whether the input Tensor contains `0` or `False`.	Ascend GPU CPU
mindspore.ops.masked_fill	Fills elements of tensor with value where mask is `True`.	Ascend GPU CPU
mindspore.ops.masked_select	Return a new 1-D tensor which indexes the *input* tensor according to the boolean *mask*.	Ascend GPU CPU
mindspore.ops.meshgrid	Creates grids of coordinates specified by the 1D inputs。	Ascend GPU CPU
mindspore.ops.narrow	Slice the tensor from the *start* position with a length of *length* along *axis* .	Ascend GPU CPU
mindspore.ops.moveaxis	Move axis of an array from source to destination.	Ascend GPU CPU
mindspore.ops.movedim	Swap two dimensions of the input tensor.	Ascend GPU CPU
mindspore.ops.nan_to_num	Replace the *NaN*, positive infinity and negative infinity values in *input* with the specified values in *nan*, *posinf* and *neginf* respectively.	Ascend CPU
mindspore.ops.nanmean	Computes the mean of *input* in specified dimension, ignoring NaN.	Ascend GPU CPU
mindspore.ops.nanmedian	Computes the median and indices of *input* in specified dimension, ignoring NaN.	CPU
mindspore.ops.nansum	Computes sum of *input* over a given dimension, ignoring NaN.	Ascend GPU CPU

continues on next page

Table 3 – continued from previous page

mindspore.ops.normal	Return a random tensor that conforms to the normal (Gaussian) distribution.	Ascend GPU CPU
mindspore.ops.nonzero	Return the positions of all non-zero values.	Ascend GPU CPU
mindspore.ops.numel	Return the total number of elements in the tensor.	Ascend GPU CPU
mindspore.ops.permute	Permute the input tensor along the specified axis.	Ascend GPU CPU
mindspore.ops.population_count	Calculate the number of 1 bits in the binary representation of each element in the input tensor.	Ascend GPU CPU
mindspore.ops.rank	Return the rank of a tensor.	Ascend GPU CPU
mindspore.ops.repeat_elements	Repeat elements of a tensor along an axis, like mindspore.numpy.repeat() .	Ascend GPU CPU
mindspore.ops.repeat_interleave	Repeat elements of a tensor along an axis, like mindspore.numpy.repeat().	Ascend GPU CPU
mindspore.ops.reshape	Reshape the input tensor based on the given shape.	Ascend GPU CPU
mindspore.ops.reverse_sequence	Partially reverse the input sequence.	Ascend GPU CPU
mindspore.ops.roll	Roll the elements of a tensor along a dimension.	Ascend GPU
mindspore.ops.row_stack	Alias for mindspore.ops.vstack() .	Ascend GPU CPU
mindspore.ops.scatter	Update the value in *src* to *input* according to the specified index.	Ascend GPU CPU
mindspore.ops.scatter_nd	Scatters a tensor into a new tensor depending on the specified indices.	Ascend GPU CPU
mindspore.ops.select	The conditional tensor determines whether the corresponding element in the output must be selected from *input* (if True) or *other* (if False) based on the value of each element.	Ascend GPU CPU
mindspore.ops.select_scatter	On the specified dimension *axis* of *input* , *src* is scattered into *input* on the specified *index* of *input* .	Ascend GPU CPU
mindspore.ops.sequence_mask	Returns a mask tensor representing the first N positions of each cell.	GPU CPU
mindspore.ops.shape	Return the shape of the input tensor.	Ascend GPU CPU
mindspore.ops.shuffle	Randomly shuffle a tensor along its first dimension.	Ascend GPU CPU
mindspore.ops.size	Count the total number of elements in *input_x* .	Ascend GPU CPU
mindspore.ops.slice	Slice a tensor in the specified shape.	Ascend GPU CPU
mindspore.ops.slice_scatter	Embed *src* into the sliced *input* along the specified *axis* .	Ascend GPU CPU
mindspore.ops.sort	Sort the elements of the input tensor along the given axis.	Ascend GPU CPU
mindspore.ops.space_to_batch_nd	Divides a tensor's spatial dimensions into blocks and combines the block sizes with the original batch.	Ascend GPU CPU
mindspore.ops.sparse_segment_mean	Computes the mean of sparse segments in the input tensor.	GPU CPU
mindspore.ops.split	Split the tensor into chunks along the given axis.	Ascend GPU CPU
mindspore.ops.squeeze	Remove length one axes from input tensor.	Ascend GPU CPU
mindspore.ops.stack	Stack input tensors in specified axis.	Ascend GPU CPU
mindspore.ops.strided_slice	Extracts a strided slice of a Tensor based on *begin/end* index and *strides*.	Ascend GPU CPU
mindspore.ops.sum	Calculate sum of tensor elements over a given dim.	Ascend GPU CPU
mindspore.ops.swapaxes	Interchange two axes of a tensor.	Ascend GPU CPU
mindspore.ops.swapdims	Interchange two dims of a tensor.	Ascend GPU CPU
mindspore.ops.tensor_scatter_add	Return a new tensor by adding the values from *updates* in *input_x* indicated by *indices* .	Ascend GPU CPU

continues on next page

Table 3 – continued from previous page

mindspore.ops.tensor_scatter_div	Return a new tensor which *input_x* is divided by the values from *updates* indicated by *indices* .	GPU CPU
mindspore.ops.tensor_scatter_max	Return a new tensor by performing a maximum update on *input_x* at the specified indices with the given update values.	GPU CPU
mindspore.ops.tensor_scatter_min	Return a new tensor by performing a minimum update on *input_x* at the specified indices with the given update values.	Ascend GPU CPU
mindspore.ops.tensor_scatter_mul	Return a new tensor by performing a multiplication update on *input_x* at the specified indices with the given update values.	GPU CPU
mindspore.ops.tensor_scatter_sub	Return a new tensor by performing a subtraction update on *input_x* at the specified indices with the given update values.	Ascend GPU CPU
mindspore.ops.tensor_scatter_elements	Return a new tensor by performing a specified operation update on *input_x* at the specified indices with the given update values.	Ascend GPU CPU
mindspore.ops.tensor_split	Split the input tensor into multiple subtensors according to the specified indices or chunks.	Ascend GPU CPU
mindspore.ops.tile	Creates a new tensor by repeating the elements in the input tensor *dims* times.	Ascend GPU CPU
mindspore.ops.tril	Zero the input tensor above the diagonal specified.	Ascend GPU CPU
mindspore.ops.triu	Zero the input tensor below the diagonal specified.	Ascend GPU CPU
mindspore.ops.transpose	Transpose dimensions of the input tensor according to input permutation.	Ascend GPU CPU
mindspore.ops.unbind	Remove a tensor dimension, return a tuple of all slices along a given dimension.	Ascend GPU CPU
mindspore.ops.unique	Remove duplicate elements from the input tensor.	Ascend GPU CPU
mindspore.ops.unique_consecutive	Remove consecutive duplicate elements in the input tensor, retaining only the first occurrence from each repeated group.	Ascend GPU CPU
mindspore.ops.unsorted_segment_max	Compute the maximum of the input tensor along segments.	Ascend GPU CPU
mindspore.ops.unsorted_segment_min	Compute the minimum of the input tensor along segments.	Ascend GPU CPU
mindspore.ops.unsorted_segment_prod	Compute the product of the input tensor along segments.	Ascend GPU CPU
mindspore.ops.unsorted_segment_sum	Compute the sum of the input tensor along segments.	Ascend GPU CPU
mindspore.ops.unsqueeze	Adds an additional dimension to the input tensor at the given dimension.	Ascend GPU CPU
mindspore.ops.unstack	Unstack the input tensor along the specified axis.	Ascend GPU CPU
mindspore.ops.view_as_real	Return a real tensor with the last dimension of size 2, composed of the real and imaginary parts of the complex elements in the input tensor.	GPU CPU
mindspore.ops.vsplit	Split the input tensor with two or more dimensions, into multiple sub-tensors vertically according to *indices_or_sections*.	Ascend GPU CPU
mindspore.ops.vstack	Stacks tensors in sequence vertically.	Ascend GPU CPU
mindspore.ops.where	Return a tensor in which the elements are selected from *input* or *other* based on the *condition*.	Ascend GPU CPU

continues on next page

Table 3 – continued from previous page

mindspore.ops.cross	Compute the cross product of two input tensors along the specified dimension.	Ascend CPU
mindspore.ops.renorm	Returns a tensor where each subtensor along the specified dimension is renormalized such that its p norm is less than or equal to *maxnorm*.	Ascend GPU CPU

mindspore.ops.argwhere

mindspore.ops.**argwhere**(*input*)

Return a tensor of containing the positions of all non-zero elements in the input tensor.

Parameters

input (Tensor) –The input tensor.

Returns

2-D Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[[1,  0], [-5, 0]]], mindspore.int32)
>>> output = mindspore.ops.argwhere(x)
>>> print(output)
[[0 0 0]
 [0 1 0]]
```

mindspore.ops.batch_to_space_nd

mindspore.ops.**batch_to_space_nd**(*input_x*, *block_shape*, *crops*)

Divides batch dimension with blocks and interleaves these blocks back into spatial dimensions.

This operation will divide batch dimension N into blocks with block_shape, the output tensor's N dimension is the corresponding number of blocks after division. The output tensor's $w_1, ..., w_M$ dimension is the product of original $w_1, ..., w_M$ dimension and block_shape with given amount to crop from dimension, respectively.

If the input shape is $(n, c_1, ...c_k, w_1, ..., w_M)$, the output shape is $(n', c_1, ...c_k, w'_1, ..., w'_M)$, where

$$n' = n//(block\_shape[0] * ... * block\_shape[M-1])$$
$$w'_i = w_i * block\_shape[i-1] - crops[i-1][0] - crops[i-1][1]$$

Parameters

- **input_x** (Tensor) –The input tensor. It must be greater or equal to 2-D tensor(equal to 4-D tensor on Ascend), batch dimension must be divisible by product of *block_shape*.
- **block_shape** (*Union[list(int), tuple(int), int]*) –The block shape of dividing block with all value greater than or equal to 1. If *block_shape* is a tuple or list, the length of *block_shape* is M corresponding to the number of spatial dimensions. If *block_shape* is an int, the block size of M dimensions are the same, equal to *block_shape*. In this case of Ascend, M must be 2.

- **crops** (*Union[list(int), tuple(int)]*) −The crops values for spatial dimensions, containing M subtraction list. Each contains 2 integer values. All values must be >= 0. crops[i] specifies the crops values for spatial dimension i, which corresponds to input dimension i + offset,where offset = N-M, and N is the number of input dimensions. It is required that $input\_shape[i + offset] * block\_shape[i] > crops[i][0] + crops[i][1]$

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> block_shape = [2, 2]
>>> crops = [[0, 0], [0, 0]]
>>> input_x = mindspore.tensor([[[[1]]], [[[2]]], [[[3]]], [[[4]]]], mindspore.float32)
>>> output = mindspore.ops.batch_to_space_nd(input_x, block_shape, crops)
>>> print(output)
[[[[1.  2.]
   [3.  4.]]]]
```

mindspore.ops.bincount

`mindspore.ops.`**`bincount`**(*input*, *weights=None*, *minlength=0*)

Count the frequency of each value in the input tensor of non-negative ints.

If you don't specify *minlength*, the length of output tensor the length of the output tensor is max(*input*) + 1.

If *minlength* is specified, the length of the output tensor is max([max(*input*) + 1, *minlength*]).

If 'weights' is specified, the output results are weighted. If *n* is the value at position *i*, i.e `out[n] += weight[i]` instead of `out[n] += 1`.

Note: If *input* contains negative value, the result will be undefined.

Parameters

- **input** (`Tensor`) −1-D input tensor.
- **weights** (`Tensor, optional`) −Weights. Default `None` .
- **minlength** (*int, optional*) −A minimum number of bins for the output tensor. Default `0` .

Returns

Tensor, a tensor of shape [max(input)+1] if input is non-empty, otherwise, the shape is [0].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([2, 4, 1, 0, 0], dtype=mindspore.int64)
>>> print(mindspore.ops.bincount(x, minlength=7))
[2. 1. 1. 0. 1. 0. 0.]
>>> weights = mindspore.tensor([0, 0.25, 0.5, 0.75, 1], dtype=mindspore.float32)
>>> print(mindspore.ops.bincount(x, weights=weights))
[1.75 0.5  0.   0.   0.25]
```

mindspore.ops.block_diag

mindspore.ops.**block_diag**(**inputs*)

Creates a block diagonal matrix from the provided tensor.

Parameters

inputs (Tensor) – One or more tensors, the dimension of tensor should be 0, 1 or 2.

Returns

2-D Tensor, with all input tensors arranged in order so that their top left and bottom right corners are diagonally adjacent. All other elements are set to 0.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x1 = mindspore.tensor([[4], [3], [2]], mindspore.int32)
>>> x2 = mindspore.tensor([7, 6, 5], mindspore.int32)
>>> x3 = mindspore.tensor(1, mindspore.int32)
>>> x4 = mindspore.tensor([[5, 4, 3], [2, 1, 0]], mindspore.int32)
>>> x5 = mindspore.tensor([[8, 7], [7, 8]], mindspore.int32)
>>> out = mindspore.ops.block_diag(x1, x2, x3, x4, x5)
>>> print(out.asnumpy())
[[4 0 0 0 0 0 0 0 0 0]
 [3 0 0 0 0 0 0 0 0 0]
 [2 0 0 0 0 0 0 0 0 0]
 [0 7 6 5 0 0 0 0 0 0]
 [0 0 0 0 1 0 0 0 0 0]
 [0 0 0 0 0 5 4 3 0 0]
 [0 0 0 0 0 2 1 0 0 0]
 [0 0 0 0 0 0 0 0 8 7]
 [0 0 0 0 0 0 0 0 7 8]]
```

mindspore.ops.broadcast_to

mindspore.ops.**broadcast_to**(*input*, *shape*)

Broadcasts input tensor to a given shape. The dim of input must be smaller than or equal to that of target. Suppose input shape is $(x_1, x_2, ..., x_m)$, target shape is $(*, y_1, y_2, ..., y_m)$, where $*$ means any additional dimension. The broadcast rules are as follows:

Compare the value of x_m and y_m, x_{m-1} and y_{m-1}, $\cdots$, x_1 and y_1 consecutively and decide whether these shapes are broadcastable and what the broadcast result is.

If the value pairs at a specific dim are equal, then that value goes right into that dim of output shape. With an input shape $(2, 3)$, target shape $(2, 3)$, the inferred output shape is $(2, 3)$.

If the value pairs are unequal, there are three cases:

Case 1: If the value of the target shape in the dimension is -1, the value of the output shape in the dimension is the value of the corresponding input shape in the dimension. With an input shape $(3, 3)$, target shape $(-1, 3)$, the output shape is $(3, 3)$.

Case 2: If the value of target shape in the dimension is not -1, but the corresponding value in the input shape is 1, then the corresponding value of the output shape is that of the target shape. With an input shape $(1, 3)$, target shape $(8, 3)$, the output shape is $(8, 3)$.

Case 3: If the corresponding values of the two shapes do not satisfy the above cases, it means that broadcasting from the input shape to the target shape is not supported.

So far we got the last m dims of the outshape, now focus on the first $*$ dims, there are two cases:

If the first $*$ dims of output shape does not have -1 in it, then fill the input shape with ones until their length are the same, and then refer to Case 2 mentioned above to calculate the output shape. With target shape $(3, 1, 4, 1, 5, 9)$, input shape $(1, 5, 9)$, the filled input shape will be $(1, 1, 1, 1, 5, 9)$ and thus the output shape is $(3, 1, 4, 1, 5, 9)$.

If the first $*$ dims of output shape have -1 in it, it implies this -1 is corresponding to a non-existing dim so they're not broadcastable. With target shape $(3, -1, 4, 1, 5, 9)$, input shape $(1, 5, 9)$, instead of operating the dim-filling process first, it raises errors directly.

Parameters

- **input** (Tensor) –The input tensor.
- **shape** (*tuple*) –The target shape.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> shape = (2, 3)
>>> x = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.ops.broadcast_to(x, shape)
>>> print(output)
[[1. 2. 3.]
 [1. 2. 3.]]
>>> shape = (-1, 2)
>>> x = mindspore.tensor([[1], [2]], mindspore.float32)
>>> output = mindspore.ops.broadcast_to(x, shape)
>>> print(output)
```

(continues on next page)

(continued from previous page)

```
[[1. 1.]
 [2. 2.]]
```

mindspore.ops.cat

mindspore.ops.**cat**(*tensors*, *axis=0*)

Connect input tensors along with the given axis.

Parameters

- **tensors** (*Union[tuple[Tensor], list[Tensor]]*) –The input tensors. The shapes of all axes except the specified concatenation *axis* should be equal.
- **axis** (*int*) –The specified axis. Default `0` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input_x1 = mindspore.tensor([[0, 1], [2, 1]], mindspore.float32)
>>> input_x2 = mindspore.tensor([[0, 1], [2, 1]], mindspore.float32)
>>> output = mindspore.ops.cat((input_x1, input_x2))
>>> print(output)
[[0. 1.]
 [2. 1.]
 [0. 1.]
 [2. 1.]]
>>> output = mindspore.ops.cat((input_x1, input_x2), 1)
>>> print(output)
[[0. 1. 0. 1.]
 [2. 1. 2. 1.]]
```

mindspore.ops.channel_shuffle

mindspore.ops.**channel_shuffle**(*x*, *groups*)

Divide the channels in a tensor of shape $(*, C, H, W)$ into g groups and rearrange them as $(*, \frac{C}{g}, g, H * W)$, while retaining the original tensor shape in the final output.

Parameters

- **x** (*Tensor*) –The input tensor.
- **groups** (*int*) –Number of groups to divide channels in.

Returns

Tensor

Supported Platforms:

Ascend CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor(mindspore.ops.arange(0, 16, dtype=mindspore.int16).reshape(1, 4, 2,␣
↪2))
>>> y = mindspore.ops.channel_shuffle(x, groups=2)
>>> print(y)
[[[[ 0  1]
   [ 2  3]]
   [[ 8  9]
   [10 11]]
   [[ 4  5]
   [ 6  7]]
   [[12 13]
   [14 15]]]]
```

mindspore.ops.chunk

mindspore.ops.**chunk**(*input*, *chunks*, *axis=0*)

Split the input tensor into multiple sub-tensors along the specified axis.

Note: This function may return less than the specified number of chunks!

Parameters

- **input** (Tensor) −A tensor to be split.
- **chunks** (*int*) −The number of splits.
- **axis** (*int, optional*) −The axis along which to split. Default 0 .

Returns

Tuple of tensors.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.ops.arange(0, 9, dtype=mindspore.float32)
>>> output = mindspore.ops.chunk(input, 3)
>>> print(output)
(Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  1.00000000e+00,  2.
↪00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value= [ 3.00000000e+00,  4.00000000e+00,  5.
↪00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value= [ 6.00000000e+00,  7.00000000e+00,  8.
↪00000000e+00]))
```

mindspore.ops.column_stack

mindspore.ops.**column_stack**(*tensors*)

Creates a new tensor by horizontally stacking the tensors in *tensors*. Similar to *mindspore.ops.hstack()*.

Parameters

tensors (*Union[tuple[Tensor], list[Tensor]]*) – The tensors to be concatenated.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x1 = mindspore.tensor([1, 1, 1])
>>> x2 = mindspore.tensor([2, 2, 2])
>>> output = mindspore.ops.column_stack((x1, x2))
>>> print(output)
[[1 2]
 [1 2]
 [1 2]]
```

mindspore.ops.concat

mindspore.ops.**concat**(*tensors*, *axis=0*)

Alias for *mindspore.ops.cat()*.

Tutorial Examples:

- Tensor - Tensor Operation
- Vision Transformer Image Classification - Building ViT as a whole
- Sentiment Classification Implemented by RNN - Dense

mindspore.ops.conj

mindspore.ops.**conj**(*input*)

Returns a tensor of complex numbers that are the complex conjugate of each element in input. The complex numbers in input must be of the form a + bj, where a is the real part and b is the imaginary part.

The complex conjugate returned by this operation is of the form a - bj.

If *input* is real, it is returned unchanged.

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor(1.3+0.4j, mindspore.complex64)
>>> output = mindspore.ops.conj(x)
>>> output
Tensor(shape=[], dtype=Complex64, value= 1.3-0.4j)
```

mindspore.ops.count_nonzero

`mindspore.ops.`**`count_nonzero`**(*x*, *axis=()*, *keep_dims=False*, *dtype=mstype.int32*)

Counts the number of non-zero values in the input tensor along the given axis. If no axis is specified then all non-zeros in the tensor are counted.

Parameters

- **x** (`Tensor`) – The input tensor.
- **axis** (*`Union[int, tuple(int), list(int)], optional`*) – Specify the axis for computation. Default `()` , which counts all non-zero elements.
- **keep_dims** (*`bool, optional`*) – Whether to maintain dimensions specified by *axis*. Default `False` , don't keep these dimensions.
- **dtype** (*`Union[Number, mindspore.bool_], optional`*) – The data type returned. Default `mstype.int32` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: each value specified.
>>> x = mindspore.tensor([[0, 1, 0], [1, 1, 0]], mindspore.float32)
>>> nonzero_num = mindspore.ops.count_nonzero(x=x, axis=[0, 1], keep_dims=True,␣
↪dtype=mindspore.int32)
>>> print(nonzero_num)
[[3]]
>>> # case 2: all value is default.
>>> nonzero_num = mindspore.ops.count_nonzero(x=x)
>>> print(nonzero_num)
3
>>> # case 3: axis value was specified 0.
>>> nonzero_num = mindspore.ops.count_nonzero(x=x, axis=[0,])
>>> print(nonzero_num)
[1 2 0]
```

(continues on next page)

(continued from previous page)

```
>>> # case 4: axis value was specified 1.
>>> nonzero_num = mindspore.ops.count_nonzero(x=x, axis=[1,])
>>> print(nonzero_num)
[1 2]
>>> # case 5: keep_dims value was specified.
>>> nonzero_num = mindspore.ops.count_nonzero(x=x,  keep_dims=True)
>>> print(nonzero_num)
[[3]]
>>> # case 6: keep_dims and axis value was specified.
>>> nonzero_num = mindspore.ops.count_nonzero(x=x, axis=[0,], keep_dims=True)
>>> print(nonzero_num)
[[1 2 0]]
```

mindspore.ops.deepcopy

mindspore.ops.**deepcopy**(*input_x*)

Return a deepcopy of input tensor.

Parameters

input_x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[0, 1], [2, 1]], dtype=mindspore.int32)
>>> output = mindspore.ops.deepcopy(input)
>>> print(output)
[[0 1]
[2 1]]
```

mindspore.ops.diag

mindspore.ops.**diag**(*input*)

Return a tensor with the *input* as its diagonal elements and 0 elsewhere.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: When input is a 1-D tensor:
>>> input = mindspore.ops.randn(3)
>>> output = mindspore.ops.diag(input)
>>> print(output)
[[ 1.7477764  0.         0.       ]
 [ 0.        -1.2616369  0.       ]
 [ 0.         0.         2.3283238]]
>>>
>>> # case 2: When input is a multi-dimensional tensor:
>>> input = mindspore.ops.randn(2, 3)
>>> print(input)
[[ 0.21546374 -0.0120403  -0.7330481 ]
 [-2.5405762   0.44775972 -1.4063131 ]]
>>> output = mindspore.ops.diag(input)
>>> print(output)
[[[[ 0.21546374  0.          0.        ]
   [ 0.          0.          0.        ]]
  [[ 0.         -0.0120403   0.        ]
   [ 0.          0.          0.        ]]
  [[ 0.          0.         -0.7330481 ]
   [ 0.          0.          0.        ]]]
 [[[ 0.          0.          0.        ]
   [-2.5405762   0.          0.        ]]
  [[ 0.          0.          0.        ]
   [ 0.          0.44775972  0.        ]]
  [[ 0.          0.          0.        ]
   [ 0.          0.         -1.4063131 ]]]]
>>> # Assume input has dimensions (D_1,... D_k), the output is a tensor of rank 2k with␣
↪dimensions
    (D_1,..., D_k, D_1,..., D_k).
>>> print(output.shape)
(2, 3, 2, 3)
```

mindspore.ops.diagflat

mindspore.ops.**diagflat**(*input*, *offset=0*)

If *input* is a vector (1-D tensor), then returns a 2-D square tensor with the elements of *input* as the diagonal, If *input* is a tensor with more than one dimension, then returns a 2-D tensor with diagonal elements equal to a flattened *input*.

Parameters

- **input** (Tensor) –Input Tensor.
- **offset** (*int, optional*) –Diagonal offset. Default `0` .
  - When *offset* is a positive integer, shift the diagonal upward.
  - When *offset* is a negative integer, shift the diagonal downward.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> mindspore.ops.diagflat(mindspore.tensor([1, 2, 3]))
Tensor(shape=[3, 3], dtype=Int64, value=
[[1, 0, 0],
 [0, 2, 0],
 [0, 0, 3]])
>>> mindspore.ops.diagflat(mindspore.tensor([1, 2, 3]), 1)
Tensor(shape=[4, 4], dtype=Int64, value=
[[0, 1, 0, 0],
 [0, 0, 2, 0],
 [0, 0, 0, 3],
 [0, 0, 0, 0]])
>>> mindspore.ops.diagflat(mindspore.tensor([[1, 2], [3, 4]]))
Tensor(shape=[4, 4], dtype=Int64, value=
[[1, 0, 0, 0],
 [0, 2, 0, 0],
 [0, 0, 3, 0],
 [0, 0, 0, 4]])
```

mindspore.ops.diagonal

`mindspore.ops.`**`diagonal`**(*input*, *offset=0*, *dim1=0*, *dim2=1*)

Returns diagonals of the input tensor along specified dimension.

If *input* is 2-D, returns a 1-D tensor containing the diagonal of *input* with the given offset.

If *input* has more than two dimensions, then the diagonals of specified 2-D sub-array determined by *dim1* and *dim2* is returned. The shape of returned tensor is the original shape with axis1 and axis2 removed and a new dimension inserted at the end corresponding to the diagonal.

Parameters

- **`input`** (`Tensor`) –The input tensor with at least two dimensions.
- **`offset`** (*`int, optional`*) –Diagonal offset. Default `0` .
  - When *offset* is a positive integer, shift the diagonal upward.
  - When *offset* is a negative integer, shift the diagonal downward.
- **`dim1`** (*`int, optional`*) –The first dimension specifying the 2D plane. Default `0` .
- **`dim2`** (*`int, optional`*) –The second dimension specifying the 2D plane. Default `1` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[[1, 0, 0],
...                            [0, 2, 0],
...                            [0, 0, 3]],
...                           [[4, 0, 0],
...                            [0, 5, 0],
...                            [0, 0, 6]],
...                           [[7, 0, 0],
...                            [0, 8, 0],
...                            [0, 0, 9]]])
>>> mindspore.ops.diagonal(input)
Tensor(shape=[3, 3], dtype=Int64, value=
[[1, 0, 0],
 [0, 5, 0],
 [0, 0, 9]])
>>> mindspore.ops.diagonal(input, offset=1)
Tensor(shape=[3, 2], dtype=Int64, value=
[[0, 0],
 [2, 0],
 [0, 6]])
>>> mindspore.ops.diagonal(input, offset=0, dim1=2, dim2=1)
Tensor(shape=[3, 3], dtype=Int64, value=
[[1, 2, 3],
 [4, 5, 6],
 [7, 8, 9]])
```

mindspore.ops.diagonal_scatter

mindspore.ops.**diagonal_scatter**(*input*, *src*, *offset=0*, *dim1=0*, *dim2=1*)

Embeds the values of the *src* tensor into *input* along the diagonal elements of input, with respect to *dim1* and *dim2* .

Note: Currently, `inf` value of elements in *input* or *src* is not supported.

Parameters

- **input** (Tensor) –The input tensor, whose dimension is larger than 1.
- **src** (Tensor) –The source tensor to embed.
- **offset** (*int, optional*) –Diagonal offset. Default `0` .
  - When *offset* is a positive integer, shift the diagonal upward.
  - When *offset* is a negative integer, shift the diagonal downward.
- **dim1** (*int, optional*) –First dimension with respect to which to take diagonal. Default `0` .
- **dim2** (*int, optional*) –Second dimension with respect to which to take diagonal. Default `1` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.ops.zeros((3, 3))
>>> output = mindspore.ops.diagonal_scatter(input, mindspore.ops.ones(3), 0)
>>> print(output)
[[1. 0. 0.]
 [0. 1. 0.]
 [0. 0. 1.]]
>>> output = mindspore.ops.diagonal_scatter(input, mindspore.ops.ones(2), 1)
>>> print(output)
[[0. 1. 0.]
 [0. 0. 1.]
 [0. 0. 0.]]
```

mindspore.ops.diag_embed

mindspore.ops.**diag_embed**(*input*, *offset=0*, *dim1=- 2*, *dim2=- 1*)

Create a tensor whose diagonals of certain 2D planes (specified by *dim1* and *dim2*) are filled by *input*, and all other positions are set to `0`. The 2D planes formed by the last two dimensions of the returned tensor are chosen by default.

Parameters

- **input** (Tensor) −Values to fill diagonal.
- **offset** (*int, optional*) −Diagonal offset. Default `0` .
  - When *offset* is a positive integer, shift the diagonal upward.
  - When *offset* is a negative integer, shift the diagonal downward.
- **dim1** (*int, optional*) −The first dimension for diagonal filling. Default `-2` .
- **dim2** (*int, optional*) −The second dimension for diagonal filling. Default `-1` .

Returns

A tensor with the same dtype as *input*, and with shape that has one dimension higher than the *input*.

Raises

ValueError −If the dimension of *input* is not 1D-6D.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1, 2, 3],
...                           [4, 5, 6],
...                           [7, 8, 9]])
>>> mindspore.ops.diag_embed(input)
Tensor(shape=[3, 3, 3], dtype=Int64, value=
[[[1, 0, 0], [0, 2, 0], [0, 0, 3]],
 [[4, 0, 0], [0, 5, 0], [0, 0, 6]],
 [[7, 0, 0], [0, 8, 0], [0, 0, 9]]])
```

(continues on next page)

(continued from previous page)

```
>>> mindspore.ops.diag_embed(input, offset=1, dim1=0, dim2=1)
Tensor(shape=[4, 4, 3], dtype=Int64, value=
[[[0, 0, 0], [1, 4, 7], [0, 0, 0], [0, 0, 0]],
 [[0, 0, 0], [0, 0, 0], [2, 5, 8], [0, 0, 0]],
 [[0, 0, 0], [0, 0, 0], [0, 0, 0], [3, 6, 9]],
 [[0, 0, 0], [0, 0, 0], [0, 0, 0], [0, 0, 0]]])
```

mindspore.ops.dyn_shape

mindspore.ops.**dyn_shape**(*input_x*)

Returns the shape of the input tensor.

Parameters

input_x (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor(mindspore.ops.ones(shape=[3, 2, 1]), mindspore.float32)
>>> output = mindspore.ops.dyn_shape(input_x)
>>> print(output)
[3 2 1]
```

mindspore.ops.dsplit

mindspore.ops.**dsplit**(*input*, *indices_or_sections*)

Splits a tensor along the 3rd axis. It is equivalent to *ops.tensor_split* with $axis = 2$.

Parameters

- **input** (Tensor) –A tensor to be divided.
- **indices_or_sections** (*Union[int, tuple(int), list(int)]*) –See *indices_or_sections* argument in *mindspore.ops.tensor_split()*.

Returns

Tuple of tensors.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.ops.arange(16.0).reshape(2, 2, 4)
>>> print(input)
[[[ 0.  1.  2.  3.]
  [ 4.  5.  6.  7.]]
 [[ 8.  9. 10. 11.]
  [12. 13. 14. 15.]]]
>>> output = mindspore.ops.dsplit(input, 2)
>>> print(output)
(Tensor(shape=[2, 2, 2], dtype=Float32, value=
[[[ 0.00000000e+00,  1.00000000e+00],
  [ 4.00000000e+00,  5.00000000e+00]],
 [[ 8.00000000e+00,  9.00000000e+00],
  [ 1.20000000e+01,  1.30000000e+01]]]), Tensor(shape=[2, 2, 2], dtype=Float32, value=
[[[ 2.00000000e+00,  3.00000000e+00],
  [ 6.00000000e+00,  7.00000000e+00]],
 [[ 1.00000000e+01,  1.10000000e+01],
  [ 1.40000000e+01,  1.50000000e+01]]]))
>>> output = mindspore.ops.dsplit(input, [3, 6])
>>> print(output)
(Tensor(shape=[2, 2, 3], dtype=Float32, value=
[[[ 0.00000000e+00,  1.00000000e+00,  2.00000000e+00],
  [ 4.00000000e+00,  5.00000000e+00,  6.00000000e+00]],
 [[ 8.00000000e+00,  9.00000000e+00,  1.00000000e+01],
  [ 1.20000000e+01,  1.30000000e+01,  1.40000000e+01]]]), Tensor(shape=[2, 2, 1],␣
↪dtype=Float32, value=
[[[ 3.00000000e+00],
  [ 7.00000000e+00]],
 [[ 1.10000000e+01],
  [ 1.50000000e+01]]]), Tensor(shape=[2, 2, 0], dtype=Float32, value=
))
```

mindspore.ops.dstack

mindspore.ops.**dstack**(*tensors*)

Stacks tensors along the third axis.

Note:

- 1-D tensors $(N,)$ should be reshaped to $(1, N, 1)$. 2-D tensors (M, N) should be reshaped to $(M, N, 1)$ before concatenation.
- The tensors must have the same shape along all but the third axis. 1-D or 2-D tensors must have the same shape.

Parameters

tensors (*Union(List[Tensor], Tuple[Tensor])*) – The list of tensors or tuple of tensors.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x1 = mindspore.tensor(mindspore.ops.arange(1, 7).reshape(2, 3))
>>> x2 = mindspore.tensor(mindspore.ops.arange(7, 13).reshape(2, 3))
>>> out = mindspore.ops.dstack([x1, x2])
>>> print(out.asnumpy())
[[[ 1.  7.]
  [ 2.  8.]
  [ 3.  9.]]
 [[ 4. 10.]
  [ 5. 11.]
  [ 6. 12.]]]
```

mindspore.ops.einsum

mindspore.ops.**einsum**(*equation*, **operands*)

According to the Einstein summation Convention (Einsum), the product of the input tensor elements is summed along the specified dimension.

Note:

- The sublist format is also supported. For example, ops.einsum(op1, sublist1, op2, sublist2, ···, sublist_out). In this format, equation can be derived by the sublists which are made up of Python's Ellipsis and list of integers in [0, 52). Each operand is followed by a sublist and an output sublist is at the end.
- The value can contain only letters, commas, ellipsis and arrow. The letters represent input tensor dimension, commas represent separate tensors, ellipsis indicates the tensor dimension that you do not care about, the left of the arrow indicates the input tensors, and the right of it indicates the desired output dimension.

Parameters

- **equation** (*str*) –Notation based on the Einstein summation convention.
- **operands** (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

GPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1.0, 2.0, 4.0], mindspore.float32)
>>> equation = "i->"
>>> output = mindspore.ops.einsum(equation, x)
>>> print(output)
[7.]
>>> x = mindspore.tensor([1.0, 2.0, 4.0], mindspore.float32)
>>> y = mindspore.tensor([2.0, 4.0, 3.0], mindspore.float32)
```

(continues on next page)

(continued from previous page)

```
>>> equation = "i,i->i"
>>> output = mindspore.ops.einsum(equation, x, y)
>>> print(output)
[ 2. 8. 12.]
>>> x = mindspore.tensor([[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]], mindspore.float32)
>>> y = mindspore.tensor([[2.0, 3.0], [1.0, 2.0], [4.0, 5.0]], mindspore.float32)
>>> equation = "ij,jk->ik"
>>> output = mindspore.ops.einsum(equation, x, y)
>>> print(output)
[[16. 22.]
 [37. 52.]]
>>> x = mindspore.tensor([[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]], mindspore.float32)
>>> equation = "ij->ji"
>>> output = mindspore.ops.einsum(equation, x)
>>> print(output)
[[1. 4.]
 [2. 5.]
 [3. 6.]]
>>> x = mindspore.tensor([[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]], mindspore.float32)
>>> equation = "ij->j"
>>> output = mindspore.ops.einsum(equation, x)
>>> print(output)
[5. 7. 9.]
>>> x = mindspore.tensor([[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]], mindspore.float32)
>>> equation = "...->"
>>> output = mindspore.ops.einsum(equation, x)
>>> print(output)
[21.]
>>> x = mindspore.tensor([1.0, 2.0, 3.0], mindspore.float32)
>>> y = mindspore.tensor([2.0, 4.0, 1.0], mindspore.float32)
>>> equation = "j,i->ji"
>>> output = mindspore.ops.einsum(equation, x, y)
>>> print(output)
[[ 2. 4. 1.]
 [ 4. 8. 2.]
 [ 6. 12. 3.]]
>>> x = mindspore.tensor([1, 2, 3, 4], mindspore.float32)
>>> y = mindspore.tensor([1, 2], mindspore.float32)
>>> output = mindspore.ops.einsum(x, [..., 1], y, [..., 2], [..., 1, 2])
>>> print(output)
[[1. 2.]
 [2. 4.]
 [3. 6.]
 [4. 8.]]
```

mindspore.ops.expand_dims

mindspore.ops.**expand_dims**(*input_x*, *axis*)

Adds an additional axis to input tensor.

Note:

- The dimension of *input_x* should be greater than or equal to 1.
- If the specified axis is a negative number, the index is counted backward from the end and starts at 1.

Parameters

- **input_x** (Tensor) –The input tensor.
- **axis** (*int*) –The newly added axis. Only constant value is allowed.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_tensor = mindspore.tensor([[2, 2], [2, 2]], mindspore.float32)
>>> output = mindspore.ops.expand_dims(input_tensor, 0)
>>> print(output)
[[[2. 2.]
  [2. 2.]]]
```

mindspore.ops.flip

mindspore.ops.**flip**(*input*, *dims*)

Reverses elements in a tensor along the given dims.

Parameters

- **input** (Tensor) –The input tensor.
- **dims** (*Union[list[int], tuple[int]]*) –The dimension to flip.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor(mindspore.ops.arange(1, 9).reshape((2, 2, 2)))
>>> output = mindspore.ops.flip(input, (0, 2))
>>> print(output)
[[[6 5]
  [8 7]]
 [[2 1]
  [4 3]]]
```

mindspore.ops.fliplr

mindspore.ops.**fliplr**(*input*)

Flip the input tensor in left/right direction.

Parameters

input (Tensor) −The input tensor, the dimension must be at least 2.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor(mindspore.ops.arange(1, 9).reshape((2, 2, 2)))
>>> output = mindspore.ops.fliplr(input)
>>> print(output)
[[[3 4]
  [1 2]]
 [[7 8]
  [5 6]]]
```

mindspore.ops.flipud

mindspore.ops.**flipud**(*input*)

Flip the input tensor in up/down direction.

Parameters

input (Tensor) −The input tensor, the dimension must be at least 2.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

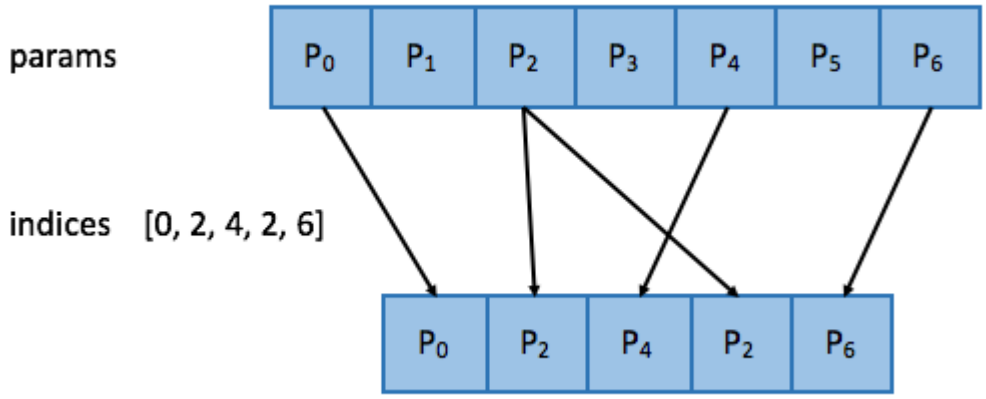
```
>>> import mindspore
>>> input = mindspore.tensor(mindspore.ops.arange(1, 9).reshape((2, 2, 2)))
>>> output = mindspore.ops.flipud(input)
>>> print(output)
[[[5 6]
  [7 8]]
 [[1 2]
  [3 4]]]
```

mindspore.ops.gather

mindspore.ops.**gather**(*input_params*, *input_indices*, *axis*, *batch_dims=0*)

Returns the slice of the input tensor corresponding to the elements of *input_indices* on the specified *axis*.

The following figure shows the calculation process of Gather commonly:



where params represents the input *input_params*, and indices represents the index to be sliced *input_indices*.

Note:

- The value of input_indices must be in the range of *[0, input_param.shape[axis])*. On CPU and GPU, an error is raised if an out of bound indice is found. On Ascend, the results may be undefined.
- The data type of input_params cannot be *mindspore.bool_* .
- The shape of returned tensor is $input\_params.shape[:axis] + input\_indices.shape[batch\_dims:] + input\_params.shape[axis+1:]$.

Parameters

- **input_params** (Tensor) –The input Tensor.
- **input_indices** (Tensor) –The specified indices.
- **axis** (*Union(int, Tensor[int])*) –The specified axis.
- **batch_dims** (*int*) –The number of batch dimensions. Default 0 .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case1: input_indices is a Tensor with shape (5, ).
>>> input_params = mindspore.tensor([1, 2, 3, 4, 5, 6, 7], mindspore.float32)
>>> input_indices = mindspore.tensor([0, 2, 4, 2, 6], mindspore.int32)
>>> axis = 0
>>> output = mindspore.ops.gather(input_params, input_indices, axis)
>>> print(output)
[1. 3. 5. 3. 7.]
>>> # case2: input_indices is a Tensor with shape (2, 2). When the input_params has one␣
 ↪dimension,
>>> # the output shape is equal to the input_indices shape.
>>> input_indices = mindspore.tensor([[0, 2], [2, 6]], mindspore.int32)
>>> axis = 0
>>> output = mindspore.ops.gather(input_params, input_indices, axis)
>>> print(output)
[[1. 3.]
 [3. 7.]]
>>> # case3: input_indices is a Tensor with shape (2, ) and
>>> # input_params is a Tensor with shape (3, 4) and axis is 0.
>>> input_params = mindspore.tensor([[1, 2, 3, 4], [5, 6, 7, 8], [9, 10, 11, 12]], mindspore.
 ↪float32)
>>> input_indices = mindspore.tensor([0, 2], mindspore.int32)
>>> axis = 0
>>> output = mindspore.ops.gather(input_params, input_indices, axis)
>>> print(output)
[[ 1.  2.  3.  4.]
 [ 9. 10. 11. 12.]]
>>> # case4: input_indices is a Tensor with shape (2, ) and
>>> # input_params is a Tensor with shape (3, 4) and axis is 1, batch_dims is 1.
>>> input_params = mindspore.tensor([[1, 2, 3, 4], [5, 6, 7, 8], [9, 10, 11, 12]], mindspore.
 ↪float32)
>>> input_indices = mindspore.tensor([0, 2, 1], mindspore.int32)
>>> axis = 1
>>> batch_dims = 1
>>> output = mindspore.ops.gather(input_params, input_indices, axis, batch_dims)
>>> print(output)
[ 1.  7. 10.]
```

mindspore.ops.gather_d

mindspore.ops.**gather_d**(*x*, *dim*, *index*)

Gathers elements along an axis specified by dim.

Refer to *mindspore.ops.gather_elements()* for more detail.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[1, 2], [3, 4]], mindspore.int32)
>>> index = mindspore.tensor([[0, 0], [1, 0]], mindspore.int32)
>>> dim = 1
>>> output = mindspore.ops.gather_d(x, dim, index)
>>> print(output)
[[1 1]
 [4 3]]
```

mindspore.ops.gather_elements

mindspore.ops.**gather_elements**(*input*, *dim*, *index*)

Gathers elements along the specified dim and indices.

Note: *input* and *index* have the same length of dimensions, and *index.shape[axis]* <= *input.shape[axis]* where axis goes through all dimensions of *input* except *dim*.

Warning: On Ascend, the behavior is unpredictable in the following cases:

- the value of *index* is not in the range *[-input.shape[dim], input.shape[dim])* in forward;
- the value of *index* is not in the range *[0, input.shape[dim])* in backward.

Parameters

- **input** (Tensor) –The input tensor.
- **dim** (*int*) –The specified dim.
- **index** (Tensor) –The specified indices.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[1, 2], [3, 4]], mindspore.int32)
>>> index = mindspore.tensor([[0, 0], [1, 0]], mindspore.int32)
>>> dim = 1
>>> output = mindspore.ops.gather_elements(x, dim, index)
>>> print(output)
[[1 1]
 [4 3]]
```

mindspore.ops.gather_nd

mindspore.ops.**gather_nd**(*input_x*, *indices*)

Gathers slices from the input tensor by specified indices.

Suppose *indices* is an K-dimensional integer tensor, follow the formula below:

$$output[(i_0, ..., i_{K-2})] = input\_x[indices[(i_0, ..., i_{K-2})]]$$

Must be satisfied $indices.shape[-1] <= input\_x.rank$.

Parameters

- **input_x** (Tensor) –The input tensor.
- **indices** (Tensor) –The specified indices.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> input_x = mindspore.tensor([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]], mindspore.float32)
>>> indices = mindspore.tensor([[0, 0], [1, 1]], mindspore.int32)
>>> output = mindspore.ops.gather_nd(input_x, indices)
>>> print(output)
[-0.1  0.5]
```

mindspore.ops.hstack

mindspore.ops.**hstack**(*tensors*)

Stacks tensors in sequence horizontally.

Note:

- Dynamic rank input of 8-D tensors with type float64 is not supported in graph mode (mode=mindspore.GRAPH_MODE).
- This is equivalent to concatenation along the second axis, except for 1-D tensors where it concatenates along the first axis.
- The tensors must have the same shape along all but the second axis, except 1-D tensors which can be any length.

Parameters

tensors (*Union[tuple[Tensor], list[Tensor]]*) –Tuple of tensors or list of tensors.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x1 = mindspore.tensor([1, 1, 1])
>>> x2 = mindspore.tensor([2, 2, 2])
>>> output = mindspore.ops.hstack((x1, x2))
>>> print(output)
[1. 1. 1. 2. 2. 2.]
```

mindspore.ops.hsplit

mindspore.ops.**hsplit**(*input*, *indices_or_sections*)

Splits a tensor into multiple sub-tensors horizontally. It is equivalent to *ops.tensor_split* with $axis = 1$.

Parameters

- **input** (Tensor) –The input tensor.
- **indices_or_sections** (*Union[int, tuple(int), list(int)]*) –See argument in *mindspore.ops.tensor_split()*.

Returns

Tuple of tensors

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.ops.arange(0, 6).reshape((2, 3))
>>> output = mindspore.ops.hsplit(mindspore.tensor(input_x, mindspore.float32), 3)
>>> print(output)
(Tensor(shape=[2, 1], dtype=Float32, value=[[ 0.00000000e+00], [ 3.00000000e+00]]),
 Tensor(shape=[2, 1], dtype=Float32, value=[[ 1.00000000e+00], [ 4.00000000e+00]]),
 Tensor(shape=[2, 1], dtype=Float32, value=[[ 2.00000000e+00], [ 5.00000000e+00]]))
```

mindspore.ops.index_add

mindspore.ops.**index_add**(*x*, *indices*, *y*, *axis*, *use_lock=True*, *check_index_bound=True*)

Add the elements of input *y* into input *x* along the given axis and indices.

Note:

- *indices* is a one-dimensional tensor, and $indices.shape[0] = y.shape[axis]$.
- The value range of the elements in *indices* is $[0, x.shape[axis] - 1]$.

Parameters

- **x** (*Union[Parameter, Tensor]*) –The input parameter or tensor.
- **indices** (Tensor) –The specified indices.

- **y** (Tensor) −The input tensor to add to *x*.
- **axis** (*int*) −The specified axis.
- **use_lock** (*bool, optional*) −Whether to enable a lock to protect the updating process of variable tensors. Default `True` .
- **check_index_bound** (*bool, optional*) −Whether to check index boundary. Default `True` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.Parameter(mindspore.tensor([[1, 2, 3], [4, 5, 6], [7, 8, 9]], mindspore.
↪float32),
...                         name="name_x")
>>> indices = mindspore.tensor([0, 2], mindspore.int32)
>>> y = mindspore.tensor([[0.5, 1.0], [1.0, 1.5], [2.0, 2.5]], mindspore.float32)
>>> output = mindspore.ops.index_add(x, indices, y, 1)
>>> print(output)
[[ 1.5  2.   4. ]
 [ 5.   5.   7.5]
 [ 9.   8.  11.5]]
```

mindspore.ops.index_fill

mindspore.ops.**index_fill**(*x*, *axis*, *index*, *value*)

Fills the elements of the input *x* with *value* along the given axis and indices.

Parameters

- **x** (Tensor) −The input tensor.
- **axis** (*Union[int, Tensor]*) −The specified axis.
- **index** (Tensor) −The specified indices.
- **value** (*Union[bool, int, float, Tensor]*) −Value to fill the returned tensor.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[1, 2, 3], [4, 5, 6], [7, 8, 9]], mindspore.float32)
>>> index = mindspore.tensor([0, 2], mindspore.int32)
>>> value = mindspore.tensor(-2.0, mindspore.float32)
>>> y = mindspore.ops.index_fill(x, 1, index, value)
>>> print(y)
[[-2. 2. -2.]
 [-2. 5. -2.]
 [-2. 8. -2.]]
```

mindspore.ops.index_select

mindspore.ops.**index_select**(*input*, *axis*, *index*)

Select the input tensor according to the specified axis and index and return a new tensor.

Note:

- The value of *index* must be in the range of *[0, input.shape[axis])*, the result is undefined out of range.
- The returned tensor has the same number of dimensions as the input tensor.The *axis* dimension has the same size as the length of *index* , other dimensions have the same size as the input tensor.

Parameters

- **input** (Tensor) –The input tensor.
- **axis** (*int*) –The specified axis.
- **index** (Tensor) –The specified indices, a 1-D tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor(mindspore.ops.arange(0, 16).reshape(2, 2, 4), mindspore.float32)
>>> print(input)
[[[ 0.  1.  2.  3.]
  [ 4.  5.  6.  7.]]
 [[ 8.  9. 10. 11.]
  [12. 13. 14. 15.]]]
>>> index = mindspore.tensor([0,], mindspore.int32)
>>> y = mindspore.ops.index_select(input, 1, index)
>>> print(y)
[[[ 0.  1.  2.  3.]]
 [[ 8.  9. 10. 11.]]]
```

mindspore.ops.inplace_add

mindspore.ops.**inplace_add**(*x*, *v*, *indices*)

Add *x* to *v* according to the indices.

for each *i*, ⋯, *j* in *indices* :

$$x[\text{indices}[i, ..., j]] \mathrel{+}= y[i, ..., j]$$

Parameters

- **x** (Tensor) −The input tensor.
- **v** (Tensor) −The input tensor to add to *x*.
- **indices** (*Union[int, tuple]*) −Indices into the input *x* along the 0th dimension.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> indices = (0, 1)
>>> x = mindspore.tensor([[1, 2], [3, 4], [5, 6]], mindspore.float32)
>>> input_v = mindspore.tensor([[0.5, 1.0], [1.0, 1.5]], mindspore.float32)
>>> output = mindspore.ops.inplace_add(x, input_v, indices)
>>> print(output)
[[1.5 3. ]
 [4.  5.5]
 [5.  6. ]]
```

mindspore.ops.inplace_index_add

mindspore.ops.**inplace_index_add**(*var*, *indices*, *updates*, *axis*)

Add *updates* to *var* according to the indices and axis.

for each *i*, ⋯, *j* in *indices* :

$$x[:, \text{indices}[i, ..., j], :] \mathrel{+}= v[:, i, ..., j, :]$$

where *i* is the index of the element in *indices*, and the axis of *indices[i]* is determined by the input *axis*.

Parameters

- **var** (*Union[Parameter, Tensor]*) −The input parameter or tensor.
- **indices** (Tensor) −The specified indices, a 1-D tensor.
- **updates** (Tensor) −The input tensor to add to *var*.
- **axis** (*int*) −The specified axis.

Returns

Tensor

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore
>>> var = mindspore.Parameter(mindspore.tensor([[1, 2], [3, 4], [5, 6]], mindspore.float32))
>>> indices = mindspore.tensor([0, 1], mindspore.int32)
>>> updates = mindspore.tensor([[0.5, 1.0], [1.0, 1.5]], mindspore.float32)
>>> mindspore.ops.inplace_index_add(var, indices, updates, axis=0)
>>> print(var.asnumpy())
[[1.5 3. ]
 [4.  5.5]
 [5.  6. ]]
```

mindspore.ops.inplace_sub

`mindspore.ops.`**`inplace_sub`**(*x*, *v*, *indices*)

Subtract *v* in *x* according to the indices.

for each *i*, ···, *j* in *indices* :

$$x[\text{indices}[i, ..., j]] \mathrel{-}= v[i, ..., j]$$

Parameters

- **x** (`Tensor`) −The input tensor.
- **v** (`Tensor`) −The input tensor to subtract from *x* .
- **indices** (*`Union[int, tuple]`*) −Indices into the input *x* along the 0th dimension.

Returns

Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> indices = (0, 1)
>>> x = mindspore.tensor([[1, 2], [3, 4], [5, 6]], mindspore.float32)
>>> input_v = mindspore.tensor([[0.5, 1.0], [1.0, 1.5]], mindspore.float32)
>>> output = mindspore.ops.inplace_sub(x, input_v, indices)
>>> print(output)
[[0.5 1. ]
 [2.  2.5]
 [5.  6. ]]
```

mindspore.ops.inplace_update

mindspore.ops.**inplace_update**(*x*, *v*, *indices*)

Updates *x* to *v* according to the indices.

> **Warning:** This is an experimental API that is subject to change or deletion.

for each *i*, ···, *j* in *indices* :

$$x[extindices[i, ..., j]] = v[i, ..., j]$$

Parameters

- **x** (Tensor) −The input tensor.
- **v** (Tensor) −The input tensor to update to *x*.
- **indices** (*Union[int, tuple[int], Tensor]*) −Indices into the input *x* along the 0th dimension.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> indices = (0, 1)
>>> x = mindspore.tensor([[1, 2], [3, 4], [5, 6]], mindspore.float32)
>>> v = mindspore.tensor([[0.5, 1.0], [1.0, 1.5]], mindspore.float32)
>>> output = mindspore.ops.inplace_update(x, v, indices)
>>> print(output)
[[0.5 1. ]
 [1.  1.5]
 [5.  6. ]]
```

mindspore.ops.is_nonzero

mindspore.ops.**is_nonzero**(*input*)

Determine whether the input Tensor contains `0` or `False`. The input can only be a single element.

Parameters

input (Tensor) −The input tensor.

Returns

Bool

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x1 = mindspore.tensor([[[False]]])
>>> x2 = mindspore.tensor([[3.5]])
>>> out1 = mindspore.ops.is_nonzero(x1)
>>> print(out1)
False
>>> out2 = mindspore.ops.is_nonzero(x2)
>>> print(out2)
True
```

mindspore.ops.masked_fill

mindspore.ops.**masked_fill**(*input_x*, *mask*, *value*)

Fills elements of tensor with value where mask is `True`.

Support broadcast.

Parameters

- **input_x** (Tensor) –The input tensor.
- **mask** (Tensor[*bool*]) –The input mask.
- **value** (*Union[Number, Tensor]*) –The value to fill in with.

Returns

Tensor

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([1., 2., 3., 4.], mindspore.float32)
>>> mask = mindspore.tensor([True, True, False, True], mindspore.bool_)
>>> output = mindspore.ops.masked_fill(input_x, mask, 0.5)
>>> print(output)
[0.5 0.5 3.  0.5]
```

mindspore.ops.masked_select

mindspore.ops.**masked_select**(*input*, *mask*)

Return a new 1-D tensor which indexes the *input* tensor according to the boolean *mask*.

Support broadcast.

Parameters

- **input** (Tensor) –The input tensor.
- **mask** (Tensor[*bool*]) –The input mask.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1, 2, 3, 4], mindspore.int64)
>>> mask = mindspore.tensor([1, 0, 1, 0], mindspore.bool_)
>>> output = mindspore.ops.masked_select(x, mask)
>>> print(output)
[1 3]
```

mindspore.ops.meshgrid

`mindspore.ops.`**`meshgrid`**(**inputs*, *indexing='xy'*)

Creates grids of coordinates specified by the 1D inputs。

Note:

- In graph mode, a tuple of N 1-D tensors and N should be greater than 1.
- In pynative mode, a tuple of N 0-D or 1-D tensors and N should be greater than 0. The data type is Number.
- In the 2-D case with inputs of length M and N, the outputs are of shape (N, M) for `'xy'` indexing and (M, N) for `'ij'` indexing.
- In the 3-D case with inputs of length M, N and P, outputs are of shape (N, M, P) for `'xy'` indexing and (M, N, P) for `'ij'` indexing.

Parameters

`inputs` (*`Union[tuple[Tensor], list[Tensor]]`*) – Tuple of tensors or list of tensors.

Keyword Arguments

`indexing` (*`str, optional`*) – Cartesian ('xy', default) or matrix ('ij') indexing of output. Valid options `'xy'` or `'ij'`. Default `'xy'` .

Returns

Tuple of N N-D tensors

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1, 2, 3, 4], mindspore.int32)
>>> y = mindspore.tensor([5, 6, 7], mindspore.int32)
>>> z = mindspore.tensor([8, 9, 0, 1, 2], mindspore.int32)
>>> output = mindspore.ops.meshgrid(x, y, z, indexing='xy')
>>> print(output)
(Tensor(shape=[3, 4, 5], dtype=Int32, value=
 [[[1, 1, 1, 1, 1],
   [2, 2, 2, 2, 2],
   [3, 3, 3, 3, 3],
   [4, 4, 4, 4, 4]],
  [[1, 1, 1, 1, 1],
   [2, 2, 2, 2, 2],
   [3, 3, 3, 3, 3],
   [4, 4, 4, 4, 4]],
  [[1, 1, 1, 1, 1],
   [2, 2, 2, 2, 2],
   [3, 3, 3, 3, 3],
   [4, 4, 4, 4, 4]]]),
 Tensor(shape=[3, 4, 5], dtype=Int32, value=
 [[[5, 5, 5, 5, 5],
   [5, 5, 5, 5, 5],
   [5, 5, 5, 5, 5],
   [5, 5, 5, 5, 5]],
  [[6, 6, 6, 6, 6],
   [6, 6, 6, 6, 6],
   [6, 6, 6, 6, 6],
   [6, 6, 6, 6, 6]],
  [[7, 7, 7, 7, 7],
   [7, 7, 7, 7, 7],
   [7, 7, 7, 7, 7],
   [7, 7, 7, 7, 7]]]),
 Tensor(shape=[3, 4, 5], dtype=Int32, value=
 [[[8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2]],
  [[8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2]],
  [[8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2]]]))
```

mindspore.ops.narrow

mindspore.ops.**narrow**(*input*, *axis*, *start*, *length*)

Slice the tensor from the *start* position with a length of *length* along *axis* .

Parameters

- **input** (Tensor) – The input tensor.
- **axis** (*int*) – the specified axis.
- **start** (*int*) – the specified starting position.
- **length** (*int*) – the specified length.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[1, 2, 3], [4, 5, 6], [7, 8, 9]], mindspore.int32)
>>> output = mindspore.ops.narrow(x, 0, 0, 2)
>>> print(output)
[[ 1 2 3]
 [ 4 5 6]]
>>> output = mindspore.ops.narrow(x, 1, 1, 2)
>>> print(output)
[[ 2 3]
 [ 5 6]
 [ 8 9]]
```

mindspore.ops.moveaxis

mindspore.ops.**moveaxis**(*x*, *source*, *destination*)

Move axis of an array from source to destination.

Refer to *mindspore.ops.movedim()* for more detail.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.ops.zeros((3, 4, 5))
>>> output = mindspore.ops.moveaxis(x, 0, -1)
>>> print(output.shape)
(4, 5, 3)
```

mindspore.ops.movedim

mindspore.ops.**movedim**(*x*, *source*, *destination*)

Swap two dimensions of the input tensor.

Parameters

- **x** (Tensor) –The input tensor.
- **source** (*Union[int, sequence[int]]*) –Original dimensions.
- **destination** (*Union[int, sequence[int]]*) –Destination positions for each of the original dimensions.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> # case1 : moving single axis
>>> import mindspore
>>> x = mindspore.tensor(mindspore.ops.zeros((3, 4, 5)))
>>> output = mindspore.ops.movedim(x, 0, -1)
>>> print(output.shape)
(4, 5, 3)
>>> # case 2 : moving multiple axes
>>> x = mindspore.tensor(mindspore.ops.zeros((3, 4, 5)))
>>> output = mindspore.ops.movedim(x, (0, 2), (1, 2))
>>> print(output.shape)
(4, 3, 5)
```

mindspore.ops.nan_to_num

mindspore.ops.**nan_to_num**(*input*, *nan=None*, *posinf=None*, *neginf=None*)

Replace the *NaN*, positive infinity and negative infinity values in *input* with the specified values in *nan*, *posinf* and *neginf* respectively.

> **Warning:** For Ascend, it is only supported on Atlas A2 Training Series Products. This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input tensor.
- **nan** (*number, optional*) –The replace value of *NaN*. Default None.
- **posinf** (*number, optional*) –the value to replace *posinf* values with. Default None, replacing *posinf* with the maximum value supported by the data type of *input*.
- **neginf** (*number, optional*) –the value to replace *neginf* values with. Default None, replacing *neginf* with the minimum value supported by the data type of *input*.

Returns

Tensor

Supported Platforms:

Ascend CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([float('nan'), float('inf'), -float('inf'), 5.0], mindspore.
↪float32)
>>> output = mindspore.ops.nan_to_num(input)
>>> print(output)
[ 0.0000000e+00  3.4028235e+38 -3.4028235e+38  5.0000000e+00]
>>> output = mindspore.ops.nan_to_num(input, 1.0)
>>> print(output)
[ 1.0000000e+00  3.4028235e+38 -3.4028235e+38  5.0000000e+00]
>>> output = mindspore.ops.nan_to_num(input, 1.0, 2.0)
>>> print(output)
[ 1.0000000e+00  2.0000000e+00 -3.4028235e+38  5.0000000e+00]
>>> output = mindspore.ops.nan_to_num(input, 1.0, 2.0, 3.0)
>>> print(output)
[1.  2.  3.  5.0]
```

mindspore.ops.nanmean

mindspore.ops.**nanmean**(*input*, *axis=None*, *keepdims=False*, *, *dtype=None*)

Computes the mean of *input* in specified dimension, ignoring NaN.

Parameters

- **input** (Tensor) –The input tensor.
- **axis** (*int, optional*) –The specified axis for computation. Default None .
- **keepdims** (*bool, optional*) –Whether the output tensor has to dim retained. Default False .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The data type returned. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[0.5, -1.1, float('nan')], [3.4, float('nan'), float('nan')]],␣
↪mindspore.float32)
>>> y = mindspore.ops.nanmean(x, axis=0, keepdims=False)
>>> print(y)
[ 1.95 -1.1    nan]
```

mindspore.ops.nanmedian

mindspore.ops.**nanmedian**(*input*, *axis=- 1*, *keepdims=False*)

Computes the median and indices of *input* in specified dimension, ignoring NaN.

> **Warning:** *indices* does not necessarily contain the first occurrence of each median value found in the *input*, unless it is unique.

Parameters

- **input** (Tensor) –The input tensor.
- **axis** (*int, optional*) –The specified axis for computation. Default `-1` .
- **keepdims** (*bool, optional*) –Whether the output tensor needs to retain dimension or not. Default `False` .

Returns

Tuple(median, median_indices)

Supported Platforms:

CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[0.57, 0.11, float("nan")],
...                       [0.38, float("nan"), float("nan")],
...                       [0.36, 0.16, float("nan")]], mindspore.float32)
>>> y, idx = mindspore.ops.nanmedian(x, axis=0, keepdims=False)
>>> print(y)
[0.38 0.11  nan]
>>> print(idx)
[1 0 0]
```

mindspore.ops.nansum

mindspore.ops.**nansum**(*input*, *axis=None*, *keepdims=False*, *, *dtype=None*)

Computes sum of *input* over a given dimension, ignoring NaN.

Parameters

- **input** (Tensor) –The input tensor.
- **axis** (*Union[int, tuple(int)], optional*) –The dimensions to reduce. Supposed the rank of *input* is r, axis must be in the range [-rank(input), rank(input)). Default None, all dimensions are reduced.
- **keepdims** (*bool, optional*) –Whether the output tensor keeps has dim retained. Default False.

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The dtype of output tensor. Default None.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[float("nan"), 2, 3], [1, float("nan"), 3], [1, 2, float("nan")]],␣
↪mindspore.float32)
>>> # case1: axis is None, keepdims is False,
>>> output1 = mindspore.ops.nansum(x, axis=None, dtype=mindspore.float32)
>>> print(output1)
12.0
>>> # case2: axis is int, set as 0, and keepdims is False
>>> output2 = mindspore.ops.nansum(x, axis=0, dtype=mindspore.float32)
>>> print(output2)
[2. 4. 6.]
>>> # case3: axis is int, set as 0, and keepdims is False
>>> output3 = mindspore.ops.nansum(x, axis=0, keepdims=True, dtype=mindspore.float32)
>>> print(output3)
[[2. 4. 6.]]
>>> # case4: axis is tuple(int) or list(int), set as (0, 1), and keepdims is False
>>> output4 = mindspore.ops.nansum(x, axis=(0, 1), dtype=mindspore.float32)
>>> print(output4)
12.0
```

mindspore.ops.normal

mindspore.ops.**normal**(*shape*, *mean*, *stddev*, *seed=None*)

Return a random tensor that conforms to the normal (Gaussian) distribution.

> **Warning:** The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **shape** (*tuple*) –The shape of returned tensor.
- **mean** (*Union[Tensor, int, float]*) –The mean of the normal distribution for the returned tensor.
- **stddev** (*Union[Tensor, int, float]*) –The standard deviation of the normal distribution for the returned tensor.
- **seed** (*int, optional*) –Random seed. Default: None , which is equivalent to 0.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> shape = (3, 1, 2)
>>> mean = mindspore.tensor([[3, 4], [5, 6]], mindspore.float32)
>>> stddev = mindspore.tensor(1.0, mindspore.float32)
>>> output = mindspore.ops.normal(shape, mean, stddev, seed=5)
>>> result = output.shape
>>> print(result)
(3, 2, 2)
>>> shape = (3, 1, 3)
>>> mean = mindspore.tensor([[3, 4, 3], [3, 5, 6]], mindspore.float32)
>>> stddev = mindspore.tensor(1.0, mindspore.float32)
>>> output = mindspore.ops.normal(shape, mean, stddev, seed=5)
>>> result = output.shape
>>> print(result)
(3, 2, 3)
>>> shape = (3, 1, 3)
>>> mean = mindspore.tensor([[1, 2, 3], [3, 4, 3], [3, 5, 6]], mindspore.float32)
>>> stddev = mindspore.tensor(1.0, mindspore.float32)
>>> output = mindspore.ops.normal(shape, mean, stddev, seed=5)
>>> result = output.shape
>>> print(result)
(3, 3, 3)
```

mindspore.ops.nonzero

mindspore.ops.**nonzero**(*input*, *, *as_tuple=False*)

Return the positions of all non-zero values.

Parameters

input (Tensor) – The input tensor.

Note:

- Ascend: Rank of Input tensor can be equal to 0 except jit level O2 mode.
- CPU/GPU: Rank of Input tensor should be greater than or eaqual to 1.

Keyword Arguments

as_tuple (bool, *optional*) – Whether the output is tuple. Default False .

Returns

Tensor or tuple of tensors

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[[1,  0], [-5, 0]]], mindspore.int32)
>>> output = mindspore.ops.nonzero(x)
>>> print(output)
[[0 0 0]
 [0 1 0]]
>>> x = mindspore.tensor([1, 0, 2, 0, 3], mindspore.int32)
>>> output = mindspore.ops.nonzero(x, as_tuple=False)
>>> print(output)
[[0]
 [2]
 [4]]
>>> x = mindspore.tensor([[[1,  0], [-5, 0]]], mindspore.int32)
>>> output = mindspore.ops.nonzero(x, as_tuple=True)
>>> print(output)
(Tensor(shape=[2], dtype=Int64, value=[0, 0]),
 Tensor(shape=[2], dtype=Int64, value=[0, 1]),
 Tensor(shape=[2], dtype=Int64, value=[0, 0]))
>>> x = mindspore.tensor([1, 0, 2, 0, 3], mindspore.int32)
>>> output = mindspore.ops.nonzero(x, as_tuple=True)
>>> print(output)
(Tensor(shape=[3], dtype=Int64, value=[0, 2, 4]), )
```

mindspore.ops.numel

mindspore.ops.**numel**(*input*)

Return the total number of elements in the tensor.

Parameters

input (Tensor) –The input tensor.

Returns

The total number of elements in tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([[2, 2], [2, 2]], mindspore.float32)
>>> print(mindspore.ops.numel(input_x))
4
```

mindspore.ops.permute

mindspore.ops.**permute**(*input*, *axis*)

Permute the input tensor along the specified axis.

Parameters

- **input** (Tensor) –The input tensor.
- **axis** (*tuple(int)*) –The axis in a specified order.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([[[1, 2, 3], [4, 5, 6]], [[7, 8, 9], [10, 11, 12]]],␣
↪mindspore.float32)
>>> input_perm = (0, 2, 1)
>>> print(mindspore.ops.permute(input_x, input_perm))
[[[ 1.  4.]
  [ 2.  5.]
  [ 3.  6.]]
 [[ 7. 10.]
  [ 8. 11.]
  [ 9. 12.]]]
```

mindspore.ops.population_count

mindspore.ops.**population_count**(*input_x*)

Calculate the number of 1 bits in the binary representation of each element in the input tensor.

Parameters

input_x (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([0, 1, 3], mindspore.int16)
>>> output = mindspore.ops.population_count(input_x)
>>> print(output)
[0 1 2]
```

mindspore.ops.rank

mindspore.ops.**rank**(*input_x*)

Return the rank of a tensor.

Parameters

input_x (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_tensor = mindspore.tensor([[2, 2], [2, 2]], mindspore.float32)
>>> output = mindspore.ops.rank(input_tensor)
>>> print(output)
2
>>> print(type(output))
<class 'int'>
```

mindspore.ops.repeat_elements

mindspore.ops.**repeat_elements**(*x*, *rep*, *axis=0*)

Repeat elements of a tensor along an axis, like *mindspore.numpy.repeat()* .

Note: It is recommended to use :func:'mindspore.mint.repeat_interleave', the dimension of input 'x' can support a maximum of 8, and get better performance.

Parameters

- **x** (Tensor) −The input tensor.
- **rep** (*int*) −The number of times to repeat, must be positive.
- **axis** (*int*) −The axis along which to repeat. Default 0.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1 : repeat on axis 0
>>> x = mindspore.tensor([[0, 1, 2], [3, 4, 5]], mindspore.int32)
>>> output = mindspore.ops.repeat_elements(x, rep = 2, axis = 0)
>>> print(output)
[[0 1 2]
 [0 1 2]
 [3 4 5]
 [3 4 5]]
>>> # case 2 : repeat on axis 1
>>> x = mindspore.tensor([[0, 1, 2], [3, 4, 5]], mindspore.int32)
>>> output = mindspore.ops.repeat_elements(x, rep = 2, axis = 1)
>>> print(output)
[[0 0 1 1 2 2]
 [3 3 4 4 5 5]]
```

mindspore.ops.repeat_interleave

mindspore.ops.**repeat_interleave**(*input*, *repeats*, *axis=None*)

Repeat elements of a tensor along an axis, like *mindspore.numpy.repeat()*.

Parameters

- **input** (Tensor) −The input tensor.
- **repeats** (*Union[int, tuple, list, Tensor]*) −The number of times to repeat, must be positive.
- **axis** (*int, optional*) −The axis along which to repeat, Default None. if dims is None, both the input and output tensors will be flattened into 1-D.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>>  # case 1 : repeat on axis 0
>>> input = mindspore.tensor([[0, 1, 2], [3, 4, 5]], mindspore.int32)
>>> output = mindspore.ops.repeat_interleave(input, repeats=2, axis=0)
>>> print(output)
[[0 1 2]
 [0 1 2]
 [3 4 5]
 [3 4 5]]
>>>  # case 2 : repeat on axis 1
>>> input = mindspore.tensor([[0, 1, 2], [3, 4, 5]], mindspore.int32)
>>> output = mindspore.ops.repeat_interleave(input, repeats=2, axis=1)
>>> print(output)
[[0 0 1 1 2 2]
[3 3 4 4 5 5]]
```

mindspore.ops.reshape

`mindspore.ops.`**`reshape`**(*input*, *shape*)

Reshape the input tensor based on the given shape.

Note: The -1 in the parameter *shape* indicates that the size of that dimension is inferred from the other dimensions and the total number of elements in input tensor.

Parameters

- **`input`** (`Tensor`) –The input tensor.
- **`shape`** (*`Union[tuple[int], list[int], Tensor[int]]`*) –New shape.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]], mindspore.float32)
>>> # case1: Parameter `shape` does not contain -1.
>>> output = mindspore.ops.reshape(input, (3, 2))
>>> print(output)
[[-0.1  0.3]
 [ 3.6  0.4]
 [ 0.5 -3.2]]
>>> # case2: Parameter `shape` contains -1.
>>> output = mindspore.ops.reshape(input, (-1, 6))
>>> print(output)
[[-0.1  0.3  3.6  0.4  0.5 -3.2]]
```

mindspore.ops.reverse_sequence

mindspore.ops.**reverse_sequence**(*x*, *seq_lengths*, *seq_dim*, *batch_dim=0*)

Partially reverse the input sequence.

Parameters

- **x** (Tensor) –The input tensor.
- **seq_lengths** (Tensor) –The specified reversing length.
- **seq_dim** (*int*) –The specified dimension for reversal.
- **batch_dim** (*int*) –The specified slice dimension. Default 0 .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[1, 2, 3], [4, 5, 6], [7, 8, 9]], mindspore.float32)
>>> seq_lengths = mindspore.tensor([1, 2, 3])
>>> output = mindspore.ops.reverse_sequence(x, seq_lengths, seq_dim=1)
>>> print(output)
[[1. 2. 3.]
 [5. 4. 6.]
 [9. 8. 7.]]
>>> x = mindspore.tensor([[1, 2, 3], [4, 5, 6], [7, 8, 9]], mindspore.float32)
>>> seq_lengths = mindspore.tensor([1, 2, 3])
>>> output = mindspore.ops.reverse_sequence(x, seq_lengths, seq_dim=0, batch_dim=1)
>>> print(output)
[[1. 5. 9.]
 [4. 2. 6.]
 [7. 8. 3.]]
>>> x = mindspore.tensor([[1, 2, 3], [4, 5, 6], [7, 8, 9]], mindspore.float32)
>>> seq_lengths = mindspore.tensor([2, 2, 3])
```

(continues on next page)

(continued from previous page)

```
>>> output = mindspore.ops.reverse_sequence(x, seq_lengths, seq_dim=1)
>>> print(output)
[[2. 1. 3.]
 [5. 4. 6.]
 [9. 8. 7.]]
>>> x = mindspore.tensor([[1, 2, 3], [4, 5, 6], [7, 8, 9]], mindspore.float32)
>>> seq_lengths = mindspore.tensor([3, 2, 3])
>>> output = mindspore.ops.reverse_sequence(x, seq_lengths, seq_dim=1)
>>> print(output)
[[3. 2. 1.]
 [5. 4. 6.]
 [9. 8. 7.]]
>>> x = mindspore.tensor([[1, 2, 3, 4], [5, 6, 7, 8]], mindspore.float32)
>>> seq_lengths = mindspore.tensor([4, 4])
>>> output = mindspore.ops.reverse_sequence(x, seq_lengths, seq_dim=1)
>>> print(output)
[[4. 3. 2. 1.]
 [8. 7. 6. 5.]]
```

mindspore.ops.roll

mindspore.ops.**roll**(*input*, *shifts*, *dims=None*)

Roll the elements of a tensor along a dimension.

Parameters

- **input** (Tensor) – The input tensor.
- **shifts** (*Union[list(int), tuple(int), int]*) – The amount of element shifting.
- **dims** (*Union[list(int), tuple(int), int], optional*) – Specify the dimension to move. Default None , which means the input tensor will be flattened before computation, and the result will be reshaped back to the original input shape.

Returns

Tensor

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0, 1, 2, 3, 4], mindspore.float32)
>>> # case1: Parameter `shifts` is positive
>>> output = mindspore.ops.roll(input, shifts=2, dims=0)
>>> print(output)
[3. 4. 0. 1. 2.]
>>> # case2: Parameter `shifts` is negative
>>> output = mindspore.ops.roll(input, shifts=-2, dims=0)
>>> print(output)
[2. 3. 4. 0. 1.]
```

mindspore.ops.row_stack

mindspore.ops.**row_stack**(*tensors*)

Alias for *mindspore.ops.vstack()* .

Supported Platforms:

Ascend GPU CPU

mindspore.ops.scatter

mindspore.ops.**scatter**(*input*, *axis*, *index*, *src*)

Update the value in *src* to *input* according to the specified index. Refer to *mindspore.ops.tensor_scatter_elements()* for more details.

Note: If *src* is a tensor, the backward is supported only for the case *src.shape == index.shape*.

Parameters

- **input** (Tensor) −The input tensor.
- **axis** (*int*) −The axis to do update operation.
- **index** (Tensor) −The index to do update operation.
- **src** (Tensor, *float*) −The data to do the update operation with *input* .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1, 2, 3, 4, 5]], dtype=mindspore.float32)
>>> src = mindspore.tensor([[8, 8]], dtype=mindspore.float32)
>>> index = mindspore.tensor([[2, 4]], dtype=mindspore.int64)
>>> out = mindspore.ops.scatter(input=input, axis=1, index=index, src=src)
>>> print(out)
[[1. 2. 8. 4. 8.]]
>>> input = mindspore.tensor(mindspore.ops.zeros((5, 5)), dtype=mindspore.float32)
>>> src = mindspore.tensor([[1, 2, 3], [4, 5, 6], [7, 8, 9]], dtype=mindspore.float32)
>>> index = mindspore.tensor([[0, 0, 0], [2, 2, 2], [4, 4, 4]], dtype=mindspore.int64)
>>> out = mindspore.ops.scatter(input=input, axis=0, index=index, src=src)
>>> print(out)
[[1. 2. 3. 0. 0.]

[0. 0. 0. 0. 0.]]
```

mindspore.ops.scatter_nd

mindspore.ops.**scatter_nd**(*indices*, *updates*, *shape*)

Scatters a tensor into a new tensor depending on the specified indices.

Creates an empty tensor with the given *shape*, and set values by scattering the update tensor depending on indices. The empty tensor has rank P and *indices* has rank Q.

The *shape* is $(s_0, s_1, ..., s_{P-1})$, where $P \geq 1$.

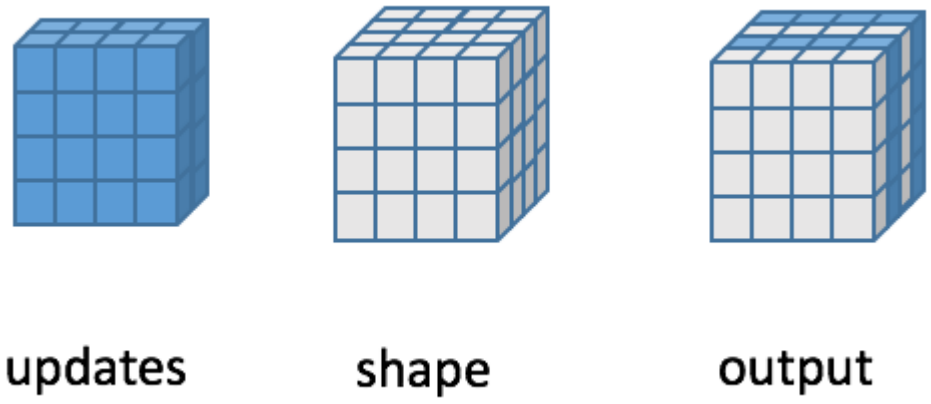
indices has shape $(i_0, i_1, ..., i_{Q-2}, N)$, where $Q \geq 2$ and $N \leq P$.

The last dimension of *indices* (with length N) indicates slices along the N th dimension of the empty tensor.

updates is a tensor of rank $Q - 1 + P - N$, and its shape is $(i_0, i_1, ..., i_{Q-2}, s_N, s_{N+1}, ..., s_{P-1})$.

If *indices* contains duplicates, the duplicate *updates* are summed.

The following figure shows the calculation process of inserting two new value matrices into the first dimension with rank-3:



Parameters

- **indices** (Tensor) −The index of scattering in the new tensor. The rank of *indices* must be at least 2 and *indices.shape[-1]* <= *len(shape)*.
- **updates** (Tensor) −The source tensor to be updated. It has shape *indices.shape[:-1] + shape[indices.shape[-1]:]*.
- **shape** (*tuple[int]*) −The shape of the output tensor. *shape* can not be empty, and the elements in *shape* must be greater than or equal to 1.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> indices = mindspore.tensor([[0], [2]], mindspore.int32)
>>> updates = mindspore.tensor([[[1, 1, 1, 1], [2, 2, 2, 2],
...                              [3, 3, 3, 3], [4, 4, 4, 4]],
...                             [[1, 1, 1, 1], [2, 2, 2, 2],
...                              [3, 3, 3, 3], [4, 4, 4, 4]]], mindspore.float32)
>>> shape = (4, 4, 4)
>>> output = mindspore.ops.scatter_nd(indices, updates, shape)
>>> print(output)
[[[1. 1. 1. 1.]
  [2. 2. 2. 2.]
  [3. 3. 3. 3.]

>>> # [
>>> #     [0. 3.2. 0.]
>>> #     [0. 1.1  0.]
>>> #     [0. 0.   0.]
```

(continues on next page)

(continued from previous page)

```
>>> # ]
>>> # The final result is as follows:
>>> print(output)
[[0. 3.2 0.]
 [0. 1.1 0.]
 [0. 0.  0.]]
```

mindspore.ops.select

mindspore.ops.**select**(*condition*, *input*, *other*)

The conditional tensor determines whether the corresponding element in the output must be selected from *input* (if True) or *other* (if False) based on the value of each element.

It can be defined as:

$$out_i = \begin{cases} input_i, & \text{if } condition_i \\ other_i, & \text{otherwise} \end{cases}$$

Parameters

- **condition** (Tensor[bool]) – The condition tensor.
- **input** (Union[Tensor, int, float]) – The first tensor or number to be selected.
- **other** (Union[Tensor, int, float]) – The second tensor or number to be selected.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case1: Both `input` and `other` are tensor
>>> cond = mindspore.tensor([True, False])
>>> x = mindspore.tensor([2,3], mindspore.float32)
>>> y = mindspore.tensor([1,2], mindspore.float32)
>>> output1 = mindspore.ops.select(cond, x, y)
>>> print(output1)
[2. 2.]
>>> # case2: Both `input` and `other` are number
>>> output2 = mindspore.ops.select(cond, input=1, other=2)
>>> print(output2)
[1 2]
>>> # case3: `input` is tensor and `other` is number
>>> output3 = mindspore.ops.select(cond, x, other=3)
>>> print(output3)
[2. 3.]
```

mindspore.ops.select_scatter

mindspore.ops.**select_scatter**(*input*, *src*, *axis*, *index*)

On the specified dimension *axis* of *input* , *src* is scattered into *input* on the specified *index* of *input* .

Parameters

- **input** (Tensor) −The input tensor.
- **src** (Tensor) −The source tensor.
- **axis** (*int*) −The dimension of *input* to be embedded.
- **index** (*int*) −The location of scattering on the specified dimension.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.ops.zeros((2, 3, 3))
>>> src = mindspore.ops.ones((2, 3))
>>> output = mindspore.ops.select_scatter(input, src, axis=1, index=1)
>>> print(output)
[[[0. 0. 0.]
  [1. 1. 1.]
  [0. 0. 0.]]
 [[0. 0. 0.]
  [1. 1. 1.]
  [0. 0. 0.]]]
```

mindspore.ops.sequence_mask

mindspore.ops.**sequence_mask**(*lengths*, *maxlen=None*)

Returns a mask tensor representing the first N positions of each cell.

If *lengths* has shape $(d_1, d_2, ..., d_n)$, then the resulting tensor mask has type and shape $(d_1, d_2, ..., d_n, maxlen)$, with mask $[i_1, i_2, ..., i_n, j] = (j < lengths[i_1, i_2, ..., i_n])$.

Parameters

- **lengths** (Tensor) −Tensor to calculate the mask for. All values in this tensor should be less than or equal to *maxlen*. Values greater than *maxlen* will be treated as *maxlen*.
- **maxlen** (*int*) −size of the last dimension of returned tensor. Must be positive and same type as elements in *lengths*. Default None .

Returns

Tensor, shape is *lengths.shape + (maxlen,)* .

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: When maxlen is assigned
>>> x = mindspore.tensor([1, 2, 3, 4])
>>> output = mindspore.ops.sequence_mask(x, 5)
>>> print(output)
[[ True False False False False]
 [ True  True False False False]
 [ True  True  True False False]
 [ True  True  True  True False]]
>>> # case 2: When there is 0 in x
>>> x = mindspore.tensor([[1, 3], [2, 0]])
>>> output = mindspore.ops.sequence_mask(x, 5)
>>> print(output)
[[[ True False False False False]
  [ True  True  True False False]]
 [[ True  True False False False]
  [False False False False False]]]
>>> # case 3: when the maxlen is not assigned
>>> x = mindspore.tensor([[1, 3], [2, 4]])
>>> output = mindspore.ops.sequence_mask(x)
>>> print(output)
[[[ True False False False ]
  [ True  True  True False ]]
 [[ True  True False False ]
  [ True  True  True  True ]]]
```

mindspore.ops.shape

mindspore.ops.**shape**(*input_x*)

Return the shape of the input tensor.

Parameters

input_x (Tensor) – The input tensor.

Returns

tuple[int]

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.ops.ones(shape=[3, 2, 1])
>>> output = mindspore.ops.shape(input_x)
>>> print(output)
(3, 2, 1)
```

mindspore.ops.shuffle

mindspore.ops.**shuffle**(*x*, *seed=None*)

Randomly shuffle a tensor along its first dimension.

Parameters

- **x** (Tensor) −The input tensor.
- **seed** (*int, optional*) −Random seed. Default None , which is equivalent to 0.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1, 2, 3, 4], mindspore.float32)
>>> output = mindspore.ops.shuffle(x, seed=1)
>>> print(output)
[3. 4. 2. 1.]
```

mindspore.ops.size

mindspore.ops.**size**(*input_x*)

Count the total number of elements in *input_x* .

Parameters

input_x (Tensor) −The input tensor.

Returns

int

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([[2, 2], [2, 2]], mindspore.float32)
>>> output = mindspore.ops.size(input_x)
>>> print(output)
4
```

mindspore.ops.slice

mindspore.ops.**slice**(*input_x*, *begin*, *size*)

Slice a tensor in the specified shape.

Note: *begin* is zero-based and *size* is one-based.

If *size[i]* is -1, all remaining elements in dimension i are included in the slice. This is equivalent to setting $size[i] = input\_x.shape(i) - begin[i]$.

Parameters

- **input_x** (Tensor) –The input tensor.
- **begin** (*Union[tuple, list]*) –The beginning of the slice which represents the offset in each dimension.
- **size** (*Union[tuple, list]*) –The size of the slice.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> data = mindspore.tensor([[[1, 1, 1], [2, 2, 2]],
...                          [[3, 3, 3], [4, 4, 4]],
...                          [[5, 5, 5], [6, 6, 6]]], mindspore.int32)
>>> output = mindspore.ops.slice(data, (1, 0, 0), (1, 1, 3))
>>> print(output)
[[[3 3 3]]]
>>> output = mindspore.ops.slice(data, (1, 0, 0), (1, 1, 2))
>>> print(output)
[[[3 3]]]
>>> output = mindspore.ops.slice(data, (1, 0, 0), (1, 1, 1))
>>> print(output)
[[[3]]]
>>> output = mindspore.ops.slice(data, (1, 1, 0), (1, 1, 3))
>>> print(output)
[[[4 4 4]]]
>>> output = mindspore.ops.slice(data, (1, 0, 1), (1, 1, 2))
>>> print(output)
[[[3 3]]]
```

mindspore.ops.slice_scatter

mindspore.ops.**slice_scatter**(*input*, *src*, *axis=0*, *start=None*, *end=None*, *step=1*)

Embed *src* into the sliced *input* along the specified *axis* .

Parameters

- **input** (Tensor) –The input tensor.
- **src** (Tensor) –The source tensor to be embedded into *input* .
- **axis** (*int, optional*) –The axis of *input* to be sliced. Default 0 .
- **start** (*int, optional*) –The start index for embedding in the specified axis. Default None , which means *start* is 0 .
- **end** (*int, optional*) –The end index for embedding in the specified axis. Default None , which means *end* is the length of *input* in the specified axis.
- **step** (*int, optional*) –The step size to skip during embedding. Default 1 .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> a = mindspore.ops.zeros((4, 6))
>>> b = mindspore.ops.ones((4, 3))
>>> output = mindspore.ops.slice_scatter(input=a, src=b, axis=1, start=0, end=5, step=2)
>>> print(output)
[[1. 0. 1. 0. 1. 0.]
 [1. 0. 1. 0. 1. 0.]
 [1. 0. 1. 0. 1. 0.]
 [1. 0. 1. 0. 1. 0.]]
```

mindspore.ops.sort

mindspore.ops.**sort**(*input_x*, *axis=- 1*, *descending=False*)

Sort the elements of the input tensor along the given axis.

Note: The Ascend backend only supports sorting the last dimension.

Parameters

- **input_x** (Tensor) –The input tensor.
- **axis** (*int, optional*) –The axis to sort along. Default -1 , means the last dimension.
- **descending** (*bool, optional*) –Sorting method. True means the elements are sorted in descending order, or else sorted in ascending order. Default False .

Warning: Currently, the data types of float16, uint8, int8, int16, int32, int64 are well supported. If use float32, it may cause loss of accuracy.

Returns

Tuple(sorted_tensor, indices) of 2 tensors.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[8, 2, 1], [5, 9, 3], [4, 6, 7]], mindspore.float16)
>>> output = mindspore.ops.sort(x)
>>> # The output below is based on the Ascend platform.
>>> print(output)
(Tensor(shape=[3, 3], dtype=Float16, value=
[[ 1.0000e+00,  2.0000e+00,  8.0000e+00],
[ 3.0000e+00,  5.0000e+00,  9.0000e+00],
[ 4.0000e+00,  6.0000e+00,  7.0000e+00]]), Tensor(shape=[3, 3], dtype=Int32, value=
[[2, 1, 0],
[2, 0, 1],
[0, 1, 2]]))
```

mindspore.ops.space_to_batch_nd

`mindspore.ops.`**`space_to_batch_nd`**(*input_x*, *block_size*, *paddings*)

Divides a tensor's spatial dimensions into blocks and combines the block sizes with the original batch.

$$n' = n * (block\_size[0] * ... * block\_size[M])$$
$$w'_i = (w_i + paddings[i][0] + paddings[i][1])//block\_size[i]$$

Note:

- This operation divides the spatial dimensions [1, ⋯, M] of the input into blocks of size *block_size* and interleaves them into the batch dimension (default: dimension 0). Before splitting, the spatial dimensions are padded with zeros according to *paddings*.
- If the input shape is $(n, c_1, ...c_k, w_1, ..., w_M)$, then the output shape will be $(n', c_1, ...c_k, w'_1, ..., w'_M)$.
- If *block_size* is a tuple or list, the length of *block_size* is M corresponding to the number of spatial dimensions. If *block_size* is an int, the block size of M dimensions are the same, equal to *block_size*. M must be 2 on Ascend.

Parameters

- **`input_x`** (`Tensor`) −The input tensor, must be a 4-D tensor on Ascend.
- **`block_size`** (*`Union[list(int), tuple(int), int]`*) −Specifies the block size for spatial dimension division.
- **`paddings`** (*`Union[tuple, list]`*) −The padding size for each spatial dimension.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> block_size = [2, 2]
>>> paddings = [[0, 0], [0, 0]]
>>> input_x = mindspore.tensor([[[[1, 2], [3, 4]]]], mindspore.float32)
>>> output = mindspore.ops.space_to_batch_nd(input_x, block_size, paddings)
>>> print(output)
[[[[1.]]]
 [[[2.]]]
 [[[3.]]]
 [[[4.]]]]
```

mindspore.ops.sparse_segment_mean

mindspore.ops.**sparse_segment_mean**(*x*, *indices*, *segment_ids*)

Computes the mean of sparse segments in the input tensor.

$$output_i = \frac{\sum_j x_{indices[j]}}{N}$$

where N is the number of elements where $segment\_ids[j] == i$. If *segment_ids* doesn't contain *i*, then $output[i] = 0$.

Note:

- On CPU, values in *segment_ids* must be sorted and *indices* must be within range[0, x.shape[0]).
- On GPU, unsorted *segment_ids* may result in undefined but safe behavior.Out-of-range *indices* will be ignored.

Parameters

- **x** (Tensor) −The input tensor with at least one dimension.
- **indices** (Tensor) −The specified indices, a 1-D tensor.
- **segment_ids** (Tensor) −A 1-D tensor, must be sorted and can contain duplicates.

Returns

Tensor

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[0, 1, 2], [1, 2, 3], [3, 6, 7]], dtype=mindspore.float32)
>>> indices = mindspore.tensor([0, 1, 2], dtype=mindspore.int32)
>>> segment_ids = mindspore.tensor([1,2,2], dtype=mindspore.int32)
>>> out = mindspore.ops.sparse_segment_mean(x, indices, segment_ids)
>>> print(out)
[[0. 0. 0.]
 [0. 1. 2.]
 [2. 4. 5.]]
```

mindspore.ops.split

mindspore.ops.**split**(*tensor*, *split_size_or_sections*, *axis=0*)

Split the tensor into chunks along the given axis.

Parameters

- **tensor** (Tensor) –The input tensor.
- **split_size_or_sections** (*Union[int, tuple(int), list(int)]*) –The size of chunks after splited.
- **axis** (*int, optional*) –The axis along which to split. Default 0 .

Note:

- If *split_size_or_sections* is an int type, the input tensor will be evenly divided into chunks of size *split_size_or_sections* . The last chunk will have a size equal to the remainder if tensor.shape[axis] is not divisible by *split_size_or_sections* .
- If *split_size_or_sections* is a tuple or list, *tensor* will be split along *axis* into len(*split_size_or_sections*) chunks with sizes specified by *split_size_or_sections* .

Returns

Tuple of tensors.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case1: `split_size_or_sections` is an int type
>>> input_x = mindspore.ops.arange(10).astype("float32")
>>> output = mindspore.ops.split(tensor=input_x, split_size_or_sections=3)
>>> print(output)
(Tensor(shape=[3], dtype=Float32, value=[0.00000000e+00, 1.00000000e+00, 2.00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value=[3.00000000e+00, 4.00000000e+00, 5.00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value=[6.00000000e+00, 7.00000000e+00, 8.00000000e+00]),
 Tensor(shape=[1], dtype=Float32, value=[9.00000000e+00]))
>>> # case2: `split_size_or_sections` is a list type
>>> output = mindspore.ops.split(tensor=input_x, split_size_or_sections=[3, 3, 4])
>>> print(output)
```

(continues on next page)

(continued from previous page)

```
(Tensor(shape=[3], dtype=Float32, value=[0.00000000e+00, 1.00000000e+00, 2.00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value=[3.00000000e+00, 4.00000000e+00, 5.00000000e+00]),
 Tensor(shape=[4], dtype=Float32, value=[6.00000000e+00, 7.00000000e+00, 8.00000000e+00, 9.
↪00000000e+00]))
```

mindspore.ops.squeeze

mindspore.ops.**squeeze**(*input*, *axis=None*)

Remove length one axes from input tensor.

Note:

- Please note that in dynamic graph mode, the output tensor will share data with the input tensor, and there is no Tensor data copy process.
- The dimension index starts at 0 and must be in the range *[-input.ndim, input.ndim]*.
- In GE mode, only support remove dimensions of size 1 from the shape of input tensor.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input tensor.
- **axis** (*Union[int, tuple(int), list(int)]*) –The axis to be removed. Default: None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.ops.ones(shape=[3, 2, 1])
>>> output = mindspore.ops.squeeze(input)
>>> print(output)
[[1. 1.]
 [1. 1.]
 [1. 1.]]
```

mindspore.ops.stack

mindspore.ops.**stack**(*tensors*, *axis=0*)

Stack input tensors in specified axis.

Parameters

- **tensors** (*Union[tuple, list]*) – The input tensors.
- **axis** (*int*) – Axis to stack. Default `0` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input_x1 = mindspore.tensor([0, 1], mindspore.float32)
>>> input_x2 = mindspore.tensor([2, 3], mindspore.float32)
>>> output = mindspore.ops.stack((input_x1, input_x2), 0)
>>> print(output)
[[0. 1.]
 [2. 3.]]
```

mindspore.ops.strided_slice

mindspore.ops.**strided_slice**(*input_x*, *begin*, *end*, *strides*, *begin_mask=0*, *end_mask=0*, *ellipsis_mask=0*, *new_axis_mask=0*, *shrink_axis_mask=0*)

Extracts a strided slice of a Tensor based on *begin/end* index and *strides*.

Note:

- *begin* , *end* and *strides* must have the same shape.
- *begin* , *end* and *strides* are all 1-D Tensor, and their shape size must not greater than the dim of *input_x*.

Example: For *input_x* with shape $(5, 6, 7)$, set *begin*, *end* and *strides* to (1, 3, 2), (3, 5, 6), (1, 1, 2) respectively, then elements from index 1 to 3 are extracted for dim 0, index 3 to 5 are extracted for dim 1 and index 2 to 6 with a *stirded* of 2 are extracted for dim 2, this process is equivalent to a pythonic slice *input_x[1:3, 3:5, 2:6:2]*.

If the length of *begin*, *end* and *strides* is smaller than the dim of *input_x*, then all elements are extracted from the missing dims, it behaves like all the missing dims are filled with zeros, size of that missing dim and ones.

Example: For Tensor *input_x* with shape $(5, 6, 7)$, set *begin*, *end* and *strides* to (1, 3), (3, 5), (1, 1) respectively, then elements from index 1 to 3 are extracted for dim 0, index 3 to 5 are extracted for dim 1 and index 3 to 5 are extracted for dim 2, this process is equivalent to a pythonic slice *input_x[1:3, 3:5, 0:7]*.

Here's how a mask works: For each specific mask, it will be converted to a binary representation internally, and then reverse the result to start the calculation. For Tensor *input_x* with shape $(5, 6, 7)$. Given mask value of 3 which can be represented as 0b011. Reverse that we get 0b110, which implies the first and second dim of the original Tensor will be effected by this mask. See examples below, for simplicity all mask mentioned below are all in their reverted binary form:

- *begin_mask* and *end_mask*

  If the ith bit of *begin_mask* is 1, *begin[i]* is ignored and the fullest possible range in that dimension is used instead. *end_mask* is analogous, except with the end range. For Tensor *input_x* with shape $(5, 6, 7, 8)$, if *begin_mask* is 0b110, *end_mask* is 0b011, the slice *input_x[0:3, 0:6, 2:7:2]* is produced.

- *ellipsis_mask*

  If the ith bit of *ellipsis_mask* is 1, as many unspecified dimensions as needed will be inserted between other dimensions. Only one non-zero bit is allowed in *ellipsis_mask*. For Tensor *input_x* with shape $(5, 6, 7, 8)$, *input_x[2:,⋯,:6]* is equivalent to *input_x[2:5,:,:,0:6]* , *input_x[2:,⋯]* is equivalent to *input_x[2:5,:,:,:]*.

- *new_axis_mask*

  If the ith bit of *new_axis_mask* is 1, *begin*, *end* and *strides* are ignored and a new length 1 dimension is added at the specified position in the output Tensor. For Tensor *input_x* with shape $(5, 6, 7)$, if *new_axis_mask* is 0b110, a new dim is added to the second dim, which will produce a Tensor with shape $(5, 1, 6, 7)$.

- *shrink_axis_mask*

  If the ith bit of *shrink_axis_mask* is 1, *begin*, *end* and *strides* are ignored and dimension i will be shrunk to 0. For Tensor *input_x* with shape $(5, 6, 7)$, if *shrink_axis_mask* is 0b010, it is equivalent to slice *x[:, 5, :]* and results in an output shape of $(5, 7)$.

Note: *new_axis_mask* and *shrink_axis_mask* are not recommended to use at the same time, it might incur unexpected result.

Parameters

- **input_x** (Tensor) −The input tensor.
- **begin** (*tuple[int]*) −Specify the index to start slicing.
- **end** (*tuple[int]*) −Specify the index to end slicing.
- **strides** (*tuple[int]*) −Specify the step size for slicing in each dimension.
- **begin_mask** (*int, optional*) −Starting index of the slice. Default `0` .
- **end_mask** (*int, optional*) −Ending index of the slice. Default `0` .
- **ellipsis_mask** (*int, optional*) −An int mask, ignore slicing operation when set to 1. Default `0` .
- **new_axis_mask** (*int, optional*) −An int mask for adding new dims. Default `0` .
- **shrink_axis_mask** (*int, optional*) −An int mask for shrinking dims. Default `0` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[[1, 1, 1],
...                            [2, 2, 2]],
...                           [[3, 3, 3],
...                            [4, 4, 4]],
...                           [[5, 5, 5],
...                            [6, 6, 6]]])
>>> mindspore.ops.strided_slice(input, [1, 0, 0], [2, 1, 3], [1, 1, 1])
Tensor(shape=[1, 1, 3], dtype=Int64, value=
[[[3, 3, 3]]])
>>> mindspore.ops.strided_slice(input, [1, 0, 0], [2, 2, 3], [1, 1, 1])
Tensor(shape=[1, 2, 3], dtype=Int64, value=
[[[3, 3, 3],
  [4, 4, 4]]])
>>> mindspore.ops.strided_slice(input, [1, -1, 0], [2, -3, 3], [1, -1, 1])
Tensor(shape=[1, 2, 3], dtype=Int64, value=
[[[4, 4, 4],
  [3, 3, 3]]])
```

mindspore.ops.sum

mindspore.ops.**sum**(*input*, *dim=None*, *keepdim=False*, *, *dtype=None*)

Calculate sum of tensor elements over a given dim.

Note: The *dim* with tensor type is only used for compatibility with older versions and is not recommended.

Parameters

- **input** (Tensor) –The input tensor.
- **dim** (*Union[None, int, tuple(int), list(int), Tensor]*) –Dimensions along which the sum is calculated. Default None .
- **keepdim** (*bool*) –Whether the output tensor has dim retained or not. If True , keep these reduced dimensions and the length is 1. If False , will not keep these dimensions. Default False .

Note:

- If *dim* is None , sum is calculated on all the elements of the input tensor.
- If *dim* is a tuple or list of ints or tensor, sum is calculated on all dimensions specified in *dim* .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The data type returned.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[[1, 1, 1, 1, 1, 1], [2, 2, 2, 2, 2, 2], [3, 3, 3, 3, 3, 3]],
...                       [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
...                       [[7, 7, 7, 7, 7, 7], [8, 8, 8, 8, 8, 8], [9, 9, 9, 9, 9, 9]]],␣
↪mindspore.float32)
>>> out = mindspore.ops.sum(input=x)
>>> print(out)
270.0
>>> out = mindspore.ops.sum(input=x, dim=1)
>>> print(out)
[[ 6.  6.  6.  6.  6.  6.]
 [15. 15. 15. 15. 15. 15.]
 [24. 24. 24. 24. 24. 24.]]
>>> out = mindspore.ops.sum(input=x, dim=2)
>>> print(out)
[[ 6. 12. 18.]
 [24. 30. 36.]
 [42. 48. 54.]]
>>> out = mindspore.ops.sum(input=x, dim=[1, 2])
>>> print(out)
[ 36.  90. 144.]
>>> out = mindspore.ops.sum(input=x, dim=2, keepdim=True)
>>> print(out)
[[[ 6.]
  [12.]
  [18.]]
 [[24.]
  [30.]
  [36.]]
 [[42.]
  [48.]
  [54.]]]
>>> print(out.ndim)
3
```

mindspore.ops.swapaxes

mindspore.ops.**swapaxes**(*input*, *axis0*, *axis1*)

Interchange two axes of a tensor.

Parameters

- **input** (Tensor) – The input tensor.
- **axis0** (*int*) – First axis.
- **axis1** (*int*) – Second axis.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor(mindspore.ops.ones(([2, 3, 4])))
>>> output = mindspore.ops.swapaxes(input, 0, 2)
>>> print(output.shape)
(4, 3, 2)
```

mindspore.ops.swapdims

mindspore.ops.**swapdims**(*input*, *dim0*, *dim1*)

Interchange two dims of a tensor. This function is equivalent to *mindspore.ops.swapaxes()* function.

Parameters

- **input** (Tensor) –The input tensor.
- **dim0** (*int*) –First dim.
- **dim1** (*int*) –Second dim.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor(mindspore.ops.ones([2, 3, 4]))
>>> output = mindspore.ops.swapdims(input, 0, 2)
>>> print(output.shape)
(4, 3, 2)
```

mindspore.ops.tensor_scatter_add

mindspore.ops.**tensor_scatter_add**(*input_x*, *indices*, *updates*)

Return a new tensor by adding the values from *updates* in *input_x* indicated by *indices* .

$$output\left[indices\right] = input\_x + update$$

Note:

- On GPU, if some values of the *indices* are out of bound, instead of raising an index error, the corresponding *updates* will not be updated to self tensor.
- On CPU, if some values of the *indices* are out of bound, raising an index error.
- On Ascend, out of bound checking is not supported, if some values of the *indices* are out of bound, unknown errors may be caused.

Parameters

- **input_x** (Tensor) −The input tensor.
- **indices** (Tensor) −The specified indices.
- **updates** (Tensor) −The update values.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]], mindspore.float32)
>>> indices = mindspore.tensor([[0, 0], [0, 0]], mindspore.int32)
>>> updates = mindspore.tensor([1.0, 2.2], mindspore.float32)
>>> output = mindspore.ops.tensor_scatter_add(input_x, indices, updates)
>>> print(output)
[[ 3.1  0.3  3.6]
 [ 0.4  0.5 -3.2]]
```

mindspore.ops.tensor_scatter_div

mindspore.ops.**tensor_scatter_div**(*input_x*, *indices*, *updates*)

Return a new tensor which *input_x* is divided by the values from *updates* indicated by *indices* .

$$output\,[indices] = input\_x \div update$$

Note:

- On GPU, if some values of the *indices* are out of bound, instead of raising an index error, the corresponding *updates* will not be updated to self tensor.
- On CPU, if some values of the *indices* are out of bound, raising an index error.
- On Ascend, out of bound checking is not supported, if some values of the *indices* are out of bound, unknown errors may be caused.
- The operator can't handle division by 0 exceptions, so the user needs to make sure there is no 0 value in *updates*.

Parameters

- **input_x** (Tensor) −The input tensor.
- **indices** (Tensor) −The specified indices.
- **updates** (Tensor) −The update values.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]], mindspore.float32)
>>> indices = mindspore.tensor([[0, 0], [0, 0]], mindspore.int32)
>>> updates = mindspore.tensor([1.0, 2.0], mindspore.float32)
>>> output = mindspore.ops.tensor_scatter_div(input_x, indices, updates)
>>> print(output)
[[-0.05  0.3  3.6  ]
 [ 0.4   0.5  -3.2 ]]
```

mindspore.ops.tensor_scatter_max

mindspore.ops.**tensor_scatter_max**(*input_x*, *indices*, *updates*)

Return a new tensor by performing a maximum update on *input_x* at the specified indices with the given update values.

$$output\,[indices] = \max(input\_x, update)$$

Note:

- On GPU, if some values of the *indices* are out of bound, instead of raising an index error, the corresponding *updates* will not be updated to self tensor.
- On CPU, if some values of the *indices* are out of bound, raising an index error.
- On Ascend, out of bound checking is not supported, if some values of the *indices* are out of bound, unknown errors may be caused.

Parameters

- **input_x** (Tensor) –The input tensor.
- **indices** (Tensor) –The specified indices. The rank must be at least 2.
- **updates** (Tensor) –The update values.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([[1, 2, 3], [4, 5, 6]])
>>> indices = mindspore.tensor([[0, 0], [1, 1]])
>>> updates = mindspore.tensor([5, 5])
>>> mindspore.ops.tensor_scatter_max(input_x, indices, updates)
Tensor(shape=[2, 3], dtype=Int64, value=
[[5, 2, 3],
 [4, 5, 6]])
```

mindspore.ops.tensor_scatter_min

mindspore.ops.**tensor_scatter_min**(*input_x*, *indices*, *updates*)

Return a new tensor by performing a minimum update on *input_x* at the specified indices with the given update values.

$$output\left[indices\right] = \min(input\_x, update)$$

Note:

- On GPU, if some values of the *indices* are out of bound, instead of raising an index error, the corresponding *updates* will not be updated to self tensor.
- On CPU, if some values of the *indices* are out of bound, raising an index error.
- On Ascend, out of bound checking is not supported, if some values of the *indices* are out of bound, unknown errors may be caused.

Parameters

- **input_x** (Tensor) −The input tensor.
- **indices** (Tensor) −The specified indices. The rank must be at least 2.
- **updates** (Tensor) −The update values.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([[1, 2, 3], [4, 5, 6]], mindspore.float32)
>>> indices = mindspore.tensor([[0, 0], [1, 1]])
>>> updates = mindspore.tensor([5, 1], mindspore.float32)
>>> mindspore.ops.tensor_scatter_min(input_x, indices, updates)
Tensor(shape=[2, 3], dtype=Float32, value=
[[ 1.00000000e+00,  2.00000000e+00,  3.00000000e+00],
 [ 4.00000000e+00,  1.00000000e+00,  6.00000000e+00]])
```

mindspore.ops.tensor_scatter_mul

mindspore.ops.**tensor_scatter_mul**(*input_x*, *indices*, *updates*)

Return a new tensor by performing a multiplication update on *input_x* at the specified indices with the given update values.

$$output\left[indices\right] = input\_x \times update$$

Note:

- If some values of the *indices* are out of bound, instead of raising an index error, the corresponding *updates* will not be updated to *input_x*.

Parameters

- **input_x** (Tensor) −The input tensor.
- **indices** (Tensor) −The specified indices. The rank must be at least 2.
- **updates** (Tensor) −The update values.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([[1, 2, 3], [4, 5, 6]])
>>> indices = mindspore.tensor([[0, 0], [1, 1]])
>>> updates = mindspore.tensor([5, 5])
>>> mindspore.ops.tensor_scatter_mul(input_x, indices, updates)
Tensor(shape=[2, 3], dtype=Int64, value=
[[ 5,  2,  3],
 [ 4, 25,  6]])
```

mindspore.ops.tensor_scatter_sub

mindspore.ops.**tensor_scatter_sub**(*input_x*, *indices*, *updates*)

Return a new tensor by performing a subtraction update on *input_x* at the specified indices with the given update values.

$$output\left[indices\right] = input\_x - update$$

Note: On GPU, if some values of the *indices* are out of bound, instead of raising an index error, the corresponding *updates* will not be updated to self tensor. On CPU, if some values of the *indices* are out of bound, raising an index error. On Ascend, out of bound checking is not supported, if some values of the *indices* are out of bound, unknown errors may be caused.

Parameters

- **input_x** (Tensor) −The input tensor.
- **indices** (Tensor) −The specified indices. The rank must be at least 2.
- **updates** (Tensor) −The update values.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1, 2, 3], [4, 5, 6]], mindspore.float32)
>>> indices = mindspore.tensor([[0, 0], [1, 1]])
>>> updates = mindspore.tensor([5, 5], mindspore.float32)
>>> mindspore.ops.tensor_scatter_sub(input, indices, updates)
Tensor(shape=[2, 3], dtype=Float32, value=
[[-4.00000000e+00,  2.00000000e+00,  3.00000000e+00],
 [ 4.00000000e+00,  0.00000000e+00,  6.00000000e+00]])
```

mindspore.ops.tensor_scatter_elements

mindspore.ops.**tensor_scatter_elements**(*input_x*, *indices*, *updates*, *axis=0*, *reduction='none'*)

Return a new tensor by performing a specified operation update on *input_x* at the specified indices with the given update values.

Not support implicit type conversion.

For example: the output of a 3-D tensor is

```
output[indices[i][j][k]][j][k] = updates[i][j][k]  # if axis == 0, reduction == "none"

output[i][indices[i][j][k]][k] += updates[i][j][k]  # if axis == 1, reduction == "add"

output[i][j][indices[i][j][k]] = updates[i][j][k]  # if axis == 2, reduction == "none"
```

Warning:

- The order in which updates are applied is nondeterministic, meaning that if there are multiple index vectors in *indices* that correspond to the same position, the value of that position in the output will be nondeterministic.
- On Ascend, the reduction only support set to "none" for now.
- On Ascend, the data type of *input_x* must be float16 or float32.
- This is an experimental API that is subject to change or deletion.

Note: If some values of the *indices* exceed the upper or lower bounds of the index of *input_x*, instead of raising an index error, the corresponding *updates* will not be updated to *input_x*. The backward is supported only for the case *updates.shape* == *indices.shape*.

Parameters

- **input_x** (Tensor) –The input tensor. The rank must be at least 1.
- **indices** (Tensor) –The specified indices.
- **updates** (Tensor) –The update values.
- **axis** (*int*) –The axis along which to index. Default 0.
- **reduction** (*str*) –The specified operation, supports none , add .
  - If none, *updates* will be assigned to *input_x* according to *indices*.
  - If add, *updates* will be added to *input_x* according to *indices*. Default none.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([[1, 2, 3, 4, 5]])
>>> indices = mindspore.tensor([[2, 4]])
>>> updates = mindspore.tensor([[8, 8]])
>>> output = mindspore.ops.tensor_scatter_elements(input_x, indices, updates, axis=1,␣
↪reduction="none")
>>> print(output)
[[1 2 8 4 8]]
>>> output = mindspore.ops.tensor_scatter_elements(input_x, indices, updates, axis=1,␣
↪reduction="add")
>>> print(output)
[[ 1  2 11  4 13]]
```

mindspore.ops.tensor_split

mindspore.ops.**tensor_split**(*input*, *indices_or_sections*, *axis=0*)

Split the input tensor into multiple subtensors according to the specified indices or chunks.

Parameters

- **input** (Tensor) –The input tensor.
- **indices_or_sections** (*Union[int, tuple(int), list(int)]*) –The specified indices or chunks.
  - If it is an integer, input tensor will be split into *indices_or_sections* sections.
    - If $input.shape[axis]$ can be divisible by *indices_or_sections*, sub-sections will have equal size $input.shape[axis]/n$.
    - If $input.shape[axis]$ can not be divisible by *indices_or_sections*, the first $input.shape[axis] \bmod n$ sections will have size $input.shape[axis]//n + 1$, and the rest will have size $input.shape[axis]//n$.
  - If it is a tuple(int) or list(int) type, it represts indices and the input tensor will be split at the indices.
- **axis** (*int, optional*) –The axis along which to split. Default 0 .

Returns

Tuple of tensors.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0, 1, 2, 3, 4, 5, 6, 7])
>>> mindspore.ops.tensor_split(input, 3)
(Tensor(shape=[3], dtype=Int64, value= [0, 1, 2]),
 Tensor(shape=[3], dtype=Int64, value= [3, 4, 5]),
 Tensor(shape=[2], dtype=Int64, value= [6, 7]))
>>> input = mindspore.tensor([0, 1, 2, 3, 4, 5, 6])
>>> mindspore.ops.tensor_split(input, 3)
(Tensor(shape=[3], dtype=Int64, value= [0, 1, 2]),
 Tensor(shape=[2], dtype=Int64, value= [3, 4]),
 Tensor(shape=[2], dtype=Int64, value= [5, 6]))
>>> mindspore.ops.tensor_split(input, (1, 6))
(Tensor(shape=[1], dtype=Int64, value= [0]),
 Tensor(shape=[5], dtype=Int64, value= [1, 2, 3, 4, 5]),
 Tensor(shape=[1], dtype=Int64, value= [6]))
>>> input = mindspore.tensor([[ 0,  1,  2,  3,  4,  5,  6],
...                           [ 7,  8,  9, 10, 11, 12, 13]])
>>> mindspore.ops.tensor_split(input, 3, axis=1)
(Tensor(shape=[2, 3], dtype=Int64, value=
 [[0, 1, 2],
  [7, 8, 9]]),
 Tensor(shape=[2, 2], dtype=Int64, value=
 [[ 3,  4],
  [10, 11]]),
 Tensor(shape=[2, 2], dtype=Int64, value=
 [[ 5,  6],
  [12, 13]]))
>>> mindspore.ops.tensor_split(input, (1, 6), axis=1)
(Tensor(shape=[2, 1], dtype=Int64, value=
 [[0],
  [7]]),
 Tensor(shape=[2, 5], dtype=Int64, value=
 [[ 1,  2,  3,  4,  5],
  [ 8,  9, 10, 11, 12]]),
 Tensor(shape=[2, 1], dtype=Int64, value=
 [[ 6],
  [13]]))
```

mindspore.ops.tile

mindspore.ops.**tile**(*input*, *dims*)

Creates a new tensor by repeating the elements in the input tensor *dims* times.

The i'th dimension of output tensor has *input.shape[i] * dims[i]* elements, and the values of *input* are repeated *dims[i]* times along the i'th dimension.

Note:

- On Ascend, the number of *dims* should not exceed 8, and currently does not support scenarios where more than 4 dimensions are repeated simultaneously.
- If *input.dim* = d, then the shape of their corresponding positions can be multiplied, and the shape of Outputs is $(x_1 * y_1, x_2 * y_2, ..., x_S * y_S)$.
- If *input.dim* < d, prepend 1 to the shape of *input* until their lengths are consistent. Such as set the shape of *input* as $(1, ..., x_1, x_2, ..., x_S)$, then the shape of their corresponding positions can be multiplied, and the shape of Outputs is $(1 * y_1, ..., x_R * y_R, x_S * y_S)$.
- If *input.dim* > d, prepend 1 to *dims* until their lengths are consistent. Such as set the *dims* as $(1, ..., y_1, y_2, ..., y_S)$, then the shape of their corresponding positions can be multiplied, and the shape of Outputs is $(x_1 * 1, ..., x_R * y_R, x_S * y_S)$.

Parameters

- **input** (Tensor) – The input tensor.
- **dims** (*tuple[int]*) – The specified number of repetitions in each dimension.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1, 2], [3, 4]])
>>> mindspore.ops.tile(input, (2, 3))
Tensor(shape=[4, 6], dtype=Int64, value=
[[1, 2, 1, 2, 1, 2],
 [3, 4, 3, 4, 3, 4],
 [1, 2, 1, 2, 1, 2],
 [3, 4, 3, 4, 3, 4]])
>>> mindspore.ops.tile(input, (2, 3, 2))
Tensor(shape=[2, 6, 4], dtype=Int64, value=
[[[1, 2, 1, 2],
  [3, 4, 3, 4],
  [1, 2, 1, 2],
  [3, 4, 3, 4],
  [1, 2, 1, 2],
  [3, 4, 3, 4]],
 [[1, 2, 1, 2],
  [3, 4, 3, 4],
```

(continues on next page)

(continued from previous page)

```
  [1, 2, 1, 2],
  [3, 4, 3, 4],
  [1, 2, 1, 2],
  [3, 4, 3, 4]]])
```

mindspore.ops.tril

mindspore.ops.**tril**(*input*, *diagonal=0*)

Zero the input tensor above the diagonal specified.

Parameters

- **input** (Tensor) – The input tensor. The rank must be at least 2.
- **diagonal** (*int, optional*) – The diagonal specified of 2-D tensor. Default 0 represents the main diagonal.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[ 1,  2,  3,  4],
...                           [ 5,  6,  7,  8],
...                           [10, 11, 12, 13],
...                           [14, 15, 16, 17]])
>>> mindspore.ops.tril(input)
Tensor(shape=[4, 4], dtype=Int64, value=
[[ 1,  0,  0,  0],
 [ 5,  6,  0,  0],
 [10, 11, 12,  0],
 [14, 15, 16, 17]])
>>> mindspore.ops.tril(input, 1)
Tensor(shape=[4, 4], dtype=Int64, value=
[[ 1,  2,  0,  0],
 [ 5,  6,  7,  0],
 [10, 11, 12, 13],
 [14, 15, 16, 17]])
>>> mindspore.ops.tril(input, -1)
Tensor(shape=[4, 4], dtype=Int64, value=
[[ 0,  0,  0,  0],
 [ 5,  0,  0,  0],
 [10, 11,  0,  0],
 [14, 15, 16,  0]])
>>> input = mindspore.tensor([[[ 1,  2,  3],
...                            [ 5,  6,  7],
...                            [10, 11, 12]],
...                           [[ 1,  2,  3],
...                            [ 5,  6,  7],
...                            [10, 11, 12]]])
```

(continues on next page)

(continued from previous page)

```
>>> mindspore.ops.tril(input)
Tensor(shape=[2, 3, 3], dtype=Int64, value=
[[[ 1,  0,  0],
  [ 5,  6,  0],
  [10, 11, 12]],
 [[ 1,  0,  0],
  [ 5,  6,  0],
  [10, 11, 12]]])
```

mindspore.ops.triu

mindspore.ops.**triu**(*input*, *diagonal=0*)

Zero the input tensor below the diagonal specified.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input tensor.
- **diagonal** (*int, optional*) –The diagonal specified of 2-D tensor. Default 0 represents the main diagonal.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[ 1,  2,  3,  4],
...                           [ 5,  6,  7,  8],
...                           [10, 11, 12, 13],
...                           [14, 15, 16, 17]])
>>> mindspore.ops.triu(input)
Tensor(shape=[4, 4], dtype=Int64, value=
[[ 1,  2,  3,  4],
 [ 0,  6,  7,  8],
 [ 0,  0, 12, 13],
 [ 0,  0,  0, 17]])
>>> mindspore.ops.triu(input, 1)
Tensor(shape=[4, 4], dtype=Int64, value=
[[ 0,  2,  3,  4],
 [ 0,  0,  7,  8],
 [ 0,  0,  0, 13],
 [ 0,  0,  0,  0]])
>>> mindspore.ops.triu(input, -1)
Tensor(shape=[4, 4], dtype=Int64, value=
[[ 1,  2,  3,  4],
 [ 5,  6,  7,  8],
```

(continues on next page)

(continued from previous page)

```
 [ 0, 11, 12, 13],
 [ 0,  0, 16, 17]])
>>> input = mindspore.tensor([[[ 1,  2,  3],
...                           [ 5,  6,  7],
...                           [10, 11, 12]],
...                          [[ 1,  2,  3],
...                           [ 5,  6,  7],
...                           [10, 11, 12]]])
>>> mindspore.ops.triu(input)
Tensor(shape=[2, 3, 3], dtype=Int64, value=
[[[ 1,  2,  3],
  [ 0,  6,  7],
  [ 0,  0, 12]],
 [[ 1,  2,  3],
  [ 0,  6,  7],
  [ 0,  0, 12]]])
```

mindspore.ops.transpose

mindspore.ops.**transpose**(*input*, *input_perm*)

Transpose dimensions of the input tensor according to input permutation.

Note: On GPU and CPU, if the value of *input_perm* is negative, its actual value is *input_perm[i] + rank(input)*. Negative value of *input_perm* is not supported on Ascend.

Parameters

- **input** (Tensor) –The input tensor.
- **input_perm** (*tuple[int]*) –Specify the new axis ordering.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[[1, 2, 3], [4, 5, 6]], [[7, 8, 9], [10, 11, 12]]], mindspore.
 ↪float32)
>>> output = mindspore.ops.transpose(input, (0, 2, 1))
>>> print(output)
[[[ 1.  4.]
  [ 2.  5.]
  [ 3.  6.]]
 [[ 7. 10.]
  [ 8. 11.]
  [ 9. 12.]]]
```

mindspore.ops.unbind

mindspore.ops.**unbind**(*input*, *dim=0*)

Remove a tensor dimension, return a tuple of all slices along a given dimension.

Parameters

- **input** (Tensor) –The input tensor.
- **dim** (*int*) –Specipy the dimension to remove. Default 0 .

Returns

tuple of tensors.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[1, 2, 3], [4, 5, 6], [7, 8, 9]])
>>> output = mindspore.ops.unbind(x, dim=0)
>>> print(output)
(Tensor(shape=[3], dtype=Int64, value=[1, 2, 3]), Tensor(shape=[3], dtype=Int64, value=[4, 5,
 ↪ 6]),
Tensor(shape=[3], dtype=Int64, value=[7, 8, 9]))
```

mindspore.ops.unique

mindspore.ops.**unique**(*input*)

Remove duplicate elements from the input tensor.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

input (Tensor) –The input tensor.

Returns

Tuple(output, indices) of 2 tensors.

- **output** (Tensor) - The deduplicated output tensor.
- **indices** (Tensor) - The indices of the elements of the input tensor in the *output* .

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1, 2, 5, 2], mindspore.int32)
>>> output, indices = mindspore.ops.unique(x)
>>> print(output)
[1 2 5]
>>> print(indices)
[0 1 2 1]
```

mindspore.ops.unique_consecutive

mindspore.ops.**unique_consecutive**(*input*, *return_inverse=False*, *return_counts=False*, *dim=None*)

Remove consecutive duplicate elements in the input tensor, retaining only the first occurrence from each repeated group.

Parameters

- **input** (Tensor) –The input tensor.
- **return_inverse** (*bool, optional*) –Whether to also return the indices for where elements in the original input ended up in the returned unique list. Default False .
- **return_counts** (*bool, optional*) –Whether to also return the counts for each unique element. Default False .
- **dim** (*int, optional*) –Specify the dimension for unique. Default None , the input tensor will be flattened.

Returns

Tensor or tuple(output, inverse_indices, counts) of tensors.

- **output** (Tensor) - The deduplicated output tensor.
- **inverse_indices** (Tensor, optional) - The indices of the elements of the input tensor in the *output* .
- **counts** (Tensor, optional) - The counts for each unique element.

Supported Platforms:

Ascend GPU CPU

Examples

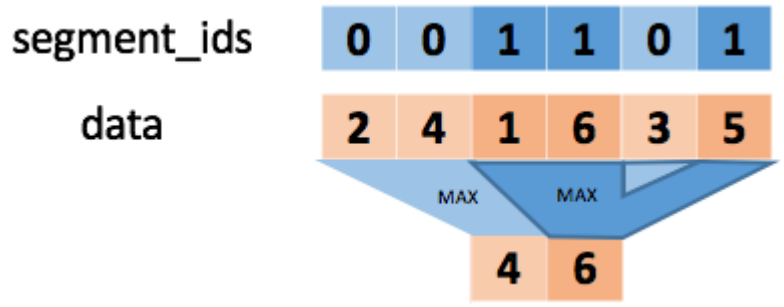
```
>>> import mindspore
>>> x = mindspore.tensor([1, 1, 2, 2, 3, 1, 1, 2], mindspore.int32)
>>> output, inverse_indices, counts = mindspore.ops.unique_consecutive(x, True, True, None)
>>> print(output)
[1 2 3 1 2]
>>> print(inverse_indices)
[0 0 1 1 2 3 3 4]
>>> print(counts)
[2 2 1 2 1]
```

mindspore.ops.unsorted_segment_max

mindspore.ops.**unsorted_segment_max**(*x*, *segment_ids*, *num_segments*)

Compute the maximum of the input tensor along segments.

The following figure shows the calculation process of unsorted_segment_max:



$$\text{output}_{i} = \max_{j...} \text{data}\,[j\ldots]$$

where *max* over tuples $j...$ such that $segment\_ids[j...] == i$.

Note:

- If the segment_id i is absent in the segment_ids, then output[i] will be filled with the minimum value of the x's type.
- The *segment_ids* must be non-negative tensor.

Parameters

- **x** (Tensor) −The input tensor.
- **segment_ids** (Tensor) −Indicate the segment to which each element belongs. Set the shape as $(x_1, x_2, ..., x_N)$, where 0 < N <= R.
- **num_segments** (*Union[int, Tensor]*) −Number of segments, it can be an int or 0-D tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

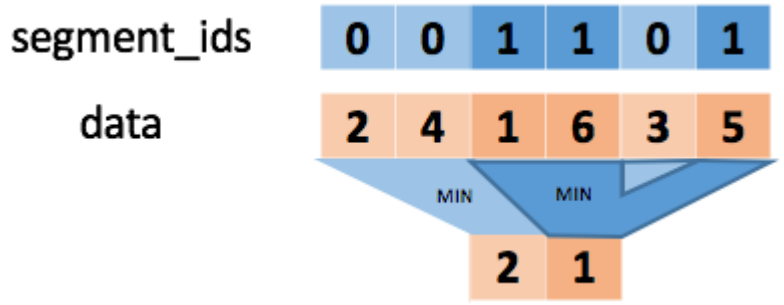
```
>>> import mindspore
>>> x = mindspore.tensor([[1, 2, 3], [4, 5, 6], [4, 2, 1]])
>>> segment_ids = mindspore.tensor([0, 1, 1])
>>> num_segments = 2
>>> mindspore.ops.unsorted_segment_max(x, segment_ids, num_segments)
Tensor(shape=[2, 3], dtype=Int64, value=
[[1, 2, 3],
 [4, 5, 6]])
```

mindspore.ops.unsorted_segment_min

mindspore.ops.**unsorted_segment_min**(*x*, *segment_ids*, *num_segments*)

Compute the minimum of the input tensor along segments.

The following figure shows the calculation process of unsorted_segment_min:



$$\text{output}_{i} = \min_{j\ldots} \text{data}\,[j\ldots]$$

where *min* over tuples $j\ldots$ such that $segment\_ids[j\ldots] == i$.

Note:

- If the segment_id i is absent in the segment_ids, then output[i] will be filled with the maximum value of the x's type.
- The *segment_ids* must be non-negative tensor.

Parameters

- **x** (Tensor) −The input tensor.
- **segment_ids** (Tensor) −Indicate the segment to which each element belongs.
- **num_segments** (*Union[int, Tensor], optional*) −Number of segments, it can be an int or 0-D tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

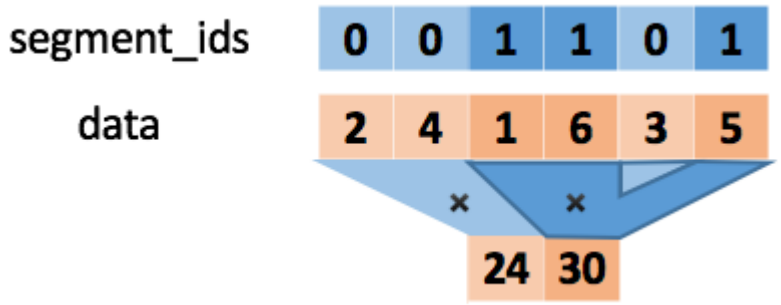
```
>>> import mindspore
>>> x = mindspore.tensor([[1, 2, 3], [4, 5, 6], [4, 2, 1]])
>>> segment_ids = mindspore.tensor([0, 1, 1])
>>> num_segments = 2
>>> mindspore.ops.unsorted_segment_min(x, segment_ids, num_segments)
Tensor(shape=[2, 3], dtype=Int64, value=
[[1, 2, 3],
 [4, 2, 1]])
```

mindspore.ops.unsorted_segment_prod

mindspore.ops.**unsorted_segment_prod**(*x*, *segment_ids*, *num_segments*)

Compute the product of the input tensor along segments.

The following figure shows the calculation process of unsorted_segment_prod:



Note:

- If the segment_id i is absent in the segment_ids, then output[i] will be filled with 1.
- The *segment_ids* must be non-negative tensor.

Parameters

- **x** (Tensor) −The input tensor.
- **segment_ids** (Tensor) −Indicate the segment to which each element belongs.
- **num_segments** (*Union[int, Tensor], optional*) −Number of segments, it can be an int or 0-D tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

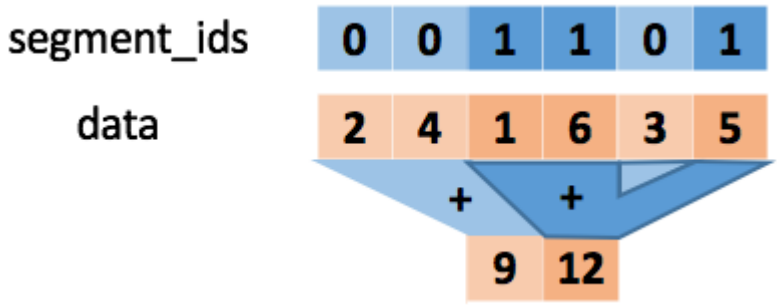
```
>>> import mindspore
>>> x = mindspore.tensor([[1, 2, 3], [4, 5, 6], [4, 2, 1]])
>>> segment_ids = mindspore.tensor([0, 1, 0])
>>> num_segments = 2
>>> mindspore.ops.unsorted_segment_prod(x, segment_ids, num_segments)
Tensor(shape=[2, 3], dtype=Int64, value=
[[4, 4, 3],
 [4, 5, 6]])
```

mindspore.ops.unsorted_segment_sum

mindspore.ops.**unsorted_segment_sum**(*input_x*, *segment_ids*, *num_segments*)

Compute the sum of the input tensor along segments.

The following figure shows the calculation process of unsorted_segment_sum:



$$\text{output}[i] = \sum_{segment\_ids[j]==i} \text{data}[j, \ldots]$$

where j, ... is a tuple describing the index of element in data. *segment_ids* selects which elements in data to sum up. Segment_ids does not need to be sorted, and it does not need to cover all values in the entire valid value range.

Note:

- If the segment_id i is absent in the segment_ids, then output[i] will be filled with 0.
- On Ascend, if the value of segment_id is less than 0 or greater than the length of the input data shape, an execution error will occur.

If the sum of the given segment_ids i is empty, then $\text{output}[i] = 0$. If the given segment_ids is negative, the value will be ignored. 'num_segments' must be equal to the number of different segment_ids.

Parameters

- **input_x** (Tensor) –The input tensor.
- **segment_ids** (Tensor) –Indicate the segment to which each element belongs.
- **num_segments** (*Union[int, Tensor], optional*) –Number of segments, it can be an int or 0-D tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([1, 2, 3, 4])
>>> segment_ids = mindspore.tensor([0, 0, 1, 2])
>>> num_segments = 3
>>> mindspore.ops.unsorted_segment_sum(input_x, segment_ids, num_segments)
Tensor(shape=[3], dtype=Int64, value= [3, 3, 4])
>>> input_x = mindspore.tensor([1, 2, 3, 4, 2, 5])
>>> segment_ids = mindspore.tensor([0, 0, 1, 2, 3, 4])
>>> num_segments = 6
>>> mindspore.ops.unsorted_segment_sum(input_x, segment_ids, num_segments)
Tensor(shape=[6], dtype=Int64, value= [3, 3, 4, 2, 5, 0])
```

mindspore.ops.unsqueeze

mindspore.ops.**unsqueeze**(*input*, *dim*)

Adds an additional dimension to the input tensor at the given dimension.

Parameters

- **input** (Tensor) −The input tensor.
- **dim** (*int*) −The dimension specified.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 2, 3, 4])
>>> mindspore.ops.unsqueeze(input, 0)
Tensor(shape=[1, 4], dtype=Int64, value=
[[1, 2, 3, 4]])
>>> mindspore.ops.unsqueeze(input, 1)
Tensor(shape=[4, 1], dtype=Int64, value=
[[1],
 [2],
 [3],
 [4]])
```

mindspore.ops.unstack

mindspore.ops.**unstack**(*input_x*, *axis=0*)

Unstack the input tensor along the specified axis.

Parameters

- **input_x** (Tensor) −The input tensor.
- **axis** (*int*) −The specified axis. Default 0 .

Returns

Tuple of tensors

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1, 1, 1, 1], [2, 2, 2, 2]])
>>> mindspore.ops.unstack(input, 0)
(Tensor(shape=[4], dtype=Int64, value= [1, 1, 1, 1]),
 Tensor(shape=[4], dtype=Int64, value= [2, 2, 2, 2]))
```

mindspore.ops.view_as_real

mindspore.ops.**view_as_real**(*input*)

Return a real tensor with the last dimension of size 2, composed of the real and imaginary parts of the complex elements in the input tensor.

Parameters

input (Tensor) −The complex input tensor.

Returns

A real tensor.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([2+1j,2+3j,2-1j,2])
>>> output = mindspore.ops.view_as_real(input)
>>> print(output)
[[ 2.  1.]
 [ 2.  3.]
 [ 2. -1.]
 [ 2.  0.]]
```

mindspore.ops.vsplit

mindspore.ops.**vsplit**(*input*, *indices_or_sections*)

Split the input tensor with two or more dimensions, into multiple sub-tensors vertically according to *indices_or_sections*.

It is equivalent to *ops.tensor_split* with $axis = 0$.

Parameters

- **input** (Tensor) –The input tensor.
- **indices_or_sections** (*Union[int, tuple(int), list(int)]*) –See *indices_or_sections* argument in *mindspore.ops.tensor_split()*.

Returns

Tuple of tensors.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[ 0,  1,  2,  3],
...                           [ 4,  5,  6,  7],
...                           [ 8,  9, 10, 11],
...                           [12, 13, 14, 15]])
>>> mindspore.ops.vsplit(input, 2)
(Tensor(shape=[2, 4], dtype=Int64, value=
 [[0, 1, 2, 3],
  [4, 5, 6, 7]]),
 Tensor(shape=[2, 4], dtype=Int64, value=
 [[ 8,  9, 10, 11],
  [12, 13, 14, 15]]))
>>> mindspore.ops.vsplit(input, [3, 6])
(Tensor(shape=[3, 4], dtype=Int64, value=
 [[ 0,  1,  2,  3],
  [ 4,  5,  6,  7],
  [ 8,  9, 10, 11]]),
 Tensor(shape=[1, 4], dtype=Int64, value=
 [[12, 13, 14, 15]]),
 Tensor(shape=[0, 4], dtype=Int64, value=
 ))
```

mindspore.ops.vstack

mindspore.ops.**vstack**(*inputs*)

Stacks tensors in sequence vertically.

This is equivalent to concatenation along the first axis. 1-D tensors $(N,)$ should firstly be reshaped to $(1, N)$, and then be concatenated along the first axis.

Parameters

inputs (*Union(List[tensor], Tuple[tensor])*) –The 1-D or 2-D input.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x1 = mindspore.tensor([1, 2, 3])
>>> x2 = mindspore.tensor([4, 5, 6])
>>> mindspore.ops.vstack((x1, x2))
Tensor(shape=[2, 3], dtype=Int64, value=
[[1, 2, 3],
 [4, 5, 6]])
>>> x1 = mindspore.tensor([[1],[2],[3]])
>>> x2 = mindspore.tensor([[4],[5],[6]])
>>> mindspore.ops.vstack([x1, x2])
Tensor(shape=[6, 1], dtype=Int64, value=
[[1],
 [2],
 [3],
 [4],
 [5],
 [6]])
```

mindspore.ops.where

`mindspore.ops.`**`where`**(*condition*, *input*, *other*)

Return a tensor in which the elements are selected from *input* or *other* based on the *condition*.

Support broadcasting.

$$output_i = \begin{cases} input_i, & if\ condition_i \\ other_i, & otherwise \end{cases}$$

Parameters

- **`condition`** (`Tensor[bool]`) −If True, yield *input*, otherwise yield *other*.
- **`input`** (`Union[Tensor, Scalar]`) −When *condition* is True, values to select from.
- **`other`** (`Union[Tensor, Scalar]`) −When *condition* is False, values to select from.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[0, 1],
...                           [2, 3]])
>>> other = mindspore.tensor([[1, 1],
...                           [1, 1]])
>>> condition = input < 3
>>> mindspore.ops.where(condition, input, other)
Tensor(shape=[2, 2], dtype=Int64, value=
[[0, 1],
 [2, 1]])
```

mindspore.ops.cross

mindspore.ops.**cross**(*input*, *other*, *dim=None*)

Compute the cross product of two input tensors along the specified dimension.

Note: *input* and *other* must have the same shape, and the size of their *dim* dimension should be *3*. If *dim* is not specified, it is set to be the first dimension found with the size *3*.

Parameters

- **input** (Tensor) –The first input tensor.
- **other** (Tensor) –The second input tensor.
- **dim** (*int, optional*) –Specify the dimension for computation. Default None.

Returns

Tensor

Supported Platforms:

Ascend CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1, 2, 3], [1, 2, 3], [1, 2, 3]])
>>> other = mindspore.tensor([[4, 5, 6], [4, 5, 6], [4, 5, 6]])
>>> mindspore.ops.cross(input, other)
Tensor(shape=[3, 3], dtype=Int64, value=
[[0, 0, 0],
 [0, 0, 0],
 [0, 0, 0]])
>>> mindspore.ops.cross(input, other, dim=1)
Tensor(shape=[3, 3], dtype=Int64, value=
[[-3,  6, -3],
 [-3,  6, -3],
 [-3,  6, -3]])
```

mindspore.ops.renorm

mindspore.ops.**renorm**(*input*, *p*, *axis*, *maxnorm*)

Returns a tensor where each subtensor along the specified dimension is renormalized such that its *p* norm is less than or equal to *maxnorm*. If the *p* norm exceeds *maxnorm*, return the values that are obtained by dividing the original values of the subtensor by its *p* norm and then multiplying by *maxnorm*.

Parameters

- **input** (Tensor) –The input tensor.
- **p** (*int*) –The power of norm calculation.
- **axis** (*int*) –Specify the axis for computation.
- **maxnorm** (*float32*) –The max norm specified.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1., 1, 1], [2, 2, 2], [3, 3, 3]])
>>> output = mindspore.ops.norm(input, 1, 1)
>>> print(output)
[3. 6. 9.]
>>> output = mindspore.ops.renorm(input, 1, 0, 6.)
>>> print(output)
[[1. 1. 1.]
 [2. 2. 2.]
 [2. 2. 2.]]
```

2.1.4 Type Cast

API Name	Description	Supported Platforms
mindspore.ops.cast	Returns a tensor with the new specified data type.	Ascend GPU CPU
mindspore.ops.is_tensor	Check whether the input object is *mindspore.Tensor*.	Ascend GPU CPU
mindspore.ops.scalar_to_tensor	Converts a scalar to a tensor with the specified dtype.	Ascend GPU CPU
mindspore.ops.tuple_to_array	Converts a tuple to a tensor.	Ascend GPU CPU

mindspore.ops.cast

mindspore.ops.**cast**(*input*, *dtype*)

Returns a tensor with the new specified data type.

Note: When converting complex numbers to boolean type, the imaginary part of the complex number is not taken into account. As long as the real part is non-zero, it returns `True`; otherwise, it returns `False`.

Parameters

- **input** (*Union[Tensor, Number]*) – The input tensor or number.
- **dtype** (*dtype.Number*) – The dtype after conversion. Only constant value is allowed.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> dtype = mindspore.float64
>>> output = mindspore.ops.cast(input, dtype)
>>> print(output.dtype)
Float64
>>> print(output)
[1. 2. 3.]
```

mindspore.ops.is_tensor

mindspore.ops.**is_tensor**(*obj*)

Check whether the input object is *mindspore.Tensor*.

Parameters

obj (*Object*) – input object.

Returns

Bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> a = mindspore.tensor([1.9, 2.2, 3.1])
>>> mindspore.ops.is_tensor(a)
True
```

mindspore.ops.scalar_to_tensor

mindspore.ops.**scalar_to_tensor**(*input_x*, *dtype=mstype.float32*)

Converts a scalar to a tensor with the specified dtype.

Parameters

- **input_x** (*Union[bool, int, float]*) – The input scalar. Only constant value is allowed.
- **dtype** (mindspore.dtype) – The dtype of returned tensor. Only constant value is allowed.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> data = 1
>>> output = mindspore.ops.scalar_to_tensor(data, mindspore.float32)
>>> print(output)
1.0
```

mindspore.ops.tuple_to_array

mindspore.ops.**tuple_to_array**(*input_x*)

Converts a tuple to a tensor.

Note: If the type of the first number in the tuple is integer, the data type of the output tensor is int. Otherwise, the data type of the output tensor is float.

Parameters

input_x (*tuple*) – A tuple of numbers. Only constant value is allowed.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = (1, 2, 3)
>>> output = mindspore.ops.tuple_to_array(input_x)
>>> print(type(output))
<class 'mindspore.common.tensor.Tensor'>
>>> print(output)
[1 2 3]
```

2.1.5 Gradient Clipping

API Name	Description	Supported Platforms
mindspore.ops.clip_by_global_norm	Clips tensor values by the ratio of the sum of their norms.	Ascend GPU CPU
mindspore.ops.clip_by_value	Clips tensor values to a specified min and max.	Ascend GPU CPU
mindspore.ops.clip_by_norm	The input Tensor is cropped based on norm.	Ascend GPU CPU

mindspore.ops.clip_by_global_norm

mindspore.ops.**clip_by_global_norm**(*x*, *clip_norm=1.0*, *use_norm=None*)

Clips tensor values by the ratio of the sum of their norms.

Note:

- On the SEMI_AUTO_PARALLEL mode or AUTO_PARALLEL mode, if the input *x* is the gradient, the gradient norm values on all devices will be automatically aggregated by allreduce inserted after the local square sum of the gradients.

Parameters

- **x** (*Union(tuple[Tensor], list[Tensor])*) – Input data to clip.
- **clip_norm** (*Union(float, int)*) – The clipping ratio, it should be greater than 0. Default `1.0` .
- **use_norm** (*None*) – The global norm. Currently only none is supported. Default `None` .

Returns

Tuple of tensors

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x1 = mindspore.tensor([[2., 3.], [1., 2.]], dtype=mindspore.float32)
>>> x2 = mindspore.tensor([[1., 4.], [3., 1.]], dtype=mindspore.float32)
>>> input_x = (x1, x2)
>>> out = mindspore.ops.clip_by_global_norm(input_x, 1.0)
>>> print(out)
(Tensor(shape=[2, 2], dtype=Float32, value=
[[ 2.98142403e-01,  4.47213590e-01],
 [ 1.49071202e-01,  2.98142403e-01]]), Tensor(shape=[2, 2], dtype=Float32, value=
[[ 1.49071202e-01,  5.96284807e-01],
 [ 4.47213590e-01,  1.49071202e-01]]))
```

mindspore.ops.clip_by_value

mindspore.ops.**clip_by_value**(*x*, *clip_value_min=None*, *clip_value_max=None*)

Clips tensor values to a specified min and max.

Limits the value of x to a range, whose lower limit is *clip_value_min* and upper limit is *clip_value_max* .

$$out_i = \begin{cases} clip\_value\_max & \text{if } x_i \geq clip\_value\_max \\ x_i & \text{if } clip\_value\_min < x_i < clip\_value\_max \\ clip\_value\_min & \text{if } x_i \leq clip\_value\_min \end{cases}$$

Note:

- *clip_value_min* and *clip_value_max* cannot be None at the same time;
- When *clip_value_min* is None and *clip_value_max* is not None, the elements in Tensor larger than *clip_value_max* will become *clip_value_max*;
- When *clip_value_min* is not None and *clip_value_max* is None, the elements in Tensor smaller than *clip_value_min* will become *clip_value_min*;
- If *clip_value_min* is greater than *clip_value_max*, the value of all elements in Tensor will be set to *clip_value_max*;
- The data type of *x*, *clip_value_min* and *clip_value_max* should support implicit type conversion and cannot be bool type.

Parameters

- **x** (*Union(Tensor, list[Tensor], tuple[Tensor])*) – Input data, which type is Tensor or a list or tuple of Tensor. Tensors of arbitrary dimensions are supported.
- **clip_value_min** (*Union(Tensor, float, int)*) – The minimum value. Default: `None` .
- **clip_value_max** (*Union(Tensor, float, int)*) – The maximum value. Default: `None` .

Returns

(Union(Tensor, tuple[Tensor], list[Tensor])), a clipped Tensor or a tuple or a list of clipped Tensor. The data type and shape are the same as x.

Raises

- **ValueError** – If both *clip_value_min* and *clip_value_max* are None.
- **TypeError** – If the type of *x* is not in Tensor or list[Tensor] or tuple[Tensor].

- **TypeError** –If the type of *clip_value_min* is not in None, Tensor, float or int.
- **TypeError** –If the type of *clip_value_max* is not in None, Tensor, float or int.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> # case 1: the data type of x is Tensor
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> import numpy as np
>>> min_value = Tensor(5, mindspore.float32)
>>> max_value = Tensor(20, mindspore.float32)
>>> x = Tensor(np.array([[1., 25., 5., 7.], [4., 11., 6., 21.]]), mindspore.float32)
>>> output = ops.clip_by_value(x, min_value, max_value)
>>> print(output)
[[ 5. 20.  5.  7.]
 [ 5. 11.  6. 20.]]
>>> # case 2: the data type of x is list[Tensor]
>>> min_value = 5
>>> max_value = 20
>>> x = Tensor(np.array([[1., 25., 5., 7.], [4., 11., 6., 21.]]), mindspore.float32)
>>> y = Tensor(np.array([[1., 25., 5., 7.], [4., 11., 6., 21.]]), mindspore.float32)
>>> output = ops.clip_by_value([x,y], min_value, max_value)
>>> for out in output:
...     print(out)
[[ 5. 20.  5.  7.]
 [ 5. 11.  6. 20.]]
[[ 5. 20.  5.  7.]
 [ 5. 11.  6. 20.]]
```

mindspore.ops.clip_by_norm

`mindspore.ops.`**`clip_by_norm`**(*x*, *max_norm*, *norm_type=2.0*, *error_if_nonfinite=False*)

The input Tensor is cropped based on norm. The computation is done by concatenating the norms of all the input elementsinto a vector and then computing the norm of that vector. The Tensor gradient value corresponding to the *identifier*.

Note: The interface is suitable for gradient clipping scenarios, and only supports input of type float.

Parameters

- **x** (*Union[Tensor, list[Tensor], tuple[Tensor]]*) –Input that wishes to be clipped.
- **max_norm** (*Union[float, int]*) –The upper limit of the norm for this group of network parameters.
- **norm_type** (*Union[float, int], optional*) –Norm type. Default: `2.0`.
- **error_if_nonfinite** (*bool, optional*) –If it is `True`, an exception is thrown if the total norm from the input is nan, inf or -inf. If it is `False`, no exception will be thrown.Default: `False` .

Returns

Tensors, a list or tuple of Tensors, representing clipped Tensors.

Raises

RuntimeError – If the total norm from the *x* is nan, inf or -inf.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor, ops
>>> x = Tensor([[0.8748, 0.1425, 0.0076], [0.7721, 0.4084, 0.0552], [4.6376, 0.2914, 2.
↪1120]])
>>> out = ops.clip_by_norm(x, max_norm=1)
>>> print(out)
[[0.16650201 0.02712224 0.00144652]
 [0.14695495 0.07773139 0.0105063 ]
 [0.8826814  0.0554626  0.40198016]]
```

2.2 Mathematical Functions

2.2.1 Element-wise Operations

API Name	Description	Supported Platforms
mindspore.ops.abs	Compute the absolute value of a tensor element-wise.	`Ascend` `GPU` `CPU`
mindspore.ops.absolute	Alias for *mindspore.ops.abs()* .	`Ascend` `GPU` `CPU`
mindspore.ops.accumulate_n	Return the element-wise sum of all input tensors.	`Ascend` `GPU`
mindspore.ops.acos	Compute arccosine of each element in input tensors.	`Ascend` `GPU` `CPU`
mindspore.ops.arccos	Alias for *mindspore.ops.acos()* .	`Ascend` `GPU` `CPU`
mindspore.ops.acosh	Computes inverse hyperbolic cosine of each element in inputs tensors.	`Ascend` `GPU` `CPU`
mindspore.ops.add	Compute the element-wise sum of the two input tensors.	`Ascend` `GPU` `CPU`
mindspore.ops.addcdiv	Divide *tensor1* by *tensor2* element-wise, multiply the result by the scalar *value* , and add it to *input* .	`Ascend` `GPU` `CPU`
mindspore.ops.addcmul	Multiply *tensor1* by *tensor2* element-wise, scale the result by the scalar *value* , and add it to *input* .	`Ascend` `GPU` `CPU`
mindspore.ops.addmv	Multiply the matrix *mat* and vector *vec* , and then add the result to the *input* .	`Ascend` `GPU` `CPU`
mindspore.ops.addn	Return the element-wise sum of all input tensors.	`Ascend` `GPU` `CPU`
mindspore.ops.angle	Returns the element-wise angle of the given complex tensor.	Ascend`` `GPU` `CPU`
mindspore.ops.arccosh	Alias for *mindspore.ops.acosh()*.	`Ascend` `GPU` `CPU`
mindspore.ops.arcsin	Alias for *mindspore.ops.asin()*.	`Ascend` `GPU` `CPU`
mindspore.ops.arcsinh	Alias for *mindspore.ops.asinh()*.	`Ascend` `GPU` `CPU`
mindspore.ops.arctan	Alias for *mindspore.ops.atan()*.	`Ascend` `GPU` `CPU`
mindspore.ops.arctanh	Alias for *mindspore.ops.atanh()*.	`Ascend` `GPU` `CPU`

continues on next page

Table 6 – continued from previous page

mindspore.ops.arctan2	Alias for mindspore.ops.atan2().	Ascend GPU CPU
mindspore.ops.asin	Computes arcsine of input tensors element-wise.	Ascend GPU CPU
mindspore.ops.asinh	Computes inverse hyperbolic sine of the input element-wise.	Ascend GPU CPU
mindspore.ops.atan	Computes the trigonometric inverse tangent of the input element-wise.	Ascend GPU CPU
mindspore.ops.atan2	Returns arctangent of input/other element-wise.	Ascend GPU CPU
mindspore.ops.atanh	Computes inverse hyperbolic tangent of the input element-wise.	Ascend GPU CPU
mindspore.ops.atleast_1d	Returns a one-dimensional tensor of each zero-dimensional tensor, while tensors with one or more dimensions remain unchanged.	Ascend GPU CPU
mindspore.ops.atleast_2d	Returns a 2-dimensional tensor of each tensor, while tensors with two or more dimensions remain unchanged.	Ascend GPU CPU
mindspore.ops.atleast_3d	Returns a 3-dimensional tensor of each tensor, while tensors with three or more dimensions remain unchanged.	Ascend GPU CPU
mindspore.ops.bessel_i0	Computes the zeroth order modified Bessel function of the first kind for each element input.	GPU CPU
mindspore.ops.bessel_i0e	Computes the exponentially scaled zeroth order modified Bessel function of the first kind for each element input.	GPU CPU
mindspore.ops.bessel_i1	Computes the first order modified Bessel function of the first kind for each element input.	GPU CPU
mindspore.ops.bessel_i1e	Computes the exponentially scaled first order modified Bessel function of the first kind for each element input.	GPU CPU
mindspore.ops.bessel_j0	Computes the zeroth order Bessel function of the first kind for each element input.	GPU CPU
mindspore.ops.bessel_j1	Computes the first order Bessel function of the first kind for each element input.	GPU CPU
mindspore.ops.bessel_k0	Computes the zeroth order modified Bessel function of the second kind for each element input.	GPU CPU
mindspore.ops.bessel_k0e	Computes the exponentially scaled zeroth order modified Bessel function of the second kind for each element input.	GPU CPU
mindspore.ops.bessel_k1	Computes the first order modified Bessel function of the second kind for each element input.	GPU CPU
mindspore.ops.bessel_k1e	Computes the exponentially scaled first order modified Bessel function of the second kind for each element input.	GPU CPU
mindspore.ops.bessel_y0	Computes the zeroth order Bessel function of the second kind for each element input.	GPU CPU
mindspore.ops.bessel_y1	Computes the first order Bessel function of the second kind for each element input.	GPU CPU
mindspore.ops.bitwise_and	Compute the bitwise AND of two input tensors.	Ascend GPU CPU
mindspore.ops.bitwise_left_shift	Perform a left bitwise shift operation on the *input* element-wise, where the number of bits to shift is specified by *other*.	Ascend GPU CPU
mindspore.ops.bitwise_or	Compute the bitwise OR of two input tensors.	Ascend GPU CPU

continues on next page

Table 6 – continued from previous page

mindspore.ops.bitwise_right_shift	Perform a right bitwise shift operation on the *input* element-wise, where the number of bits to shift is specified by *other*.	Ascend GPU CPU
mindspore.ops.bitwise_xor	Compute the bitwise XOR of two input tensors.	Ascend GPU CPU
mindspore.ops.ceil	Rounds a tensor up to the closest integer element-wise.	Ascend GPU CPU
mindspore.ops.clamp	Clamp all elements of the input tensor within the range [min, max].	Ascend GPU CPU
mindspore.ops.clip	Alias for mindspore.ops.clamp() .	Ascend GPU CPU
mindspore.ops.combinations	Return all r-length subsequences of input tensor.	Ascend GPU CPU
mindspore.ops.copysign	Create a float tensor composed of the absolute values of *x* and the signs of *other* .	Ascend GPU CPU
mindspore.ops.cos	Computes cosine of input element-wise.	Ascend GPU CPU
mindspore.ops.cosh	Computes hyperbolic cosine of input element-wise.	Ascend GPU CPU
mindspore.ops.cosine_similarity	Calculate cosine similarity between two input tensors along the specified dimension.	Ascend GPU CPU
mindspore.ops.cov	Return the covariance matrix of the input tensor, where the rows of the input tensor represent variables and the columns represent observations.	Ascend GPU CPU
mindspore.ops.diff	Computes the n-th forward difference along the given axis.	Ascend GPU CPU
mindspore.ops.deg2rad	Convert angles from degrees to radians element-wise.	Ascend GPU CPU
mindspore.ops.digamma	Computes the logarithmic derivative of the gamma function on input tensor.	GPU CPU
mindspore.ops.div	Divide the first input tensor by the second input tensor in floating-point type element-wise.	Ascend GPU CPU
mindspore.ops.divide	Alias for mindspore.ops.div() .	Ascend GPU CPU
mindspore.ops.erf	Compute the Gauss error of input tensor element-wise.	Ascend GPU CPU
mindspore.ops.erfc	Compute the complementary error function of input tensor element-wise.	Ascend GPU CPU
mindspore.ops.erfinv	Compute the inverse error of input tensor element-wise.	Ascend GPU CPU
mindspore.ops.exp	Compute exponential of the input tensor element-wise.	Ascend GPU CPU
mindspore.ops.exp2	Compute base two exponential of the input tensor element-wise.	Ascend GPU CPU
mindspore.ops.expm1	Compute exponential of the input tensor, then minus 1, element-wise.	Ascend`` GPU CPU
mindspore.ops.floor	Rounds a tensor down to the closest integer element-wise.	Ascend GPU CPU
mindspore.ops.floor_div	Alias for mindspore.ops.floor_divide() .	Ascend GPU CPU
mindspore.ops.floor_divide	Compute element-wise division of *input* by *other* and floor the result.	Ascend GPU CPU
mindspore.ops.floor_mod	Compute the remainder of element-wise flooring division of first input by second input.	Ascend GPU CPU
mindspore.ops.float_power	Computes the first input to the power of the second input.	GPU CPU

continues on next page

Table 6 – continued from previous page

mindspore.ops.fmax	Compute the maximum of input tensors element-wise.	CPU
mindspore.ops.fmod	Compute the remainder of element-wise division of first input by the second input.	Ascend GPU CPU
mindspore.ops.frac	Return the fractional part of each element in the input tensor.	Ascend GPU CPU
mindspore.ops.gcd	Computes greatest common divisor of input tensors element-wise.	Ascend GPU CPU
mindspore.ops.hypot	Given the legs of a right triangle, return its hypotenuse, element-wise.	Ascend GPU CPU
mindspore.ops.igamma	Calculates lower regularized incomplete Gamma function.	Ascend GPU CPU
mindspore.ops.igammac	Calculates upper regularized incomplete Gamma function.	Ascend GPU CPU
mindspore.ops.imag	Return a new tensor containing imaginary value of the input tensor, element-wise.	Ascend GPU CPU
mindspore.ops.i0	For details, please refer to mindspore.ops.bessel_i0().	GPU CPU
mindspore.ops.inv	Computes Reciprocal of input tensor element-wise.	Ascend GPU CPU
mindspore.ops.invert	Flip all bits of input tensor element-wise.	Ascend GPU CPU
mindspore.ops.lcm	Computes least common multiplier of input tensors element-wise.	Ascend GPU CPU
mindspore.ops.ldexp	Multiplies input tensor by 2^{other} element-wise.	Ascend GPU CPU
mindspore.ops.lerp	Does a linear interpolation of two tensors input and end based on a float or tensor weight.	Ascend GPU CPU
mindspore.ops.log	Compute the natural logarithm of the input tensor element-wise.	Ascend GPU CPU
mindspore.ops.log2	Compute the logarithm to the base 2 of the input tensor element-wise.	Ascend GPU CPU
mindspore.ops.log10	Compute the logarithm to the base 10 of the input tensor element-wise.	Ascend GPU CPU
mindspore.ops.log1p	Compute the natural logarithm of (tensor + 1) element-wise.	Ascend GPU CPU
mindspore.ops.logaddexp	Computes the logarithm of the sum of exponentiations of the inputs.	Ascend GPU CPU
mindspore.ops.logaddexp2	Computes the logarithm of the sum of exponentiations in base of 2 of the inputs.	Ascend GPU CPU
mindspore.ops.logical_and	Compute the "logical AND" of two tensors element-wise.	Ascend GPU CPU
mindspore.ops.logical_not	Compute the "logical NOT" of the input tensor element-wise.	Ascend GPU CPU
mindspore.ops.logical_or	Compute the "logical OR" of two tensors element-wise.	Ascend GPU CPU
mindspore.ops.logical_xor	Compute the "logical XOR" of two tensors element-wise.	Ascend CPU
mindspore.ops.logit	Calculate the logit of a tensor element-wise.	Ascend GPU CPU
mindspore.ops.mul	Multiplies two tensors element-wise.	Ascend GPU CPU
mindspore.ops.multiply	Alias for mindspore.ops.asinh().	Ascend GPU CPU
mindspore.ops.mvlgamma	Compute the multivariate log-gamma function with dimension p element-wise.	Ascend GPU CPU

continues on next page

Table 6 – continued from previous page

mindspore.ops.neg	Returns a tensor with negative values of the input tensor element-wise.	Ascend GPU CPU
mindspore.ops.negative	Alias for mindspore.ops.neg() .	Ascend GPU CPU
mindspore.ops.nextafter	Returns the next representable floating-point value after *input* towards *other* element-wise.	Ascend GPU CPU
mindspore.ops.polar	Converts polar coordinates to Cartesian coordinates.	Ascend GPU CPU
mindspore.ops.polygamma	Computes the *n*-th derivative of the polygamma function on *input*.	GPU CPU
mindspore.ops.positive	Return self tensor.	Ascend GPU CPU
mindspore.ops.pow	Calculate the *exponent* power of each element in *input*.	Ascend GPU CPU
mindspore.ops.rad2deg	Converts angles in radians to angles in degrees element-wise.	Ascend GPU CPU
mindspore.ops.ravel	Expand the multidimensional Tensor into 1D along the 0 axis direction.	Ascend GPU CPU
mindspore.ops.real	Return a tensor that is the real part of the input.	Ascend GPU CPU
mindspore.ops.reciprocal	Returns reciprocal of a tensor element-wise.	Ascend GPU CPU
mindspore.ops.remainder	Compute the remainder of division for the input tensor element-wise.	Ascend GPU CPU
mindspore.ops.rot90	Rotate a n-D tensor by 90 degrees in the plane specified by dims axis.	Ascend GPU CPU
mindspore.ops.round	Round elements of input to the nearest integer.	Ascend GPU CPU
mindspore.ops.rsqrt	Compute reciprocal of square root of input tensor element-wise.	Ascend GPU CPU
mindspore.ops.sgn	Extension of mindspore.ops.sign() in complex domain.	Ascend GPU CPU
mindspore.ops.sign	Return an element-wise indication of the sign of a number.	Ascend GPU CPU
mindspore.ops.signbit	Determine the symbol of each element.	Ascend GPU CPU
mindspore.ops.sin	Compute sine of the input tensor element-wise.	Ascend GPU CPU
mindspore.ops.sinc	Compute the normalized sinc of input.	Ascend GPU CPU
mindspore.ops.sinh	Compute hyperbolic sine of the input element-wise.	Ascend GPU CPU
mindspore.ops.sqrt	Return sqrt of a tensor element-wise.	Ascend GPU CPU
mindspore.ops.square	Return square of a tensor element-wise.	Ascend GPU CPU
mindspore.ops.sub	Subtract the second input from the first input element-wise.	Ascend GPU CPU
mindspore.ops.subtract	Subtract *other* scaled by *alpha* from *input*.	Ascend GPU CPU
mindspore.ops.t	Transpose a 2-D tensor.	Ascend GPU CPU
mindspore.ops.tan	Computes tangent of *input* element-wise.	Ascend GPU CPU
mindspore.ops.tanhshrink	Apply the element-wise Tanhshrink function.	Ascend GPU CPU
mindspore.ops.trapz	Compute the trapezoidal rule along dim.	Ascend GPU CPU
mindspore.ops.tril_indices	Return a 2-by-N tensor containing the indices of the lower triangular elements of a *row* * *col* matrix.	Ascend GPU CPU
mindspore.ops.triu_indices	Return a 2-by-N tensor containing the indices of the upper triangular elements of a *row* * *col* matrix.	Ascend GPU CPU
mindspore.ops.true_divide	Alias for mindspore.ops.div() with rounding_mode=None .	Ascend GPU CPU
mindspore.ops.trunc	Returns a tensor with the truncated integer values of the elements of the input tensor.	Ascend GPU CPU

continues on next page

Table 6 – continued from previous page

mindspore.ops.truncate_div	Divide the first input tensor x by the second input tensor y element-wise and rounds the results of division towards zero.	Ascend GPU CPU
mindspore.ops.truncate_mod	Return the remainder of division element-wise.	Ascend GPU CPU
mindspore.ops.xdivy	Divide x by y element-wise.	Ascend GPU CPU
mindspore.ops.xlogy	Compute *input* multiplied by the logarithm of *other* element-wise.	Ascend GPU CPU
mindspore.ops.zeta	Elemental-wise compute the Hurwitz zeta function values.	Ascend GPU CPU

mindspore.ops.abs

mindspore.ops.**abs**(*input*)

Compute the absolute value of a tensor element-wise.

$$out_i = |input_i|$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.abs(mindspore.tensor([-1.0, 1.0, 0.0]))
>>> print(output)
[1. 1. 0.]
```

mindspore.ops.absolute

mindspore.ops.**absolute**(*input*)

Alias for *mindspore.ops.abs()* .

Supported Platforms:

Ascend GPU CPU

mindspore.ops.accumulate_n

mindspore.ops.**accumulate_n**(*x*)

Return the element-wise sum of all input tensors.

mindspore.ops.accumulate_n() is similar to *mindspore.ops.addn()*, but accumulate_n will not wait for all of its inputs to be ready before summing, which is able to reduce peak memory.

Parameters

x (*Union(tuple[Tensor], list[Tensor])*) – List of tensors or tuple of tensors.

Returns

Tensor

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> y = mindspore.tensor([4, 5, 6], mindspore.float32)
>>> output = mindspore.ops.accumulate_n([x, y, x, y])
>>> print(output)
[10. 14. 18.]
```

mindspore.ops.acos

mindspore.ops.**acos**(*input*)

Compute arccosine of each element in input tensors.

$$out_i = \cos^{-1}(input_i)$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.acos(mindspore.tensor([0.74, 0.04, 0.30, 0.56]))
>>> print(output)
[0.737726  1.5307857 1.2661036 0.9764105]
```

mindspore.ops.arccos

mindspore.ops.**arccos**(*input*)

Alias for *mindspore.ops.acos()* .

Supported Platforms:

Ascend GPU CPU

mindspore.ops.acosh

mindspore.ops.**acosh**(*input*)

Computes inverse hyperbolic cosine of each element in inputs tensors.

$$out_i = \cosh^{-1}(input_i)$$

Note: Given an input tensor input, the function computes inverse hyperbolic cosine of every element. Input range is [1, inf].

Parameters

input (Tensor) −The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.acosh(mindspore.tensor([1.0, 1.5, 3.0, 100.0]))
>>> print(output)
[0.        0.9624237 1.7627472 5.298292 ]
```

mindspore.ops.add

mindspore.ops.**add**(*input*, *other*)

Compute the element-wise sum of the two input tensors.

$$out_i = input_i + other_i$$

Note:

- The two inputs can not be bool type at the same time, [True, Tensor(True, bool_), Tensor(np.array([True]), bool_)] are all considered bool type.
- Support broadcast, support implicit type conversion and type promotion.
- When the input is a tensor, the dimension should be greater than or equal to 1.

Parameters

- **input** (*Union[Tensor, number.Number, bool]*) – The first input tensor.
- **other** (*Union[Tensor, number.Number, bool]*) – The second input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: x and y are both tensor.
>>> x = mindspore.tensor([1., 2., 3.])
>>> y = mindspore.tensor([4., 5., 6.])
>>> output = mindspore.ops.add(x, y)
>>> print(output)
[5. 7. 9.]
>>> # case 2: x is a scalar and y is a tensor
>>> x = mindspore.tensor(1, mindspore.int32)
>>> y = mindspore.tensor([4., 5., 6.])
>>> output = mindspore.ops.add(x, y)
>>> print(output)
[5. 6. 7.]
>>> # the data type of x is int32, the data type of y is float32,
>>> # and the output is the data format of higher precision float32.
>>> print(output.dtype)
Float32
```

mindspore.ops.addcdiv

mindspore.ops.**addcdiv**(*input*, *tensor1*, *tensor2*, *value=1*)

Divide *tensor1* by *tensor2* element-wise, multiply the result by the scalar *value* , and add it to *input* .

$$y[i] = input[i] + value[i] * (tensor1[i]/tensor2[i])$$

Parameters

- **input** (Tensor) –The input tensor.
- **tensor1** (Tensor) –Tensor1, the numerator.
- **tensor2** (Tensor) –Tensor2, the denominator.
- **value** (*Union[Tensor, number]*) –The multiplier for (*tensor1* / *tensor2*). Default 1 .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1, 1, 1, 1], mindspore.float32)
>>> x1 = mindspore.tensor([1, 2, 3, 4], mindspore.float32)
>>> x2 = mindspore.tensor([4, 4, 2, 1], mindspore.float32)
>>> y = mindspore.ops.addcdiv(x, x1, x2, 0.1)
>>> print(y)
[1.025 1.05  1.15  1.4  ]
```

mindspore.ops.addcmul

mindspore.ops.**addcmul**(*input*, *tensor1*, *tensor2*, *value=1*)

Multiply *tensor1* by *tensor2* element-wise, scale the result by the scalar *value* , and add it to *input* .

$$output[i] = input[i] + value[i] * (tensor1[i] * tensor2[i])$$

Parameters

- **input** (Tensor) –The input tensor.
- **tensor1** (Tensor) –The first tensor to be multiplied.
- **tensor2** (Tensor) –The second tensor to be multiplied.
- **value** (*Union[Tensor, number]*) –The multiplier for (*tensor1* * *tensor2*). Default 1 .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor(([1, 1, 1]), mindspore.float32)
>>> x1 = mindspore.tensor([[1], [2], [3]], mindspore.float32)
>>> x2 = mindspore.tensor([[1, 2, 3]], mindspore.float32)
>>> value = mindspore.tensor([1], mindspore.float32)
>>> y = mindspore.ops.addcmul(x, x1, x2, value)
>>> print(y)
[[ 2.  3.  4.]
 [ 3.  5.  7.]
 [ 4.  7. 10.]]
```

mindspore.ops.addmv

mindspore.ops.**addmv**(*input*, *mat*, *vec*, *, *beta=1*, *alpha=1*)

Multiply the matrix *mat* and vector *vec* , and then add the result to the *input* .

Note:

- If mat is a (N, M) tensor, vec is a 1-D tensor of size M, then *input* must be broadcastable with a 1-D tensor of size N, *out* will be a 1-D tensor of size N.
- If *beta* is 0, *input* will be ignored.

$$output = input + (mat@vec)$$

Parameters

- **input** (Tensor) –The input tensor.
- **mat** (Tensor) –The matrix tensor to be multiplied.
- **vec** (Tensor) –The vector tensor to be multiplied.

Keyword Arguments

- **beta** (*scalar[int, float, bool], optional*) –Scale factor for *input* . Default 1 .
- **alpha** (*scalar[int, float, bool], optional*) –Scale factor for (*mat* @ *vec*). Default 1 .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([2., 3.])
>>> mat = mindspore.tensor([[2., 5., 3.], [4., 2., 2.]])
>>> vec = mindspore.tensor([3., 2., 4.])
>>> output = mindspore.ops.addmv(input, mat, vec)
>>> print(output)
[30. 27.]
```

mindspore.ops.addn

mindspore.ops.**addn**(*x*)

Return the element-wise sum of all input tensors.

Parameters

x (*Union(tuple[Tensor], list[Tensor])*) – List of tensors or tuple of tensors.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1, 2, 3])
>>> y = mindspore.tensor([4, 5, 6])
>>> mindspore.ops.addn([x, y, x, y])
Tensor(shape=[3], dtype=Int64, value= [10, 14, 18])
```

mindspore.ops.angle

mindspore.ops.**angle**(*input*)

Returns the element-wise angle of the given complex tensor.

$$output_i = angle(input_i)$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([-1 + 1j, -2 + 2j, 3 - 3j], mindspore.complex64)
>>> output = mindspore.ops.angle(input)*180/3.14159
>>> print(output)
[135.0001  135.0001  -45.00004]
```

mindspore.ops.arccosh

mindspore.ops.**arccosh**(*input*)

Alias for *mindspore.ops.acosh()*.

Supported Platforms:

Ascend GPU CPU

mindspore.ops.arcsin

mindspore.ops.**arcsin**(*x*)

Alias for *mindspore.ops.asin()*.

Supported Platforms:

Ascend GPU CPU

mindspore.ops.arcsinh

mindspore.ops.**arcsinh**(*input*)

Alias for *mindspore.ops.asinh()*.

Supported Platforms:

Ascend GPU CPU

mindspore.ops.arctan

mindspore.ops.**arctan**(*input*)

Alias for *mindspore.ops.atan()*.

Supported Platforms:

Ascend GPU CPU

mindspore.ops.arctanh

mindspore.ops.**arctanh**(*input*)

Alias for *mindspore.ops.atanh()*.

Supported Platforms:

Ascend GPU CPU

mindspore.ops.arctan2

mindspore.ops.**arctan2**(*input*, *other*)

Alias for *mindspore.ops.atan2()*.

Supported Platforms:

Ascend GPU CPU

mindspore.ops.asin

mindspore.ops.**asin**(*input*)

Computes arcsine of input tensors element-wise.

$$out_i = \sin^{-1}(input_i)$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.asin(mindspore.tensor([0.74, 0.04, 0.30, 0.56]))
>>> print(output)
[0.8330704  0.04001067  0.30469266  0.5943858 ]
```

mindspore.ops.asinh

mindspore.ops.**asinh**(*input*)

Computes inverse hyperbolic sine of the input element-wise.

$$out_i = \sinh^{-1}(input_i)$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.asinh(mindspore.tensor([-5.0, 1.5, 3.0, 100.0]))
>>> print(output)
[-2.3124382  1.1947632  1.8184465  5.298342 ]
```

mindspore.ops.atan

mindspore.ops.**atan**(*input*)

Computes the trigonometric inverse tangent of the input element-wise.

$$out_i = \tan^{-1}(input_i)$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.atan(mindspore.tensor([1.0, 0.0]))
>>> print(output)
[0.7853982 0.       ]
```

mindspore.ops.atan2

mindspore.ops.**atan2**(*input*, *other*)

Returns arctangent of input/other element-wise.

It returns $\theta \in [-\pi, \pi]$ such that $input = r * \sin(\theta), other = r * \cos(\theta)$, where $r = \sqrt{input^2 + other^2}$.

Parameters

- **input** (Tensor, *Number.number*) –The input tensor or scalar.
- **other** (Tensor, *Number.number*) –The input tensor or scalar.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.atan2(mindspore.tensor([0., 1.]), mindspore.tensor([1., 1.]))
>>> print(output)
[0.        0.7853982]
```

mindspore.ops.atanh

mindspore.ops.**atanh**(*input*)

Computes inverse hyperbolic tangent of the input element-wise.

$$out_i = \tanh^{-1}(input_i)$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.atanh(mindspore.tensor([0, -0.5]))
>>> print(output)
[ 0.         -0.54930615]
```

mindspore.ops.atleast_1d

mindspore.ops.**atleast_1d**(*inputs*)

Returns a one-dimensional tensor of each zero-dimensional tensor, while tensors with one or more dimensions remain unchanged.

Parameters

inputs (*Union[Tensor, list[Tensor]]*) – The input tensor or list of tensors.

Returns

Tensor or list of tensors.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: Input is a zero-dimensional tensor.
>>> x = mindspore.tensor(1)
>>> mindspore.ops.atleast_1d(x)
Tensor(shape=[1], dtype=Int64, value= [1])
>>>
>>> # case 2: Input is a one-dimensional tensor.
>>> y = mindspore.tensor([0, 1])
>>> mindspore.ops.atleast_1d(y)
Tensor(shape=[2], dtype=Int64, value= [0, 1])
>>>
>>> # case 3: Input is a list containing tensors of various dimensions.
>>> mindspore.ops.atleast_1d([x, y])
(Tensor(shape=[1], dtype=Int64, value= [1]), Tensor(shape=[2], dtype=Int64, value= [0, 1]))
```

mindspore.ops.atleast_2d

mindspore.ops.**atleast_2d**(*inputs*)

Returns a 2-dimensional tensor of each tensor, while tensors with two or more dimensions remain unchanged.

Parameters

inputs (*Union[Tensor, list[Tensor]]*) – The input tensor or list of tensors.

Returns

Tensor or list of tensors.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: Input is a zero-dimensional tensor.
>>> x = mindspore.tensor(1)
>>> mindspore.ops.atleast_2d(x)
Tensor(shape=[1, 1], dtype=Int64, value= [[1]])
>>>
>>> # case 2: Input is a 2-dimensional tensor.
>>> y = mindspore.tensor([[0, 1], [2, 3]])
>>> mindspore.ops.atleast_2d(y)
Tensor(shape=[2, 2], dtype=Int64, value=
[[0, 1],
 [2, 3]])
>>>
>>> # case 3: Input is a list containing tensors of various dimensions.
>>> mindspore.ops.atleast_2d([x, y])
(Tensor(shape=[1, 1], dtype=Int64, value=
 [[1]]),
 Tensor(shape=[2, 2], dtype=Int64, value=
 [[0, 1],
  [2, 3]]))
```

mindspore.ops.atleast_3d

mindspore.ops.**atleast_3d**(*inputs*)

Returns a 3-dimensional tensor of each tensor, while tensors with three or more dimensions remain unchanged.

Parameters

inputs (*Union[Tensor, list[Tensor]]*) – The input tensor or list of tensors.

Returns

Tensor or list of tensors.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: Input is a zero-dimensional tensor.
>>> x = mindspore.tensor(1)
>>> mindspore.ops.atleast_3d(x)
Tensor(shape=[1, 1, 1], dtype=Int64, value= [[[1]]])
>>>
>>> # case 2: Input is a 3-dimensional tensor.
>>> y = mindspore.tensor([[[0, 1], [2, 3]]])
>>> mindspore.ops.atleast_3d(y)
Tensor(shape=[1, 2, 2], dtype=Int64, value=
[[[0, 1],
  [2, 3]]])
>>>
>>> # case 3: Input is a list containing tensors of various dimensions.
>>> mindspore.ops.atleast_3d([x, y])
(Tensor(shape=[1, 1, 1], dtype=Int64, value=
 [[[1]]]),
 Tensor(shape=[1, 2, 2], dtype=Int64, value=
 [[[0, 1],
   [2, 3]]])
```

mindspore.ops.bessel_i0

mindspore.ops.**bessel_i0**(*x*)

Computes the zeroth order modified Bessel function of the first kind for each element input.

$$I_0(x) = J_0(\mathrm{i}x) = \sum_{m=0}^{\infty} \frac{x^{2m}}{2^{2m}(m!)^2}$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([-1., -0.5, 0.5, 1.])
>>> output = mindspore.ops.bessel_i0(x)
>>> print(output)
[1.266066  1.0634835 1.0634835 1.266066]
```

mindspore.ops.bessel_i0e

mindspore.ops.**bessel_i0e**(*x*)

Computes the exponentially scaled zeroth order modified Bessel function of the first kind for each element input.

$$\mathrm{I}_0e(x) = e^{(-|x|)} * I_0(x) = e^{(-|x|)} * \sum_{m=0}^{\infty} \frac{x^{2m}}{2^{2m}(m!)^2}$$

Parameters

x (Tensor) −The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([-1., -0.5, 0.5, 1.])
>>> output = mindspore.ops.bessel_i0e(x)
>>> print(output)
[0.46575961  0.64503527  0.64503527  0.46575961]
```

mindspore.ops.bessel_i1

mindspore.ops.**bessel_i1**(*x*)

Computes the first order modified Bessel function of the first kind for each element input.

$$I_1(x) = \mathrm{i}^{-1}J_1(\mathrm{i}x) = \sum_{m=0}^{\infty} \frac{x^{2m+1}}{2^{2m+1}m!(m+1)!}$$

Parameters

x (Tensor) −The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([-1., -0.5, 0.5, 1.])
>>> output = mindspore.ops.bessel_i1(x)
>>> print(output)
[-0.5651591  -0.25789431  0.25789431  0.5651591]
```

mindspore.ops.bessel_i1e

mindspore.ops.**bessel_i1e**(*x*)

Computes the exponentially scaled first order modified Bessel function of the first kind for each element input.

$$\mathrm{I}_1e(x) = e^{(-|x|)} * I_1(x) = e^{(-|x|)} * \sum_{m=0}^{\infty} \frac{x^{2m+1}}{2^{2m+1}m!(m+1)!}$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([-1., -0.5, 0.5, 1.])
>>> output = mindspore.ops.bessel_i1e(x)
>>> print(output)
[-0.20791042  -0.15642083  0.15642083  0.20791042]
```

mindspore.ops.bessel_j0

mindspore.ops.**bessel_j0**(*x*)

Computes the zeroth order Bessel function of the first kind for each element input.

$$J_0(x) = \frac{1}{\pi}\int_0^{\pi}\cos(x\sin\theta)d\theta = \sum_{m=0}^{\infty}\frac{(-1)^m x^{2m}}{2^{2m}(m!)^2}$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([0.5, 1., 2., 4.])
>>> output = mindspore.ops.bessel_j0(x)
>>> print(output)
[0.93846981  0.76519769  0.22389078  -0.39714981]
```

mindspore.ops.bessel_j1

mindspore.ops.**bessel_j1**(*x*)

Computes the first order Bessel function of the first kind for each element input.

$$J_1(x) = \frac{1}{\pi}\int_0^{\pi}\cos(x\sin\theta-\theta)d\theta = \sum_{m=0}^{\infty}\frac{(-1)^m x^{2m+1}}{2^{2m+1}m!(m+1)!}$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([0.5, 1., 2., 4.])
>>> output = mindspore.ops.bessel_j1(x)
>>> print(output)
[0.24226846  0.44005059  0.57672481 -0.06604333]
```

mindspore.ops.bessel_k0

mindspore.ops.**bessel_k0**(*x*)

Computes the zeroth order modified Bessel function of the second kind for each element input.

$$K_0(x) = \lim_{\nu\to 0}\left(\frac{\pi}{2}\right)\frac{I_{-\nu}(x)-I_{\nu}(x)}{\sin(\nu\pi)} = \int_0^{\infty} e^{-x\cosh t}dt$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([0.5, 1., 2., 4.])
>>> output = mindspore.ops.bessel_k0(x)
>>> print(output)
[0.92441907  0.42102444  0.11389387  0.01115968]
```

mindspore.ops.bessel_k0e

mindspore.ops.**bessel_k0e**(*x*)

Computes the exponentially scaled zeroth order modified Bessel function of the second kind for each element input.

$$K_0e(x) = e^{(-|x|)} * K_0(x) = e^{(-|x|)} * \int_0^\infty e^{-x\cosh t} dt$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([0.5, 1., 2., 4.])
>>> output = mindspore.ops.bessel_k0e(x)
>>> print(output)
[1.52410939  1.14446308  0.84156822  0.60929767]
```

mindspore.ops.bessel_k1

mindspore.ops.**bessel_k1**(*x*)

Computes the first order modified Bessel function of the second kind for each element input.

$$K_1(x) = \lim_{\nu\to 1}\left(\frac{\pi}{2}\right)\frac{I_{-\nu}(x)-I_\nu(x)}{\sin(\nu\pi)} = \int_0^\infty e^{-x\cosh t}\cosh(t)dt$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([0.5, 1., 2., 4.])
>>> output = mindspore.ops.bessel_k1(x)
>>> print(output)
[1.65644112  0.60190723  0.13986588  0.0124835]
```

mindspore.ops.bessel_k1e

mindspore.ops.**bessel_k1e**(*x*)

Computes the exponentially scaled first order modified Bessel function of the second kind for each element input.

$$K_1e(x) = e^{(-|x|)} * K_1(x) = e^{(-|x|)} * \int_0^\infty e^{-x\cosh t}\cosh(t)dt$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([0.5, 1., 2., 4.])
>>> output = mindspore.ops.bessel_k1e(x)
>>> print(output)
[2.73100971  1.63615349  1.03347685  0.68157595]
```

mindspore.ops.bessel_y0

mindspore.ops.**bessel_y0**(*x*)

Computes the zeroth order Bessel function of the second kind for each element input.

$$Y_0(x) = \lim_{n\to 0} \frac{J_n(x)\cos n\pi - J_{-n}(x)}{\sin n\pi}$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([0.5, 1., 2., 4.])
>>> output = mindspore.ops.bessel_y0(x)
>>> print(output)
[-0.44451874  0.08825696  0.51037567  -0.01694074]
```

mindspore.ops.bessel_y1

mindspore.ops.**bessel_y1**(*x*)

Computes the first order Bessel function of the second kind for each element input.

$$Y_1(x) = \lim_{n \to 1} \frac{J_n(x)\cos n\pi - J_{-n}(x)}{\sin n\pi}$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([0.5, 1., 2., 4.])
>>> output = mindspore.ops.bessel_y1(x)
>>> print(output)
[-1.47147239  -0.78121282  -0.10703243  0.39792571]
```

mindspore.ops.bitwise_and

mindspore.ops.**bitwise_and**(*input*, *other*)

Compute the bitwise AND of two input tensors. If *input* and *other* have different data types, the implicit type conversion rules and type promotion rules are followed.

Parameters

- **input** (Tensor) – The first input tensor.
- **other** (Tensor) – The second input tensor.

Returns

Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([-1, -2, 3])
>>> other = mindspore.tensor([1, 0, 3])
>>> mindspore.ops.bitwise_and(input, other)
Tensor(shape=[3], dtype=Int64, value= [1, 0, 3])
>>> # Same as calling via the | operator:
>>> input & other
Tensor(shape=[3], dtype=Int64, value= [1, 0, 3])
```

mindspore.ops.bitwise_left_shift

mindspore.ops.**bitwise_left_shift**(*input*, *other*)

Perform a left bitwise shift operation on the *input* element-wise, where the number of bits to shift is specified by *other*.

$$out_i = input_i << other_i$$

Parameters

- **input** (*Union[Tensor, int, bool]*) – The input to be left shifted.
- **other** (*Union[Tensor, int, bool]*) – The number of bit to be applied on left arithmetic shift.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 2, 4, 8])
>>> mindspore.ops.bitwise_left_shift(input, 1)
Tensor(shape=[4], dtype=Int64, value= [ 2,  4,  8, 16])
```

mindspore.ops.bitwise_or

mindspore.ops.**bitwise_or**(*input*, *other*)

Compute the bitwise OR of two input tensors. If *input* and *other* have different data types, the implicit type conversion rules and type promotion rules are followed.

Parameters

- **input** (Tensor) – The first input tensor.
- **other** (Tensor) – The second input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([-1, -2, 3])
>>> other = mindspore.tensor([1, 0, 3])
>>> mindspore.ops.bitwise_or(input, other)
Tensor(shape=[3], dtype=Int64, value= [-1, -2,  3])
>>> # Same as calling via the | operator:
>>> input | other
Tensor(shape=[3], dtype=Int64, value= [-1, -2,  3])
```

mindspore.ops.bitwise_right_shift

mindspore.ops.**bitwise_right_shift**(*input*, *other*)

Perform a right bitwise shift operation on the *input* element-wise, where the number of bits to shift is specified by *other*.

$$out_i = input_i >> other_i$$

Parameters

- **input** (*Union[Tensor, int, bool]*) – The input to be right shifted.
- **other** (*Union[Tensor, int, bool]*) – The number of bit to be applied on right arithmetic shift.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 2, 4, 8])
>>> mindspore.ops.bitwise_right_shift(input, 1)
Tensor(shape=[4], dtype=Int64, value= [0, 1, 2, 4])
```

mindspore.ops.bitwise_xor

mindspore.ops.**bitwise_xor**(*input*, *other*)

Compute the bitwise XOR of two input tensors. If *input* and *other* have different data types, the implicit type conversion rules and type promotion rules are followed.

Parameters

- **input** (Tensor) – The first input tensor.
- **other** (Tensor) – The second input tensor.

Returns

Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([-1, -2, 3])
>>> other = mindspore.tensor([1, 0, 3])
>>> mindspore.ops.bitwise_xor(input, other)
Tensor(shape=[3], dtype=Int64, value= [-2, -2,  0])
>>> # Same as calling via the ^ operator:
>>> input ^ other
Tensor(shape=[3], dtype=Int64, value= [-2, -2,  0])
```

mindspore.ops.ceil

mindspore.ops.**ceil**(*input*)

Rounds a tensor up to the closest integer element-wise.

$$out_i = \lceil input_i \rceil$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor(([1.1, 2.5, -1.5]))
>>> output = mindspore.ops.ceil(input)
>>> print(output)
[ 2.  3. -1.]
```

mindspore.ops.clamp

mindspore.ops.**clamp**(*input*, *min=None*, *max=None*)

Clamp all elements of the input tensor within the range [min, max].

$$out_i = \begin{cases} max & \text{if } input_i \geq max \\ input_i & \text{if } min < input_i < max \\ min & \text{if } input_i \leq min \end{cases}$$

Note:

- *min* and *max* cannot be None at the same time;
- If *min* is None , there is no lower bound.
- if *max* is None , there is no upper bound.

- If *min* is greater than *max*, the value of all elements in Tensor will be set to *max*;

Parameters

- **input** (Tensor) –The input tensor.
- **min** (*Union(Tensor, float, int), optional*) –The minimum value. Default None .
- **max** (*Union(Tensor, float, int), optional*) –The maximum value. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: `min` and `max` are integer
>>> input = mindspore.tensor([[1, 25, 5, 7], [4, 11, 6, 21]])
>>> mindspore.ops.clamp(input, 5, 20)
Tensor(shape=[2, 4], dtype=Int64, value=
[[ 5, 20,  5,  7],
 [ 5, 11,  6, 20]])
>>>
>>> # case 2: If `min` and `max` are tensors, their shapes need to be broadcastable with␣
↪input.
>>> min = mindspore.tensor([2, 4, 6, 8])
>>> max = mindspore.tensor([10, 12, 14, 18])
>>> mindspore.ops.clamp(input, min, max)
Tensor(shape=[2, 4], dtype=Int64, value=
[[ 2, 12,  6,  8],
 [ 4, 11,  6, 18]])
```

mindspore.ops.clip

mindspore.ops.**clip**(*input*, *min=None*, *max=None*)

Alias for *mindspore.ops.clamp()* .

Supported Platforms:

Ascend GPU CPU

mindspore.ops.combinations

mindspore.ops.**combinations**(*input*, *r=2*, *with_replacement=False*)

Return all r-length subsequences of input tensor.

When *with_replacement* is set to `False`, it works similar to Python's *itertools.combinations*, and when *with_replacement* is set to `True`, it behaves like *itertools.combinations_with_replacement*.

Parameters

- **input** (Tensor) –One-dimensional input tensor.
- **r** (*int, optional*) –Number of elements to perform combination. Default `2` .
- **with_replacement** (*bool, optional*) –Allow duplication or not. Default `False` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 2, 3])
>>> mindspore.ops.combinations(input)
Tensor(shape=[3, 2], dtype=Int64, value=
[[1, 2],
 [1, 3],
 [2, 3]])
>>> mindspore.ops.combinations(input, r=3)
Tensor(shape=[1, 3], dtype=Int64, value=
[[1, 2, 3]])
>>> mindspore.ops.combinations(input, with_replacement=True)
Tensor(shape=[6, 2], dtype=Int64, value=
[[1, 1],
 [1, 2],
 [1, 3],
 [2, 2],
 [2, 3],
 [3, 3]])
>>> # It has the same results as using itertools.combinations.
>>> import itertools
>>> input = [1, 2, 3]
>>> list(itertools.combinations(input, r=2))
[(1, 2), (1, 3), (2, 3)]
>>> list(itertools.combinations(input, r=3))
[(1, 2, 3)]
>>> list(itertools.combinations_with_replacement(input, r=2))
[(1, 1), (1, 2), (1, 3), (2, 2), (2, 3), (3, 3)]
```

mindspore.ops.copysign

mindspore.ops.**copysign**(*x*, *other*)

Create a float tensor composed of the absolute values of *x* and the signs of *other* . Support broadcasting.

Parameters

- **x** (*Union[Tensor]*) –The input tensor.
- **other** (*Union[int, float, Tensor]*) –A tensor that determines the sign of the return value.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: When other is a tensor
>>> x = mindspore.tensor([[0.3, -0.7],
...                       [0.5, 0.5]])
>>> other = mindspore.tensor([-0.4, 0.6])
>>> output = mindspore.ops.copysign(x, other)
>>> print(output)
[[-0.3  0.7]
 [-0.5  0.5]]
>>> # case 2: When other is a scalar
>>> output = mindspore.ops.copysign(x, 2)
>>> print(output)
[[0.3 0.7]
 [0.5 0.5]]
```

mindspore.ops.cos

mindspore.ops.**cos**(*input*)

Computes cosine of input element-wise.

$$out_i = \cos(x_i)$$

Warning: Using float64 may cause a problem of missing precision.

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # The datatype of output will be float32 when datatype of input is in [bool, int8, uint8,
 ↪ int16, int32, int64](Datatype only supported on Ascend).
>>> input = mindspore.tensor([0, 1, 2], mindspore.int32)
>>> mindspore.ops.cos(input)
Tensor(shape=[3], dtype=Float32, value= [ 1.00000000e+00,  5.40302306e-01, -4.16146837e-01])
>>>
>>> # Otherwise output has the same dtype as the `input`.
>>> input = mindspore.tensor([0.74, 0.04, 0.30, 0.56], mindspore.float64)
>>> mindspore.ops.cos(input)
Tensor(shape=[4], dtype=Float64, value= [ 7.38468559e-01,  9.99200107e-01,  9.55336489e-01,
 ↪8.47255111e-01])
```

mindspore.ops.cosh

mindspore.ops.**cosh**(*input*)

Computes hyperbolic cosine of input element-wise.

$$out_i = \cosh(input_i)$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.74, 0.04, 0.30, 0.56])
>>> output = mindspore.ops.cosh(input)
>>> print(output)
[1.2865248 1.0008001 1.0453385 1.1609408]
```

mindspore.ops.cosine_similarity

mindspore.ops.**cosine_similarity**(*x1*, *x2*, *dim=1*, *eps=1e-08*)

Calculate cosine similarity between two input tensors along the specified dimension.

$$\text{similarity} = \frac{x_1 \cdot x_2}{\max(\|x_1\|_2 \cdot \|x_2\|_2, \epsilon)}$$

Note: Currently, broadcast of input is not supported.

Parameters

- **x1** (Tensor) –The first input tensor.
- **x2** (Tensor) –The second input tensor.
- **dim** (*int, optional*) –Specify the dimension for computation. Default 1 .
- **eps** (*float, optional*) –Minimal value to avoid division by zero. Default 1e-08 .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[-0.0256, 0.0127, -0.2475, 0.2316, 0.8037],
...                           [0.5809, -1.2712, -0.7038, -0.2558, 0.7494]])
>>> other = mindspore.tensor([[-0.6115, -0.1965, -0.8484, 0.2389, 0.2409],
...                           [1.8940, -2.1997, 0.1915, 0.0856, 0.7542]])
>>> output = mindspore.ops.cosine_similarity(input, other)
>>> print(output)
[0.4843164  0.81647635]
```

mindspore.ops.cov

mindspore.ops.**cov**(*input*, *, *correction=1*, *fweights=None*, *aweights=None*)

Return the covariance matrix of the input tensor, where the rows of the input tensor represent variables and the columns represent observations. The diagonal of the covariance matrix contains the variance of each variable in the input tensor, while the off-diagonal elements represent the covariance between pairs of variables. If the input is a 0-D or 1-D tensor, its variance is returned.

The unbiased sample covariance of the variables a and b is given by the following formula:

$$\text{cov}_w(a, b) = \frac{\sum_{i=1}^{N}(a_i - \bar{a})(b_i - \bar{b})}{N - 1}$$

where $\bar{a}$ and $\bar{b}$ are the simple means of the a and b respectively.

If *fweights* and/or *aweights* are provided, the unbiased weighted covariance is calculated, which is given by:

$$\text{cov}_w(a, b) = \frac{\sum_{i=1}^{N} w_i(a_i - \mu_a^*)(b_i - \mu_b^*)}{\sum_{i=1}^{N} w_i - 1}$$

where w denotes *fweights* or *aweights* based on whichever is provided, or $w = fweights \times aweights$ if both are provided, and $\mu_x^* = \frac{\sum_{i=1}^{N} w_i x_i}{\sum_{i=1}^{N} w_i}$ is the weighted mean of the variable.

Warning: The values of *fweights* and *aweights* cannot be negative, and the negative weight scene result is undefined.

Note: Currently, complex number is not supported.

Parameters

input (Tensor) –The 0-D, 1-D or 2-D tensor.

Keyword Arguments

- **correction** (int, *optional*) –The difference between sample size and sample degrees of freedom. *correction = 0* will return the simple average. Defaults to Bessel's correction, *correction = 1* which returns the unbiased estimate, even if both *fweights* and *aweights* are specified.
- **fweights** (Tensor, *optional*) –0D or 1D tensor containing integer frequency weight, indicating the number of repetition of each observation vector. Its numel must equal the number of columns of *input*. Ignored if *None*. Default None .
- **aweights** (Tensor, *optional*) –A scalar or 1D Tensor containing float observation weights represents the importance of each observation vector. The higher the importance, the greater the corresponding value. Its numel must equal the number of columns of *input*. Must have floating point dtype. Ignored if *None*. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[0., 5., 7.],
...                           [3., 5., 0.]])
>>> output = mindspore.ops.cov(input)
>>> print(output)
[[13.         -3.5       ]
 [-3.5         6.3333335]]
>>> output = mindspore.ops.cov(input, correction=0)
>>> print(output)
[[ 8.666667  -2.3333333]
 [-2.3333333  4.2222223]]
>>> fw = mindspore.tensor([5, 2, 4], dtype=mindspore.int64)
>>> aw = mindspore.tensor([0.4588, 0.9083, 0.7616], mindspore.float32)
>>> output = mindspore.ops.cov(input, fweights=fw, aweights=aw)
>>> print(output)
[[10.146146 -3.47241 ]
 [-3.47241   4.716825]]
```

mindspore.ops.diff

mindspore.ops.**diff**(*x*, *n=1*, *axis=- 1*, *prepend=None*, *append=None*)

Computes the n-th forward difference along the given axis.

The first-order differences is calculated as $out[i] = x[i+1] - x[i]$. Higher-order differences are calculated by using *mindspore.ops.diff()* recursively.

Note: Zero-shaped Tensor is not supported, a value error is raised if an empty Tensor is encountered. Any dimension of a Tensor is 0, which is considered an empty Tensor. Tensor with shape of $(0,)$, $(1, 2, 0, 4)$ are all empty Tensor.

Parameters

- **x** (Tensor) −The input tensor.
- **n** (*int, optional*) −The number of times to compute the difference. Currently only 1 is supported. Default 1 .
- **axis** (*int, optional*) −The axis to compute the difference along. Default −1 .
- **prepend** (Tensor, *optional*) −Values to prepend to *x* along *axis* before performing the difference. Their dimensions must be equivalent to that of *x*, and their shapes must match input's shape except on dim. Default None .
- **append** (Tensor, *optional*) −Values to append to *x* along *axis* before performing the difference. Their dimensions must be equivalent to that of *x*, and their shapes must match input's shape except on dim. Default None .

Returns

Tensor, the n-th differences of input. The shape of the output is the same as *x* except along *axis* where the size is reduced by *n*. The type of the output is the same as *x*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1, 3, 2])
>>> # case 1: By default, compute the first-order differences along axis -1.
>>> mindspore.ops.diff(x)
Tensor(shape=[2], dtype=Int64, value= [ 2, -1])
>>>
>>> # case 2: When argument prepend is setting:
>>> n = mindspore.tensor([4, 5])
>>> mindspore.ops.diff(x, prepend=n)
Tensor(shape=[4], dtype=Int64, value= [ 1, -4,  2, -1])
>>>
>>> # case 3: When argument append is setting:
>>> mindspore.ops.diff(x, append=n)
Tensor(shape=[4], dtype=Int64, value= [ 2, -1,  2,  1])
>>>
>>> # case 4: When input is 2-D dimensional tensor, compute forward difference along␣
 ↪different axis.
>>> x = mindspore.tensor([[1, 2, 3], [3, 4, 5]])
>>> mindspore.ops.diff(x, axis=0)
Tensor(shape=[1, 3], dtype=Int64, value=
[[2, 2, 2]])
>>> mindspore.ops.diff(x, axis=1)
Tensor(shape=[2, 2], dtype=Int64, value=
[[1, 1],
 [1, 1]])
```

mindspore.ops.deg2rad

mindspore.ops.**deg2rad**(*x*)

Convert angles from degrees to radians element-wise.

Parameters

x (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[90.0, -90.0], [180.0, -180.0], [270.0, -270.0]])
>>> output = mindspore.ops.deg2rad(input)
>>> print(output)
[[ 1.5707964 -1.5707964]
 [ 3.1415927 -3.1415927]
 [ 4.712389  -4.712389 ]]
```

mindspore.ops.digamma

mindspore.ops.**digamma**(*input*)

Computes the logarithmic derivative of the gamma function on input tensor.

$$P(x) = \frac{d}{dx}(\ln(\Gamma(x)))$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1.5, 0.5, 9])
>>> output = mindspore.ops.digamma(input)
>>> print(output)
[ 0.03648992 -1.9635109   2.1406415 ]
```

mindspore.ops.div

mindspore.ops.**div**(*input*, *other*, *, *rounding_mode=None*)

Divide the first input tensor by the second input tensor in floating-point type element-wise.

$$out_i = input_i / other_i$$

Note:

- The two input tensors must be broadcastable.
- The two input tensors can not be bool type at the same time,
- The two input tensors comply with the implicit type conversion rules to make the data types consistent.

Parameters

- **input** (*Union[Tensor, Number, bool]*) – The first input tensor.
- **other** (*Union[Tensor, Number, bool]*) – The second input tensor.

Keyword Arguments

rounding_mode (*str, optional*) – Type of rounding applied to the result. Default `None` . Three types are defined as:

- None: the same as true division in Python or *true_divide* in NumPy.
- "floor": rounds the results of the division down, which is the same as floor division in Python or *floor_divide* in NumPy.
- "trunc": rounds the results of the division towards zero, which is the same as C-style integer division.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[-0.3711, -1.9353, -0.4605, -0.2917],
...                           [ 0.1815, -1.0111,  0.9805, -1.5923],
...                           [ 0.1062,  1.4581,  0.7759, -1.2344],
...                           [-0.1830, -0.0313,  1.1908, -1.4757]])
>>> other = mindspore.tensor([ 0.8032,  0.2930, -0.8113, -0.2308])
>>> output = mindspore.ops.div(input, other)
```

(continues on next page)

(continued from previous page)

```
>>> print(output)
[[-0.4620269  -6.605119    0.5676076   1.2638649 ]
 [ 0.22597112 -3.4508533  -1.2085541   6.899047  ]
 [ 0.13222112  4.97645    -0.95636636  5.348354  ]
 [-0.22783864 -0.10682594 -1.4677677   6.3938475 ]]
>>> output = mindspore.ops.div(input, other, rounding_mode='floor')
>>> print(output)
[[-1. -7.  0.  1.]
 [ 0. -4. -2.  6.]
 [ 0.  4. -1.  5.]
 [-1. -1. -2.  6.]]
```

mindspore.ops.divide

mindspore.ops.**divide**(*input*, *other*, *, *rounding_mode=None*)

Alias for *mindspore.ops.div()* .

Supported Platforms:

Ascend GPU CPU

mindspore.ops.erf

mindspore.ops.**erf**(*input*)

Compute the Gauss error of input tensor element-wise.

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # The datatype of output will be float32 when datatype of input is in [int64,␣
↪bool](Datatype only supported on Ascend).
>>> input = mindspore.tensor([-1, 0, 1, 2, 3], mindspore.int64)
>>> mindspore.ops.erf(input)
Tensor(shape=[5], dtype=Float32, value= [-8.42700793e-01,  0.00000000e+00,  8.42700793e-01, ␣
↪9.95322265e-01,  9.99977910e-01])
>>>
>>> # Otherwise output has the same dtype as the input.
>>> input = mindspore.tensor([-1, 0, 1, 2, 3], mindspore.float64)
```

(continues on next page)

(continued from previous page)

```
>>> mindspore.ops.erf(input)
Tensor(shape=[5], dtype=Float64, value= [-8.42700793e-01,  0.00000000e+00,  8.42700793e-01, ␣
↪9.95322265e-01,  9.99977910e-01])
```

mindspore.ops.erfc

mindspore.ops.**erfc**(*input*)

Compute the complementary error function of input tensor element-wise.

$$\operatorname{erfc}(x) = 1 - \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # The datatype of output will be float32 when datatype of input is in [int64,␣
↪bool](Datatype only supported on Ascend).
>>> input = mindspore.tensor([-1, 0, 1, 2, 3], mindspore.int64)
>>> mindspore.ops.erfc(input)
Tensor(shape=[5], dtype=Float32, value= [ 1.84270079e+00,  1.00000000e+00,  1.57299207e-01, ␣
↪4.67773498e-03,  2.20904970e-05])
>>>
>>> # Otherwise output has the same dtype as the input.
>>> input = mindspore.tensor([-1, 0, 1, 2, 3], mindspore.float64)
>>> mindspore.ops.erfc(input)
Tensor(shape=[5], dtype=Float64, value= [ 1.84270079e+00,  1.00000000e+00,  1.57299207e-01, ␣
↪4.67773498e-03,  2.20904970e-05])
```

mindspore.ops.erfinv

mindspore.ops.**erfinv**(*input*)

Compute the inverse error of input tensor element-wise.

It is defined in the range *(-1, 1)* as:

$$erfinv(erf(x)) = x$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # When the `input` is int8, int16, int32, int64, uint8 or bool, the return value type is␣
↪float32.
>>> input = mindspore.tensor([0, 0.5, -0.9], mindspore.int64)
>>> mindspore.ops.erfinv(input)
Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  0.00000000e+00,  0.00000000e+00])
>>> # Otherwise, the return value type is the same as the input type.
>>> input = mindspore.tensor([0, 0.5, -0.9], mindspore.float32)
>>> mindspore.ops.erfinv(input)
Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  4.76936132e-01, -1.16308689e+00])
```

mindspore.ops.exp

mindspore.ops.**exp**(*input*)

Compute exponential of the input tensor element-wise.

$$out_i = e^{x_i}$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.0, 1.0, 3.0], mindspore.float32)
>>> output = mindspore.ops.exp(input)
>>> print(output)
[ 1.        2.7182817 20.085537]
```

mindspore.ops.exp2

mindspore.ops.**exp2**(*input*)

Compute base two exponential of the input tensor element-wise.

$$out_i = 2^{input_i}$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.0, 1.0, 3.0], mindspore.float32)
>>> output = mindspore.ops.exp2(input)
>>> print(output)
[1. 2. 8.]
```

mindspore.ops.expm1

mindspore.ops.**expm1**(*input*)

Compute exponential of the input tensor, then minus 1, element-wise.

$$out_i = e^{x_i} - 1$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.0, 1.0, 3.0], mindspore.float32)
>>> output = mindspore.ops.expm1(input)
>>> print(output)
[ 0.         1.7182817 19.085537 ]
```

mindspore.ops.floor

mindspore.ops.**floor**(*input*)

Rounds a tensor down to the closest integer element-wise.

$$out_i = \lfloor input_i \rfloor$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1.1, 2.5, -1.5])
>>> output = mindspore.ops.floor(input)
>>> print(output)
[ 1.  2. -2.]
```

mindspore.ops.floor_div

mindspore.ops.**floor_div**(*x*, *y*)

Alias for *mindspore.ops.floor_divide()* .

Supported Platforms:

Ascend GPU CPU

mindspore.ops.floor_divide

mindspore.ops.**floor_divide**(*input*, *other*)

Compute element-wise division of *input* by *other* and floor the result.

If *input* and *other* have different data types, the implicit type conversion rules are followed. Inputs must be two tensors or one tensor and one scalar. When the inputs are two tensors, their shapes must be broadcastable, and their data types cannot both be bool simultaneously.

$$out_i = \text{floor}(\frac{input_i}{other_i})$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (*Union[Tensor, Number, bool]*) – The first input tensor.

- **other** (*Union[Tensor, Number, bool]*) – The second input tensor.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: Two tensors with boolean and integer data type.
>>> input = mindspore.tensor([True, True, False])
>>> other = mindspore.tensor([1, 2, 4])
>>> output = mindspore.ops.floor_divide(input, other)
>>> print(output)
[1 0 0]
>>>
>>> # case 2: One tensor and one scalar.
>>> input = mindspore.tensor([1, 2, 4])
>>> other = mindspore.tensor(1.5)
>>> output = mindspore.ops.floor_divide(input, other)
>>> print(output)
[0. 1. 2.]
>>>
>>> # case 3: When inputs have different data types, type promotion rules are followed.
>>> input = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> other = mindspore.tensor([1.1, 2.5, -1.5], mindspore.float32)
>>> output = mindspore.ops.floor_divide(input, other)
>>> print(output)
[ 0.  0. -3.]
```

mindspore.ops.floor_mod

`mindspore.ops.`**`floor_mod`**(*x*, *y*)

Compute the remainder of element-wise flooring division of first input by second input.

If two input have different data types, implicit type conversion rules are followed. Inputs must be two tensors or one tensor and one scalar. When the inputs are two tensors, their shapes must be broadcastable, and their data types cannot both be bool simultaneously.

$$out_i = \text{floor}(x_i // y_i)$$

Warning:

- Data of input *y* should not be 0, or the maximum value of its dtype will be returned.
- When the elements of input exceed 2048, the accuracy of operator cannot guarantee the requirement of double thousandths in the mini form.
- Due to different architectures, the calculation results of this operator on NPU and CPU may be inconsistent.
- If shape is expressed as $(D1, D2..., Dn)$, then D1*D2$\cdots$*DN<=1000000,n<=8.

Parameters

- **x** (*Union[Tensor, Number, bool]*) – The first input tensor.
- **y** (*Union[Tensor, Number, bool]*) – The second input tensor.

Returns

Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: Two tensors with boolean and integer data type.
>>> input = mindspore.tensor([True, True, False])
>>> other = mindspore.tensor([1, 2, 4])
>>> output = mindspore.ops.floor_mod(input, other)
>>> print(output)
[0 1 0]
>>>
>>> # case 2: One tensor and one scalar.
>>> input = mindspore.tensor([1, 2, 4])
>>> other = mindspore.tensor(1.5)
>>> output = mindspore.ops.floor_mod(input, other)
>>> print(output)
[1.  0.5 1. ]
>>>
>>> # case 3: When inputs have different data types, type promotion rules are followed.
>>> input = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> other = mindspore.tensor([1.1, 2.5, -1.5], mindspore.float32)
>>> output = mindspore.ops.floor_mod(input, other)
>>> print(output)
[ 1.   2.  -0.5]
```

mindspore.ops.float_power

mindspore.ops.**float_power**(*input*, *exponent*)

Computes the first input to the power of the second input. For the real number type, cast *input* and *exponent* to mindspore.float64 to calculate.

Note: Currently, complex type calculation is not supported.

Parameters

- **input** (*Union[Tensor, Number]*) – The first input.
- **exponent** (*Union[Tensor, Number]*) – The second input, if the first input is Number, it must be a Tensor.

Returns

Tensor whose data type is mindspore.float64.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: When exponent is scalar:
>>> input = mindspore.tensor([-1.5, 0., 2.])
>>> output = mindspore.ops.float_power(input, 2)
>>> print(output)
[2.25 0.   4.  ]
>>>
>>> # case 2: When exponent is a tensor:
>>> exponent = mindspore.tensor([0, 1, 2])
>>> output = mindspore.ops.float_power(input, exponent)
>>> print(output)
[1. 0. 4.]
```

mindspore.ops.fmax

mindspore.ops.**fmax**(*input*, *other*)

Compute the maximum of input tensors element-wise.

$$output_i = \max(x1_i, x2_i)$$

Note:

- Support implicit type conversion and type promotion.
- Shapes of *input* and *other* should be able to broadcast.
- If one of the elements to be compared is NaN, another element is returned.

Parameters

- **input** (Tensor) –The first input.
- **other** (Tensor) –The second input.

Returns

Tensor

Supported Platforms:

CPU

Examples

```
>>> import mindspore
>>> x1 = mindspore.tensor([1.0, 5.0, 3.0], mindspore.float32)
>>> x2 = mindspore.tensor([4.0, 2.0, 6.0], mindspore.float32)
>>> output = mindspore.ops.fmax(x1, x2)
>>> print(output)
[4. 5. 6.]
```

mindspore.ops.fmod

mindspore.ops.**fmod**(*input*, *other*)

Compute the remainder of element-wise division of first input by the second input.

Support broadcasting and type promotion.

$$out = input - n * other$$

Where n is $input/other$ with its fractional part truncated. The returned value has the same sign as *input* and is less than *other* in magnitude.

Parameters

- **input** (*Union[Tensor, Number]*) – the dividend.
- **other** (*Union[Tensor, Number]*) – the divisor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: When other is scalar:
>>> input = mindspore.tensor([-3., -2, -1, 3, 4, 5])
>>> output = mindspore.ops.fmod(input, 2)
>>> print(output)
[-1.  0. -1.  1.  0.  1.]
>>>
>>> # case 2: When other is a tensor:
>>> other = mindspore.tensor([-1., 1, 2, 2.5, 1.5, 1.7])
>>> output = mindspore.ops.fmod(input, other)
>>> print(output)
[ 0.         0.        -1.         0.5        1.         1.5999999]
```

mindspore.ops.frac

mindspore.ops.**frac**(*x*)

Return the fractional part of each element in the input tensor.

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([2, 4.2, -2.5])
>>> output = mindspore.ops.frac(input)
>>> print(output)
[ 0.          0.19999981 -0.5       ]
```

mindspore.ops.gcd

mindspore.ops.**gcd**(*input*, *other*)

Computes greatest common divisor of input tensors element-wise.

Support broadcasting and type promotion. Data types should be one of: int16 (supported when using the Ascend backend, Graph mode is only supported when the graph compilation level is O0), int32, int64.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) – The first input tensor.
- **other** (Tensor) – The second input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([7, 8, 9])
>>> other = mindspore.tensor([14, 6, 12])
>>> mindspore.ops.gcd(input, other)
Tensor(shape=[3], dtype=Int64, value= [7, 2, 3])
```

mindspore.ops.hypot

mindspore.ops.**hypot**(*input*, *other*)

Given the legs of a right triangle, return its hypotenuse, element-wise.

Support broadcasting and type promotion.

$$out_i = \sqrt{input_i^2 + other_i^2}$$

Parameters

- **input** (Tensor) –The first input tensor.
- **other** (Tensor) –The second input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([3., 5., 7.])
>>> other = mindspore.tensor([4., 12., 24.])
>>> output = mindspore.ops.hypot(input, other)
>>> print(output)
[ 5. 13. 25.]
```

mindspore.ops.igamma

mindspore.ops.**igamma**(*input*, *other*)

Calculates lower regularized incomplete Gamma function.

If we define *input* as a and *other* as x, the lower regularized incomplete Gamma function is defined as:

$$P(a,x) = Gamma(a,x)/Gamma(a) = 1 - Q(a,x)$$

where

$$Gamma(a,x) = \int_0^x t^{a-1} \exp^{-t}\, dt$$

is the lower incomplete Gamma function.

Above $Q(a, x)$ is the upper regularized complete Gamma function.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The first input tensor.
- **other** (Tensor) –The second input tensor.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([2.0, 4.0, 6.0, 8.0])
>>> other = mindspore.tensor([2.0, 3.0, 4.0, 5.0])
>>> output = mindspore.ops.igamma(input, other)
>>> print(output)
[0.5939941  0.35276785 0.21486954 0.13337176]
```

mindspore.ops.igammac

mindspore.ops.**igammac**(*input*, *other*)

Calculates upper regularized incomplete Gamma function.

If we define *input* as a and *other* as x, the upper regularized incomplete Gamma function is defined as:

$$Q(a, x) = Gamma(a, x)/Gamma(a) = 1 - P(a, x)$$

where

$$Gamma(a, x) = \int_x^\infty t^{a-1} exp(-t) dt$$

is the upper incomplete Gama function.

Above $P(a, x)$ is the lower regularized incomplete Gamma function.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The first input tensor.
- **other** (Tensor) –The second input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([2.0, 4.0, 6.0, 8.0])
>>> other = mindspore.tensor([2.0, 3.0, 4.0, 5.0])
>>> output = mindspore.ops.igammac(input, other)
>>> print(output)
[0.40600574 0.6472322  0.78513044 0.8666282 ]
```

mindspore.ops.imag

mindspore.ops.**imag**(*input*)

Return a new tensor containing imaginary value of the input tensor, element-wise. If element in the input tensor is real, it will return zero.

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.22+0.3511j, -0.55-0.6796j, -1.92-0.033j, -0.38-0.2991j])
>>> output = mindspore.ops.imag(input)
>>> print(output)
[ 0.3511 -0.6796 -0.033  -0.2991]
```

mindspore.ops.i0

mindspore.ops.**i0**(*input*)

For details, please refer to *mindspore.ops.bessel_i0()*. The parameter *input* of the current interface is the same as the parameter *x* of the reference interface.

Supported Platforms:

GPU CPU

mindspore.ops.inv

mindspore.ops.**inv**(*x*)

Computes Reciprocal of input tensor element-wise.

$$out_i = \frac{1}{x_i}$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.25, 0.4, 0.31, 0.52])
>>> output = mindspore.ops.inv(input)
>>> print(output)
[4.        2.5       3.2258065 1.923077 ]
```

mindspore.ops.invert

mindspore.ops.**invert**(*x*)

Flip all bits of input tensor element-wise. For example, 01010101 becomes 10101010.

$$out_i = \sim x_i$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> mindspore.ops.invert(mindspore.tensor([25, 4, 13, 9], mindspore.int16))
Tensor(shape=[4], dtype=Int16, value= [-26,  -5, -14, -10])
```

mindspore.ops.lcm

mindspore.ops.**lcm**(*input*, *other*)

Computes least common multiplier of input tensors element-wise.

Support broadcast, support implicit type conversion and type promotion.

Parameters

- **input** (Tensor) –The first input tensor.
- **other** (Tensor) –The second input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> mindspore.ops.lcm(mindspore.tensor([7, 8, 9]), mindspore.tensor([14, 6, 12]))
Tensor(shape=[3], dtype=Int64, value= [14, 24, 36])
```

mindspore.ops.ldexp

mindspore.ops.**ldexp**(*x*, *other*)

Multiplies input tensor by 2^{other} element-wise.

Typically this function is used to construct floating point numbers by multiplying mantissas in *x* with integral powers of two created from the exponents in *other*:

$$out_i = x_i * (2^{other_i})$$

Parameters

- **x** (Tensor) –Mantissas tensor.
- **other** (Tensor) –Exponents tensor, typically integers.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1.], mindspore.float32)
>>> other = mindspore.tensor([1, 2, 3, 4], mindspore.int32)
>>> out = mindspore.ops.ldexp(x, other)
>>> print(out)
[ 2.  4.  8. 16.]
>>> x = mindspore.tensor([[1.], [2]], mindspore.float32)
>>> other = mindspore.tensor([[1.], [2]], mindspore.int32)
>>> out = mindspore.ops.ldexp(x, other)
>>> print(out)
[[2.]
 [8.]]
```

mindspore.ops.lerp

mindspore.ops.**lerp**(*input*, *end*, *weight*)

Does a linear interpolation of two tensors input and end based on a float or tensor weight.

$$output_i = input_i + weight_i * (end_i - input_i)$$

Note:

- The shapes of *input* and *end* must be broadcastable.
- If weight is a tensor, then the shapes of *weight* , *start* , and *end* must be broadcastable.
- On the Ascend platform, if *weight* dtype is float, the type of *input* and *end* need to be float32.

Parameters

- **input** (Tensor) –The tensor with the starting points.
- **end** (Tensor) –The tensor with the ending points.
- **weight** (*Union[float, Tensor]*) –The weight for the interpolation formula.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> start = mindspore.tensor([1., 2., 3., 4.], mindspore.float32)
>>> end = mindspore.tensor([10., 10., 10., 10.], mindspore.float32)
>>> output = mindspore.ops.lerp(start, end, 0.5)
>>> print(output)
[5.5 6.  6.5 7. ]
>>> output = mindspore.ops.lerp(start, end, mindspore.tensor([0.5, 0.5, 0.5, 0.5], mindspore.
↪float32))
>>> print(output)
[5.5 6.  6.5 7. ]
```

mindspore.ops.log

mindspore.ops.**log**(*input*)

Compute the natural logarithm of the input tensor element-wise.

$$y_i = \log_e(x_i)$$

Warning: If the input value of operator Log is within the range (0, 0.01] or [0.95, 1.05], the output accuracy may be affacted.

Parameters

input (Tensor) −The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1.0, 2.0, 4.0], mindspore.float32)
>>> output = mindspore.ops.log(x)
>>> print(output)
[0.        0.6931472 1.3862944]
```

mindspore.ops.log2

mindspore.ops.**log2**(*input*)

Compute the logarithm to the base 2 of the input tensor element-wise.

$$y_i = \log_2(input_i)$$

Warning: If the input value of operator log2 is within the range (0, 0.01] or [0.95, 1.05], the output accuracy may be affected.

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([2, 4, 8], mindspore.float16)
>>> output = mindspore.ops.log2(x)
>>> print(output)
[1. 2. 3.]
```

mindspore.ops.log10

mindspore.ops.**log10**(*input*)

Compute the logarithm to the base 10 of the input tensor element-wise.

$$y_i = \log_{10}(input_i)$$

Warning: If the input value of operator log10 is within the range (0, 0.01] or [0.95, 1.05], the output accuracy may be affected.

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([2, 4, 10], mindspore.float16)
>>> output = mindspore.ops.log10(x)
>>> print(output)
[0.301 0.602 1.   ]
```

mindspore.ops.log1p

mindspore.ops.**log1p**(*input*)

Compute the natural logarithm of (tensor + 1) element-wise.

$$out_i = \log_e(input_i + 1)$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1.0, 2.0, 4.0], mindspore.float32)
>>> output = mindspore.ops.log1p(x)
>>> print(output)
[0.6931472 1.0986123 1.609438 ]
```

mindspore.ops.logaddexp

mindspore.ops.**logaddexp**(*input*, *other*)

Computes the logarithm of the sum of exponentiations of the inputs. This function is useful in statistics where the calculated probabilities of events may be too small (exceed the range of normal floating point numbers).

$$out_i = \log(exp(input_i) + \exp(other_i))$$

Parameters

- **input** (Tensor) –The input tensor.
- **other** (Tensor) –The input tensor.

Returns

Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x1 = mindspore.tensor([1, 2, 3], mindspore.float16)
>>> x2 = mindspore.tensor(2, mindspore.float16)
>>> output = mindspore.ops.logaddexp(x1, x2)
>>> print(output)
[2.312 2.693 3.312]
```

mindspore.ops.logaddexp2

mindspore.ops.**logaddexp2**(*input*, *other*)

Computes the logarithm of the sum of exponentiations in base of 2 of the inputs.

$$out_i = \log_2(2^{input_i} + 2^{other_i})$$

Parameters

- **input** (Tensor) –The input tensor.
- **other** (Tensor) –The input tensor.

Returns

Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x1 = mindspore.tensor([1, 2, 3], mindspore.float16)
>>> x2 = mindspore.tensor(2, mindspore.float16)
>>> output = mindspore.ops.logaddexp2(x1, x2)
>>> print(output)
[2.586 3.    3.586]
```

mindspore.ops.logical_and

mindspore.ops.**logical_and**(*input*, *other*)

Compute the "logical AND" of two tensors element-wise.

$$out_i = input_i \wedge other_i$$

Note:

- Broadcasting is supported.
- Support implicit type conversion.

Parameters

- **input** (*Union[Tensor, bool]*) –The first input.
- **other** (*Union[Tensor, bool]*) –The second input.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([True, False, True], mindspore.bool_)
>>> y = mindspore.tensor([True, True, False], mindspore.bool_)
>>> output = mindspore.ops.logical_and(x, y)
>>> print(output)
[ True False False]
>>> x = mindspore.tensor(1, mindspore.bool_)
>>> y = mindspore.tensor(0, mindspore.bool_)
>>> output = mindspore.ops.logical_and(x, y)
>>> print(output)
False
>>> x = True
>>> y = mindspore.tensor(0, mindspore.bool_)
>>> output = mindspore.ops.logical_and(x, y)
>>> print(output)
False
>>> x = True
>>> y = mindspore.tensor([True, False], mindspore.bool_)
>>> output = mindspore.ops.logical_and(x, y)
>>> print(output)
[True False]
```

mindspore.ops.logical_not

mindspore.ops.**logical_not**(*input*)

Compute the "logical NOT" of the input tensor element-wise.

$$out_i = \neg input_i$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([True, False, True], mindspore.bool_)
>>> output = mindspore.ops.logical_not(x)
>>> print(output)
[False  True False]
```

mindspore.ops.logical_or

mindspore.ops.**logical_or**(*input*, *other*)

Compute the "logical OR" of two tensors element-wise.

$$out_i = input_i \vee other_i$$

Note:

- Broadcasting is supported.
- Support implicit type conversion.

Parameters

- **input** (*Union[Tensor, bool]*) – The first input.
- **other** (*Union[Tensor, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([True, False, True], mindspore.bool_)
>>> y = mindspore.tensor([True, True, False], mindspore.bool_)
>>> output = mindspore.ops.logical_or(x, y)
>>> print(output)
[ True  True  True]
>>> x = mindspore.tensor(1, mindspore.bool_)
>>> y = mindspore.tensor(0, mindspore.bool_)
>>> output = mindspore.ops.logical_or(x, y)
>>> print(output)
True
>>> x = True
>>> y = mindspore.tensor(0, mindspore.bool_)
>>> output = mindspore.ops.logical_or(x, y)
>>> print(output)
True
```

(continues on next page)

(continued from previous page)

```
>>> x = True
>>> y = mindspore.tensor([True, False], mindspore.bool_)
>>> output = mindspore.ops.logical_or(x, y)
>>> print(output)
[True True]
```

mindspore.ops.logical_xor

mindspore.ops.**logical_xor**(*input*, *other*)

Compute the "logical XOR" of two tensors element-wise.

$$out_i = input_i \oplus other_i$$

Note:

- Broadcasting is supported.
- Support implicit type conversion.

Parameters

- **input** (Tensor) –The first input tensor.
- **other** (Tensor) –The second input tensor.

Returns

Tensor

Supported Platforms:

Ascend CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([True, False, True], mindspore.bool_)
>>> y = mindspore.tensor([True, True, False], mindspore.bool_)
>>> output = mindspore.ops.logical_xor(x, y)
>>> print(output)
[False  True  True]
>>> x = mindspore.tensor(1, mindspore.bool_)
>>> y = mindspore.tensor(0, mindspore.bool_)
>>> output = mindspore.ops.logical_xor(x, y)
>>> print(output)
True
>>> x = True
>>> y = mindspore.tensor(0, mindspore.bool_)
>>> output = mindspore.ops.logical_xor(x, y)
>>> print(output)
True
>>> x = True
>>> y = mindspore.tensor([True, False], mindspore.bool_)
```

(continues on next page)

(continued from previous page)

```
>>> output = mindspore.ops.logical_xor(x, y)
>>> print(output)
[False  True]
```

mindspore.ops.logit

mindspore.ops.**logit**(*input*, *eps=None*)

Calculate the logit of a tensor element-wise.

The formula is defined as:

$$
\begin{aligned}
y_i &= \ln(\frac{z_i}{1-z_i}) \\
z_i &= \begin{cases} input_i & \text{if eps is None} \\ \text{eps} & \text{if } input_i < \text{eps} \\ input_i & \text{if eps} \leq input_i \leq 1-\text{eps} \\ 1-\text{eps} & \text{if } input_i > 1-\text{eps} \end{cases}
\end{aligned}
$$

Parameters

- **input** (Tensor) – The input tensor.
- **eps** (*float, optional*) – The epsilon for input clamp bound. If eps is not None, the input clamp bound is defined as [eps, 1-eps], otherwise, the *input* is not clamped. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([0.1, 0.2, 0.3], mindspore.float32)
>>> output = mindspore.ops.logit(x, eps=1e-5)
>>> print(output)
[-2.1972246 -1.3862944 -0.8472978]
```

mindspore.ops.mul

mindspore.ops.**mul**(*input*, *other*)

Multiplies two tensors element-wise.

$$out_i = input_i * other_i$$

Note:

- When the two inputs have different shapes, they must be able to broadcast to a common shape.
- The two inputs can not be bool type at the same time, [True, Tensor(True, bool_), Tensor(np.array([True]), bool_)] are all considered bool type.

- Support implicit type conversion and type promotion.

Parameters

- **input** (*Union[Tensor, number.Number, bool]*) – The first input.
- **other** (*Union[Tensor, number.Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> # case 1: The shape of two inputs are different
>>> import mindspore
>>> x = mindspore.tensor([1.0, 2.0, 3.0], mindspore.float32)
>>> output = mindspore.ops.mul(x, 100)
>>> print(output)
[100. 200. 300.]
>>> # case 2: The shape of two inputs are the same
>>> import mindspore
>>> x = mindspore.tensor([1.0, 2.0, 3.0], mindspore.float32)
>>> y = mindspore.tensor([4.0, 5.0, 6.0], mindspore.float32)
>>> output = mindspore.ops.mul(x, y)
>>> print(output)
[ 4. 10. 18.]
```

mindspore.ops.multiply

mindspore.ops.**multiply**(*input*, *other*)

Alias for *mindspore.ops.asinh()*.

Supported Platforms:

`Ascend` `GPU` `CPU`

mindspore.ops.mvlgamma

mindspore.ops.**mvlgamma**(*input*, *p*)

Compute the multivariate log-gamma function with dimension p element-wise. The mathematical calculation process of Mvlgamma is shown as follows:

$$\log(\Gamma_p(input)) = C + \sum_{i=1}^{p} \log(\Gamma(input - \frac{i-1}{2}))$$

where $C = \log(\pi) \times \frac{p(p-1)}{4}$ and $\Gamma(\cdot)$ is the Gamma function.

Parameters

- **input** (Tensor) –The input tensor of the multivariate log-gamma function, And the value of any element in *input* must be greater than $(p-1)/2$.
- **p** (*int*) –The number of dimensions. And the value of p must be greater than or equal to 1.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[3, 4, 5], [4, 2, 6]], mindspore.float32)
>>> y = mindspore.ops.mvlgamma(x, p=3)
>>> print(y)
[[2.694925 5.402975 9.140645]
 [5.402975 1.596312 13.64045]]
```

mindspore.ops.neg

mindspore.ops.**neg**(*input*)

Returns a tensor with negative values of the input tensor element-wise.

$$out_i = -input_i$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 2, -1, 2, 0, -3.5], mindspore.float32)
>>> output = mindspore.ops.neg(input)
>>> print(output)
[-1.  -2.   1.  -2.   0.   3.5]
```

mindspore.ops.negative

mindspore.ops.**negative**(*input*)

Alias for *mindspore.ops.neg()* .

Supported Platforms:

Ascend GPU CPU

mindspore.ops.nextafter

mindspore.ops.**nextafter**(*input*, *other*)

Returns the next representable floating-point value after *input* towards *other* element-wise.

$$out_i = \begin{cases} input_i + eps, & \text{if } input_i < other_i \\ input_i - eps, & \text{if } input_i > other_i \\ input_i, & \text{if } input_i = other_i \end{cases}$$

Where eps is the smallest representable increment value for the input tensor's dtype.

For more detailed information, refer to A Self Regularized Non-Monotonic Neural Activation Function.

Parameters

- **input** (Tensor) –The first input tensor.
- **other** (Tensor) –The second input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.0], mindspore.float32)
>>> other = mindspore.tensor([0.1], mindspore.float32)
>>> output = mindspore.ops.nextafter(input, other)
>>> print(output)
[1.e-45]
```

mindspore.ops.polar

mindspore.ops.**polar**(*abs*, *angle*)

Converts polar coordinates to Cartesian coordinates.

Returns a complex tensor, its elements are Cartesian coordinates constructed with the polar coordinates which is specified by radial distance *abs* and polar angle *angle*.

$$y_i = abs_i * \cos(angle_i) + abs_i * \sin(angle_i) * j$$

Parameters

- **abs** (Tensor, *float*) –Radial distance.
- **angle** (Tensor, *float*) –Polar angle.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> abs = mindspore.tensor([1, 2], mindspore.float32)
>>> angle = mindspore.tensor([np.pi / 2, 5 * np.pi / 4], mindspore.float32)
>>> output = mindspore.ops.polar(abs, angle)
>>> print(output)
[ -4.3711388e-08+1.j         -1.4142137e+00-1.4142134j]
```

mindspore.ops.polygamma

mindspore.ops.**polygamma**(*n*, *input*)

Computes the *n*-th derivative of the polygamma function on *input*.

$$\psi^{(a)}(x) = \frac{d^{(a)}}{dx^{(a)}}\psi(x)$$

where $\psi(x)$ is the digamma function.

Parameters

- **n** (Tensor) –The order of the polygamma function.
- **input** (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([3.14, -2.71], mindspore.float64)
>>> a = mindspore.tensor(1, mindspore.int64)
>>> output = mindspore.ops.polygamma(a, x)
>>> print(output)
[ 0.37446456 15.49884838]
```

mindspore.ops.positive

mindspore.ops.**positive**(*input*)

Return self tensor.

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([-5.0, 1.5, 3.0, 100.0], mindspore.float32)
>>> print(mindspore.ops.positive(x))
[ -5.    1.5   3.  100. ]
```

mindspore.ops.pow

mindspore.ops.**pow**(*input*, *exponent*)

Calculate the *exponent* power of each element in *input*.

Note:

- Broadcasting is supported.
- Support implicit type conversion and type promotion.

$$out_i = input_i^{exponent_i}$$

Parameters

- **input** (*Union[Tensor, Number]*) – The first input.
- **exponent** (*Union[Tensor, Number]*) – The second input.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1.0, 2.0, 4.0], mindspore.float32)
>>> output = mindspore.ops.pow(input, exponent=3.0)
>>> print(output)
[ 1.  8. 64.]
>>>
>>> input = mindspore.tensor([1.0, 2.0, 4.0], mindspore.float32)
>>> exponent = mindspore.tensor([2.0, 4.0, 3.0], mindspore.float32)
>>> output = mindspore.ops.pow(input, exponent)
>>> print(output)
[ 1. 16. 64.]
```

mindspore.ops.rad2deg

mindspore.ops.**rad2deg**(*x*)

Converts angles in radians to angles in degrees element-wise.

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[6.283, -3.142],[1.570, -6.283],[3.142, -1.570]], mindspore.
↪float32)
>>> output = mindspore.ops.rad2deg(x)
>>> print(output)
[[ 359.98935 -180.02333]
 [  89.95438 -359.98935]
 [ 180.02333  -89.95438]]
```

mindspore.ops.ravel

mindspore.ops.**ravel**(*input*)

Expand the multidimensional Tensor into 1D along the 0 axis direction.

Parameters

input (Tensor) – A tensor to be flattened.

Returns

Tensor, a 1-D tensor, containing the same elements of the input.

Raises

TypeError – If argument *input* is not Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[0, 1], [2, 1]]).astype(np.float32))
>>> output = ops.ravel(x)
>>> print(output)
[0. 1. 2. 1.]
>>> print(output.shape)
(4,)
```

mindspore.ops.real

mindspore.ops.**real**(*input*)

Return a tensor that is the real part of the input. If input is real, it is returned unchanged.

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor(1.3+0.4j, mindspore.complex64)
>>> output = mindspore.ops.real(input)
>>> print(output)
1.3
```

mindspore.ops.reciprocal

mindspore.ops.**reciprocal**(*input*)

Returns reciprocal of a tensor element-wise.

$$out_i = \frac{1}{x_i}$$

Parameters

input (Tensor) −The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1.0, 2.0, 4.0], mindspore.float32)
>>> output = mindspore.ops.reciprocal(input)
>>> print(output)
[1.   0.5  0.25]
```

mindspore.ops.remainder

mindspore.ops.**remainder**(*input*, *other*)

Compute the remainder of division for the input tensor element-wise.

Support implicit type conversion and type promotion.

```
remainder(input, other) == input - input.div(other, rounding_mode="floor") * other
```

Warning:

- When the elements of input exceed 2048, there might be accuracy problems.
- The calculation results of this operator on Ascend and CPU might be inconsistent.
- If shape is expressed as (D1,D2⋯,Dn), then D1*D2⋯*DN<=1000000,n<=8.

Parameters

- **input** (*Union[Tensor, numbers.Number, bool]*) –The first input.
- **other** (*Union[Tensor, numbers.Number, bool]*) –The second input.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> x = mindspore.tensor([-4.0, 5.0, 6.0], mindspore.float16)
>>> y = mindspore.tensor([3.0], mindspore.float16)
>>> output = mindspore.ops.remainder(x, y)
>>> print(output)
[2. 2. 0.]
>>> # case 2: The shape of two inputs are the same
>>> x = mindspore.tensor([-4.0, 5.0, 6.0], mindspore.float16)
>>> y = mindspore.tensor([3.0, 2.0, 3.0], mindspore.float16)
>>> output = mindspore.ops.remainder(x, y)
>>> print(output)
[2. 1. 0.]
```

mindspore.ops.rot90

`mindspore.ops.`**`rot90`**(*input*, *k*, *dims*)

Rotate a n-D tensor by 90 degrees in the plane specified by dims axis. Rotation direction is from the first towards the second axis if k > 0, and from the second towards the first for k < 0.

Parameters

- **input** (`Tensor`) –The input tensor.
- **k** (*int*) –Number of times to rotate.
- **dims** (*Union[list(int), tuple(int)]*) –Axis to rotate.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[1, 2, 3],
...                       [4, 5, 6]], mindspore.float32)
>>> output = mindspore.ops.rot90(x, k=1, dims=(0, 1))
>>> print(output)
[[3. 6.]
 [2. 5.]
 [1. 4.]]
>>> mindspore.ops.rot90(x, k=1, dims=(1, 0)) == mindspore.ops.rot90(x, k=-1, dims=(0,1))
Tensor(shape=[3, 2], dtype=Bool, value=
[[ True,  True],
 [ True,  True],
 [ True,  True]])
>>> # when input array has ndim>2
>>> x = mindspore.tensor([[[1, 2, 3],
...                        [4, 5, 6]],
...                       [[7, 8, 9],
...                        [10, 11, 12]]], mindspore.float32)
>>> output = mindspore.ops.rot90(x, k=1, dims=(2, 1))
>>> print(output)
[[[ 4.  1.]
  [ 5.  2.]
  [ 6.  3.]]
 [[10.  7.]
  [11.  8.]
  [12.  9.]]]
```

mindspore.ops.round

mindspore.ops.**round**(*input*, *, *decimals=0*)

Round elements of input to the nearest integer.

$$out_i \approx input_i$$

Note: The input data types supported by the Ascend platform include bfloat16 (Atlas training series products are not supported), float16, float32, float64, int32, and int64.

Parameters

input (Tensor) −The input tensor.

Keyword Arguments

decimals (int, *optional*) −Number of decimal places to round. If decimals is negative, it specifies the number of positions to the left of the decimal point. Default 0 .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.round(mindspore.tensor([4.7, -2.3, 9.1, -7.7]))
>>> print(output)
[ 5. -2.  9. -8.]
>>> # Values equidistant from two integers are rounded towards the
>>> # the nearest even value (zero is treated as even)
>>> output = mindspore.ops.round(mindspore.tensor([-0.5, 0.5, 1.5, 2.5]))
>>> print(output)
[0. 0.  2.  2.]
>>> # A positive decimals argument rounds to the to that decimal place
>>> output = mindspore.ops.round(mindspore.tensor([0.1234567]), decimals=3)
>>> print(output)
[0.123]
>>> # A negative decimals argument rounds to the left of the decimal
>>> output = mindspore.ops.round(mindspore.tensor([1200.1234567]), decimals=-3)
>>> print(output)
[1000.]
```

mindspore.ops.rsqrt

mindspore.ops.**rsqrt**(*input*)

Compute reciprocal of square root of input tensor element-wise.

$$out_i = \frac{1}{\sqrt{input_i}}$$

Parameters

input (Tensor) −The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([-0.0370,  0.2970,  1.5420, -0.9105])
>>> output = mindspore.ops.rsqrt(input)
>>> print(output)
[       nan 1.8349396  0.8053002        nan]
```

mindspore.ops.sgn

mindspore.ops.**sgn**(*input*)

Extension of *mindspore.ops.sign()* in complex domain. For real number input, this function is the same as *mindspore.ops.sign()*. For complex input, this function is calculated according to the following formula.

$$\text{out}_i = \begin{cases} 0 & |\text{input}_i| == 0 \\ \frac{\text{input}_i}{|\text{input}_i|} & \text{otherwise} \end{cases}$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[3+4j, 7-24j, 0, 6+8j, 8], [15+20j, 7-24j, 0, 3+4j, 20]],␣
↪mindspore.complex64)
>>> output = mindspore.ops.sgn(input)
>>> print(output)
[[0.6 +0.8j  0.28-0.96j 0.  +0.j   0.6 +0.8j  1.  +0.j  ]
 [0.6 +0.8j  0.28-0.96j 0.  +0.j   0.6 +0.8j  1.  +0.j  ]]
```

mindspore.ops.sign

mindspore.ops.**sign**(*input*)

Return an element-wise indication of the sign of a number.

$$\text{out}_i = \begin{cases} -1 & \text{input}_i < 0 \\ 0 & \text{input}_i = 0 \\ 1 & \text{input}_i > 0 \end{cases}$$

Note: When the input is NaN and dtype is float64, the output of this operator is NaN.

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[-1, 0, 2, 4, 6], [2, 3, 5, -6, 0]])
>>> output = mindspore.ops.sign(input)
>>> print(output)
[[-1  0  1  1  1]
 [ 1  1  1 -1  0]]
>>> mindspore.set_device(device_target="CPU")
>>> x = mindspore.tensor([[-1, 0, float('inf'), 4, float('nan')], [2, 3, float('-inf'), -6,␣
↪0]])
>>> output = mindspore.ops.sign(x)
>>> print(output)
[[-1.  0.  1.  1.  0.]
 [ 1.  1. -1. -1.  0.]]
```

mindspore.ops.signbit

mindspore.ops.**signbit**(*input*)

Determine the symbol of each element. If the element value is less than 0, the corresponding output position is True; otherwise, it is False.

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.3, 1.2, 0., -2.5])
>>> output = mindspore.ops.signbit(input)
>>> print(output)
[False False False  True]
```

mindspore.ops.sin

mindspore.ops.**sin**(*input*)

Compute sine of the input tensor element-wise.

$$output_i = \sin(input_i)$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.62, 0.28, 0.43, 0.62], mindspore.float32)
>>> output = mindspore.ops.sin(input)
>>> print(output)
[0.58103514 0.27635565 0.4168708 0.58103514]
```

mindspore.ops.sinc

mindspore.ops.**sinc**(*input*)

Compute the normalized sinc of input.

$$out_i = \begin{cases} \frac{sin(\pi input_i)}{\pi input_i} & input_i \neq 0 \\ 1 & input_i = 0 \end{cases}$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.62, 0.28, 0.43, 0.62], mindspore.float32)
>>> output = mindspore.ops.sinc(input)
>>> print(output)
[0.47735003 0.8759357  0.7224278  0.47735003]
```

mindspore.ops.sinh

mindspore.ops.**sinh**(*input*)

Compute hyperbolic sine of the input element-wise.

$$output_i = \sinh(input_i)$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.62, 0.28, 0.43, 0.62], mindspore.float32)
>>> output = mindspore.ops.sinh(input)
>>> print(output)
[0.6604918  0.28367308 0.44337422 0.6604918 ]
```

mindspore.ops.sqrt

mindspore.ops.**sqrt**(*x*)

Return sqrt of a tensor element-wise.

$$out_i = \sqrt{x_i}$$

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1.0, 4.0, 9.0], mindspore.float32)
>>> output = mindspore.ops.sqrt(x)
>>> print(output)
[1. 2. 3.]
```

mindspore.ops.square

mindspore.ops.**square**(*input*)

Return square of a tensor element-wise.

$$y_i = input_i^2$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1.0, 2.0, 3.0], mindspore.float32)
>>> output = mindspore.ops.square(input)
>>> print(output)
[1. 4. 9.]
```

mindspore.ops.sub

mindspore.ops.**sub**(*input*, *other*)

Subtract the second input from the first input element-wise.

$$out_i = input_i - other_i$$

Note:

- When the two inputs have different shapes, they must be able to broadcast to a common shape.
- The two inputs can not be bool type at the same time, [True, Tensor(True, bool_), Tensor(np.array([True]), bool_)] are all considered bool type.
- Support implicit type conversion and type promotion.

Parameters

- **input** (*Union[Tensor, number.Number, bool]*) – The first input.
- **other** (*Union[Tensor, number.Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([4, 5, 6], mindspore.int32)
>>> output = mindspore.ops.sub(input, other)
>>> print(output)
[-3 -3 -3]
```

mindspore.ops.subtract

mindspore.ops.**subtract**(*input*, *other*, *, *alpha=1*)

Subtract *other* scaled by *alpha* from *input*.

Support implicit type conversion and type promotion.

$$output[i] = input[i] - alpha * other[i]$$

Parameters

- **input** (*Union[Tensor, number.Number]*) –The first input.
- **other** (*Union[Tensor, number.Number]*) –The second input.

Keyword Arguments

alpha (*number*) –The multiplier for *other*. Default `1` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([4, 5, 6], mindspore.float32)
>>> y = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> z = mindspore.ops.subtract(input, y, alpha=1)
>>> print(z)
[3. 3. 3.]
```

mindspore.ops.t

mindspore.ops.**t**(*input*)

Transpose a 2-D tensor. 0-D and 1-D tensor are returned as it is.

Parameters

input (`Tensor`) –The input tensor.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: Input is a 0-D tensor
>>> mindspore.ops.t(mindspore.tensor(6))
Tensor(shape=[], dtype=Int64, value= 6)
>>>
>>> # case 2: Input is a 1-D tensor
>>> mindspore.ops.t(mindspore.tensor([1, 2]))
Tensor(shape=[2], dtype=Int64, value= [1, 2])
>>>
>>> # case 3: Input is a 2-D tensor
>>> mindspore.ops.t(mindspore.tensor([[1, 2, 3], [2, 3, 4]]))
Tensor(shape=[3, 2], dtype=Int64, value=
[[1, 2],
 [2, 3],
 [3, 4]])
```

mindspore.ops.tan

mindspore.ops.**tan**(*input*)

Computes tangent of *input* element-wise.

$$out_i = \tan(input_i)$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.tan(mindspore.tensor([-1.0, 0.0, 1.0]))
>>> print(output)
[-1.5574077 0. 1.5574077]
```

mindspore.ops.tanhshrink

mindspore.ops.**tanhshrink**(*input*)

Apply the element-wise Tanhshrink function.

$$Tanhshrink(x) = x - Tanh(x)$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> output = mindspore.ops.tanhshrink(mindspore.tensor([1., 2., 3., 2., 1.]))
>>> print(output)
[0.23840582 1.0359724  2.0049443  1.0359724  0.23840582]
```

mindspore.ops.trapz

`mindspore.ops.`**`trapz`**(*y*, *x=None*, ***, *dx=1.0*, *dim=-1*)

Compute the trapezoidal rule along dim.

The spacing between elements is specified by the tensor *x* or the scalar *dx* , default `1` .

$$\int y(x)\mathrm{d}x$$

Parameters

- **y** (`Tensor`) – The input tensor to integrate.
- **x** (`Tensor, optional`) – If specified, defines spacing between values.

Keyword Arguments

- **dx** (`float, optional`) – The spacing between elements. Default `1.0` . If *x* is specified, *dx* does not take effect.
- **dim** (`int, optional`) – The dimension along which to compute the trapezoidal rule. Default `-1` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> y = mindspore.tensor([[1., 2., 3.], [2., 3., 4.], [3., 2., 1.]])
>>> # case 1: Integrate over a regular grid, with spacing 1.
>>> output = mindspore.ops.trapz(y, dx=1.)
>>> print(output)
[4. 6. 4.]
>>>
>>> # case 2: Integrate over an irregular grid.
>>> x = mindspore.tensor([[1, 2, 3], [1, 3, 5], [1, 4, 7]])
>>> output = mindspore.ops.trapz(y, x)
```

(continues on next page)

(continued from previous page)

```
>>> print(output)
[ 4. 12. 12.]
```

mindspore.ops.tril_indices

mindspore.ops.**tril_indices**(*row*, *col*, *offset=0*, *, *dtype=mstype.int64*)

Return a 2-by-N tensor containing the indices of the lower triangular elements of a *row* * *col* matrix. The first row of the Tensor contains row coordinates, and the second row contains column coordinates. The coordinates are sorted by rows and then columns.

Note: When running on CUDA, row * col must be less than 2^59 to prevent overflow during calculation.

Parameters

- **row** (*int*) −number of rows in the 2-D matrix.
- **col** (*int*) −number of columns in the 2-D matrix.
- **offset** (*int, optional*) −Diagonal offset. Default `0` .
  - When *offset* is a positive integer, the diagonal is shifted upward.
  - When *offset* is a negative integer, the diagonal is shifted downward.

Keyword Arguments

dtype (*mindspore.dtype*, optional) −The specified type of output tensor. An optional data type of *mindspore.int32* and *mindspore.int64*. Default `mstype.int64` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: By default, offset=0, all elements on and below the main diagonal are retained.
>>> mindspore.ops.tril_indices(3, 2, 0)
Tensor(shape=[2, 5], dtype=Int64, value=
[[0, 1, 1, 2, 2],
 [0, 0, 1, 0, 1]])
>>>
>>> # case 2: Offset=1, the indices on and below the first sub-diagonal above the main␣
↪diagonal are returned.
>>> mindspore.ops.tril_indices(3, 2, 1)
Tensor(shape=[2, 6], dtype=Int64, value=
[[0, 0, 1, 1, 2, 2],
 [0, 1, 0, 1, 0, 1]])
>>>
>>> # case 3: Offset=-1, the indices on and below the first sub-diagonal below the main␣
↪diagonal are returned.
>>> mindspore.ops.tril_indices(3, 2, -1)
```

(continues on next page)

(continued from previous page)

```
Tensor(shape=[2, 3], dtype=Int64, value=
[[1, 2, 2],
 [0, 0, 1]])
```

mindspore.ops.triu_indices

mindspore.ops.**triu_indices**(*row*, *col*, *offset=0*, *, *dtype=mstype.int64*)

Return a 2-by-N tensor containing the indices of the upper triangular elements of a *row* * *col* matrix. The first row of the Tensor contains row coordinates, and the second row contains column coordinates. The coordinates are sorted by rows and then columns.

Note: When running on CUDA, row * col must be less than 2^59 to prevent overflow during calculation.

Parameters

- **row** (*int*) −number of rows in the 2-D matrix.
- **col** (*int*) −number of columns in the 2-D matrix.
- **offset** (*int, optional*) −Diagonal offset. Default `0` .
  - When *offset* is a positive integer, the diagonal is shifted upward.
  - When *offset* is a negative integer, the diagonal is shifted downward.

Keyword Arguments

dtype (*mindspore.dtype*, optional) −The specified type of output tensor. An optional data type of *mindspore.int32* and *mindspore.int64*. Default `mstype.int64` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: By default, offset=0, all elements on and below the main diagonal are retained.
>>> mindspore.ops.triu_indices(3, 2, 0)
Tensor(shape=[2, 3], dtype=Int64, value=
[[0, 0, 1],
 [0, 1, 1]])
>>>
>>> # case 2: If offset=-1, the indices on and above the first sub-diagonal below the main␣
 ↪diagonal are returned.
>>> mindspore.ops.triu_indices(3, 2, -1)
Tensor(shape=[2, 5], dtype=Int64, value=
[[0, 0, 1, 1, 2],
 [0, 1, 0, 1, 1]])
```

mindspore.ops.true_divide

mindspore.ops.**true_divide**(*dividend*, *divisor*)

Alias for *mindspore.ops.div()* with rounding_mode=None .

Supported Platforms:

Ascend GPU CPU

mindspore.ops.trunc

mindspore.ops.**trunc**(*input*)

Returns a tensor with the truncated integer values of the elements of the input tensor.

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.trunc(mindspore.tensor([3.4742, 0.5466, -0.8008, -3.9079]))
>>> print(output)
[3. 0. 0. -3.]
```

mindspore.ops.truncate_div

mindspore.ops.**truncate_div**(*x*, *y*)

Divide the first input tensor *x* by the second input tensor *y* element-wise and rounds the results of division towards zero.

Note: Support implicit type conversion and broadcasting.

Parameters

- **x** (*Union[Tensor, Number, bool]*) –The first input tensor.
- **y** (*Union[Tensor, Number, bool]*) –The second input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> mindspore.ops.truncate_div(mindspore.tensor([2, 4, -1]), mindspore.tensor([3, 3, 3]))
Tensor(shape=[3], dtype=Int64, value= [0, 1, 0])
```

mindspore.ops.truncate_mod

mindspore.ops.**truncate_mod**(*x*, *y*)

Return the remainder of division element-wise.

Support implicit type conversion and broadcasting.

Warning:

- The input data does not support 0.
- When the elements of input exceed 2048 , the accuracy of operator cannot guarantee the requirement of double thousandths in the mini form.
- Due to different architectures, the calculation results of this operator on NPU and CPU may be inconsistent.
- If shape is expressed as (D1,D2⋯,Dn), then D1*D2⋯*DN<=1000000,n<=8.

Parameters

- **x** (*Union[Tensor, Number, bool]*) – The first input tensor.
- **y** (*Union[Tensor, Number, bool]*) – The second input tensor.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> output = mindspore.ops.truncate_mod(mindspore.tensor([2., 4., -1.]), mindspore.tensor([3.
↪, 3., 3.]))
>>> print(output)
[ 2.  1. -1.]
```

mindspore.ops.xdivy

mindspore.ops.**xdivy**(*x*, *y*)

Divide *x* by *y* element-wise.

Note:

- Support broadcast, support implicit type conversion and type promotion.
- When *x* and *y* are both of datatype complex, they should be both complex64 or complex128 at the same time.
- *x* and *y* can not be both bool at the same time.

Parameters

- **x** (*Union[Tensor, Number, bool]*) – Numerator tensor.
- **y** (*Union[Tensor, Number, bool]*) – Denominator tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.xdivy(mindspore.tensor([2., 4., -1.]), mindspore.tensor([2., 2.,␣
↪2.]))
>>> print(output)
[ 1.   2.  -0.5]
```

mindspore.ops.xlogy

mindspore.ops.**xlogy**(*input*, *other*)

Compute *input* multiplied by the logarithm of *other* element-wise.

$$out_i = input_i * lnother_i$$

Note:

- Support broadcast, support implicit type conversion and type promotion.

Warning: On Ascend, the data type of *input* and *other* must be float16 or float32.

Parameters

- **input** (*Union[Tensor, numbers.Number, bool]*) – The first input tensor.

- **other** (*Union[Tensor, numbers.Number, bool]*) – The second input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.xlogy(mindspore.tensor([-5., 0., 4.]), mindspore.tensor([2., 2.,␣
↪2.]))
>>> print(output)
[-3.465736   0.         2.7725887]
```

mindspore.ops.zeta

mindspore.ops.**zeta**(*input*, *other*)

Elemental-wise compute the Hurwitz zeta function values.

$$\zeta(x, q) = \sum_{k=0}^{\infty} \frac{1}{(k+q)^x}$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (*Union[Tensor, int, float]*) – The first input tensor. Represented as x in the formula.
- **other** (*Union[Tensor, int, float]*) – The second input tensor. Represented as q in the formula.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> z = mindspore.ops.zeta(mindspore.tensor([10.]), mindspore.tensor([1.]))
>>> print(z)
[1.0009946]
```

2.2.2 Reduction Functions

API Name	Description	Supported Platforms
mindspore.ops.all	Tests if all element in *input* evaluates to *True* along the given axes.	Ascend GPU CPU
mindspore.ops.amax	Return the maximum values along the given axis of the tensor.	Ascend GPU CPU
mindspore.ops.amin	Return the minimum values along the given axis of the tensor.	Ascend GPU CPU
mindspore.ops.aminmax	Return the minimum values and maximum values along the given axes of the tensor.	Ascend GPU CPU
mindspore.ops.any	Tests if any element in *input* evaluates to *True* along the given axes.	Ascend GPU CPU
mindspore.ops.argmax	Return the indices of the maximum values along a specified dimension of the tensor.	Ascend GPU CPU
mindspore.ops.argmin	Return the indices of the minimum values along a specified dimension of the tensor.	Ascend GPU CPU
mindspore.ops.cummax	Return the cumulative maximum values and their indices along the given axis of the tensor.	Ascend GPU CPU
mindspore.ops.cummin	Return the cumulative minimum values and their indices along the given axis of the tensor.	Ascend GPU CPU
mindspore.ops.cumprod	Return the cumulative product along the given dimension of the tensor.	Ascend GPU CPU
mindspore.ops.cumsum	Return the cumulative sum along the given axis of the tensor.	Ascend GPU CPU
mindspore.ops.histc	Computes the histogram of a tensor.	Ascend CPU
mindspore.ops.logcumsumexp	Calculate the log of cumulative summed exponentials of the tensor along a specified dimension.	Ascend CPU GPU
mindspore.ops.logsumexp	Calculate the log of summed exponentials of the tensor along a specified dimension.	Ascend GPU CPU
mindspore.ops.max	Return the maximum values and their indices along the given axis of the tensor.	Ascend GPU CPU
mindspore.ops.mean	Compute the mean(s) of the tensor along the specified axis(axes).	Ascend GPU CPU
mindspore.ops.median	Return the median(s) and indice(s) of the tensor along the specified axis.	GPU CPU
mindspore.ops.min	Return the minimum values and their indices along the given axis of the tensor.	Ascend GPU CPU
mindspore.ops.norm	Compute the matrix norm or vector norm of the tensor along a specified dimension.	Ascend GPU CPU
mindspore.ops.prod	Return the product(s) of the tensor along the specified axis(axes).	Ascend GPU CPU
mindspore.ops.std	Compute the standard deviation of the tensor along a specified axis.	Ascend GPU CPU
mindspore.ops.std_mean	Compute the standard deviation and the mean of the tensor along a specified axis.	Ascend GPU CPU
mindspore.ops.var	Compute the variance of the tensor along a specified axis.	Ascend GPU CPU
mindspore.ops.var_mean	Compute the variance and the mean of the tensor along a specified axis.	Ascend GPU CPU

mindspore.ops.all

mindspore.ops.**all**(*input*, *axis=None*, *keep_dims=False*)

Tests if all element in *input* evaluates to *True* along the given axes.

Parameters

- **input** (Tensor) –The input Tensor.
- **axis** (*Union[int, tuple(int), list(int), Tensor], optional*) –The dimensions to reduce. If None , all dimensions are reduced. Default None .
- **keep_dims** (*bool, optional*) –Whether the output tensor has dim retained or not. Default False .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[True, False], [True, True]])
>>>
>>> # case 1:  By default, mindspore.ops.all tests along all the axes.
>>> mindspore.ops.all(input)
Tensor(shape=[], dtype=Bool, value= False)
>>>
>>> # case 2: Reduces a dimension along axis 1, with keep_dims False.
>>> mindspore.ops.all(input, axis=1)
Tensor(shape=[2], dtype=Bool, value= [False,  True])
>>>
>>> # case 3: Reduces a dimension along axis (0,1), with keep_dims False.
>>> mindspore.ops.all(input, axis=(0,1))
Tensor(shape=[], dtype=Bool, value= False)
>>>
>>> # case 4: Reduces a dimension along axis [0,1], with keep_dims True.
>>> mindspore.ops.all(input, axis=[0,1], keep_dims=True)
Tensor(shape=[1, 1], dtype=Bool, value=
[[False]])
```

mindspore.ops.amax

mindspore.ops.**amax**(*input*, *axis=None*, *keepdims=False*, ***, *initial=None*, *where=None*)

Return the maximum values along the given axis of the tensor.

Parameters

- **input** (Tensor*[Number]*) –The input tensor.
- **axis** (*Union[int, tuple(int), list(int), Tensor], optional*) –Specify the axis for computation. If None , compute all elements in the *input* . Default None .
- **keepdims** (*bool, optional*) –Whether the output tensor has dim retained. Default False .

Keyword Arguments

- **initial** (*scalar, optional*) –Initial value for the maximum. Default `None` .
- **where** (`Tensor[bool], optional`) –Specifies the range over which to compute the maximum values. The shape of this tensor must be broadcastable to the shape of *input* . An *initial* value must be specified. Default `None` , indicating that all elements are to be computed.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[9, 3, 4, 5],
...                           [5, 2, 7, 4],
...                           [8, 1, 3, 6]])
>>> # case 1: By default, compute the maximum of all elements.
>>> mindspore.ops.amax(input)
Tensor(shape=[], dtype=Int64, value= 9)
>>>
>>> # case 2: Compute maximum along axis 1.
>>> mindspore.ops.amax(input, axis=1)
Tensor(shape=[3], dtype=Int64, value= [9, 7, 8])
>>>
>>> # case 3: If keepdims=True, the output shape will be same of that of the input.
>>> mindspore.ops.amax(input, axis=1, keepdims=True)
Tensor(shape=[3, 1], dtype=Int64, value=
[[9],
 [7],
 [8]])
>>>
>>> # case 4: Use "where" to include only specific elements in computing the maximum.
>>> where = mindspore.tensor([[0, 0, 1, 0],
...                           [0, 0, 1, 1],
...                           [1, 1, 1, 0]], dtype=mindspore.bool_)
>>> mindspore.ops.amax(input, axis=1, keepdims=True, initial=0, where=where)
Tensor(shape=[3, 1], dtype=Int64, value=
[[4],
 [7],
 [8]])
>>>
>>> # case 5: The shape of "where" must be broadcast compatible with input.
>>> where = mindspore.tensor([[False],
...                           [False],
...                           [False]])
>>> mindspore.ops.amax(input, axis=0, keepdims=True, initial=0, where=where)
Tensor(shape=[1, 4], dtype=Int64, value=
[[0, 0, 0, 0]])
```

mindspore.ops.amin

mindspore.ops.**amin**(*input*, *axis=None*, *keepdims=False*, *, *initial=None*, *where=None*)

Return the minimum values along the given axis of the tensor.

Parameters

- **input** (Tensor[Number]) –The input tensor.
- **axis** (Union[int, tuple(int), list(int), Tensor], optional) –Specify the axis for computation. If None , compute all elements in the *input* . Default None .
- **keepdims** (bool, optional) –Whether the output tensor has dim retained. Default False .

Keyword Arguments

- **initial** (scalar, optional) –Initial value for the minimum. Default None .
- **where** (Tensor[bool], optional) –Specifies the range over which to compute the minimum values. The shape of this tensor must bebroadcastable to the shape of *input* . An *initial* value must be specified. Default None , indicating that all elements are to be computed.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[2, 5, 1, 6],
...                           [3, -7, -2, 4],
...                           [8, -4, 1, -3]])
>>> # case 1: By default, compute the minimum of all elements.
>>> mindspore.ops.amin(input)
Tensor(shape=[], dtype=Int64, value= -7)
>>>
>>> # case 2: Compute minimum along axis 1.
>>> mindspore.ops.amin(input, axis=1)
Tensor(shape=[3], dtype=Int64, value= [ 1, -7, -4])
>>>
>>> # case 3: If keepdims=True, the output shape will be same of that of the input.
>>> mindspore.ops.amin(input, axis=1, keepdims=True)
Tensor(shape=[3, 1], dtype=Int64, value=
[[ 1],
 [-7],
 [-4]])
>>>
>>> # case 4: Use "where" to include only specific elements in computing the minimum.
>>> where = mindspore.tensor([[1, 0, 1, 0],
...                           [0, 0, 1, 1],
...                           [1, 1, 1, 0]], dtype=mindspore.bool_)
>>> mindspore.ops.amin(input, axis=1, keepdims=True, initial=0, where=where)
Tensor(shape=[3, 1], dtype=Int64, value=
 [[ 0],
  [-2],
```

(continues on next page)

(continued from previous page)

```
  [-4]])
>>>
>>> # case 5: The shape of "where" must be broadcast compatible with input.
>>> where = mindspore.tensor([[False],
...                           [False],
...                           [False]])
>>> mindspore.ops.amin(input, axis=0, keepdims=True, initial=0, where=where)
Tensor(shape=[1, 4], dtype=Int64, value=
 [[0, 0, 0, 0]])
```

mindspore.ops.aminmax

mindspore.ops.**aminmax**(*input*, ***, *axis=0*, *keepdims=False*)

Return the minimum values and maximum values along the given axes of the tensor.

Parameters

input (Tensor) – The input tensor.

Keyword Arguments

- **axis** (int, *optional*) – Specify the axis for computation. If None , compute all elements in the *input* . Default 0 .
- **keepdims** (bool, *optional*) – Whether the output tensor has dim retained. Default False .

Returns

Tuple(min, max) of 2 tensors.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[9, 3, 4, 5],
...                           [5, 2, 7, 4],
...                           [8, 1, 3, 6]])
>>>
>>> # case 1: By default, compute along axis 0.
>>> mindspore.ops.aminmax(input)
(Tensor(shape=[4], dtype=Int64, value= [5, 1, 3, 4]),
 Tensor(shape=[4], dtype=Int64, value= [9, 3, 7, 6]))
>>>
>>> # case 2: Disregard NaN (Not a Number) values present in the input during computation.
>>> input = mindspore.tensor([[9, 3, 4, 5],
...                           [5, 2, 7, 4],
...                           [8, 1, 3, float('nan')]])
>>> mindspore.ops.aminmax(input, axis=None)
(Tensor(shape=[], dtype=Float32, value= 1),
 Tensor(shape=[], dtype=Float32, value= 9))
>>>
>>> # case 3: If keepdims=True, the output shape will be same of that of the input.
>>> mindspore.ops.aminmax(input, axis=None, keepdims=True)
```

(continues on next page)

(continued from previous page)

```
(Tensor(shape=[1, 1], dtype=Float32, value=
 [[ 1.00000000e+00]]),
 Tensor(shape=[1, 1], dtype=Float32, value=
 [[ 9.00000000e+00]]))
```

mindspore.ops.any

mindspore.ops.**any**(*input*, *axis=None*, *keep_dims=False*)

Tests if any element in *input* evaluates to *True* along the given axes.

Parameters

- **input** (Tensor) – The input tensor.
- **axis** (*Union[int, tuple(int), list(int), Tensor], optional*) – The dimensions to reduce. If None , all dimensions are reduced. Default None .
- **keep_dims** (*bool, optional*) – Whether the output tensor has dim retained or not. Default False .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[True, False], [True, True]])
>>>
>>> # case 1:  By default, mindspore.ops.any tests along all the axes.
>>> mindspore.ops.any(input)
Tensor(shape=[], dtype=Bool, value= True)
>>>
>>> # case 2: Reduces a dimension along axis 1, with keep_dims False.
>>> mindspore.ops.any(input, axis=1)
Tensor(shape=[2], dtype=Bool, value= [ True,  True])
>>>
>>> # case 3: Reduces a dimension along axis (0, 1), with keep_dims False.
>>> mindspore.ops.any(input, axis=(0,1))
Tensor(shape=[], dtype=Bool, value= True)
>>>
>>> # case 4: Reduces a dimension along axis [0, 1], with keep_dims True.
>>> mindspore.ops.any(input, axis=[0,1], keep_dims=True)
Tensor(shape=[1, 1], dtype=Bool, value=
[[ True]])
```

mindspore.ops.argmax

mindspore.ops.**argmax**(*input*, *dim=None*, *keepdim=False*)

Return the indices of the maximum values along a specified dimension of the tensor.

Parameters

- **input** (Tensor) –The input tensor.
- **dim** (*Union[int, None], optional*) –Specify the dimension for computation. If None , compute maximum value indexes of all elements in the *input* . Default None .
- **keepdim** (*bool, optional*) –Whether the output tensor has dim retained. Default False .

Returns

Tensor, contains the index of the maximum value.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[9, 3, 4, 5],
...                           [5, 2, 7, 4],
...                           [8, 1, 3, 6]])
>>> # case 1: By default, compute the maximum indice of all elements.
>>> mindspore.ops.argmax(input)
Tensor(shape=[], dtype=Int64, value= 0)
>>>
>>> # case 2: Compute maximum indice along dim 1.
>>> mindspore.ops.argmax(input, dim=1)
Tensor(shape=[3], dtype=Int64, value= [0, 2, 0])
>>>
>>> # case 3: If keepdim=True, the output shape will be same of that of the input.
>>> mindspore.ops.argmax(input, dim=1, keepdim=True)
Tensor(shape=[3, 1], dtype=Int64, value=
[[0],
 [2],
 [0]])
```

mindspore.ops.argmin

mindspore.ops.**argmin**(*input*, *axis=None*, *keepdims=False*)

Return the indices of the minimum values along a specified dimension of the tensor.

Parameters

- **input** (Tensor) –The input tensor.
- **axis** (*Union[int, None], optional*) –Specify the dimension for computation. If None , compute all elements in the *input* . Default None .
- **keepdims** (*bool, optional*) –Whether the output tensor has dim retained. Default False .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[2, 5, 1, 6],
...                           [3, -7, -2, 4],
...                           [8, -4, 1, -3]])
>>> # case 1: By default, compute the minimum indice of all elements.
>>> mindspore.ops.argmin(input)
Tensor(shape=[], dtype=Int32, value= 5)
>>>
>>> # case 2: Compute the minimum indices along axis 1.
>>> mindspore.ops.argmin(input, axis=1)
Tensor(shape=[3], dtype=Int32, value= [2, 1, 1])
>>>
>>> # case 3: If keepdims=True, the output shape will be same of that of the input.
>>> mindspore.ops.argmin(input, axis=1, keepdims=True)
Tensor(shape=[3, 1], dtype=Int32, value=
[[2],
 [1],
 [1]])
```

mindspore.ops.cummax

mindspore.ops.**cummax**(*input*, *axis*)

Return the cumulative maximum values and their indices along the given axis of the tensor.

$$y_i = \max(x_1, x_2, ..., x_i)$$

Parameters

- **input** (Tensor) −The input tensor.
- **axis** (*int*) −Specify the axis for computation.

Returns

Tuple(max, max_indices) of 2 tensors.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[3, 4, 6, 10],
...                           [1, 6, 7, 9],
...                           [4, 3, 8, 7],
...                           [1, 3, 7, 9]])
>>> mindspore.ops.cummax(input, axis=0)
(Tensor(shape=[4, 4], dtype=Int64, value=
 [[ 3,  4,  6, 10],
  [ 3,  6,  7, 10],
  [ 4,  6,  8, 10],
  [ 4,  6,  8, 10]]),
 Tensor(shape=[4, 4], dtype=Int64, value=
 [[0, 0, 0, 0],
  [0, 1, 1, 0],
  [2, 1, 2, 0],
  [2, 1, 2, 0]]))
```

mindspore.ops.cummin

mindspore.ops.**cummin**(*input*, *axis*)

Return the cumulative minimum values and their indices along the given axis of the tensor.

$$y_i = \min(x_1, x_2, ..., x_i)$$

Parameters

- **input** (Tensor) −The input tensor.
- **axis** (*int*) −Specify the axis for computation.

Returns

Tuple(min, min_indices) of 2 tensors.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import Tensor, ops
>>> import mindspore
>>> a = Tensor([-0.2284, -0.6628,  0.0975,  0.2680, -1.3298, -0.4220], mindspore.float32)
>>> output = ops.cummin(a, axis=0)
>>> print(output[0])
[-0.2284 -0.6628 -0.6628 -0.6628 -1.3298 -1.3298]
>>> print(output[1])
[0 1 1 1 4 4]
```

mindspore.ops.cumprod

mindspore.ops.**cumprod**(*input*, *dim*, *dtype=None*)

Return the cumulative product along the given dimension of the tensor.

$$y_i = x_1 * x_2 * x_3 * ... * x_i$$

Parameters

- **input** (Tensor) −The input tensor.
- **dim** (*int*) −Specify the dimension for computation.
- **dtype** (*mindspore.dtype*, optional) −The data type returned. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1, 2, 3],
...                           [4, 5, 6]])
>>> mindspore.ops.cumprod(input, dim=0)
Tensor(shape=[2, 3], dtype=Int64, value=
[[ 1,  2,  3],
 [ 4, 10, 18]])
>>> mindspore.ops.cumprod(input, dim=1)
Tensor(shape=[2, 3], dtype=Int64, value=
[[  1,   2,   6],
 [  4,  20, 120]])
```

mindspore.ops.cumsum

mindspore.ops.**cumsum**(*x*, *axis*, *dtype=None*)

Return the cumulative sum along the given axis of the tensor.

$$y_i = x_1 + x_2 + x_3 + ... + x_i$$

Parameters

- **x** (Tensor) −The input tensor.
- **axis** (*int*) −Specify the axis for computation.
- **dtype** (*mindspore.dtype*, optional) −The data type returned. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1, 2, 3],
...                           [4, 5, 6]], mindspore.int32)
>>> mindspore.ops.cumsum(input, axis=0)
Tensor(shape=[2, 3], dtype=Int32, value=
[[1, 2, 3],
 [5, 7, 9]])
>>> mindspore.ops.cumsum(input, axis=1)
Tensor(shape=[2, 3], dtype=Int32, value=
[[ 1,  3,  6],
 [ 4,  9, 15]])
```

mindspore.ops.histc

mindspore.ops.**histc**(*input*, *bins=100*, *min=0.*, *max=0.*)

Computes the histogram of a tensor.

The elements are sorted into equal width bins between *min* and *max*. If *min* and *max* are both zero, the minimum and maximum values of the data are used.

Elements lower than min or higher than max are ignored.

Parameters

- **input** (Tensor) –The input tensor.
- **bins** (*int, optional*) –Number of histogram bins. Default 100 .
- **min** (*int, float, optional*) –Minimum value of the histogram data range. Default 0. .
- **max** (*int, float, optional*) –Maximum value of the histogram data range. Default 0. .

Returns

Tensor

Supported Platforms:

Ascend CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1., 1, 2, 2, 2, 5, 8])
>>> output = mindspore.ops.histc(input, bins=5, min=0, max=9)
>>> print(output)
[2. 3. 1. 0. 1.]
```

mindspore.ops.logcumsumexp

mindspore.ops.**logcumsumexp**(*input*, *axis*)

Calculate the log of cumulative summed exponentials of the tensor along a specified dimension.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input tensor.
- **axis** (*int*) –Specify the axis for computation.

Returns

Tensor

Supported Platforms:

Ascend CPU GPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[9., 3, 4, 5],
...                           [5, 2, 7, 4],
...                           [8, 1, 3, 6]])
>>> # case 1: Compute the log of cumulative summed exponential along dim 0.
>>> output = mindspore.ops.logcumsumexp(input, 0)
>>> print(output)
[[9.        3.        4.        5.       ]
 [9.01815   3.3132617 7.0485873 5.3132615]
 [9.326563  3.407606  7.065884  6.407606 ]]
>>>
>>> # case 2: Compute the log of cumulative summed exponential along dim 1.
>>> output = mindspore.ops.logcumsumexp(input, 1)
>>> print(output)
[[9.        9.002476  9.009174  9.02716  ]
 [5.        5.0485873 7.1328454 7.175515 ]
 [8.        8.000912  8.007621  8.133643 ]]
```

mindspore.ops.logsumexp

mindspore.ops.**logsumexp**(*input*, *dim*, *keepdim=False*)

Calculate the log of summed exponentials of the tensor along a specified dimension.

$$logsumexp(input) = \log(\sum(e^{input-input_{max}})) + input_{max}$$

Parameters

- **input** (Tensor) –The input tensor.
- **dim** (*Union[int, tuple(int), list(int)]*) –Specify the dimension for computation. If `()` , compute all elements in the *input* .
- **keepdim** (*bool, optional*) –Whether the output tensor has dim retained. Default `False` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[9., 3, 4, 5],
...                           [5, 2, 7, 4],
...                           [8, 1, 3, 6]])
>>> # case 1: By default, compute the log of summed exponential of all elements.
>>> output = mindspore.ops.logsumexp(input, ())
>>> print(output)
9.475807
>>>
>>> # case 2: Compute the log of summed exponential along dim 0.
>>> output = mindspore.ops.logsumexp(input, 0)
>>> print(output)
[9.326562  3.4076054 7.065884  6.4076056]
>>>
>>> # case 3: If keepdim=True, the output shape will be same of that of the input.
>>> output = mindspore.ops.logsumexp(input, 1, True)
>>> print(output)
[[9.02716 ]
 [7.175515]
 [8.133643]]
```

mindspore.ops.max

`mindspore.ops.`**`max`**(*input*, *axis=None*, *keepdims=False*, ***, *initial=None*, *where=None*)

Return the maximum values and their indices along the given axis of the tensor.

Parameters

- **`input`** (`Tensor`) −The input tensor.
- **`axis`** (*`int`*) −Specify the axis for computation. If `None` , compute all elements in the *input* . Default: `False` .
- **`keepdims`** (*`bool`*) −Whether the output tensor has dim retained. Default `False`.

Keyword Arguments

- **`initial`** (*`scalar, optional`*) −Initial value for the maximum. Default `None`.
- **`where`** (`Tensor`*`[bool], optional`*) −Specifies the range over which to compute the maximum values. The shape of this tensor must be broadcastable to the shape of *input* . An *initial* value must be specified. Default `None` , indicating that all elements are to be computed.

Returns

Tuple(max, max_indices) of 2 tensors.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[9, 3, 4, 5],
...                           [5, 2, 7, 4],
...                           [8, 1, 3, 6]])
>>> # case 1: By default, compute the maximum of all elements.
>>> mindspore.ops.max(input)
(Tensor(shape=[], dtype=Int64, value= 9),
 Tensor(shape=[], dtype=Int64, value= 0))
>>>
>>> # case 2: Compute maximum along axis 1.
>>> mindspore.ops.max(input, axis=1)
(Tensor(shape=[3], dtype=Int64, value= [9, 7, 8]),
 Tensor(shape=[3], dtype=Int64, value= [0, 2, 0]))
>>>
>>> # case 3: If keepdims=True, the output shape will be same of that of the input.
>>> mindspore.ops.max(input, axis=1, keepdims=True)
(Tensor(shape=[3, 1], dtype=Int64, value=
 [[9],
  [7],
  [8]]),
 Tensor(shape=[3, 1], dtype=Int64, value=
 [[0],
  [2],
  [0]]))
>>>
>>> # case 4: Use "where" to include only specific elements in computing the maximum.
>>> where = mindspore.tensor([[0, 0, 1, 0],
...                           [0, 0, 1, 1],
...                           [1, 1, 1, 0]], dtype=mindspore.bool_)
>>> mindspore.ops.max(input, axis=1, keepdims=True, initial=0, where=where)
(Tensor(shape=[3, 1], dtype=Int64, value=
 [[4],
  [7],
  [8]]),
 Tensor(shape=[3, 1], dtype=Int64, value=
 [[2],
  [2],
  [0]]))
>>>
>>> # case 5: The shape of "where" must be broadcast compatible with input.
>>> where = mindspore.tensor([[False],
...                           [False],
...                           [False]])
>>> mindspore.ops.max(input, axis=0, keepdims=True, initial=0, where=where)
(Tensor(shape=[1, 4], dtype=Int64, value=
 [[0, 0, 0, 0]]),
 Tensor(shape=[1, 4], dtype=Int64, value=
 [[0, 0, 0, 0]]))
```

mindspore.ops.mean

mindspore.ops.**mean**(*x*, *axis=None*, *keep_dims=False*)

Compute the mean(s) of the tensor along the specified axis(axes).

Parameters

- **x** (Tensor[*Number*]) –The input tensor.
- **axis** (*Union[int, tuple(int), list(int), Tensor]*) –Specify the axis(axes) for computation. If None , compute all elements in the *input* .
- **keep_dims** (*bool*) –Whether the output tensor has dim retained. Default False .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[9, 3, 4, 5],
...                           [5, 2, 7, 4],
...                           [8, 1, 3, 6]])
>>> # case 1: By default, compute the mean of all elements.
>>> mindspore.ops.mean(input)
Tensor(shape=[], dtype=Int64, value= 4)
>>>
>>> # case 2: Compute the mean along axis 1.
>>> mindspore.ops.mean(input, axis=1)
Tensor(shape=[3], dtype=Int64, value= [5, 4, 4])
>>>
>>> # case 3: If keep_dims=True, the output shape will be same of that of the input.
>>> mindspore.ops.mean(input, axis=1, keep_dims=True)
Tensor(shape=[3, 1], dtype=Int64, value=
[[5],
 [4],
 [4]])
```

mindspore.ops.median

mindspore.ops.**median**(*input*, *axis=- 1*, *keepdims=False*)

Return the median(s) and indice(s) of the tensor along the specified axis.

Warning:

- *indices* does not necessarily contain the first occurrence of each median value found in the *input*, unless it is unique. The specific implementation of this API is device-specific. The results may be different on CPU and GPU.

Parameters

- **input** (Tensor) –The input tensor.

- **axis** (*int, optional*) –Specify the axis for computation. Default `-1` .
- **keepdims** (*bool, optional*) –Whether the output tensor has dim retained. Default `False` .

Returns

Tuple(median, median_indices) of 2 tensors.

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[9, 3, 4, 5],
...                           [5, 2, 7, 4],
...                           [8, 1, 3, 6]])
>>> # case 1: By default, compute the median along axis -1.
>>> mindspore.ops.median(input)
(Tensor(shape=[3], dtype=Int64, value= [4, 4, 3]),
 Tensor(shape=[3], dtype=Int64, value= [2, 3, 2]))
>>>
>>> # case 2: Compute the median along axis 0.
>>> mindspore.ops.median(input, axis=0)
(Tensor(shape=[4], dtype=Int64, value= [8, 2, 4, 5]),
 Tensor(shape=[4], dtype=Int64, value= [2, 1, 0, 0]))
>>>
>>> # case 3: If keepdims=True, the output shape will be same of that of the input.
>>> mindspore.ops.median(input, axis=0, keepdims=True)
(Tensor(shape=[1, 4], dtype=Int64, value=
 [[8, 2, 4, 5]]),
 Tensor(shape=[1, 4], dtype=Int64, value=
 [[2, 1, 0, 0]]))
```

mindspore.ops.min

`mindspore.ops.`**`min`**(*input*, *axis=None*, *keepdims=False*, ***, *initial=None*, *where=None*)

Return the minimum values and their indices along the given axis of the tensor.

Parameters

- **input** (`Tensor`) –The input tensor.
- **axis** (*int*) –Specify the axis for computation. If `None` , compute all elements in the *input* . Default `None` .
- **keepdims** (*bool*) –Whether the output tensor has dim retained. Default `False` .

Keyword Arguments

- **initial** (*scalar, optional*) –Initial value for the minimum. Default `None` .
- **where** (*Tensor[bool], optional*) –Specifies the range over which to compute the maximum values. The shape of this tensor must be broadcastable to the shape of *input* . An *initial* value must be specified. Default `None` , indicating that all elements are to be computed.

Returns

Tuple(min, min_indices) of 2 tensors.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[2, 5, 1, 6],
...                           [3, -7, -2, 4],
...                           [8, -4, 1, -3]])
>>> # case 1: By default, compute the minimum of all elements.
>>> mindspore.ops.min(input)
(Tensor(shape=[], dtype=Int64, value= -7),
 Tensor(shape=[], dtype=Int64, value= 0))
>>>
>>> # case 2: Compute minimum along axis 1.
>>> mindspore.ops.min(input, axis=1)
(Tensor(shape=[3], dtype=Int64, value= [ 1, -7, -4]),
 Tensor(shape=[3], dtype=Int64, value= [2, 1, 1]))
>>>
>>> # case 3: If keepdims=True, the output shape will be same of that of the input.
>>> mindspore.ops.min(input, axis=1, keepdims=True)
(Tensor(shape=[3, 1], dtype=Int64, value=
 [[ 1],
  [-7],
  [-4]]),
 Tensor(shape=[3, 1], dtype=Int64, value=
 [[2],
  [1],
  [1]]))
>>>
>>> # case 4: Use "where" to include only specific elements in computing the minimum.
>>> where = mindspore.tensor([[1, 0, 1, 0],
...                           [0, 0, 1, 1],
...                           [1, 1, 1, 0]], dtype=mindspore.bool_)
>>> mindspore.ops.min(input, axis=1, keepdims=True, initial=0, where=where)
(Tensor(shape=[3, 1], dtype=Int64, value=
 [[ 0],
  [-2],
  [-4]]),
 Tensor(shape=[3, 1], dtype=Int64, value=
 [[0],
  [2],
  [1]]))
>>>
>>> # case 5: The shape of "where" must be broadcast compatible with input.
>>> where = mindspore.tensor([[False],
...                           [False],
...                           [False]])
>>> mindspore.ops.min(input, axis=0, keepdims=True, initial=0, where=where)
(Tensor(shape=[1, 4], dtype=Int64, value=
 [[0, 0, 0, 0]]),
 Tensor(shape=[1, 4], dtype=Int64, value=
 [[0, 0, 0, 0]]))
```

mindspore.ops.norm

mindspore.ops.**norm**(*A*, *ord=None*, *dim=None*, *keepdim=False*, *, *dtype=None*)

Compute the matrix norm or vector norm of the tensor along a specified dimension.

ord is the calculation mode of norm. The following norm modes are supported.

ord	norm for matrices	norm for vectors
None (default)	Frobenius norm	*2*-norm (see below)
'fro'	Frobenius norm	–not supported –
'nuc'	nuclear norm	–not supported –
inf	$max(sum(abs(x), dim = 1))$	$max(abs(x))$
-inf	$min(sum(abs(x), dim = 1))$	$min(abs(x))$
0	–not supported –	$sum(x! = 0)$
1	$max(sum(abs(x), dim = 0))$	as below
-1	$min(sum(abs(x), dim = 0))$	as below
2	largest singular value	as below
-2	smallest singular value	as below
other *int* or *float*	–not supported –	$sum(abs(x)^{ord})^{(1/ord)}$

Parameters

- **A** (Tensor) –The input tensor.
- **ord** (*Union[int, float, inf, -inf, 'fro', 'nuc'], optional*) –Specify the kind of norm to take. Default None .
- **dim** (*Union[int, Tuple(int)], optional*) –Specify the dimension for computation. Default None .
  - If *dim* is int, calculate the vector norm.
  - if *dim* is a 2-tuple, calculate the matrix norm.
  - If *dim* is None and *ord* is None , flattened *A* to 1D and calculate 2-norm of the vector.
  - If *dim* is None and *ord* is not None, *A* must be 1D or 2D.
- **keepdim** (*bool*) –Whether the output tensor has dim retained. Default False .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The data type returned. The data type returned. When set, *A* will be converted to the specified data type, before calculaing. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Note: Currently, complex numbers are not supported.

Examples

```
>>> import mindspore
>>> # Vector norms:
>>> A = mindspore.tensor([3., 4., 12.])
>>> mindspore.ops.norm(A)
Tensor(shape=[], dtype=Float32, value= 13)
>>> mindspore.ops.norm(A, ord=1)
Tensor(shape=[], dtype=Float32, value= 19)
>>> mindspore.ops.norm(A, ord=0)
Tensor(shape=[], dtype=Float32, value= 3)
>>>
>>> # Matrix norms:
>>> A = mindspore.tensor([[1., 2., 3.],
...                       [4., 5., 7.]])
>>> mindspore.ops.norm(A)  # Frobenius norm
Tensor(shape=[], dtype=Float32, value= 10.198)
>>> mindspore.ops.norm(A, ord='nuc')  # nuclear norm
Tensor(shape=[], dtype=Float32, value= 10.7625)
>>> mindspore.ops.norm(A, ord=1)  # 1-norm
Tensor(shape=[], dtype=Float32, value= 10)
>>>
>>> # Batched vector norm:
>>> mindspore.ops.norm(A, dim=1)
Tensor(shape=[2], dtype=Float32, value= [ 3.74165726e+00,  9.48683262e+00])
```

mindspore.ops.prod

mindspore.ops.**prod**(*input*, *axis=None*, *keep_dims=False*, *dtype=None*)

Return the product(s) of the tensor along the specified axis(axes).

Parameters

- **input** (*Tensor[Number]*) – The input tensor.
- **axis** (*Union[int, tuple(int), list(int), Tensor]*) – Specify the axis(axes) for computation. If None , compute all elements in the *input* . Default None .
- **keep_dims** (*bool*) – Whether the output tensor has dim retained. Default False .
- **dtype** (*mindspore.dtype*) – The data type returned. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[9, 3, 4, 5],
...                           [5, 2, 7, 4],
...                           [8, 1, 3, 6]])
>>> # case 1: By default, compute the product of all elements.
>>> mindspore.ops.prod(input)
Tensor(shape=[], dtype=Int64, value= 21772800)
>>>
>>> # case 2: Compute the product along axis 1.
>>> mindspore.ops.prod(input, axis=1)
Tensor(shape=[3], dtype=Int64, value= [540, 280, 144])
>>>
>>> # case 3: If keep_dims=True, the output shape will be same of that of the input.
>>> mindspore.ops.prod(input, axis=1, keep_dims=True)
Tensor(shape=[3, 1], dtype=Int64, value=
[[540],
 [280],
 [144]])
```

mindspore.ops.std

mindspore.ops.**std**(*input*, *axis=None*, *ddof=0*, *keepdims=False*)

Compute the standard deviation of the tensor along a specified axis.

Parameters

- **input** (*Tensor[Number]*) – The input tensor.
- **axis** (*Union[int, tuple(int)], optional*) – Specify the axis for computation. If `None` , compute all elements in the *input* . Default `None` .
- **ddof** (*Union[int, bool], optional*) – Means Delta Degrees of Freedom. Default `0` .
  - If ddof is an integer, the divisor used in calculations is $N - ddof$, where N represents the number of elements.
  - If ddof is a boolean, `True` and `False` correspond to when ddof is an integer `1` and `0` respectively.
  - If ddof is 0, 1, True or False, the supported device is only Ascend and CPU. In other cases, the supported device is Ascend, GPU and CPU.
- **keepdims** (*bool, optional*) – Whether the output tensor has dim retained. Default `False` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1., 3, 4, 2],
...                           [4, 2, 5, 3],
...                           [5, 4, 2, 3]])
>>> # case 1: By default, compute the standard deviation of all elements.
>>> output = mindspore.ops.std(input)
>>> print(output)
1.2133516
>>>
>>> # case 2: Compute the standard deviation along axis 0.
>>> output = mindspore.ops.std(input, axis=0)
>>> print(output)

```

mindspore.ops.std_mean

mindspore.ops.**std_mean**(*input*, *axis=None*, *ddof=0*, *keepdims=False*)

Compute the standard deviation and the mean of the tensor along a specified axis.

Parameters

- **input** (*Tensor[Number]*) – The input tensor.
- **axis** (*Union[int, tuple(int)], optional*) – Specify the axis for computation. If `None`, compute all elements in the *input*. Default `None`.
- **ddof** (*Union[int, bool], optional*) – Means Delta Degrees of Freedom. Default `0`.
  - If ddof is an integer, the divisor used in calculations is $N - ddof$, where N represents the number of elements.
  - If ddof is a boolean, `True` and `False` correspond to when ddof is an integer `1` and `0` respectively.
  - If ddof is 0, 1, True or False, the supported device is only Ascend and CPU. In other cases, the supported device is Ascend, GPU and CPU.
- **keepdims** (*bool, optional*) – Whether the output tensor has dim retained. Default `False`.

Returns

Tuple(std, mean) of 2 tensors.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1., 3, 4, 2],
...                           [4, 2, 5, 3],
...                           [5, 4, 2, 3]])
>>> # case 1: By default, compute the standard deviation and mean of all elements.
>>> mindspore.ops.std_mean(input)
(Tensor(shape=[], dtype=Float32, value= 1.21335),
 Tensor(shape=[], dtype=Float32, value= 3.16667))
>>>
>>> # case 2: Compute the standard deviation and mean along axis 0.
>>> mindspore.ops.std_mean(input, axis=0)

```

mindspore.ops.var

mindspore.ops.**var**(*input*, *axis=None*, *ddof=0*, *keepdims=False*)

Compute the variance of the tensor along a specified axis.

Parameters

- **input** (*Tensor[Number]*) – The input tensor.
- **axis** (*Union[int, tuple(int)], optional*) – Specify the axis for computation. If `None` , compute all elements in the *input* . Default `None` .
- **ddof** (*Union[int, bool], optional*) – Means Delta Degrees of Freedom. Default `0` .
  - If ddof is an integer, the divisor used in calculations is $N - ddof$, where N represents the number of elements.
  - If ddof is a boolean, `True` and `False` correspond to when ddof is an integer `1` and `0` respectively.
  - If ddof is 0, 1, True or False, the supported device is only Ascend and CPU. In other cases, the supported device is Ascend, GPU and CPU.
- **keepdims** (*bool, optional*) – Whether the output tensor has dim retained. Default `False` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1., 3, 4, 2],
...                           [4, 2, 5, 3],
...                           [5, 4, 2, 3]])
>>> # case 1: By default, compute the variance of all elements.

```

mindspore.ops.var_mean

mindspore.ops.**var_mean**(*input*, *axis=None*, *ddof=0*, *keepdims=False*)

Compute the variance and the mean of the tensor along a specified axis.

Parameters

- **input** (*Tensor[Number]*) – The input tensor.
- **axis** (*Union[int, tuple(int)], optional*) – Specify the axis for computation. If `None` , compute all elements in the *input* . Default `None` .
- **ddof** (*Union[int, bool], optional*) – Means Delta Degrees of Freedom. Default `0` .
  - If ddof is an integer, the divisor used in calculations is $N - ddof$, where N represents the number of elements.
  - If ddof is a boolean, `True` and `False` correspond to when ddof is an integer `1` and `0` respectively.
  - If ddof is 0, 1, True or False, the supported device is only Ascend and CPU. In other cases, the supported device is Ascend, GPU and CPU.
- **keepdims** (*bool, optional*) – Whether the output tensor has dim retained. Default `False` .

Returns

Tuple(var, mean) of 2 tensors.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1., 3, 4, 2],

```

2.2.3 Comparison Functions

API Name	Description	Supported Platforms
mindspore.ops.argsort	Return the indices that sort the tensor along the specified axis.	Ascend GPU CPU
mindspore.ops.approximate_equal	Return a boolean tensor where two tensors are element-wise equal within a tolerance.	Ascend GPU CPU
mindspore.ops.bucketize	Return the indices of the buckets to which each element in the input tensor belongs.	Ascend GPU CPU
mindspore.ops.eq	Compute the equivalence of the two inputs element-wise.	Ascend GPU CPU
mindspore.ops.equal	Compute the equivalence of the two inputs element-wise.	Ascend GPU CPU
mindspore.ops.ge	Compute the value of $input >= other$ element-wise.	Ascend GPU CPU
mindspore.ops.greater	Compute the value of $input > other$ element-wise.	Ascend GPU CPU
mindspore.ops.greater_equal	Compute the value of $input >= other$ element-wise.	Ascend GPU CPU
mindspore.ops.gt	Compute the value of $input > other$ element-wise.	Ascend GPU CPU
mindspore.ops.intopk	Return whether the elements in second input tensor exist among the top k elements of the first input tensor.	Ascend GPU CPU

continues on next page

Table 8 – continued from previous page

mindspore.ops.isclose	Return a boolean tensor where two tensors are element-wise equal within a tolerance.	Ascend GPU CPU
mindspore.ops.isfinite	Return a boolean tensor indicating which elements are finite.	Ascend GPU CPU
mindspore.ops.isinf	Return a boolean tensor indicating which elements are +/- inifnity.	Ascend CPU GPU
mindspore.ops.isnan	Return a boolean tensor indicating which elements are NaN.	Ascend GPU CPU
mindspore.ops.isneginf	Return a boolean tensor indicating which elements are negative infinity.	Ascend GPU CPU
mindspore.ops.isposinf	Return a boolean tensor indicating which elements are positive infinity.	Ascend GPU CPU
mindspore.ops.isreal	Return a boolean tensor indicating which elements are real.	GPU CPU
mindspore.ops.is_complex	Return a boolean tensor indicating which elements are complex.	Ascend GPU CPU
mindspore.ops.is_floating_point	If the data type of the tensor is a floating point data type, return True.	Ascend GPU CPU
mindspore.ops.le	Compute the value of *input* <= *other* element-wise.	Ascend GPU CPU
mindspore.ops.less	Compute the value of *input* < *other* element-wise.	Ascend GPU CPU
mindspore.ops.less_equal	Compute the value of *input* <= *other* element-wise.	Ascend GPU CPU
mindspore.ops.lt	Alias for mindspore.ops.less() .	Ascend GPU CPU
mindspore.ops.maximum	Compute the maximum of the two input tensors element-wise.	Ascend GPU CPU
mindspore.ops.minimum	Compute the minimum of the two input tensors element-wise.	Ascend GPU CPU
mindspore.ops.msort	Return a tensor obtained by sorting the input tensor in ascending order along its first dimension.	Ascend GPU CPU
mindspore.ops.ne	Compute the non-equivalence of two inputs element-wise.	Ascend GPU CPU
mindspore.ops.not_equal	Alias for mindspore.ops.ne() .	Ascend GPU CPU
mindspore.ops.searchsorted	Return the position indices where the elements can be inserted into the input tensor to maintain the increasing order of the input tensor.	Ascend GPU CPU
mindspore.ops.topk	Return the top *k* largest or smallest elements of the input tensor along a specified dimension.	Ascend GPU CPU

mindspore.ops.argsort

mindspore.ops.**argsort**(*input*, *axis=- 1*, *descending=False*)

Return the indices that sort the tensor along the specified axis.

Note: The Ascend backend only supports sorting the last dimension.

Parameters

- **input** (Tensor) – The input tensor.

- **axis** (*int*) −Specify the axis to sort along. Default `-1` .
- **descending** (*bool*) −Specify the sorting order (ascending or descending).

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: 1-dimensional sort
>>> input = mindspore.tensor([1, 3, 5, 4, 2, 1])
>>> mindspore.ops.argsort(input)
Tensor(shape=[6], dtype=Int32, value= [0, 5, 4, 1, 3, 2])
>>>
>>> # case 2: multi-dimensional sort
>>> input = mindspore.tensor([[2, 1, 3],
...                           [6, 4, 3]])
>>> mindspore.ops.argsort(input, axis=1)
Tensor(shape=[2, 3], dtype=Int32, value=
[[1, 0, 2],
 [2, 1, 0]])
>>> mindspore.ops.argsort(input, axis=1, descending=True)
Tensor(shape=[2, 3], dtype=Int32, value=
[[2, 0, 1],
 [0, 1, 2]])
```

mindspore.ops.approximate_equal

`mindspore.ops.`**`approximate_equal`**(*x*, *y*, *tolerance=1e-5*)

Return a boolean tensor where two tensors are element-wise equal within a tolerance.

Support implicit type conversion and type promotion.

Math function is defined as:

$$out_i = \begin{cases} \text{if } |x_i - y_i| < \text{tolerance}, & True \\ \text{if } |x_i - y_i| \geq \text{tolerance}, & False \end{cases}$$

Two infinite values and two NaN values are not considered equal.

Parameters

- **x** (`Tensor`) −The first input tensor.
- **y** (`Tensor`) −The second input tensor.
- **tolerance** (*float*) −The maximum deviation that two elements can be considered equal. Default `1e-5` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> mindspore.ops.approximate_equal(mindspore.tensor([1e6, 2e6, float("inf"), float("-inf"),␣
↪float("nan")]),
...                                 mindspore.tensor([1e6, 2e7, float("inf"), float("-inf"),␣
↪float("nan")]))
Tensor(shape=[6], dtype=Bool, value= [ True, False, False, False, False])
>>>
>>> mindspore.ops.approximate_equal(mindspore.tensor([1e6, 2e6, 3e6]),
...                                 mindspore.tensor([1.00001e6, 2.00002e6, 3.00009e6]),␣
↪tolerance=1e3)
Tensor(shape=[3], dtype=Bool, value= [ True,  True,  True])
>>>
>>> # If `x` and `y` have different datatypes, the lower precision data type will be␣
↪converted to the
    relatively highest precision data type.
>>> mindspore.ops.approximate_equal(mindspore.tensor([1, 2], mindspore.int32),
...                                 mindspore.tensor([1., 2], mindspore.float32))
Tensor(shape=[2], dtype=Bool, value= [ True,  True])
```

mindspore.ops.bucketize

mindspore.ops.**bucketize**(*input*, *boundaries*, *, *right=False*)

Return the indices of the buckets to which each element in the input tensor belongs. If *right* is `False`, the left boundary is open. For each element x in *input*, the returned index satisfies the following rules:

$$\begin{cases} boundaries[i-1] < x <= boundaries[i], & \text{if right} = False \\ boundaries[i-1] <= x < boundaries[i], & \text{if right} = True \end{cases}$$

Parameters

- **input** (Tensor) –The input tensor.
- **boundaries** (*list*) –A sorted ascending list of bucket boundary values.

Keyword Arguments

right (*bool, optional*) –if `False`, gets the lower bound index for each value in input from boundaries; If `True`, gets the upper bound index instead. Default: `False`.

Returns

Tensor

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[3, 6, 9], [3, 6, 9]])
>>> boundaries = [1., 3., 5., 7., 9.]
>>> output = mindspore.ops.bucketize(input, boundaries, right=True)
>>> output
Tensor(shape=[2, 3], dtype=Int32, value=
[[2, 3, 5],
 [2, 3, 5]])
```

mindspore.ops.eq

mindspore.ops.**eq**(*input*, *other*)

Compute the equivalence of the two inputs element-wise.

$$out_i = \begin{cases} \text{True, if } input_i = other_i \\ \text{False, if } input_i \neq other_i \end{cases}$$

Note:

- Support implicit type conversion.
- The input must be two Tensors, or a Tensor and a Scalar.
- The shapes of the inputs can be broadcasted to each other.

Parameters

- **input** (*Union[Tensor, Number]*) – The first input.
- **other** (*Union[Tensor, Number]*) – The second input.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> x = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.ops.eq(x, 2.0)
>>> print(output)
[False  True False]
>>> # case 2: The shape of two inputs are the same
>>> x = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> y = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.ops.eq(x, y)
>>> print(output)
[ True  True False]
```

mindspore.ops.equal

mindspore.ops.**equal**(*input*, *other*)

Compute the equivalence of the two inputs element-wise.

$$out_i = \begin{cases} \text{True, if } input_i = other_i \\ \text{False, if } input_i \neq other_i \end{cases}$$

Note:

- Support implicit type conversion.
- The input must be two Tensors, or a Tensor and a Scalar.
- The shapes of the inputs can be broadcasted to each other.

Parameters

- **input** (*Union[Tensor, Number]*) – The first input.
- **other** (*Union[Tensor, Number]*) – The second input.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.ops.equal(input, 2.0)
>>> print(output)
[False  True False]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.ops.equal(input, other)
>>> print(output)
[ True  True False]
```

mindspore.ops.ge

mindspore.ops.**ge**(*input*, *other*)

Compute the value of $input >= other$ element-wise.

Note:

- Support implicit type conversion.
- The inputs must be two tensors or one tensor and one scalar.

- When the inputs are two tensors, dtypes of them cannot be bool at the same time, and the shapes of them can be broadcast.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.
- Broadcasting is supported.
- If the input Tensor can be broadcast, the low dimension will be extended to the corresponding high dimension in another input by copying the value of the dimension.

$$out_i = \begin{cases} \text{True, if } input_i >= other_i \\ \text{False, if } input_i < other_i \end{cases}$$

Parameters

- **input** (*Union[Tensor, Number, bool]*) –The first input.
- **other** (*Union[Tensor, Number, bool]*) –The second input.

Returns

Tensor

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.ops.ge(input, 2.0)
>>> print(output)
[False  True True]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.ops.ge(input, other)
>>> print(output)
[ True  True False]
```

mindspore.ops.greater

mindspore.ops.**greater**(*input*, *other*)

Compute the value of $input > other$ element-wise.

Parameters

- **input** (*Union[Tensor, Number]*) –The first input.
- **other** (*Union[Tensor, Number]*) –The second input.

Returns

Tensor

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.ops.greater(input, 2.0)
>>> print(output)
[False False True]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.ops.greater(input, other)
>>> print(output)
[ False False False]
```

mindspore.ops.greater_equal

mindspore.ops.**greater_equal**(*input*, *other*)

Compute the value of $input >= other$ element-wise.

Parameters

- **input** (*Union[Tensor, Number]*) – The first input.
- **other** (*Union[Tensor, Number]*) – The second input.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.ops.greater_equal(input, 2.0)
>>> print(output)
[False  True True]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.ops.greater_equal(input, other)
>>> print(output)
[ True  True False]
```

mindspore.ops.gt

mindspore.ops.**gt**(*input*, *other*)

Compute the value of $input > other$ element-wise.

$$out_i = \begin{cases} \text{True, if } input_i > other_i \\ \text{False, if } input_i <= other_i \end{cases}$$

Note:

- Support implicit type conversion.
- The inputs must be two tensors or one tensor and one scalar.
- When the inputs are two tensors, dtypes of them cannot be bool at the same time, and the shapes of them can be broadcast.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.
- Broadcasting is supported.
- If the input Tensor can be broadcast, the low dimension will be extended to the corresponding high dimension in another input by copying the value of the dimension.

Parameters

- **input** (*Union[Tensor, number.Number, bool]*) – The first input.
- **other** (*Union[Tensor, number.Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.ops.gt(input, 2.0)
>>> print(output)
[False False True]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.ops.gt(input, other)
>>> print(output)
[ False False False]
```

mindspore.ops.intopk

mindspore.ops.**intopk**(*x1*, *x2*, *k*)

Return whether the elements in second input tensor exist among the top *k* elements of the first input tensor.

Parameters

- **x1** (Tensor) –The 2-D input tensor.
- **x2** (Tensor) –The 1-D input tensor, should satisfy $x2.shape[0] = x1.shape[0]$.
- **k** (*int*) –Top *k* elements.

Returns

A 1-D tensor whose data type is bool, has the same shape with *x2*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x1 = mindspore.tensor([[1, 8, 5, 2, 7], [4, 9, 1, 3, 5]], mindspore.float32)
>>> x2 = mindspore.tensor([1, 3], mindspore.int32)
>>> mindspore.ops.intopk(x1, x2, 3)
Tensor(shape=[2], dtype=Bool, value= [ True, False])
```

mindspore.ops.isclose

mindspore.ops.**isclose**(*input*, *other*, *rtol=1e-05*, *atol=1e-08*, *equal_nan=False*)

Return a boolean tensor where two tensors are element-wise equal within a tolerance. Math function is defined as:

$$|input - other| atol + rtol » |other|$$

Two Infinite values are considered equal if they have the same sign, Two NaN values are considered equal if *equal_nan* is True .

Parameters

- **input** (Tensor) –The first input tensor.
- **other** (Tensor) –The second input tensor.
- **rtol** (*Union[float, int, bool], optional*) –Relative tolerance. Default 1e-05 .
- **atol** (*Union[float, int, bool], optional*) –Absolute tolerance. Default 1e-08 .
- **equal_nan** (*bool, optional*) –Whether two NaNs are considered equal. Default False .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> mindspore.ops.isclose(mindspore.tensor([2e6, float("inf"), float("-inf"), float("inf"),␣
↪float("nan")]),
...                       mindspore.tensor([2e7, float("inf"), float("-inf"), float("-inf"),␣
↪float("nan")]))
Tensor(shape=[5], dtype=Bool, value= [False,  True,  True, False, False])
>>>
>>> mindspore.ops.isclose(mindspore.tensor([1e6, 2e6, 3e6]),
...                       mindspore.tensor([1.00008e6, 2.00008e7, 3.00008e8]), rtol=1e3)
Tensor(shape=[3], dtype=Bool, value= [ True,  True,  True])
>>>
>>> mindspore.ops.isclose(mindspore.tensor([1e6, 2e6, 3e6]),
...                       mindspore.tensor([1.00001e6, 2.00002e6, 3.00009e6]), atol=1e3)
Tensor(shape=[3], dtype=Bool, value= [ True,  True,  True])
>>> mindspore.ops.isclose(mindspore.tensor([float("nan"), 1, 2]),
...                       mindspore.tensor([float("nan"), 1, 2]), equal_nan=True)
Tensor(shape=[3], dtype=Bool, value= [ True,  True,  True])
```

mindspore.ops.isfinite

mindspore.ops.**isfinite**(*input*)

Return a boolean tensor indicating which elements are finite.

An element is considered finite if it is not `NaN` , `-INF` , or `INF` .

Parameters

input (`Tensor`) −The input tensor.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([-1, 3, float("inf"), float("-inf"), float("nan")])
>>> mindspore.ops.isfinite(input)
Tensor(shape=[5], dtype=Bool, value= [ True,  True, False, False, False])
```

mindspore.ops.isinf

mindspore.ops.**isinf**(*input*)

Return a boolean tensor indicating which elements are +/- inifnity.

> **Warning:**
>
> - This is an experimental API that is subject to change.
> - For Ascend, it is only supported on platforms above Atlas A2.

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend CPU GPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([-1, 3, float("inf"), float("-inf"), float("nan")])
>>> mindspore.ops.isinf(input)
Tensor(shape=[5], dtype=Bool, value= [False, False,  True,  True, False])
```

mindspore.ops.isnan

mindspore.ops.**isnan**(*input*)

Return a boolean tensor indicating which elements are NaN.

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([-1, 3, float("inf"), float("-inf"), float("nan")])
>>> mindspore.ops.isnan(input)
Tensor(shape=[5], dtype=Bool, value= [False, False, False, False,  True])
```

mindspore.ops.isneginf

mindspore.ops.**isneginf**(*input*)

Return a boolean tensor indicating which elements are negative infinity.

> **Warning:** For Ascend, it is only supported on platforms above Atlas A2.

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([-1, 3, float("inf"), float("-inf"), float("nan")])
>>> mindspore.ops.isneginf(input)
Tensor(shape=[5], dtype=Bool, value= [False, False, False,  True, False])
```

mindspore.ops.isposinf

mindspore.ops.**isposinf**(*input*)

Return a boolean tensor indicating which elements are positive infinity.

> **Warning:** For Ascend, it is only supported on platforms above Atlas A2.

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([-1, 3, float("inf"), float("-inf"), float("nan")])
>>> mindspore.ops.isposinf(input)
Tensor(shape=[5], dtype=Bool, value= [False, False,  True, False, False])
```

mindspore.ops.isreal

mindspore.ops.**isreal**(*input*)

Return a boolean tensor indicating which elements are real.

A complex value is considered real when its imaginary part is 0.

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([False, 0j, 1, 2.1, 1+2j])
>>> mindspore.ops.isreal(input)
Tensor(shape=[5], dtype=Bool, value= [ True,  True,  True,  True, False])
```

mindspore.ops.is_complex

mindspore.ops.**is_complex**(*input*)

Return a boolean tensor indicating which elements are complex.

Parameters

input (Tensor) – The input tensor.

Returns

Bool

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 1+1j, 2+2j], mindspore.dtype.complex64)
>>> mindspore.ops.is_complex(input)
True
>>>
>>> input = mindspore.tensor([1, 1+1j, 2+2j], mindspore.dtype.complex128)
>>> mindspore.ops.is_complex(input)
True
>>> input = mindspore.tensor([1, 1+1j, 2+2j], mindspore.dtype.int32)
>>> mindspore.ops.is_complex(input)
False
```

mindspore.ops.is_floating_point

mindspore.ops.**is_floating_point**(*input*)

If the data type of the tensor is a floating point data type, return True. Otherwise return False.

Parameters

input (Tensor) −The input Tensor.

Returns

Bool

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([False, 0j, 1, 2.1, 1+2j], mindspore.float64)
>>> mindspore.ops.is_floating_point(input)
True
>>>
>>> input = mindspore.tensor([False, 0j, 1, 2.1, 1+2j], mindspore.float32)
>>> mindspore.ops.is_floating_point(input)
True
>>>
>>> input = mindspore.tensor([False, 0j, 1, 2.1, 1+2j], mindspore.float16)
>>> mindspore.ops.is_floating_point(input)
True
>>>
>>> input = mindspore.tensor([False, 0j, 1, 2.1, 1+2j], mindspore.int32)
>>> mindspore.ops.is_floating_point(input)
False
```

mindspore.ops.le

mindspore.ops.**le**(*input*, *other*)

Compute the value of $input <= other$ element-wise.

$$out_i = \begin{cases} \text{True, if } input_i <= other_i \\ \text{False, if } input_i > other_i \end{cases}$$

Note:

- Support implicit type conversion.
- The inputs must be two tensors or one tensor and one scalar.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.

Parameters

- **input** (*Union[Tensor, Number, bool]*) – The first input.
- **other** (*Union[Tensor, Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.ops.le(input, 2.0)
>>> print(output)
[True  True False]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.ops.le(input, other)
>>> print(output)
[ True  True  True]
```

mindspore.ops.less

mindspore.ops.**less**(*input*, *other*)

Compute the value of $input < other$ element-wise.

$$out_i = \begin{cases} \text{True, if } input_i < other_i \\ \text{False, if } input_i >= other_i \end{cases}$$

Note: Support implicit type conversion.

Parameters

- **input** (*Union[Tensor, Number, bool]*) – The first input.
- **other** (*Union[Tensor, Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.ops.less(input, 2.0)
>>> print(output)
[True  False False]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.ops.less(input, other)
>>> print(output)
[ False  False  True]
```

mindspore.ops.less_equal

`mindspore.ops.`**`less_equal`**(*input*, *other*)

Compute the value of $input <= other$ element-wise.

$$out_i = \begin{cases} \text{True, if } input_i <= other_i \\ \text{False, if } input_i > other_i \end{cases}$$

Note:

- Support implicit type conversion.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.

Parameters

- **input** (*Union[Tensor, Number, bool]*) – The first input.
- **other** (*Union[Tensor, Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.ops.less_equal(input, 2.0)
>>> print(output)
[True  True False]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.ops.less_equal(input, other)
>>> print(output)
[ True  True  True]
```

mindspore.ops.lt

mindspore.ops.**lt**(*input*, *other*)

Alias for *mindspore.ops.less()*.

Supported Platforms:

Ascend GPU CPU

mindspore.ops.maximum

mindspore.ops.**maximum**(*input*, *other*)

Compute the maximum of the two input tensors element-wise.

$$output_i = \max(input_i, other_i)$$

Note:

- Inputs of *input* and *other* comply with the implicit type conversion rules to make the data types consistent.
- When the inputs are two tensors, dtypes of them cannot be bool at the same time, and the shapes of them could be broadcast.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.
- Broadcasting is supported.
- If one of the elements being compared is a NaN, then that element is returned.

Warning: If all inputs are scalar of integers. In Graph mode, the output will be Tensor of int32, while in PyNative mode, the output will be Tensor of int64.

Parameters

- **input** (*Union[Tensor, Number, bool]*) – The first input.
- **other** (*Union[Tensor, Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1 : same data type
>>> input = mindspore.tensor([1.0, 5.0, 3.0], mindspore.float32)
>>> other = mindspore.tensor([4.0, 2.0, 6.0], mindspore.float32)
>>> mindspore.ops.maximum(input, other)
Tensor(shape=[3], dtype=Float32, value= [ 4.00000000e+00,  5.00000000e+00,  6.00000000e+00])
>>>
>>> # case 2 : the data type is the one with higher precision or higher digits among the two␣
↪inputs.
>>> input = mindspore.tensor([1.0, 5.0, 3.0], mindspore.int64)
>>> other = mindspore.tensor([4.0, 2.0, 6.0], mindspore.float64)
>>> mindspore.ops.maximum(input, other)
Tensor(shape=[3], dtype=Float64, value= [ 4.00000000e+00,  5.00000000e+00,  6.00000000e+00])
```

mindspore.ops.minimum

`mindspore.ops.`**`minimum`**(*input*, *other*)

Compute the minimum of the two input tensors element-wise.

$$output_i = \min(input_i, other_i)$$

Note:

- Inputs of *input* and *other* comply with the implicit type conversion rules to make the data types consistent.
- When the inputs are two tensors, dtypes of them cannot be bool at the same time.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.
- Shapes of them are supposed to be broadcast.
- If one of the elements being compared is a NaN, then that element is returned.

Parameters

- **`input`** (*Union[Tensor, Number, bool]*) – The first input.
- **`other`** (*Union[Tensor, Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1 : same data type
>>> input = mindspore.tensor([1.0, 5.0, 3.0], mindspore.float32)
>>> other = mindspore.tensor([4.0, 2.0, 6.0], mindspore.float32)
>>> mindspore.ops.minimum(input, other)
Tensor(shape=[3], dtype=Float32, value= [ 1.00000000e+00,  2.00000000e+00,  3.00000000e+00])
>>>
>>> # case 2 : the data type is the one with higher precision or higher digits among the two␣
 ↪inputs.
>>> input = mindspore.tensor([1.0, 5.0, 3.0], mindspore.int64)
>>> other = mindspore.tensor([4.0, 2.0, 6.0], mindspore.float64)
>>> mindspore.ops.minimum(input, other)
Tensor(shape=[3], dtype=Float64, value= [ 1.00000000e+00,  2.00000000e+00,  3.00000000e+00])
```

mindspore.ops.msort

mindspore.ops.**msort**(*input*)

Return a tensor obtained by sorting the input tensor in ascending order along its first dimension.

ops.msort(input) is equivalent to *ops.sort(axis=0)(input)[0]*. See also `mindspore.ops.Sort()` for more details.

Parameters

input (Tensor) – The input tensor to sort.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[8, 2, 1],
...                           [5, 9, 3],
...                           [4, 6, 7]])
>>> mindspore.ops.msort(input)
Tensor(shape=[3, 3], dtype=Int64, value=
[[4, 2, 1],
 [5, 6, 3],
 [8, 9, 7]])
>>> # is equivalent to `ops.sort(axis=0)(input)[0]`
>>> mindspore.ops.sort(input, axis=0)[0]
Tensor(shape=[3, 3], dtype=Int64, value=
[[4, 2, 1],
 [5, 6, 3],
 [8, 9, 7]])
```

mindspore.ops.ne

mindspore.ops.**ne**(*input*, *other*)

Compute the non-equivalence of two inputs element-wise.

$$out_i = \begin{cases} \text{True, if } input_i \neq other_i \\ \text{False, if } input_i = other_i \end{cases}$$

Note:

- Support implicit type conversion.
- When the inputs are two tensors, the shapes of them could be broadcast.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.
- Broadcasting is supported.

Parameters

- **input** (*Union[Tensor, Number, bool]*) – The first input.
- **other** (*Union[Tensor, Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.ops.ne(input, 2.0)
>>> print(output)
[True False  True]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.ops.ne(input, other)
>>> print(output)
[ False False  True]
```

mindspore.ops.not_equal

mindspore.ops.**not_equal**(*input*, *other*)

Alias for *mindspore.ops.ne()* .

Supported Platforms:

Ascend GPU CPU

mindspore.ops.searchsorted

mindspore.ops.**searchsorted**(*sorted_sequence*, *values*, *, *out_int32=False*, *right=False*, *side=None*, *sorter=None*)

Return the position indices where the elements can be inserted into the input tensor to maintain the increasing order of the input tensor.

Parameters

- **sorted_sequence** (Tensor) –The input tensor. If *sorter* not provided, it must contain a increasing sequence on the innermost dimension.
- **values** (Tensor) –The value that need to be inserted.

Keyword Arguments

- **out_int32** (bool, *optional*) –Whether the output datatype will be mindspore.int32. if False , the output datatype will be mindspore.int64. Default False .
- **right** (bool, *optional*) –Search Strategy. If True , return the last suitable index found; if False , return the first such index. Default False .
- **side** (*str*, *optional*) –the same as right but preferred. left corresponds to False for *right* and right corresponds to True for *right*. An error will be reported if this parameter is set to left while *right* is True. Default None .
- **sorter** (Tensor, *optional*) –An index sequence sorted in ascending order along the innermost dimension of *sorted_sequence* , which is used together with the unsorted *sorted_sequence* . CPU and GPU only support None. Default None .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> sorted_sequence = mindspore.tensor([1, 2, 2, 3, 4, 5, 5])
>>> values = mindspore.tensor([2])
>>> mindspore.ops.searchsorted(sorted_sequence, values)
Tensor(shape=[1], dtype=Int64, value= [1])
```

mindspore.ops.topk

mindspore.ops.**topk**(*input*, *k*, *dim=None*, *largest=True*, *sorted=True*)

Return the top *k* largest or smallest elements of the input tensor along a specified dimension.

Warning:

- If sorted is set to False, it will use the aicpu operator, the performance may be reduced. In addition, due to different memory layout and traversal methods on different platforms, the display order of calculation results may be inconsistent when *sorted* is False.

Parameters

- **input** (Tensor) –The input tensor.
- **k** (*int*) –The number elements to be returned.
- **dim** (*int, optional*) –Specify the dimension for sorting. Default None .
- **largest** (*bool, optional*) –If True , return largest elements. If False , then return smallest elements. Default True .
- **sorted** (*bool, optional*) –If True , the elements are returned in descending order. If False , the obtained elements will not be sorted. Default True .

Returns

Tuple(values, indices) of 2 tensors.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[8, 2, 1],
...                           [5, 9, 3],
...                           [4, 6, 7]])
>>> # case 1: If dim is not given, the last dimension of the input is chosen.
>>> mindspore.ops.topk(input, 2)
(Tensor(shape=[3, 2], dtype=Int64, value=
 [[8, 2],
  [9, 5],
  [7, 6]]),
 Tensor(shape=[3, 2], dtype=Int32, value=
 [[0, 1],
  [1, 0],
  [2, 1]]))
>>> # case 2: when dim is 0:
>>> mindspore.ops.topk(input, 2, dim=0)
(Tensor(shape=[2, 3], dtype=Int64, value=
[[8, 9, 7],
 [5, 6, 3]]),
Tensor(shape=[2, 3], dtype=Int32, value=
[[0, 1, 2],
 [1, 2, 1]]))
```

(continues on next page)

(continued from previous page)

```
>>> # case 3: when largest is False, return smallest values.
>>> mindspore.ops.topk(input, 2, dim=0, largest=False)
(Tensor(shape=[2, 3], dtype=Int64, value=
 [[4, 2, 1],

```

2.2.4 Linear Algebraic Functions

API Name	Description	Supported Platforms
mindspore.ops.addbmm	Apply batch matrix multiplication to *batch1* and *batch2*, with a reduced add step and add *input* to the result.	Ascend GPU CPU
mindspore.ops.addmm	Multiply matrix *mat1* and matrix *mat2*.	Ascend GPU CPU
mindspore.ops.addr	Compute the outer product of two vector *vec1* and *vec2*, and add the resulting matrix to *x*.	Ascend GPU CPU
mindspore.ops.adjoint	Calculate the conjugation of tensor element-wise, and transpose the last two dimensions.	Ascend GPU CPU
mindspore.ops.baddbmm	Perform a batch matrix-matrix product of matrices in *batch1* and *batch2* , *input* is added to the final result.	Ascend GPU CPU
mindspore.ops.batch_dot	Computation of batch dot product between samples in two tensors containing batch dims.	Ascend GPU CPU
mindspore.ops.bmm	Perform a batch matrix-matrix product of matrices in input tensors.	Ascend GPU CPU
mindspore.ops.cholesky	Return the Cholesky decomposition of zero or more batch dimensions consisting of symmetric positive-definite matrices.	GPU CPU
mindspore.ops.cholesky_solve	Computes the solution of a set of linear equations with a positive definite matrix, according to its Cholesky decomposition factor *input2* .	Ascend GPU CPU
mindspore.ops.cond	Return the matrix norm or vector norm of a given tensor.	GPU CPU
mindspore.ops.dot	Computation a dot product of two input tensors.	Ascend GPU CPU
mindspore.ops.eigvals	Compute the eigenvalues of a square matrix.	Ascend CPU
mindspore.ops.geqrf	Perform a QR decomposition on the input tensor $A = QR$.	Ascend GPU CPU
mindspore.ops.ger	Calculate the outer product of two arrays *input* and *vec2*.	Ascend GPU CPU
mindspore.ops.inner	Return the dot product of two 1-D tensors.	Ascend GPU CPU
mindspore.ops.inverse	Compute the inverse of the input matrix.	GPU CPU
mindspore.ops.kron	Compute the Kronecker product of two tensors.	Ascend GPU CPU
mindspore.ops.logdet	Calculate log determinant of one or a batch of square matrices.	CPU
mindspore.ops.lu_solve	Compute the solution to a system of linear equations $Ay = b$.	Ascend GPU CPU

continues on next page

Table 9 – continued from previous page

mindspore.ops.lu_unpack	Unpack the LU decomposition returned by mindspore.scipy.linalg.lu_factor() into the P, L, U matrices.	GPU CPU
mindspore.ops.matmul	Return the matrix product of two tensors.	Ascend GPU CPU
mindspore.ops.matrix_band_part	Copy a tensor setting everything outside a central band in each innermost matrix to zero.	Ascend GPU CPU
mindspore.ops.matrix_solve	Solves systems of linear equations.	Ascend CPU
mindspore.ops.matrix_diag	Return a tensor with the contents in *x* as k[0]-th to k[1]-th diagonals of a matrix, with everything else padded with *padding_value* .	Ascend GPU CPU
mindspore.ops.matrix_diag_part	Return a tensor that retains the values of the specified diagonal while setting all other elements to zero.	Ascend GPU CPU
mindspore.ops.matrix_set_diag	Return a tensor by replacing the elements on the k[0]-th to k[1]-th diagonals of the matrix *x* with the values from the input *diagonal* .	Ascend GPU CPU
mindspore.ops.mm	Returns the matrix product of two arrays.	Ascend GPU CPU
mindspore.ops.mv	Multiplies matrix *mat* and vector *vec*.	Ascend GPU CPU
mindspore.ops.outer	Compute outer product of two tensors.	Ascend GPU CPU
mindspore.ops.orgqr	Compute the first *N* columns of a product of Householder matrices.	Ascend GPU CPU
mindspore.ops.ormqr	Calculates the product of a matrix *other* and a matrix Q (represented by Householder vectors *input* and Householder reflection coefficients *tau*).	GPU
mindspore.ops.pinv	Computes the (Moore-Penrose) pseudo-inverse of a matrix.	CPU
mindspore.ops.svd	Computes the singular value decompositions of one or more matrices.	Ascend GPU CPU
mindspore.ops.slogdet	Computes the sign and the log of the absolute value of the determinant of one or more square matrices.	Ascend GPU CPU
mindspore.ops.trace	Return the sum of the elements along the diagonal of the input tensor.	Ascend GPU CPU
mindspore.ops.tensor_dot	Compute the tensor dot product along the specified axes.	Ascend GPU CPU
mindspore.ops.vander	Generates a Vandermonde matrix.	Ascend GPU CPU
mindspore.ops.vecdot	Calculates the dot product of two batches of vectors along the specified dimension.	Ascend GPU CPU

mindspore.ops.addbmm

mindspore.ops.**addbmm**(*input*, *batch1*, *batch2*, *, *beta=1*, *alpha=1*)

Apply batch matrix multiplication to *batch1* and *batch2*, with a reduced add step and add *input* to the result.

Note:

- *batch1* and *batch2* must be 3-D tensors each containing the same number of matrices.
- When batch1 is a (C, W, T) tensor and batch2 is a (C, T, H) tensor, input must be broadcastable with (W, H) tensor, and out will be a (W, H) tensor.
- If *beta* is 0, then *input* will be ignored.

$$output = \beta input + \alpha(\sum_{i=0}^{b-1} batch1_i @ batch2_i)$$

Parameters

- **input** (Tensor) –The input tensor.
- **batch1** (Tensor) –The first batch of tensor to be multiplied.
- **batch2** (Tensor) –The second batch of tensor to be multiplied.

Keyword Arguments

- **beta** (*Union[int, float], optional*) –Scale factor for *input*. Default 1 .
- **alpha** (*Union[int, float], optional*) –Scale factor for (*batch1* @ *batch2*). Default 1 .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> m = mindspore.ops.ones((3, 3))
>>> arr1 = mindspore.tensor([[8., 7., 6.], [5., 4., 3.], [2., 1., 0.]])
>>> arr2 = mindspore.tensor([[5., 4., 3.], [2., 1., 0.], [8., 7., 6.]])
>>> output = mindspore.ops.addbmm(m, arr1, arr2)
>>> print(output)
[[172. 136. 100.]
 [172. 136. 100.]
 [172. 136. 100.]]
```

mindspore.ops.addmm

mindspore.ops.**addmm**(*input*, *mat1*, *mat2*, *, *beta=1*, *alpha=1*)

Multiply matrix *mat1* and matrix *mat2*. The matrix *input* is added to the final result.

Note:

- If *beta* is 0, then *input* will be ignored.

$$output = \beta input + \alpha(mat1 @ mat2)$$

Parameters

- **input** (Tensor) –The input tensor.
- **mat1** (Tensor) –The first tensor to be multiplied.
- **mat2** (Tensor) –The second tensor to be multiplied.

Keyword Arguments

- **beta** (*Union[int, float], optional*) –Scale factor for *input*. Default 1 .

- **alpha** (*Union[int, float], optional*) –Scale factor for (*mat1* @ *mat2*) . Default 1 .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> m = mindspore.ops.ones((3, 3))
>>> arr1 = mindspore.tensor([[8., 7., 6.], [5., 4., 3.], [2., 1., 0.]])
>>> arr2 = mindspore.tensor([[5., 4., 3.], [2., 1., 0.], [8., 7., 6.]])
>>> output = mindspore.ops.addmm(m, arr1, arr2)
>>> print(output)
[[103.  82.  61.]
 [ 58.  46.  34.]
 [ 13.  10.   7.]]
```

mindspore.ops.addr

mindspore.ops.**addr**(*x*, *vec1*, *vec2*, *, *beta=1*, *alpha=1*)

Compute the outer product of two vector *vec1* and *vec2*, and add the resulting matrix to *x*.

Note:

- Given *vec1* and *vec2* of sizes N and M, *x* must be able to broadcast to a matrix of shape (N, M), and out will be a matrix of shape (N, M) .
- Setting *beta* to 0 will exclude *x* from the computation.

$$output = x + (vec1vec2)$$

Parameters

- **x** (Tensor) –Vector to be added.
- **vec1** (Tensor) –The first tensor to be multiplied.
- **vec2** (Tensor) –The second tensor to be multiplied.

Keyword Arguments

- **beta** (*scalar[int, float, bool], optional*) –Scale factor for *x* Default 1 .
- **alpha** (*scalar[int, float, bool], optional*) –Scale factor for (*vec1* ⊗ *vec2*). Default 1 .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[2., 2.], [3., 2.], [3., 4.]])
>>> vec1 = mindspore.tensor([2., 3., 2.])
>>> vec2 = mindspore.tensor([3., 4.])
>>> output = mindspore.ops.addr(x, vec1, vec2)
>>> print(output)
[[ 8. 10.]
 [12. 14.]
 [ 9. 12.]]
```

mindspore.ops.adjoint

mindspore.ops.**adjoint**(*x*)

Calculate the conjugation of tensor element-wise, and transpose the last two dimensions.

Parameters

x (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor(([[0. + 0.j, 1. + 1.j], [2. + 2.j, 3. + 3.j]]), mindspore.
↪complex128)
>>> mindspore.ops.adjoint(x)
Tensor(shape=[2, 2], dtype=Complex128, value=
[[0-0j, 2-2j],
 [1-1j, 3-3j]])
```

mindspore.ops.baddbmm

mindspore.ops.**baddbmm**(*input*, *batch1*, *batch2*, *beta=1*, *alpha=1*)

Perform a batch matrix-matrix product of matrices in *batch1* and *batch2* , *input* is added to the final result.

Note:

- *batch1* and *batch2* must be 3-D tensors each containing the same number of matrices.
- When batch1 is a (C, W, T) tensor and batch2 is a (C, T, H) tensor, input must be broadcastable with (C, W, H) tensor, and out will be a (C, W, H) tensor.
- If *beta* is 0, then *input* will be ignored.
- *beta* and *alpha* must be integers when inputs of type not FloatTensor.

$$\text{out}_i = \beta\text{input}_i + \alpha(\text{batch1}_i \text{ @ } \text{batch2}_i)$$

Parameters

- **input** (Tensor) –The input tensor.
- **batch1** (Tensor) –The first batch of matrices to be multiplied.
- **batch2** (Tensor) –The second batch of matrices to be multiplied.
- **beta** (*Union[float, int], optional*) –Scale factor for *input*. Default 1 .
- **alpha** (*Union[float, int], optional*) –Scale factor for (*batch1* @ *batch2*). Default 1 .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.ops.ones((3, 3))
>>> batch1 = mindspore.tensor([[8., 7., 6.], [5., 4., 3.], [2., 1., 0.]])
>>> batch2 = mindspore.tensor([[5., 4., 3.], [2., 1., 0.], [8., 7., 6.]])
>>> output = mindspore.ops.baddbmm(input, batch1, batch2)
>>> print(output)
[[103.  82.  61.]
 [ 58.  46.  34.]
 [ 13.  10.   7.]]
```

mindspore.ops.batch_dot

mindspore.ops.**batch_dot**(*x1*, *x2*, *axes=None*)

Computation of batch dot product between samples in two tensors containing batch dims.

Note:

- *x1* or *x2* first dimension is batch size. Datatype must be float32 and the rank must be greater than or equal to 2.

$$output = x1[batch, :] \text{ů} x2[batch, :]$$

Parameters

- **x1** (Tensor) –The first input tensor.
- **x2** (Tensor) –The second input tensor.
- **axes** (*Union[int, tuple(int), list(int)]*) –Specify the axes for computation. Default None .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> # case 1: axes is a tuple(axes of `x1` , axes of `x2` )
>>> x1 = mindspore.ops.ones([2, 2, 3])
>>> x2 = mindspore.ops.ones([2, 3, 2])
>>> axes = (-1, -2)
>>> output = mindspore.ops.batch_dot(x1, x2, axes)
>>> print(output)
[[[3. 3.]
  [3. 3.]]
 [[3. 3.]
  [3. 3.]]]
>>> print(output.shape)
(2, 2, 2)
>>> x1 = mindspore.ops.ones([2, 2], mindspore.float32)
>>> x2 = mindspore.ops.ones([2, 3, 2], mindspore.float32)
>>> axes = (1, 2)
>>> output = mindspore.ops.batch_dot(x1, x2, axes)
>>> print(output)
[[2. 2. 2.]
 [2. 2. 2.]]
>>> print(output.shape)
(2, 3)
>>>
>>> # case 2: axes is None
>>> x1 = mindspore.ops.ones([6, 2, 3, 4], mindspore.float32)
>>> x2 = mindspore.ops.ones([6, 5, 4, 8], mindspore.float32)
>>> output = mindspore.ops.batch_dot(x1, x2)
>>> print(output.shape)
(6, 2, 3, 5, 8)
>>>
>>> # case 3: axes is a int data.
>>> x1 = mindspore.ops.ones([2, 2, 4])
>>> x2 = mindspore.ops.ones([2, 5, 4, 5])
>>> output = mindspore.ops.batch_dot(x1, x2, 2)
>>> print(output.shape)
(2, 2, 5, 5)
```

mindspore.ops.bmm

`mindspore.ops.`**`bmm`**(*input_x*, *mat2*)

Perform a batch matrix-matrix product of matrices in input tensors.

$$\text{output}[..., :, :] = \text{matrix}(input_x[..., :, :]) * \text{matrix}(mat2[..., :, :])$$

The dim of *input_x* can not be less than *3* and the dim of *mat2* can not be less than *2*.

Parameters

- **`input_x`** (`Tensor`) −The first tensor to be multiplied.
- **`mat2`** (`Tensor`) −The second tensor to be multiplied.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input_x = mindspore.ops.arange(24, dtype=mindspore.float32).reshape(2, 4, 1, 3)
>>> mat2 = mindspore.ops.arange(72, dtype=mindspore.float32).reshape(2, 4, 3, 3)
>>> out = mindspore.ops.bmm(input_x, mat2)
>>> print(out)
[[[[  15.,   18.,   21.]],
  [[ 150.,  162.,  174.]],
  [[ 447.,  468.,  489.]],
  [[ 906.,  936.,  966.]]],
 [[[1527., 1566., 1605.]],
  [[2310., 2358., 2406.]],
  [[3255., 3312., 3369.]],
  [[4362., 4428., 4494.]]]]
```

mindspore.ops.cholesky

`mindspore.ops.`**`cholesky`**(*input_x*, *upper=False*)

Return the Cholesky decomposition of zero or more batch dimensions consisting of symmetric positive-definite matrices.

If *upper* is *True*, return an upper-triangular matrix, U, and the decomposition has the form:

$$A = U^T U$$

If *upper* is *False*, return a lower-triangular matrix, L, and the decomposition has the form:

$$A = LL^T$$

where A is the symmetric positive-definite matrix.

Parameters

- **`input_x`** (`Tensor`) −The input tensor of shape $(*, N, N)$, where $*$ is batch dimensions. In the above formula, A .
- **`upper`** (*`bool, optional`*) −Return an upper-triangular matrix or not. Default: `False` .

Returns

Tensor

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import mindspore
>>> input_x = mindspore.tensor([[1.0, 1.0], [1.0, 2.0]])
>>> output = mindspore.ops.cholesky(input_x, upper=False)
>>> print(output)
[[1. 0.]
 [1. 1.]]
```

mindspore.ops.cholesky_solve

mindspore.ops.**cholesky_solve**(*input*, *input2*, *upper=False*)

Computes the solution of a set of linear equations with a positive definite matrix, according to its Cholesky decomposition factor *input2* .

If *upper* is set to `True` and *input2* is upper triangular, the output tensor is that:

$$output = (input2^T * input2)^{-1} input$$

If *upper* is set to `False` and *input2* is lower triangular, the output is that:

$$output = (input2 * input2^T)^{-1} input$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (`Tensor`) –The input tensor of shape $(*, N, M)$.
- **input2** (`Tensor`) –The tensor of shape $(*, N, N)$, composed of upper or lower triangular Cholesky factor.
- **upper** (*bool, optional*) –Whether to treat the Cholesky factor as an upper triangular matrix. Default `False` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input1 = mindspore.tensor([[1., 0., 0.], [0., 1., 0.], [0., 0., 1.]])
>>> input2 = mindspore.tensor([[2., 0., 0.], [4., 1., 0.], [-1., 1., 2.]])
>>> out = mindspore.ops.cholesky_solve(input1, input2, upper=False)
>>> print(out)
[[ 5.8125 -2.625   0.625 ]
 [-2.625   1.25   -0.25  ]
 [ 0.625  -0.25    0.25  ]]
```

mindspore.ops.cond

mindspore.ops.**cond**(*A*, *p=None*)

Return the matrix norm or vector norm of a given tensor.

p is the calculation mode of norm. The following norm modes are supported.

p	norm for matrices	norm for vectors
None (default)	2-norm (see below)	2-norm (see below)
'fro'	Frobenius norm	–not supported –
'nuc'	nuclear norm	–not supported –
inf	$max(sum(abs(x), dim = 1))$	$max(abs(x))$
-inf	$min(sum(abs(x), dim = 1))$	$min(abs(x))$
0	–not supported –	$sum(x! = 0)$
1	$max(sum(abs(x), dim = 0))$	as below
-1	$min(sum(abs(x), dim = 0))$	as below
2	largest singular value	as below
-2	smallest singular value	as below
other int or float	–not supported –	$sum(abs(x)^p)^{(1/p)}$

Note: Currently, complex numbers are not supported.

Parameters

- **A** (Tensor) –The input tensor which is zero or more batch dimensions.
- **p** (*Union[int, float, inf, -inf, 'fro', 'nuc'], optional*) –Norm's mode. Refer to the table above for behavior. Default None.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[1.0, 0.0, -1.0], [0.0, 1.0, 0.0], [1.0, 0.0, 1.0]])
>>> print(mindspore.ops.cond(x))
1.4142
>>> print(mindspore.ops.cond(x, 'fro'))
3.1622777
```

mindspore.ops.dot

mindspore.ops.**dot**(*input*, *other*)

Computation a dot product of two input tensors.

Note:

- Datatype of the input tensors must be float16 or float32, and the rank must be greater than or equal to 2.

Parameters

- **input** (Tensor) – The first input tensor.
- **other** (Tensor) – The second input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.ops.ones([2, 3])
>>> other = mindspore.ops.ones([1, 3, 2])
>>> output = mindspore.ops.dot(input, other)
>>> print(output)
[[[3. 3.]]
 [[3. 3.]]]
>>> print(output.shape)
(2, 1, 2)
>>> input = mindspore.ops.ones([1, 2, 3])
>>> other = mindspore.ops.ones([1, 3, 2])
>>> output = mindspore.ops.dot(input, other)
>>> print(output)
[[[[3. 3.]]
  [[3. 3.]]]]
>>> print(output.shape)
(1, 2, 1, 2)
>>> input = mindspore.ops.ones([1, 2, 3])
>>> other = mindspore.ops.ones([2, 3, 2])
>>> output = mindspore.ops.dot(input, other)
>>> print(output)
[[[[3. 3.]
   [3. 3.]]
  [[3. 3.]
   [3. 3.]]]]
>>> print(output.shape)
(1, 2, 2, 2)
>>> input = mindspore.ops.ones([3, 2, 3])
>>> other = mindspore.ops.ones([2, 1, 3, 2])
>>> output = mindspore.ops.dot(input, other)
>>> print(output)
```

(continues on next page)

(continued from previous page)

```
[[[[[3. 3.]]
   [[3. 3.]]]
  [[[3. 3.]]
   [[3. 3.]]]]
 [[[[3. 3.]]
   [[3. 3.]]]
  [[[3. 3.]]
   [[3. 3.]]]]
 [[[[3. 3.]]
   [[3. 3.]]]
  [[[3. 3.]]
   [[3. 3.]]]]]
>>> print(output.shape)
(3, 2, 2, 1, 2)
```

mindspore.ops.eigvals

mindspore.ops.**eigvals**(*A*)

Compute the eigenvalues of a square matrix.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

A (Tensor) –Square matrices with shape $(*, N, N)$.

Returns

Tensor

Supported Platforms:

Ascend CPU

Examples

```
>>> import mindspore
>>> mindspore.ops.eigvals(mindspore.tensor([[1.0, 0.0], [0.0, 2.0]]))
Tensor(shape=[2], dtype=Complex64, value= [1+0j, 2+0j])
```

mindspore.ops.geqrf

mindspore.ops.**geqrf**(*input*)

Perform a QR decomposition on the input tensor $A = QR$.

The tensor is decomposed into the product of an orthogonal matrix Q and an upper triangular matrix R.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

input (Tensor) – The input tensor.

Returns

Tuple(*y*, *tau*) of 2 tensors.

- **y** (Tensor) - Store the matrices *Q* and *R* implicitly. The matrix *Q* (Householder vectors) is stored below the diagonal, and the elements of matrix *R* are stored on and above the diagonal.
- **tau** (Tensor) - Store the scaling factors of each Householder transformation (Householder reflection coefficients).

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[-2.0, -1.0], [1.0, 2.0]])
>>> y, tau = mindspore.ops.geqrf(input)
>>> print(y)
[[ 2.236068   1.7888544]
 [-0.236068   1.3416407]]
>>> print(tau)
[1.8944271 0.       ]
```

mindspore.ops.ger

mindspore.ops.**ger**(*input*, *vec2*)

Calculate the outer product of two arrays *input* and *vec2*.

Note: Currently Ascend does not support float64 data input.

Parameters

- **input** (Tensor) – The 1-D input tensor.
- **vec2** (Tensor) – The 1-D input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1., 2., 3., 4.])
>>> vec2 = mindspore.tensor([1., 2., 3.])
>>> output = mindspore.ops.ger(input, vec2)
>>> print(output)
[[ 1.  2.  3.]
 [ 2.  4.  6.]
 [ 3.  6.  9.]
 [ 4.  8. 12.]]
```

mindspore.ops.inner

mindspore.ops.**inner**(*input*, *other*)

Return the dot product of two 1-D tensors.

For higher dimensions, return a sum product over the last axis.

Note: If *input* or *other* is a Tensor scalar, *mindspore.ops.inner()* will be the same as *mindspore.ops.mul()* .

Parameters

- **input** (Tensor) –The first input.
- **other** (Tensor) –The second input.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1: Two 1D tensors
>>> input = mindspore.tensor([1., 2., 3.])
>>> y = mindspore.tensor([4., 5., 6.])
>>> mindspore.ops.inner(input, y)
Tensor(shape=[], dtype=Float32, value= 32)
>>> # case2: Tensor scalar and tensor
>>> input = mindspore.tensor([[[1., 2., 3.], [3., 2., 1.]], [[4., 5., 6.], [4., 5., 6.]]])
>>> y = mindspore.tensor(2.)
>>> output = mindspore.ops.inner(input, y)
>>> print(output)
[[[ 2.  4.  6.]
  [ 6.  4.  2.]]
 [[ 8. 10. 12.]
  [ 8. 10. 12.]]]
>>> # case3: Two tensors
>>> input = mindspore.tensor([[[1., 2., 3.], [3., 2., 1.]], [[4., 5., 6.], [4., 5., 6.]]])
```

(continues on next page)

(continued from previous page)

```
>>> y = mindspore.tensor([[2., 3., 4.], [4., 3., 2.]])
>>> output = mindspore.ops.inner(input, y)
>>> print(output)
[[[20. 16.]
  [16. 20.]]
 [[47. 43.]
  [47. 43.]]]
```

mindspore.ops.inverse

mindspore.ops.**inverse**(*input*)

Compute the inverse of the input matrix.

Note: The *input* must be at least two dimensions, and the size of the last two dimensions must be the same size. The matrix must be invertible. Dtype of complex numbers is not supported.

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> print(mindspore.ops.inverse(mindspore.tensor([[1., 2.], [3., 4.]])))
[[-2.   1. ]
 [ 1.5 -0.5]]
```

mindspore.ops.kron

mindspore.ops.**kron**(*input*, *other*)

Compute the Kronecker product of two tensors.

If the shape of *input* is (a_0 input a_1 input $\cdots$input a_n) and the shape of *other* is (b_0 input b_1 input $\cdots$input b_n) , the result will be ($a_0 * b_0$ input $a_1 * b_1$ input $\cdots$input $a_n * b_n$) .

$$(inputother)_{k_0,k_1,\ldots k_n} = input_{i_0,i_1,\ldots i_n} * other_{j_0,j_1,\ldots j_n},$$

where $k_t = i_t * b_t + j_t$ for $0 \leq t \leq n$.

Note: Supports real-valued and complex-valued inputs.

Parameters

- **input** (Tensor) –First input tensor.
- **other** (Tensor) –Second input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[0., 1., 2.], [3., 4., 5.]])
>>> other = mindspore.tensor([[-1., -2., -3.], [-4., -6., -8.]])
>>> output = mindspore.ops.kron(input, other)
>>> print(output)
[[  0.   0.   0.  -1.  -2.  -3.  -2.  -4.  -6.]
 [  0.   0.   0.  -4.  -6.  -8.  -8. -12. -16.]
 [ -3.  -6.  -9.  -4.  -8. -12.  -5. -10. -15.]
 [-12. -18. -24. -16. -24. -32. -20. -30. -40.]]
```

mindspore.ops.logdet

mindspore.ops.**logdet**(*input*)

Calculate log determinant of one or a batch of square matrices.

Parameters

input (Tensor) –The input tensor of shape $(*, N, N)$ where $*$ means batch dimensions.

Returns

Tensor

Supported Platforms:

CPU

Examples

```
>>> import mindspore
>>> a = mindspore.tensor([[[8., 9.], [1., 2.]], [[5., 6.], [3., 4.]]])
>>> mindspore.ops.logdet(a)
Tensor(shape=[2], dtype=Float32, value= [ 1.94591010e+00,  6.93146825e-01])
```

mindspore.ops.lu_solve

mindspore.ops.**lu_solve**(*b*, *LU_data*, *LU_pivots*)

Compute the solution to a system of linear equations $Ay = b$.

Note:

- *b* of shape $(*, m, k)$, *LU_data* of shape $(*, m, m)$, *LU_pivots* of shape $(*, m)$, where $*$ means batch dimensions.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **b** (Tensor) −Column vector *b* in the above equation.
- **LU_data** (Tensor) −LU decomposition. The *A* in the formula above.
- **LU_pivots** (Tensor) −Permutation matrix P of LU decomposition.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> b = mindspore.tensor([[1.], [3.], [3.]])
>>> LU_data = mindspore.tensor([[2., 1., 1.], [0.5, 1., 1.5], [0.5, 0., 2.5]])
>>> LU_pivots = mindspore.tensor(([2, 2, 3]), mindspore.int32)
>>> y = mindspore.ops.lu_solve(b, LU_data, LU_pivots)
>>> print(y)
[[ 1.9000001]
 [-1.4000001]
 [ 0.6      ]]
```

mindspore.ops.lu_unpack

mindspore.ops.**lu_unpack**(*LU_data*, *LU_pivots*, *unpack_data=True*, *unpack_pivots=True*)

Unpack the LU decomposition returned by *mindspore.scipy.linalg.lu_factor()* into the P, L, U matrices.

Note:

- *LU_data* of shape $(*, M, N)$, *LU_pivots* of shape $(*, min(M, N))$, where $*$ is batch dimensions.

Parameters

- **LU_data** (Tensor) −The packed LU factorization data, the rank is greater than or equal to 2.
- **LU_pivots** (Tensor) −The packed LU factorization pivots.

- **unpack_data** (*bool, optional*) – A flag indicating if the *LU_data* should be unpacked. If `False` , then the returned L and U are None. Default `True` .
- **unpack_pivots** (*bool, optional*) – A flag indicating if the *LU_pivots* should be unpacked into a permutation matrix P. If `False` , then the returned P is None. Default `True` .

Returns

Tuple of tensors(Pivots, L, U).

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import mindspore
>>> LU_data = mindspore.tensor([[[-0.3806, -0.4872,  0.5536],
...                              [-0.1287,  0.6508, -0.2396],
...                              [ 0.2583,  0.5239,  0.6902]],
...                             [[ 0.6706, -1.1782,  0.4574],
...                              [-0.6401, -0.4779,  0.6701],
...                              [ 0.1015, -0.5363,  0.6165]]])
>>> LU_pivots = mindspore.tensor(([[1, 3, 3], [2, 3, 3]]), mindspore.int32)
>>> pivots, L, U = mindspore.ops.lu_unpack(LU_data, LU_pivots)
>>> print(pivots)
[[[1. 0. 0.]
  [0. 0. 1.]
  [0. 1. 0.]]
 [[0. 0. 1.]
  [1. 0. 0.]
  [0. 1. 0.]]]
>>> print(L)
[[[ 1.       0.       0.]
  [-0.1287   1.       0.]
  [ 0.2583   0.5239   1.]]
 [[ 1.0000   0.       0.]
  [-0.6401   1.       0.]
  [ 0.1015  -0.5363   1.]]]
>>> print(U)
[[[-0.3806  -0.4872   0.5536]
  [ 0.       0.6508  -0.2396]
  [ 0.       0.       0.6902]]
 [[ 0.6706  -1.1782   0.4574]
  [ 0.      -0.4779   0.6701]
  [ 0.       0.       0.6165]]]
```

mindspore.ops.matmul

mindspore.ops.**matmul**(*input*, *other*)

Return the matrix product of two tensors.

Note:

- The dtype of *input* and *other* must be same.
- On Ascend, the rank of *input* or *other* must be between 1 and 6.

Parameters

- **input** (Tensor) – The first input tensor.
- **other** (Tensor) – The second input tensor.

Returns

Tensor or scalar

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> # case 1 : Reasonable application of broadcast mechanism.
>>> input = mindspore.ops.arange(24, dtype=mindspore.float32).reshape(2, 3, 4)
>>> other = mindspore.ops.arange(20, dtype=mindspore.float32).reshape(4, 5)
>>> output = mindspore.ops.matmul(input, other)
>>> print(output)
[[[  70,   76,   82,   88,   94],
  [ 190,  212,  234,  256,  278],
  [ 310,  348,  386,  424,  462]],
 [[ 430,  484,  538,  592,  646],
  [ 550,  620,  690,  760,  830],
  [ 670,  756,  842,  928, 1014]]]
>>>
>>> # case 2 : The rank of `input` is 1.
>>> input = mindspore.ops.ones(([1, 2]))
>>> other = mindspore.ops.ones(([2]))
>>> mindspore.ops.matmul(input, other)
Tensor(shape=[1], dtype=Float32, value= [ 2.00000000e+00])
```

mindspore.ops.matrix_band_part

mindspore.ops.**matrix_band_part**(*x*, *lower*, *upper*)

Copy a tensor setting everything outside a central band in each innermost matrix to zero.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **x** (Tensor) – The input tensor.
- **lower** (*Union[int, Tensor]*) – Number of subdiagonals to keep. If negative, keep entire lower triangle.
- **upper** (*Union[int, Tensor]*) – Number of superdiagonals to keep. If negative, keep entire upper triangle.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.ops.ones([2, 4, 4])
>>> output = mindspore.ops.matrix_band_part(x, 2, 1)
>>> print(output)
[[[1. 1. 0. 0.]
  [1. 1. 1. 0.]
  [1. 1. 1. 1.]
  [0. 1. 1. 1.]]
 [[1. 1. 0. 0.]
  [1. 1. 1. 0.]
  [1. 1. 1. 1.]
  [0. 1. 1. 1.]]]
```

mindspore.ops.matrix_solve

mindspore.ops.**matrix_solve**(*matrix*, *rhs*, *adjoint=False*)

Solves systems of linear equations.

$$matrix[..., M, M] * x[..., M, K] = rhs[..., M, K]$$
$$adjoint(matrix[..., M, M]) * x[..., M, K] = rhs[..., M, K]$$

> **Warning:** On GPU, if the matrix is irreversible, an error may be reported or an unknown result may be returned.

Parameters

- **matrix** (Tensor) – The first input tensor.
- **rhs** (Tensor) – The second input tensor.

- **adjoint** (*bool, optional*) –Indicating whether to solve with matrix or its (block-wise) adjoint. Default `False` .

Returns

Tensor

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore
>>> matrix = mindspore.tensor([[5., 4.], [3., 1.]])
>>> rhs = mindspore.tensor([[7.], [2.]])
>>> result = mindspore.ops.matrix_solve(matrix, rhs)
>>> print(result)
[[0.14285707]
 [1.5714287 ]]
```

mindspore.ops.matrix_diag

`mindspore.ops.`**`matrix_diag`**(*x*, *k=0*, *num_rows=- 1*, *num_cols=- 1*, *padding_value=0*, *align='RIGHT_LEFT'*)

Return a tensor with the contents in *x* as k[0]-th to k[1]-th diagonals of a matrix, with everything else padded with *padding_value* .

num_rows and *num_cols* are tensors type of int32 with only one value, which is -1, indicating that the innermost matrix of the output tensor is a square.

Parameters

- **x** (`Tensor`) –The input tensor.
- **k** (*`Union[int, Tensor], optional`*) –Diagonal offsets. Positive value means superdiagonal, and negative value means subdiagonals. When *k* is a pair of integers specifying the low and high ends of a matrix band. Default `0` .
- **num_rows** (*`Union[int, Tensor], optional`*) –The number of rows of the output tensor. Default `-1` .
- **num_cols** (*`Union[int, Tensor], optional`*) –The number of columns of the output tensor. Default `-1` .
- **padding_value** (*`Union[int, float, Tensor], optional`*) –The number to fill the area outside the specified diagonal band. Default `0` .
- **align** (*`str, optional`*) –specifies how superdiagonals and subdiagonals should be aligned. Supported values `"RIGHT_LEFT"` , `"LEFT_RIGHT"` , `"LEFT_LEFT"` , `"RIGHT_RIGHT"` . Default `"RIGHT_LEFT"` .
  - When set to "RIGHT_LEFT", the alignment of superdiagonals will be towards the right side (padding the row on the left), while subdiagonals will be towards the left side (padding the row on the right)
  - When set to "LEFT_RIGHT", the alignment of superdiagonals will be towards the left side (padding the row on the right), while subdiagonals will be towards the right side (padding the row on the left)
  - When set to "LEFT_LEFT", the alignment of both superdiagonals and subdiagonals will be towards the left side(padding the row on the right).
  - When set to "RIGHT_RIGHT", the alignment of both superdiagonals and subdiagonals will be towards the right side(padding the row on the left).

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[8., 9., 0.],
...                       [1., 2., 3.],
...                       [0., 4., 5.]])
>>> k = mindspore.tensor([-1, 1], mindspore.int32)
>>> padding_value = mindspore.tensor(11.)
>>> num_rows = mindspore.tensor(3, mindspore.int32)
>>> num_cols = mindspore.tensor(3, mindspore.int32)
>>> output = mindspore.ops.matrix_diag(x, k, num_rows, num_cols, padding_value, align='LEFT_
↪RIGHT')
>>> print(output)
[[ 1.  8. 11.]
 [ 4.  2.  9.]
 [11.  5.  3.]]
>>> print(output.shape)
(3, 3)
```

mindspore.ops.matrix_diag_part

`mindspore.ops.`**`matrix_diag_part`**(*x*, *k*, *padding_value*, *align='RIGHT_LEFT'*)

Return a tensor that retains the values of the specified diagonal while setting all other elements to zero.

Input *k* and *padding_value* must be const tensor when taking graph mode.

Parameters

- **x** (`Tensor`) –The input tensor with rank r, where r >= 2.
- **k** (*`Union[int, Tensor], optional`*) –Diagonal offsets. Positive value means superdiagonal, and negative value means subdiagonals. When *k* is a pair of integers specifying the low and high ends of a matrix band.
- **padding_value** (`Tensor`) –The number to fill the area outside the specified diagonal band.
- **align** (*`str, optional`*) –specifies how superdiagonals and subdiagonals should be aligned. Supported values `"RIGHT_LEFT"` , `"LEFT_RIGHT"` , `"LEFT_LEFT"` , `"RIGHT_RIGHT"` . Default `"RIGHT_LEFT"` .
  - When set to "RIGHT_LEFT", the alignment of superdiagonals will be towards the right side (padding the row on the left), while subdiagonals will be towards the left side (padding the row on the right)
  - When set to "LEFT_RIGHT", the alignment of superdiagonals will be towards the left side (padding the row on the right), while subdiagonals will be towards the right side (padding the row on the left)
  - When set to "LEFT_LEFT", the alignment of both superdiagonals and subdiagonals will be towards the left side(padding the row on the right).
  - When set to "RIGHT_RIGHT", the alignment of both superdiagonals and subdiagonals will be towards the right side(padding the row on the left).

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[1., 2., 3., 4.],
...                       [5., 6., 7., 8.],
...                       [9., 8., 7., 6.]])
>>> k = mindspore.tensor([1, 3], mindspore.int32)
>>> output = mindspore.ops.matrix_diag_part(x, k, mindspore.tensor(9.), align='RIGHT_LEFT')
>>> print(output)
[[9. 9. 4.]
 [9. 3. 8.]
 [2. 7. 6.]]
>>> print(output.shape)
(3, 3)
```

mindspore.ops.matrix_set_diag

mindspore.ops.**matrix_set_diag**(*x*, *diagonal*, *k=0*, *align='RIGHT_LEFT'*)

Return a tensor by replacing the elements on the k[0]-th to k[1]-th diagonals of the matrix *x* with the values from the input *diagonal* .

Parameters

- **x** (Tensor) −The input tensor with rank r, where r >= 2.
- **diagonal** (Tensor) −A diagonal tensor.
- **k** (*Union[int, Tensor], optional*) −Diagonal offsets. Positive value means superdiagonal, and negative value means subdiagonals. When *k* is a pair of integers specifying the low and high ends of a matrix band. Default 0 .
- **align** (*str, optional*) −specifies how superdiagonals and subdiagonals should be aligned. Supported values "RIGHT_LEFT" , "LEFT_RIGHT" , "LEFT_LEFT" , "RIGHT_RIGHT" . Default "RIGHT_LEFT" .
  - When set to "RIGHT_LEFT", the alignment of superdiagonals will be towards the right side (padding the row on the left), while subdiagonals will be towards the left side (padding the row on the right)
  - When set to "LEFT_RIGHT", the alignment of superdiagonals will be towards the left side (padding the row on the right), while subdiagonals will be towards the right side (padding the row on the left)
  - When set to "LEFT_LEFT", the alignment of both superdiagonals and subdiagonals will be towards the left side(padding the row on the right).
  - When set to "RIGHT_RIGHT", the alignment of both superdiagonals and subdiagonals will be towards the right side(padding the row on the left).

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[7., 7., 7., 7.],
...                       [7., 7., 7., 7.],
...                       [7., 7., 7., 7.]])
>>> diagonal = mindspore.tensor([[0., 9., 1.],
...                     [6., 5., 8.],
...                     [1., 2., 3.],
...                     [4., 5., 0.]])
>>> k = mindspore.tensor(([-1, 2]), mindspore.int32)
>>> align = 'RIGHT_LEFT'
>>> output = ops.matrix_set_diag(x, diagonal, k, align)
>>> print(output)
[[1. 6. 9. 7.]
 [4. 2. 5. 1.]
 [7. 5. 3. 8.]]
>>> print(output.shape)
(3, 4)
```

mindspore.ops.mm

mindspore.ops.**mm**(*input*, *mat2*)

Returns the matrix product of two arrays.

If *input* is a $(n \times m)$ tensor, *mat2* is a $(m \times p)$ tensor, *out* will be a $(n \times p)$ tensor.

Note:

- This function cannot support broadcasting. Refer to *mindspore.ops.matmul()* instead if you need a broadcastable function.
- On Ascend, float64 doesn't be supported.

Parameters

- **input** (Tensor) –The first matrix of matrix multiplication.
- **mat2** (Tensor) –The second matrix of matrix multiplication.

Returns

Tensor or scalar

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> out = mindspore.ops.mm(mindspore.ops.ones((2, 3)), mindspore.ops.ones((3, 4)))
>>> print(out.shape)
(2, 4)
```

mindspore.ops.mv

mindspore.ops.**mv**(*mat*, *vec*)

Multiplies matrix *mat* and vector *vec*.

If *mat* is a (N, M) tensor, *vec* is a 1-D M tensor, out will be a 1-D N tensor.

Parameters

- **mat** (Tensor) −Input matrix.
- **vec** (Tensor) −Input vector.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.mv(mindspore.tensor([[3., 4.], [1., 6.], [1., 3.]]), mindspore.
↪tensor([1., 2.]))
>>> print(output)
[11. 13. 7.]
```

mindspore.ops.outer

mindspore.ops.**outer**(*input*, *vec2*)

Compute outer product of two tensors.

If *input*' s length is n and *vec2*' s length is m , then output must be a matrix of shape (n, m) .

Note: This function does not broadcast.

Parameters

- **input** (Tensor) −The 1-D input tensor.
- **vec2** (Tensor) −The 1-D input tensor.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 2, 3])
>>> vec2 = mindspore.tensor([4, 5, 6])
>>> mindspore.ops.outer(input, vec2)
Tensor(shape=[3, 3], dtype=Int64, value=
[[ 4,  5,  6],
 [ 8, 10, 12],
 [12, 15, 18]])
```

mindspore.ops.orgqr

`mindspore.ops.`**`orgqr`**(*input*, *input2*)

Compute the first N columns of a product of Householder matrices.

Usually used to calculate the explicit representation of the orthogonal matrix Q returned by *mindspore.ops.Geqrf*.

Take the case of input without batch dimension as an example: Suppose input *input* is a matrix of size (M, N) after householder transformation. When the diagonal of *input* is set to 1, every column of lower triangular in *input* is denoted as w_j for j for $j = 1, \ldots, M$, this function returns the first N columns of the matrix

$$H_1 H_2 \ldots H_k \quad \text{with} \quad H_j = \mathrm{I}_M - \tau_j w_j w_j^{\mathrm{H}}$$

where I_M is the M-dimensional identity matrix. And when w is complex, w^{H} is the conjugate transpose, otherwise the transpose. The output matrix is the same size as the input matrix *input*. tau is corresponding to *input2*.

Parameters

- **input** (Tensor) −2-D or 3-D input tensor, householder vectors, shape $(*, M, N)$.
- **input2** (Tensor) −1-D or 2-D input tensor, householder reflection coefficients, shape $(*, K)$, where K is less than or equal to N, indicating.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[-2.0, -1.0], [1.0, 2.0]])
>>> y, tau = mindspore.ops.geqrf(input)
>>> mindspore.ops.orgqr(y, tau)
Tensor(shape=[2, 2], dtype=Float32, value=
[[-8.94427061e-01,  4.47213590e-01],
 [ 4.47213590e-01,  8.94427180e-01]])
```

mindspore.ops.ormqr

mindspore.ops.**ormqr**(*input*, *tau*, *other*, *left=True*, *transpose=False*)

Calculates the product of a matrix *other* and a matrix Q (represented by Householder vectors *input* and Householder reflection coefficients *tau*).

If *left* is True, computes Q * *other* , otherwise, compute *other* * Q.

Parameters

- **input** (Tensor) –The input tensor, shape $(*, mn, k)$, when *left* is True, mn equals to m, otherwise, mn equals to n.
- **tau** (Tensor) –The input tensor, shape $(*, min(mn, k))$.
- **other** (Tensor) –The input tensor, shape $(*, m, n)$.
- **left** (*bool, optional*) –The order of computation. Default `True` .
- **transpose** (*bool, optional*) –Whether the matrix Q is conjugate transposed or not. Default `False` .

Returns

Tensor

Supported Platforms:

`GPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor(([[-114.6, 10.9, 1.1], [-0.304, 38.07, 69.38], [-0.45, -0.17,␣
↪62]]),
...                           mindspore.float32)
>>> tau = mindspore.tensor(([1.55, 1.94, 3.0]), mindspore.float32)
>>> other = mindspore.tensor(([[-114.6, 10.9, 1.1],
...                            [-0.304, 38.07, 69.38],
...                            [-0.45, -0.17, 62]]), mindspore.float32)
>>> output = mindspore.ops.ormqr(input, tau, other)
>>> print(output)
[[  63.82713   -13.823125 -116.28614 ]
 [ -53.659264  -28.157839  -70.42702 ]
 [ -79.54292    24.00183   -41.34253 ]]
```

mindspore.ops.pinv

mindspore.ops.**pinv**(*x*, ***, *atol=None*, *rtol=None*, *hermitian=False*)

Computes the (Moore-Penrose) pseudo-inverse of a matrix.

This function is computed using SVD. If $x = U * S * V^T$,Than the pseudo-inverse of x is: $x^+ = V * S^+ * U^T$, S^+ is the reciprocal of each non-zero element on the diagonal of S, and zero remains in place. Batch matrices are supported. If x is a batch matrix, the output has the same batch dimension when atol or rtol is float. If atol or rtol is a Tensor, its shape must be broadcast to the singular value returned by x.svd . If x.shape is (B, M, N), and the shape of atol or rtol is (K, B), the output shape is (K, B, N, M). When the Hermitian is True, temporary support only real domain, x is treated as a real symmetric, so x is not checked internally, and only use the lower triangular part in the computations. When the singular value of x (or the norm of the eigenvalues when hermitian = True) that are below threshold $(max(atol, \sigma \cdot rtol)$, σ as the largest singular value or characteristic value), it is set to zero, and is not used in the computations. If rtol is not specified and x is a matrix of dimensions (M, N), then rtol is set to be

$rtol = max(M, N) * \varepsilon$, ε is the eps value of x.dtype. If rtol is not specified and atol specifies a value larger than zero, rtol is set to zero.

Note: This function uses svd internally, (or eigh , when *hermitian* = *True*). So it has the same problem as these functions. For details, see the warnings in svd() and eigh().

Parameters

x (Tensor) –The input tensor whose shape is $(*, M, N)$, * is zero or more batch dimensions. When *hermitian* is `True`, batch dimensions are not supported temporarily.

Keyword Arguments

- **atol** (float, Tensor) –The absolute tolerance value. Default `None` .
- **rtol** (float, Tensor) –The relative tolerance value. Default `None` .
- **hermitian** (bool) –Whether *x* is assumed to be symmetric if real. Default `False` .

Outputs:

A tensor whose shape is $(*, N, M)$, * is zero or more batch dimensions.

Supported Platforms:

`CPU`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[4., 0.], [0., 5.]], mindspore.float32)
>>> output = mindspore.ops.pinv(x)
>>> print(output)
[[0.25 0.  ]
 [0.   0.2 ]]
```

mindspore.ops.svd

mindspore.ops.**svd**(*input*, *full_matrices=False*, *compute_uv=True*)

Computes the singular value decompositions of one or more matrices.

If A is a matrix, the svd returns the singular values S, the left singular vectors U and the right singular vectors V. It meets:

$$A = U * diag(S) * V^T$$

Parameters

- **input** (Tensor) –The input tensor, shape is $(*, M, N)$.
- **full_matrices** (*bool, optional*) –If `True` , compute full-sized U and V. If `False`, compute only the leading P singular vectors, with P is the minimum of M and N. Default `False` .
- **compute_uv** (*bool, optional*) –If `True` , compute the left and right singular vectors. If `False`, compute only the singular values. Default `True` .

Returns

If compute_uv is `True` , a tuple(*s* , *u* , *v*) of tensors will be returned. Otherwise, only a single tensor -> *s* will be returned.

- *s* is the singular value tensor. The shape is $(*, P)$.
- *u* is the left singular tensor. If *compute_uv* is `False` , *u* will not be returned. The shape is $(*, M, P)$. If *full_matrices* is `True` , the shape will be $(*, M, M)$.
- *v* is the right singular tensor. If *compute_uv* is `False` , *v* will not be returned. The shape is $(*, N, P)$. If *full_matrices* is `True` , the shape will be $(*, N, N)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1, 2], [-4, -5], [2, 1]], mindspore.float32)
>>> s, u, v = mindspore.ops.svd(input, full_matrices=True, compute_uv=True)
>>> print(s)
[7.0652843 1.040081 ]
>>> print(u)
[[ 0.30821905 -0.48819482  0.81649697]
 [-0.90613353  0.11070572  0.40824813]
 [ 0.2896955   0.8656849   0.4082479 ]]
>>> print(v)
[[ 0.63863593  0.769509  ]
 [ 0.769509   -0.63863593]]
```

mindspore.ops.slogdet

`mindspore.ops.`**`slogdet`**(*input*)

Computes the sign and the log of the absolute value of the determinant of one or more square matrices.

Note: The type of output always be real-value, even *input* is complex.

Parameters

`input` (`Tensor`) −The input tensor, shape is $(..., M, M)$.

Returns

Tuple of 2 tensors which are sign and the log of the absolute value.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1., 2], [3, 4]])
>>> sign, value = mindspore.ops.slogdet(input)
>>> print(sign)
-1.0
>>> print(value)
0.6931472
>>> input = mindspore.tensor([[[-4.5, -1.5], [7.0, 6.0]], [[2.5, 0.5], [3.0, 9.0]]])
>>> sign, value = mindspore.ops.slogdet(input)
>>> print(sign)
[-1.  1.]
>>> print(value)
[2.8033605 3.0445223]
```

mindspore.ops.trace

mindspore.ops.**trace**(*input*)

Return the sum of the elements along the diagonal of the input tensor.

Note: Input must be matrix, and complex number is not supported at present.

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[0, 1, 2],
...                           [3, 4, 5],
...                           [6, 7, 8]])
>>> mindspore.ops.trace(input)
Tensor(shape=[], dtype=Int64, value= 12)
```

mindspore.ops.tensor_dot

mindspore.ops.**tensor_dot**(*x1*, *x2*, *axes*)

Compute the tensor dot product along the specified axes.

Parameters

- **x1** (Tensor) –Input tensor.
- **x2** (Tensor) –Input tensor.
- **axes** (*Union[int, tuple(int), tuple(tuple(int)), list(list(int))]*) –The number of dimensions to sum over. If an integer *k* is provided, then sum over the last *k* axes of *x1* and the first *k* axes of *x2*, in order. If a tuple or list is provided, then *axes[0]* specifies the axes of *x1* and *axes[1]* specifies the axes of *x2*.

Returns

Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import Tensor, ops
>>> import mindspore
>>> import numpy as np
>>> input_x1 = Tensor(np.ones(shape=[1, 2, 3]), mindspore.float32)
>>> input_x2 = Tensor(np.ones(shape=[3, 1, 2]), mindspore.float32)
>>> output = ops.tensor_dot(input_x1, input_x2, ((0,1),(1,2)))
>>> print(output)
[[2. 2. 2]
 [2. 2. 2]
 [2. 2. 2]]
```

mindspore.ops.vander

mindspore.ops.**vander**(*x*, *N=None*)

Generates a Vandermonde matrix. The columns of the output matrix are powers of the input vector. The i-th output column is the input vector raised element-wise to the power of $N - i - 1$.

Parameters

- **x** (Tensor) –The 1-D input tensor.
- **N** (*int, optional*) –Number of columns in the output. Default None, *N* will be assigned as $len(x)$.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1., 2., 3., 5.])
>>> output = mindspore.ops.vander(input)
>>> print(output)
[[  1.   1.   1.   1.]
 [  8.   4.   2.   1.]
 [ 27.   9.   3.   1.]
 [125.  25.   5.   1.]]
>>> output = mindspore.ops.vander(input, N=3)
>>> print(output)
[[ 1.  1.  1.]
 [ 4.  2.  1.]
 [ 9.  3.  1.]
 [25.  5.  1.]]
```

mindspore.ops.vecdot

mindspore.ops.**vecdot**(*x*, *y*, ***, *axis=- 1*)

Calculates the dot product of two batches of vectors along the specified dimension.

Support broadcasting.

The formula of calculation is as follows. $\bar{x_i}$ represents the conjugate for complex vectors, and $\bar{x_i}$ is the raw value for real vectors.

$$\sum_{i=1}^{n} \bar{x_i} y_i$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **x** (Tensor) −The first batch of tensors.
- **y** (Tensor) −The second batch of tensors.

Keyword Arguments

axis (int) −Specify the axis for computation. Default `-1` .

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Note: Currently, complex numbers are not supported on GPU.

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[1, 3], [5, 7], [9, 8]])
>>> y = mindspore.tensor([[4, 5], [6, 7], [3, 2]])
>>> mindspore.ops.vecdot(x, y)
Tensor(shape=[3], dtype=Int64, value= [19, 79, 43])
>>> mindspore.ops.vecdot(x, y, axis=0)
Tensor(shape=[2], dtype=Int64, value= [61, 80])
```

2.2.5 Spectral Functions

API Name	Description	Supported Platforms
mindspore.ops.bartlett_window	Bartlett window function.	Ascend GPU CPU
mindspore.ops.blackman_window	Blackman window function.	Ascend GPU CPU
mindspore.ops.hamming_window	Hamming window function.	Ascend GPU CPU
mindspore.ops.hann_window	Hann window function.	Ascend GPU CPU
mindspore.ops.kaiser_window	Kaiser window function.	Ascend GPU CPU

mindspore.ops.bartlett_window

mindspore.ops.**bartlett_window**(*window_length*, *periodic=True*, *, *dtype=None*)

Bartlett window function.

A triangular-shaped weighting function used for smoothing or frequency analysis of signals in digital signal processing.

$$w[n] = 1 - \left|\frac{2n}{N-1} - 1\right| = \begin{cases} \frac{2n}{N-1} & \text{if } 0 \le n \le \frac{N-1}{2} \\ 2 - \frac{2n}{N-1} & \text{if } \frac{N-1}{2} < n < N \end{cases},$$

where N is the full window size, and n is natural number less than N :[0, 1, ⋯, N-1].

Parameters

- **window_length** (Tensor) –The size of window.
- **periodic** (*bool, optional*) –If True , return a periodic window. If False, return a symmetric window. Default True .

Keyword Arguments

dtype (mindspore.dtype, *optional*) –The data type specified. Default None .

Returns

A 1-D tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> window_length = mindspore.tensor(5)
>>> output = mindspore.ops.bartlett_window(window_length)
>>> print(output)
[0.  0.4 0.8 0.8 0.4]
>>> output = mindspore.ops.bartlett_window(window_length, periodic=False)
>>> print(output)
[0.  0.5 1.  0.5 0. ]
```

mindspore.ops.blackman_window

mindspore.ops.**blackman_window**(*window_length*, *periodic=True*, ***, *dtype=None*)

Blackman window function.

Usually used to extract finite signal segment for FFT.

$$w[n] = 0.42 - 0.5cos(\frac{2\pi n}{N-1}) + 0.08cos(\frac{4\pi n}{N-1})$$

where N is the full window size, and n is natural number less than N :[0, 1, ⋯, N-1].

Parameters

- **window_length** (Tensor) –The size of window.
- **periodic** (*bool, optional*) –If `True` , return a periodic window. If `False`, return a symmetric window. Default `True` .

Keyword Arguments

dtype (mindspore.dtype, *optional*) –The data type specified. Default `None` .

Returns

A 1-D tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> window_length = mindspore.tensor(10)
>>> output = mindspore.ops.blackman_window(window_length)
>>> print(output)
[-2.9802322e-08  4.0212840e-02  2.0077014e-01  5.0978714e-01
  8.4922993e-01  1.0000000e+00  8.4922981e-01  5.0978690e-01
  2.0077008e-01  4.0212870e-02]
```

mindspore.ops.hamming_window

mindspore.ops.**hamming_window**(*window_length*, *periodic=True*, *alpha=0.54*, *beta=0.46*, ***, *dtype=None*)

Hamming window function.

$$w[n] = \alpha\beta\cos\left(\frac{2\pi n}{N-1}\right),$$

where N is the full window size, and n is natural number less than N :[0, 1, ⋯, N-1].

Parameters

- **window_length** (*int*) –The size of window.
- **periodic** (*bool, optional*) –If `True` , return a periodic window. If `False`, return a symmetric window. Default `True` .
- **alpha** (*float, optional*) –The coefficient α. Default `0.54` .
- **beta** (*float, optional*) –The coefficient β. Default `0.46` .

Keyword Arguments

dtype (mindspore.dtype, *optional*) –The data type specified. Default `None` .

Returns

A 1-D tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> output = mindspore.ops.hamming_window(5)
>>> print(output)
[0.08000001 0.3978522  0.9121478  0.9121478  0.3978522 ]
>>> output = mindspore.ops.hamming_window(5, periodic=False)
>>> print(output)
[0.08000001 0.54       1.         0.54       0.08000001]
```

mindspore.ops.hann_window

mindspore.ops.**hann_window**(*window_length*, *periodic=True*, ***, *dtype=None*)

Hann window function.

$$w(n) = \frac{1}{2} - \frac{1}{2}\cos\left(\frac{2\pi n}{M-1}\right), \qquad 0 \le n \le M-1$$

Parameters

- **window_length** (*int*) –The size of window.
- **periodic** (*bool, optional*) –If `True` , return a periodic window. If `False`, return a symmetric window. Default `True` .

Keyword Arguments

dtype (mindspore.dtype, *optional*) –The data type specified. Default None .

Returns

A 1-D tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.hann_window(5)
>>> print(output)
[0.        0.3454915 0.9045085 0.9045085 0.3454915]
>>> output = mindspore.ops.hann_window(5, periodic=False)
>>> print(output)
[0.  0.5 1.  0.5 0. ]
```

mindspore.ops.kaiser_window

mindspore.ops.**kaiser_window**(*window_length*, *periodic=True*, *beta=12.0*, ***, *dtype=None*)

Kaiser window function.

$$w(n) = \frac{I_0\left(\beta\sqrt{1-\frac{4n^2}{(M-1)^2}}\right)}{I_0(\beta)}$$

with

$$-\frac{M-1}{2} \leq n \leq \frac{M-1}{2}$$

where I_0 is the modified zeroth-order Bessel function.

Parameters

- **window_length** (*int*) –The size of window.
- **periodic** (*bool, optional*) –If True , return a periodic window. If False, return a symmetric window. Default True .
- **beta** (*float, optional*) –Shape parameter, when *beta* gets large, the window narrows. Default: 12.0 .

Keyword Arguments

dtype (mindspore.dtype, *optional*) –The data type specified. Default None .

Returns

A 1-D tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> output = mindspore.ops.kaiser_window(5)
>>> print(output)
[5.27734413e-05 1.01719688e-01 7.92939834e-01 7.92939834e-01
 1.01719688e-01]
>>> output = mindspore.ops.kaiser_window(5, periodic=False)
>>> print(output)
[5.27734413e-05 2.15672745e-01 1.00000000e+00 2.15672745e-01
 5.27734413e-05]
```

2.3 Neural Network Layer Functions

2.3.1 Neural Network

API Name	Description	Supported Platforms
mindspore.ops.adaptive_avg_pool1d	Applies a 1D adaptive average pooling over an input Tensor which can be regarded as a composition of 1D input planes.	Ascend GPU CPU
mindspore.ops.adaptive_avg_pool2d	Performs 2D adaptive average pooling on a multi-plane input signal.	Ascend GPU CPU
mindspore.ops.adaptive_avg_pool3d	Performs 3D adaptive average pooling on a multi-plane input signal.	Ascend GPU CPU
mindspore.ops.adaptive_max_pool1d	Applies a 1D adaptive maximum pooling over an input Tensor which can be regarded as a composition of 1D input planes.	Ascend GPU CPU
mindspore.ops.adaptive_max_pool2d	This operator applies a 2D adaptive max pooling to an input signal composed of multiple input planes.	Ascend GPU CPU
mindspore.ops.avg_pool1d	Applies a 1D average pooling over an input Tensor which can be regarded as a composition of 1D input planes.	Ascend GPU CPU
mindspore.ops.avg_pool2d	Applies a 2D average pooling over an input Tensor which can be regarded as a composition of 2D input planes.	Ascend GPU CPU
mindspore.ops.avg_pool3d	Applies a 3D average pooling over an input Tensor which can be regarded as a composition of 3D input planes.	Ascend GPU CPU
mindspore.ops.batch_norm	Batch Normalization for input data and updated parameters.	Ascend GPU CPU
mindspore.ops.bias_add	Returns the sum of the *input_x* and the *bias* Tensor.	Ascend GPU CPU
mindspore.ops.bidense	Applies bilinear dense connected layer for *input1* and *input2*.	Ascend GPU CPU
mindspore.ops.ctc_greedy_decoder	Performs greedy decoding on the logits given in inputs.	Ascend GPU CPU
mindspore.ops.conv1d	Applies a 1D convolution over an input tensor.	Ascend GPU
mindspore.ops.conv2d	Applies a 2D convolution over an input tensor.	Ascend GPU
mindspore.ops.conv3d	Applies a 3D convolution over an input tensor.	Ascend GPU

continues on next page

Table 11 – continued from previous page

mindspore.ops.deformable_conv2d	Given 4D tensor inputs *x*, *weight* and *offsets*, compute a 2D deformable convolution.	Ascend GPU CPU
mindspore.ops.dense	Applies the dense connected operation to the *input*.	Ascend GPU CPU
mindspore.ops.dropout	During training, randomly zeroes some of the elements of the input tensor with probability *p* from a Bernoulli distribution.	Ascend GPU CPU
mindspore.ops.dropout1d	During training, randomly zeroes some channels of the input tensor with probability p from a Bernoulli distribution(For a 3-dimensional tensor with a shape of NCL, the channel feature map refers to a 1-dimensional feature map with the shape of L).	Ascend GPU CPU
mindspore.ops.dropout2d	During training, randomly zeroes some channels of the input tensor with probability p from a Bernoulli distribution(For a 4-dimensional tensor with a shape of $NCHW$, the channel feature map refers to a 2-dimensional feature map with the shape of HW).	Ascend GPU CPU
mindspore.ops.dropout3d	During training, randomly zeroes some channels of the input tensor with probability p from a Bernoulli distribution(For a 5-dimensional tensor with a shape of $NCDHW$, the channel feature map refers to a 3-dimensional feature map with a shape of DHW).	Ascend GPU CPU
mindspore.ops.embedding	Retrieve the word embeddings in *weight* using indices specified in *input*.	Ascend
mindspore.ops.flatten	Flatten a tensor along dimensions from *start_dim* to *start_dim*.	Ascend GPU CPU
mindspore.ops.fold	Combines an array of sliding local blocks into a large containing tensor.	Ascend GPU CPU
mindspore.ops.fractional_max_pool3d	Applies the 3D FractionalMaxPool operation over *input*.	GPU CPU
mindspore.ops.fused_infer_attention_score	This is a FlashAttention function designed for both incremental and full inference scenarios.	Ascend
mindspore.ops.speed_fusion_attention	The interface is used for self-attention fusion computing.	Ascend
mindspore.ops.group_norm	Group Normalization over a mini-batch of inputs.	Ascend GPU CPU
mindspore.ops.layer_norm	Applies the Layer Normalization on the mini-batch input.	Ascend
mindspore.ops.lp_pool1d	Applying 1D LPPooling operation on an input Tensor can be regarded as forming a 1D input plane.	Ascend GPU CPU
mindspore.ops.lp_pool2d	Applying 2D LPPooling operation on an input Tensor can be regarded as forming a 2D input plane.	Ascend GPU CPU
mindspore.ops.lrn	Local Response Normalization.	GPU CPU
mindspore.ops.max_pool2d	Performs a 2D max pooling on the input Tensor.	Ascend GPU CPU
mindspore.ops.max_pool3d	Performs a 3D max pooling on the input Tensor.	Ascend GPU CPU
mindspore.ops.max_unpool1d	Computes the inverse of *max_pool1d*.	Ascend GPU CPU
mindspore.ops.max_unpool2d	Computes the inverse of *max_pool2d*.	Ascend GPU CPU
mindspore.ops.max_unpool3d	Computes the inverse of mindspore.ops.max_pool3d().	Ascend GPU CPU
mindspore.ops.moe_token_permute	Permute the *tokens* based on the *indices*.	Ascend

continues on next page

Table 11 – continued from previous page

mindspore.ops.moe_token_unpermute	Unpermute a tensor of permuted tokens based on sorted indices, and optionally merge the tokens with their corresponding probabilities.	Ascend
mindspore.ops.incre_flash_attention	The interface for incremental inference.	Ascend
mindspore.ops.prompt_flash_attention	The interface for fully inference.	Ascend
mindspore.ops.flash_attention_score	Implement self-attention calculations in training scenarios.	Ascend
mindspore.ops.rms_norm	The RmsNorm(Root Mean Square Layer Normalization) operator is a normalization operation.	Ascend
mindspore.ops.unfold	Extracts sliding local blocks from a batched input tensor.	Ascend GPU CPU

mindspore.ops.adaptive_avg_pool1d

mindspore.ops.**adaptive_avg_pool1d**(*input*, *output_size*)

Applies a 1D adaptive average pooling over an input Tensor which can be regarded as a composition of 1D input planes.

Typically, the input is of shape (N, C, L_{in}), adaptive_avg_pool1d outputs regional average in the L_{in}-dimension. The output is of shape (N, C, L_{out}), where L_{out} is defined by *output_size*.

Note: L_{in} must be divisible by *output_size*.

Parameters

- **input** (Tensor) –Tensor of shape (N, C, L_{in}), with float16 or float32 data type.
- **output_size** (*int*) –the target output size L_{out}.

Returns

Tensor of shape (N, C, L_{out}), has the same type as *input*.

Raises

- **TypeError** –If *output_size* is not an int.
- **TypeError** –If *input* is neither float16 nor float32.
- **ValueError** –If *output_size* is less than 1.
- **ValueError** –If length of shape of *input* is not equal to 3.
- **ValueError** –If the last dimension of *input* is smaller than *output_size*.
- **ValueError** –If the last dimension of *input* is not divisible by *output_size*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.random.randint(0, 10, [1, 3, 6]), mindspore.float32)
>>> output = ops.adaptive_avg_pool1d(input, output_size=2)
>>> print(output.shape)
(1, 3, 2)
```

mindspore.ops.adaptive_avg_pool2d

mindspore.ops.**adaptive_avg_pool2d**(*input*, *output_size*)

Performs 2D adaptive average pooling on a multi-plane input signal. That is, for any input size, the size of the specified output is H x W. The number of output features is equal to the number of input features.

The input and output data format can be "NCHW" and "CHW". N is the batch size, C is the number of channels, H is the feature height, and W is the feature width.

For adaptive average pooling for 2D:

$$
\begin{aligned}
h_{start} &= floor(i * H_{in}/H_{out}) \\
h_{end} &= ceil((i+1) * H_{in}/H_{out}) \\
w_{start} &= floor(j * W_{in}/W_{out}) \\
w_{end} &= ceil((j+1) * W_{in}/W_{out}) \\
Output(i,j) &= \frac{\sum Input[h_{start}:h_{end}, w_{start}:w_{end}]}{(h_{end}-h_{start})*(w_{end}-w_{start})}
\end{aligned}
$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input of adaptive_avg_pool2d, which is a 3D or 4D tensor, with float16, float32 or float64 data type.
- **output_size** (*Union[int, tuple]*) –The target output size. *output_size* can be a tuple (H, W), or an int H for (H, H). H and W can be int or None. If it is None, it means the output size is the same as the input size.

Returns

Tensor, with the same type as the *input*.

Shape of the output is *input_shape[:len(input_shape) - len(out_shape)] + out_shape*.

$$
out\_shape = \begin{cases}
input\_shape[-2] + output\_size[1], & \text{if } output\_size \text{ is (None, w);} \\
output\_size[0] + input\_shape[-1], & \text{if } output\_size \text{ is (h, None);} \\
input\_shape[-2:], & \text{if } output\_size \text{ is (None, None);} \\
(h, h), & \text{if } output\_size \text{ is h;} \\
(h, w), & \text{if } output\_size \text{ is (h, w)}
\end{cases}
$$

Raises

- **ValueError** –If *output_size* is a tuple and the length of *output_size* is not 2.

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If dtype of *input* is not float16, float32 or float64.
- **ValueError** – If the dimension of *input* is less than or equal to the dimension of *output_size*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> # case 1: output_size=(None, 2)
>>> input = Tensor(np.array([[[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]],

mindspore.ops.adaptive_avg_pool3d

mindspore.ops.**adaptive_avg_pool3d**(*input*, *output_size*)

Performs 3D adaptive average pooling on a multi-plane input signal. That is, for any input size, the size of the specified output is (D, H, W). The number of output features is equal to the number of input planes.

Suppose the last 3 dimension size of x is (inD, inH, inW), the last 3 dimension size of output is $(outD, outH, outW)$.

$$
\begin{aligned}
&\forall \quad od \in [0, outD-1], oh \in [0, outH-1], ow \in [0, outW-1] \\
&output[od, oh, ow] = \\
&\qquad mean(x[istartD : iendD+1, istartH : iendH+1, istartW : iendW+1]) \\
&where, \\
&\qquad istartD = \left\lceil \frac{od * inD}{outD} \right\rceil \\
&\qquad iendD = \left\lfloor \frac{(od+1) * inD}{outD} \right\rfloor \\
&\qquad istartH = \left\lceil \frac{oh * inH}{outH} \right\rceil \\
&\qquad iendH = \left\lfloor \frac{(oh+1) * inH}{outH} \right\rfloor \\
&\qquad istartW = \left\lceil \frac{ow * inW}{outW} \right\rceil \\
&\qquad iendW = \left\lfloor \frac{(ow+1) * inW}{outW} \right\rfloor
\end{aligned}
$$

Parameters

- **input** (Tensor) –The input of adaptive_avg_pool3d, which is a 5D or 4D Tensor.
- **output_size** (*Union[int, tuple]*) –The target output size. *output_size* can be a tuple (D, H, W), or an int D for (D, D, D). D, H and W can be int or None which means the output size is the same as that of the input.

Returns

Tensor, with the same type as the *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If dtype of *input* is not float16, float32 or float64.
- **ValueError** –If the dimension of *input* is not 4D or 5D.
- **ValueError** –If *output_size* value is not positive.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> # case 1: output_size=(3, 3, 4)
>>> output_size=(3, 3, 4)
>>> input_val = np.random.randn(4, 3, 5, 6, 7)
>>> input = Tensor(input_val, mindspore.float32)
>>> output = ops.adaptive_avg_pool3d(input, output_size)
>>> print(output.shape)
(4, 3, 3, 3, 4)
```

(continues on next page)

(continued from previous page)

```
>>> # case 2: output_size=4
>>> output_size=5
>>> input_val = np.random.randn(2, 3, 8, 6, 12)
>>> input = Tensor(input_val, mindspore.float32)
>>> output = ops.adaptive_avg_pool3d(input, output_size)
>>> print(output.shape)
(2, 3, 5, 5, 5)
>>> # case 3: output_size=(None, 4, 5)
>>> output_size=(None, 4, 5)
>>> input_val = np.random.randn(4, 1, 9, 10, 8)
>>> input = Tensor(input_val, mindspore.float32)
>>> output = ops.adaptive_avg_pool3d(input, output_size)
>>> print(output.shape)
(4, 1, 9, 4, 5)
```

mindspore.ops.adaptive_max_pool1d

mindspore.ops.**adaptive_max_pool1d**(*input*, *output_size*)

Applies a 1D adaptive maximum pooling over an input Tensor which can be regarded as a composition of 1D input planes.

Typically, the input is of shape (N, C, L_{in}), adaptive_max_pool1d outputs regional maximum in the L_{in}-dimension. The output is of shape (N, C, L_{out}), where L_{out} is defined by *output_size*.

Note:

- L_{in} must be divisible by *output_size*.
- Ascend platform only supports float16 type for input.

Parameters

- **input** (Tensor) –Tensor of shape (N, C, L_{in}), with float16 or float32 data type.
- **output_size** (*int*) –the target output size L_{out}.

Returns

Tensor of shape (N, C, L_{out}), has the same type as *input*.

Raises

- **TypeError** –If *input* is neither float16 nor float32.
- **TypeError** –If *output_size* is not an int.
- **ValueError** –If *output_size* is less than 1.
- **ValueError** –If the last dimension of *input* is smaller than *output_size*.
- **ValueError** –If the last dimension of *input* is not divisible by *output_size*.
- **ValueError** –If length of shape of *input* is not equal to 3.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.random.randint(0, 10, [1, 3, 6]), mindspore.float32)
>>> output = ops.adaptive_max_pool1d(input, output_size=2)
>>> print(output.shape)
(1, 3, 2)
```

mindspore.ops.adaptive_max_pool2d

mindspore.ops.**adaptive_max_pool2d**(*input*, *output_size*, *return_indices=False*)

This operator applies a 2D adaptive max pooling to an input signal composed of multiple input planes. That is, for any input size, the size of the specified output is H x W. The number of output features is equal to the number of input planes.

The input and output data format can be "NCHW" and "CHW". N is the batch size, C is the number of channels, H is the feature height, and W is the feature width.

$$
\begin{aligned}
h_{start} &= floor(i * H_{in}/H_{out}) \\
h_{end} &= ceil((i+1) * H_{in}/H_{out}) \\
w_{start} &= floor(j * W_{in}/W_{out}) \\
w_{end} &= ceil((j+1) * W_{in}/W_{out}) \\
Output(i,j) &= \max Input[h_{start}:h_{end}, w_{start}:w_{end}]
\end{aligned}
$$

Note: In KBK mode, *output_size* does not support mutable.

Parameters

- **input** (Tensor) −A 3D or 4D tensor, with float16, float32 or float64 data type.
- **output_size** (*Union[int, tuple]*) −The target output size. *output_size* can be a tuple (H, W), or an int H for (H, H). H and W can be int or None. If it is None, it means the output size is the same as the input size.
- **return_indices** (*bool, optional*) −If *return_indices* is True , the indices of max value would be output. Default: False .

Returns

Tensor, with the same shape and dtype as the *input*.

Raises

- **TypeError** −If *output_size* is not int or tuple.
- **TypeError** −If *input* is not a tensor.
- **TypeError** −If *return_indices* is not a bool.
- **TypeError** −If dtype of *input* is not float16, float32 or float64.
- **ValueError** −If *output_size* is a tuple and the length of *output_size* is not 2.
- **ValueError** −If the data format of *input* is not "NCHW" or "CHW".

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> # case 1: output_size=(None, 2)
>>> input = Tensor(np.array([[[[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]],
...                           [[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]],
...                           [[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]]]]),␣
↪mindspore.float32)
>>> output = ops.adaptive_max_pool2d(input, (None, 2))
>>> print(output)
[[[[2. 3.]
   [5. 6.]
   [8. 9.]]
  [[2. 3.]
   [5. 6.]

  [[2. 3.]
   [5. 6.]
   [8. 9.]]]]
>>> # case 2: output_size=2
>>> output = ops.adaptive_max_pool2d(input, 2)
>>> print(output)
[[[[5. 6.]
   [8. 9.]]
  [[5. 6.]
   [8. 9.]]
  [[5. 6.]
   [8. 9.]]]]
>>> # case 3: output_size=(1, 2)
>>> output = ops.adaptive_max_pool2d(input, (1, 2))
>>> print(output)
[[[[8. 9.]]
  [[8. 9.]]
  [[8. 9.]]]]
```

mindspore.ops.avg_pool1d

mindspore.ops.**avg_pool1d**(*input_x*, *kernel_size=1*, *stride=1*, *padding=0*, *ceil_mode=False*, *count_include_pad=True*)

Applies a 1D average pooling over an input Tensor which can be regarded as a composition of 1D input planes.

Typically the input is of shape (N_{in}, C_{in}, L_{in}), avg_pool1d outputs regional average in the (L_{in})-dimension. Given kernel size $ks = l_{ker}$ and *stride* $s = s_0$, the operation is as follows.

$$\text{output}(N_i, C_j, l) = \frac{1}{l_{ker}} \sum_{n=0}^{l_{ker}-1} \text{input}(N_i, C_j, s_0 \times l + n)$$

Warning: *kernel_size* is in the range *[1, 255]*. *stride* is in the range *[1, 63]*.

Parameters

- **input_x** (Tensor) −Tensor of shape (N, C_{in}, L_{in}).

- **kernel_size** (*int, optional*) –The size of kernel window used to take the average value. Default: `1` .
- **stride** (*Union(int, tuple[int]), optional*) –The distance of kernel moving. *stride* can either be an int number or a tuple of one int number. Default: `1` .
- **padding** (*Union(int, tuple[int]), optional*) –The pad value to be filled. *padding* can either be an integer or a tuple of one integer. Default: `0` .
- **ceil_mode** (*bool, optional*) –If True, apply ceil instead of floor to compute the output shape. Default: `False`.
- **count_include_pad** (*bool, optional*) –If True, include the zero-padding in the averaging calculation. Default: `True` .

Returns

Tensor of shape (N, C_{out}, L_{out}).

Raises

- **TypeError** –If *input_x* is not a Tensor.
- **TypeError** –If *kernel_size* or *stride* is not an int.
- **TypeError** –If *ceil_mode* or *count_include_pad* is not a bool.
- **ValueError** –If length of shape of *input_x* is not equal to *3*.
- **ValueError** –If *kernel_size* or *stride* is less than *1*.
- **ValueError** –If *padding* is not int nor a tuple whose length is equal to *2*.
- **ValueError** –If value(s) of *padding* is less than *0*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.random.randint(0, 10, [1, 3, 6]), mindspore.float32)
>>> output = ops.avg_pool1d(input_x, kernel_size=6, stride=1)
>>> print(output.shape)
(1, 3, 1)
```

mindspore.ops.avg_pool2d

mindspore.ops.**avg_pool2d**(*input_x*, *kernel_size=1*, *stride=1*, *padding=0*, *ceil_mode=False*, *count_include_pad=True*, *divisor_override=0*)

Applies a 2D average pooling over an input Tensor which can be regarded as a composition of 2D input planes. Typically the input is of shape $(N_{in}, C_{in}, H_{in}, W_{in})$, outputs regional average in the (H_{in}, W_{in})-dimension. Given kernel size (k_h, k_w) and *strides* , the operation is as follows.

$$\text{output}(N_i, C_j, h, w) = \frac{1}{k_h * k_w} \sum_{m=0}^{k_h-1} \sum_{n=0}^{k_w-1} \text{input}(N_i, C_j, stride[0] \times h + m, stride[1] \times w + n)$$

Warning: *kernel_size* is in the range *[1, 255]*. *stride* is in the range *[1, 63]*.

Note: This interface currently does not support Atlas A2 training series products.

Parameters

- **input_x** (Tensor) −Tensor of shape $(N, C_{in}, H_{in}, W_{in})$.
- **kernel_size** (*Union[int, tuple[int]]*) −The size of kernel used to take the average value. It is an int number that represents height and width of the kernel, or a tuple of two int numbers that represent height and width respectively. Default: `1` .
- **stride** (*Union[int, tuple[int]]*) −The distance of kernel moving, an int number that represents the height and width of movement are both strides, or a tuple of two int numbers that represent height and width of movement respectively. Default: `1` .
- **padding** (*Union(int, tuple[int])*) −The pad value to be filled. Default: 0. If *padding* is an integer, the paddings of top, bottom, left and right are the same, equal to pad. If *padding* is a tuple of *4* integers, the padding of top, bottom, left and right equal to *padding[0]*, *padding[1]*, *padding[2]* and *padding[3]* correspondingly. Default: `0` .
- **ceil_mode** (*bool*) −If True, apply ceil instead of floor to compute the output shape. Default: `False`.
- **count_include_pad** (*bool*) −If True, include the zero-padding in the averaging calculation. Default: `True` .
- **divisor_override** (*int*) −If specified, it will be used as divisor in the averaging calculation, otherwise *kernel_size* will be used. Default: `0`, which means not specified.

Returns

Tensor, with shape $(N, C_{out}, H_{out}, W_{out})$.

Raises

- **TypeError** −If *input_x* is not a Tensor.
- **TypeError** −If *kernel_size* or *stride* is neither int nor tuple.
- **TypeError** −If *ceil_mode* or *count_include_pad* is not a bool.
- **TypeError** −If *divisor_override* is not an int.
- **ValueError** −If length of shape of *input_x* is not equal to *4*.
- **ValueError** −If *kernel_size* or *stride* is less than 1.
- **ValueError** −If *kernel_size* or *stride* is a tuple whose length is not equal to *2*.
- **ValueError** −If *padding* is not int nor a tuple whose length is equal to *4*.
- **ValueError** −If value(s) of *padding* is less than *0*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.arange(1 * 3 * 3 * 4).reshape(1, 3, 3, 4), mindspore.float32)
>>> output = ops.avg_pool2d(x, kernel_size=2, stride=1)
>>> print(output)
[[[[ 2.5   3.5   4.5]
   [ 6.5   7.5   8.5]]
  [[14.5  15.5  16.5]
   [18.5  19.5  20.5]]
  [[26.5  27.5  28.5]
   [30.5  31.5  32.5]]]]
```

mindspore.ops.avg_pool3d

mindspore.ops.**avg_pool3d**(*input_x*, *kernel_size=1*, *stride=1*, *padding=0*, *ceil_mode=False*, *count_include_pad=True*, *divisor_override=0*)

Applies a 3D average pooling over an input Tensor which can be regarded as a composition of 3D input planes. Typically the input is of shape $(N, C, D_{in}, H_{in}, W_{in})$, avg_pool3d outputs regional average in the (D_{in}, H_{in}, W_{in})-dimension. Given kernel size $ks = (d_{ker}, h_{ker}, w_{ker})$ and stride $s = (s_0, s_1, s_2)$, the operation is as follows.

$$\text{output}(N_i, C_j, d, h, w) = \frac{1}{d_{ker} * h_{ker} * w_{ker}} \sum_{l=0}^{d_{ker}-1} \sum_{m=0}^{h_{ker}-1} \sum_{n=0}^{w_{ker}-1} \text{input}(N_i, C_j, s_0 \times d + l, s_1 \times h + m, s_2 \times w + n)$$

Warning: *kernel_size* is in the range *[1, 255]*. *stride* is in the range *[1, 63]*.

Note: This interface currently does not support Atlas A2 training series products.

Parameters

- **input_x** (Tensor) –Tensor of shape $(N, C, D_{in}, H_{in}, W_{in})$. Currently support float16 and float32 data type.
- **kernel_size** (*Union[int, tuple[int]], optional*) –The size of kernel used to take the average value, is an int number that represents depth, height and width are both *kernel_size*, or a tuple of three int numbers that represent depth, height and width respectively. Default: `1` .
- **stride** (*Union[int, tuple[int]], optional*) –The distance of kernel moving, an int number that represents the depth, height and width of movement are both stride, or a tuple of three int numbers that represent depth, height and width of movement respectively. Default: `1` .
- **padding** (*Union(int, tuple[int]), optional*) –The pad value to be filled. If *padding* is an integer, the addings of head, tail, top, bottom, left and right are the same, equal to pad. If *padding* is a tuple of six integers, the padding of head, tail, top, bottom, left and right equal to padding[0], padding[1], padding[2], padding[3], padding[4] and padding[5] correspondingly. Default: `0` .
- **ceil_mode** (*bool, optional*) –If `True` , ceil instead of floor to compute the output shape. Default: `False` .
- **count_include_pad** (*bool, optional*) –If `True` , averaging calculation will include the zero-padding. Default: `True` .

- **divisor_override** (*int, optional*) –If specified, it will be used as divisor in the averaging calculation, otherwise *kernel_size* will be used. Default: `0` , which means not specified.

Returns

Tensor, with shape $(N, C, D_{out}, H_{out}, W_{out})$. Has the same data type with *input_x*.

Raises

- **TypeError** –If *input_x* is not a Tensor.
- **TypeError** –If *kernel_size*, *stride* or *padding* is neither an int not a tuple.
- **TypeError** –If *ceil_mode* or *count_include_pad* is not a bool.
- **TypeError** –If *divisor_override* is not an int.
- **ValueError** –If length of shape of *input_x* is not equal to *5*.
- **ValueError** –If numbers in *kernel_size* or *stride* are not positive.
- **ValueError** –If *kernel_size* or *stride* is a tuple whose length is not equal to *3*.
- **ValueError** –If *padding* is a tuple whose length is not equal to *6*.
- **ValueError** –If element of *padding* is less than *0*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.arange(1 * 2 * 2 * 2 * 3).reshape((1, 2, 2, 2, 3)), mindspore.
↪float16)
>>> output = ops.avg_pool3d(input_x, kernel_size=2, stride=1)
>>> print(output)
[[[[[ 5.  6.]]]
  [[[17. 18.]]]]]
```

mindspore.ops.batch_norm

mindspore.ops.**batch_norm**(*input_x*, *running_mean*, *running_var*, *weight*, *bias*, *training=False*, *momentum=0.1*, *eps=1e-5*)

Batch Normalization for input data and updated parameters.

Batch Normalization is widely used in convolutional neural networks. This operation applies Batch Normalization over inputs to avoid internal covariate shift as described in the paper Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift. It rescales and recenters the features using a mini-batch of data and the learned parameters can be described in the following formula,

$$y = \frac{x - mean}{\sqrt{variance + \epsilon}} * \gamma + \beta$$

where γ is *weight*, β is *bias*, ϵ is *eps*, $mean$ is the mean of x, $variance$ is the variance of x.

Warning:

- For Atlas 200/300/500 inference product, the result accuracy fails to reach 1‰ due to the square root instruction.

Note:

- If *training* is *False*, *weight*, *bias*, *running_mean* and *running_var* are Tensors.
- If *training* is *True*, *weight*, *bias*, *running_mean* and *running_var* are Parameters.

Parameters

- **input_x** (Tensor) −Tensor of shape (N, C), with float16 or float32 data type.
- **running_mean** (*Union[Tensor, Parameter]*) −The shape $(C,)$, has the same data type with *weight*.
- **running_var** (*Union[Tensor, Parameter]*) −The shape $(C,)$, has the same data type with *weight*.
- **weight** (*Union[Tensor, Parameter]*) −The shape $(C,)$, with float16 or float32 data type.
- **bias** (*Union[Tensor, Parameter]*) −The shape $(C,)$, has the same data type with *weight*.
- **training** (*bool, optional*) −If *training* is *True*, *mean* and *variance* are computed during training. If *training* is *False*, they're loaded from checkpoint during inference. Default: `False` .
- **momentum** (*float, optional*) −The hyper parameter to compute moving average for *running_mean* and *running_var* (e.g. $new\_running\_mean = (1 - momentum) * running\_mean + momentum * current\_mean$). Momentum value must be *[0, 1]*. Default: `0.1` .
- **eps** (*float, optional*) −A small value added for numerical stability. Default: `1e-5`, value must be *(0, 1]* .

Returns

output_x (Tensor) - The same type and shape as the *input_x*. The shape is (N, C).

Raises

- **TypeError** −If *training* is not a bool.
- **TypeError** −If dtype of *eps* or *momentum* is not float.
- **TypeError** −If *input_x*, *weight*, *bias*, *running_mean* or *running_var* is not a Tensor.
- **TypeError** −If dtype of *input_x*, *weight* is neither float16 nor float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> input_x = Tensor([[1.0, 2.0], [3.0, 4.0]], mindspore.float32)
>>> running_mean = Tensor([0.5, 1.5], mindspore.float32)
>>> running_var = Tensor([0.1, 0.2], mindspore.float32)
>>> weight = Tensor([2.0, 2.0], mindspore.float32)
>>> bias = Tensor([-1.0, -1.0], mindspore.float32)
>>> output = ops.batch_norm(input_x, running_mean, running_var, weight, bias)
```

(continues on next page)

(continued from previous page)

```
>>> print(output)
[[ 2.1621194  1.2360122]
 [14.810596  10.180061 ]]
```

mindspore.ops.bias_add

mindspore.ops.**bias_add**(*input_x*, *bias*)

Returns the sum of the *input_x* and the *bias* Tensor. Before adding, the *bias* Tensor will be broadcasted to be consistent with the shape of the *input_x* Tensor.

Parameters

- **input_x** (Tensor) –The input tensor. The shape can be 2-5 dimensions. Supported dtypes:
  - Ascend/CPU: all Number type.
  - GPU: float16, float32, int8.
- **bias** (Tensor) –The bias tensor, with shape (C). C must be the same as channel dimension C of *input_x*. It has the same type as *input_x*.

Returns

Tensor, with the same shape and data type as *input_x*.

Raises

- **TypeError** –If *input_x* or *bias* is not a Tensor.
- **TypeError** –If dtype of *input_x* and *bias* is inconsistent.
- **TypeError** –If dimension of *input_x* is not in the range [2, 5].

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.arange(6).reshape((2, 3)), mindspore.float32)
>>> bias = Tensor(np.random.random(3).reshape((3)), mindspore.float32)
>>> output = ops.bias_add(input_x, bias)
>>> print(output.shape)
(2, 3)
```

mindspore.ops.bidense

mindspore.ops.**bidense**(*input1*, *input2*, *weight*, *bias=None*)

Applies bilinear dense connected layer for *input1* and *input2*. The bilinear dense function is defined as:

$$output = x_1^T A x_2 + b$$

x_1 represents *input1* , x_2 represents *input2* , A represents *weight* , b represents *bias* .

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input1** (Tensor) –Input Tensor of shape $(*, in1\_channels)$, where $*$ means any number of additional dimensions. All but the last dimension should be the same with *input2*.
- **input2** (Tensor) –Input Tensor of shape $(*, in2\_channels)$, where $*$ means any number of additional dimensions. All but the last dimension should be the same with *input1*.
- **weight** (Tensor) –The weight applied to the input1 and input2. The shape is $(out\_channels, in1\_channels, in2\_channels)$.
- **bias** (Tensor, *optional*) –Additive biases to the output. The shape is $(out\_channels)$ or (). Defaults: None , the *bias* is 0.

Returns

Tensor, shape $(*, out\_channels)$, where $*$ means any number of additional dimensions. All but the last dimension should be the same with the input Tensors.

Raises

- **TypeError** –If *input1* is not Tensor.
- **TypeError** –If *input2* is not Tensor.
- **TypeError** –If *weight* is not Tensor.
- **TypeError** –If *bias* is not Tensor.
- **ValueError** –If dimensions except the last of 'input1' are different from 'input2' .

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> input1 = mindspore.Tensor([[-1.1283, 1.2603],
...                            [0.0214, 0.7801],

mindspore.ops.ctc_greedy_decoder

mindspore.ops.**ctc_greedy_decoder**(*inputs*, *sequence_length*, *merge_repeated=True*)

Performs greedy decoding on the logits given in inputs.

Note: On Ascend, 'merge_repeated' can not be set to false.

Parameters

- **inputs** (Tensor) – The input Tensor must be a 3-D tensor whose shape is $(max\_time, batch\_size, num\_classes)$. *num_classes* must be *num_labels* + *1* classes, *num_labels* indicates the number of actual labels. Blank labels are reserved. Default blank label is *num_classes* - *1*. Data type must be float32 or float64.
- **sequence_length** (Tensor) – A tensor containing sequence lengths with the shape of $(batch\_size,)$. The type must be int32. Each value in the tensor must be equal to or less than *max_time*.
- **merge_repeated** (*bool*) – If `true` , merge repeated classes in output. Default: `True` .

Returns

decoded_indices (Tensor), A tensor with shape of $(total\_decoded\_outputs, 2)$. Data type is int64.

decoded_values (Tensor), A tensor with shape of $(total\_decoded\_outputs,)$, it stores the decoded classes. Data type is int64.

decoded_shape (Tensor), A tensor with shape of $(batch\_size, max\_decoded\_length)$. Data type is int64.

log_probability (Tensor), A tensor with shape of $(batch\_size, 1)$, containing sequence log-probability, has the same type as *inputs*.

Raises

- **TypeError** – If *merge_repeated* is not a bool.
- **ValueError** – If length of shape of *inputs* is not equal to 3.
- **ValueError** – If length of shape of *sequence_length* is not equal to 1.
- **ValueError** – If value in the *sequence_length* is larger than *max_time*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> inputs = Tensor(np.array([[[0.6, 0.4, 0.2], [0.8, 0.6, 0.3]],
...                           [[0.0, 0.6, 0.0], [0.5, 0.4, 0.5]]]), mindspore.float32)
>>> sequence_length = Tensor(np.array([2, 2]), mindspore.int32)
>>> decoded_indices, decoded_values, decoded_shape, log_probability = ops.ctc_greedy_
↪decoder(inputs,
...                                                                                 ␣
↪sequence_length)
>>> print(decoded_indices)
[[0 0]
 [0 1]
 [1 0]]
>>> print(decoded_values)
[0 1 0]
>>> print(decoded_shape)
[2 2]
>>> print(log_probability)
[[-1.2]
 [-1.3]]
```

mindspore.ops.conv1d

mindspore.ops.**conv1d**(*input*, *weight*, *bias=None*, *stride=1*, *pad_mode='valid'*, *padding=0*, *dilation=1*, *groups=1*)

Applies a 1D convolution over an input tensor. The input Tensor is typically of shape (N, C_{in}, L_{in}), where N is batch size, C is channel number, L is input sequence width.

The output is calculated based on formula:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{in}-1} \text{ccor}(\text{weight}(C_{\text{out}_j}, k), \text{X}(N_i, k))$$

where $bias$ is the output channel bias, $ccor$ is the cross-correlation, , $weight$ is the convolution kernel value and X represents the input feature map.

Here are the indices' meanings:

- i corresponds to the batch number, the range is $[0, N-1]$, where N is the batch size of the input.
- j corresponds to the output channel, ranging from $[0, C_{out}-1]$, where C_{out} is the number of output channels, which is also equal to the number of kernels.
- k corresponds to the input channel, ranging from $[0, C_{in}-1]$, where C_{in} is the number of input channels, which is also equal to the number of channels in the convolutional kernels.

Therefore, in the above formula, $bias(C_{\text{out}_j})$ represents the bias of the j-th output channel, $weight(C_{\text{out}_j}, k)$ represents the slice of the j-th convolutional kernel in the k-th channel, and $X(N_i, k)$ represents the slice of the k-th input channel in the i-th batch of the input feature map.

The shape of the convolutional kernel is given by (kernel_size), where kernel_size is the width of the kernel. If we consider the input and output channels as well as the *groups* parameter, the complete kernel shape will be $(C_{out}, C_{in}/\text{groups}, \text{kernel\_size})$, where *groups* is the number of groups dividing *x*'s input channel when applying group convolution.

For more details about convolution layer, please refer to Gradient Based Learning Applied to Document Recognition and ConvNets .

Note: On Ascend platform, only group convolution in depthwise convolution scenarios is supported. That is, when *groups>1*, condition $C_{in} = C_{out} = groups$ must be satisfied.

Parameters

- **input** (Tensor) −Input Tensor of shape (N, C_{in}, L_{in}).
- **weight** (Tensor) −The convolutional kernel value, it should has shape $(N, C_{in}/\text{groups}, \text{kernel\_size})$.
- **bias** (Tensor, *optional*) −Bias Tensor with shape (C_{out}). When bias is None, zeros will be used. Default: None .
- **stride** (*Union(int, tuple[int])*, *optional*) −The distance of kernel moving, an int number or a tuple of one int that represents width of movement. Default: 1.
- **pad_mode** (*str*, *optional*) −Specifies padding mode. The optional values are "same" , "valid" and "pad" . Default: "valid" .
  - "same": Adopts the way of completion. The height and width of the output will be equal to the input *x* divided by stride. The padding will be evenly calculated in left and right possiblily. Otherwise, the last extra padding will be calculated from the right side. If this mode is set, *padding* must be 0.
  - "valid": Adopts the way of discarding. The possible largest width of output will be returned without padding. Extra pixels will be discarded. If this mode is set, *padding* must be 0.
  - "pad": Implicit paddings on both sides of the input *x*. The number of *padding* will be padded to the input Tensor borders. *padding* must be greater than or equal to 0.
- **padding** (*Union(int, tuple[int], list[int])*, *optional*) −Specifies the amount of padding to apply on both side of *input* when *pad_mode* is set to "pad". The paddings of left and right are the same, equal to padding or padding[0] when padding is a tuple of 1 integer. Default: 0 .
- **dilation** (*Union(int, tuple[int])*, *optional*) −Specifies the dilation rate to use for dilated convolution. It can be a single int or a tuple of 1 integer. Assuming $dilation = (d0,)$, the convolutional kernel samples the input with a spacing of $d0 - 1$ elements in the width direction. The value should be in the ranges [1, L]. Default: 1 .
- **groups** (*int*, *optional*) −Splits *input* into groups. Default: 1 .

Returns

Tensor, the value that applied 1D convolution. The shape is (N, C_{out}, L_{out}). To see how different pad modes affect the output shape, please refer to *mindspore.nn.Conv1d* for more details.

Raises

- **TypeError** −If *stride*, *padding* or *dilation* is neither an int nor a tuple.
- **TypeError** −*groups* is not an int.
- **TypeError** −If *bias* is not a Tensor.
- **ValueError** −If the shape of *bias* is not (C_{out}) .
- **ValueError** −If *stride* or *dilation* is less than 1.
- **ValueError** −If *pad_mode* is not one of 'same', 'valid' or 'pad'.
- **ValueError** −If *padding* is a tuple whose length is not equal to 1.
- **ValueError** −If *pad_mode* is not equal to 'pad' and *padding* is greater than 0.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.arange(64).reshape((4, 4, 4)), mindspore.float32)
>>> weight = Tensor(np.arange(8).reshape((2, 2, 2)), mindspore.float32)
>>> bias = Tensor([-0.12345, 2.7683], mindspore.float32)
>>> output = ops.conv1d(x, weight, pad_mode='pad', padding=(1,), bias=bias, groups=2)
>>> print(output.shape)
(4, 2, 5)
```

mindspore.ops.conv2d

mindspore.ops.**conv2d**(*input*, *weight*, *bias=None*, *stride=1*, *pad_mode='valid'*, *padding=0*, *dilation=1*, *groups=1*)

Applies a 2D convolution over an input tensor. The input tensor is typically of shape $(N, C_{in}, H_{in}, W_{in})$, where N is batch size, C is channel number, H is feature height, W is feature width.

The output is calculated based on formula:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{in}-1} \text{ccor}(\text{weight}(C_{\text{out}_j}, k), \text{X}(N_i, k))$$

where $bias$ is the output channel bias, $ccor$ is the cross-correlation, , $weight$ is the convolution kernel value and X represents the input feature map.

Here are the indices' meanings:

- i corresponds to the batch number, the range is $[0, N-1]$, where N is the batch size of the input.
- j corresponds to the output channel, the range is $[0, C_{out}-1]$, where C_{out} is the number of output channels, which is also equal to the number of kernels.
- k corresponds to the input channel, the range is $[0, C_{in}-1]$, where C_{in} is the number of input channels, which is also equal to the number of channels in the convolutional kernels.

Therefore, in the above formula, $bias(C_{out_j})$ represents the bias of the j-th output channel, $weight(C_{out_j}, k)$ represents the slice of the j-th convolutional kernel in the k-th channel, and $X(N_i, k)$ represents the slice of the k-th input channel in the i-th batch of the input feature map.

The shape of the convolutional kernel is given by (kernel_size[0], kernel_size[1]), where kernel_size[0] and kernel_size[1] are the height and width of the kernel, respectively. If we consider the input and output channels as well as the *groups* parameter, the complete kernel shape will be $(C_{out}, C_{in}/\text{groups}, \text{kernel\_size}[0], \text{kernel\_size}[1])$, where *groups* is the number of groups dividing *x*'s input channel when applying group convolution.

For more details about convolution layer, please refer to Gradient Based Learning Applied to Document Recognition and ConvNets.

Note: On Ascend platform, only group convolution in depthwise convolution scenarios is supported. That is, when *groups>1*, condition $C_{in} = C_{out} = groups$ must be satisfied.

Parameters

- **input** (Tensor) –Tensor of shape $(N, C_{in}, H_{in}, W_{in})$.
- **weight** (Tensor) –Tensor of shape $(N, C_{in}/\text{groups}, \text{kernel\_size}[0], \text{kernel\_size}[1])$, then the size of kernel is (kernel_size[0], kernel_size[1]).
- **bias** (Tensor, *optional*) –Bias Tensor with shape (C_{out}). When bias is None , zeros will be used. Default: None .
- **stride** (*Union(int, tuple[int])*, *optional*) –The distance of kernel moving, an int number that represents the height and width of movement are both strides, or a tuple of two int numbers that represent height and width of movement respectively. Default: 1 .
- **pad_mode** (*str*, *optional*) –Specifies padding mode. The optional values are "same" , "valid" and "pad" . Default: "valid" .
  - same: Adopts the way of completion. The height and width of the output will be equal to the input *x* divided by stride. The padding will be evenly calculated in top and bottom, left and right possiblily. Otherwise, the last extra padding will be calculated from the bottom and the right side. If this mode is set, *padding* must be 0.
  - valid: Adopts the way of discarding. The possible largest height and width of output will be returned without padding. Extra pixels will be discarded. If this mode is set, *padding* must be 0.
  - pad: Implicit paddings on both sides of the input *x*. The number of *padding* will be padded to the input Tensor borders. *padding* must be greater than or equal to 0.
- **padding** (*Union(int, tuple[int], list[int])*, *optional*) –Implicit paddings on both sides of the input *x*. If *padding* is one integer, the paddings of top, bottom, left and right are the same, equal to padding. If *padding* is a tuple/list with 2 integers, the padding of top adn bottom is padding[0], and the padding of left and right is padding[1]. Default: 0 .
- **dilation** (*Union(int, tuple[int])*, *optional*) –Gaps between kernel elements.The data type is int or a tuple of 2 integers. Specifies the dilation rate to use for dilated convolution. If set to be $k > 1$, there will be $k - 1$ pixels skipped for each sampling location. Its value must be greater than or equal to 1 and bounded by the height and width of the input *x*. Default: 1 .
- **groups** (*int*, *optional*) –Splits *input* into groups. Default: 1 .

Returns

Tensor, the value that applied 2D convolution. The shape is $(N, C_{out}, H_{out}, W_{out})$. To see how different pad modes affect the output shape, please refer to *mindspore.nn.Conv2d* for more details.

Raises

- **TypeError** –If *stride*, *padding* or *dilation* is neither an int nor a tuple.
- **TypeError** –*groups* is not an int.
- **TypeError** –If *bias* is not a Tensor.
- **ValueError** –If the shape of *bias* is not (C_{out}) .
- **ValueError** –If *stride* or *dilation* is less than 1.
- **ValueError** –If *pad_mode* is not one of 'same', 'valid' or 'pad'.
- **ValueError** –If *padding* is a tuple/list whose length is not equal to 2.
- **ValueError** –If *pad_mode* is not equal to 'pad' and *padding* is greater than 0.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.ones([10, 32, 32, 32]), mindspore.float32)
>>> weight = Tensor(np.ones([32, 32, 3, 3]), mindspore.float32)
>>> output = ops.conv2d(x, weight)
>>> print(output.shape)
(10, 32, 30, 30)
```

mindspore.ops.conv3d

mindspore.ops.**conv3d**(*input*, *weight*, *bias=None*, *stride=1*, *pad_mode='valid'*, *padding=0*, *dilation=1*, *groups=1*)

Applies a 3D convolution over an input tensor. The input tensor is typically of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$, where N is batch size, C is channel number, D, H, W are the depth, height and width of the feature graph, respectively.

The output is calculated based on formula:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{in}-1} \text{ccor}(\text{weight}(C_{\text{out}_j}, k), \text{X}(N_i, k))$$

where $bias$ is the output channel bias, $ccor$ is the cross-correlation , $weight$ is the convolution kernel value and X represents the input feature map.

Here are the indices' meanings:

- i corresponds to the batch number, the range is $[0, N-1]$, where N is the batch size of the input.
- j corresponds to the output channel, the range is $[0, C_{out}-1]$, where C_{out} is the number of output channels, which is also equal to the number of kernels.
- k corresponds to the input channel, the range is $[0, C_{in}-1]$, where C_{in} is the number of input channels, which is also equal to the number of channels in the convolutional kernels.

Therefore, in the above formula, $bias(C_{\text{out}_j})$ represents the bias of the j-th output channel, $weight(C_{\text{out}_j}, k)$ represents the slice of the j-th convolutional kernel in the k-th channel, and $X(N_i, k)$ represents the slice of the k-th input channel in the i-th batch of the input feature map.

The shape of the convolutional kernel is given by (kernel_size[0], kernel_size[1], kernel_size[2]) where kernel_size[0] , kernel_size[1] and kernel_size[2] are the depth, height and width of the kernel, respectively. If we consider the input and output channels as well as the *groups* parameter, the complete kernel shape will be $(C_{out}, C_{in}/\text{groups}, \text{kernel\_size}[0], \text{kernel\_size}[1], \text{kernel\_size}[2])$, where *groups* is the number of groups dividing x's input channel when applying group convolution.

For more details about convolution layer, please refer to Gradient Based Learning Applied to Document Recognition.

Note:

1. On Ascend platform, $groups = 1$ must be satisfied.
2. On Ascend platform, $dilation = 1$ must be satisfied.

Parameters

- **input** (Tensor) –Tensor of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$.

- **weight** (Tensor) −Set size of kernel is (kernel_size[0], kernel_size[1], kernel_size[2]), then the shape is $(C_{out}, C_{in}$, kernel_size[0], kernel_size[1], kernel_size[1]).
- **bias** (Tensor, *optional*) −Bias Tensor with shape (C_{out}). When bias is None, zeros will be used. Default: None .
- **stride** (*Union[int, tuple[int]], optional*) −The distance of kernel moving, it can be an int number that represents the depth, height and width of movement or a tuple of three int numbers that represent depth, height and width movement respectively. Default: 1 .
- **pad_mode** (*str, optional*) −Specifies padding mode. The optional values are "same" , "valid" and "pad" . Default: "valid" .
  - "same": Adopts the way of completion. The depth, height and width of the output will be equal to the input *x* divided by stride. The padding will be evenly calculated in head and tail, top and bottom, left and right directions possiblily. Otherwise, the last extra padding will be calculated from the tail, bottom and the right side. If this mode is set, *pad* must be 0.
  - "valid": Adopts the way of discarding. The possible largest depth, height and width of output will be returned without padding. Extra pixels will be discarded. If this mode is set, *pad* must be 0.
  - "pad": Implicit paddings on both sides of the input in depth, height and width. The number of *pad* will be padded to the input Tensor borders. *pad* must be greater than or equal to 0.
- **padding** (*Union[int, tuple[int], list[int]], optional*) −The pad value to be filled. If *pad* is an integer, the paddings of head, tail, top, bottom, left and right are the same, equal to pad. If *pad* is a tuple/list of 3 integers, the padding of head, tail, top, bottom, left and right equal to pad[0], pad[0], pad[1], pad[1], pad[2] and pad[2] correspondingly. Default: 0 .
- **dilation** (*Union[int, tuple[int]], optional*) −The data type is int or a tuple of 3 integers $(dilation_d, dilation_h, dilation_w)$. Currently, dilation on depth only supports the case of 1 on Ascend backend. Specifies the dilation rate to use for dilated convolution. If set $k > 1$, there will be $k - 1$ pixels skipped for each sampling location. The value ranges for the depth, height, and width dimensions are [1, D], [1, H], and [1, W], respectively. Default: 1 .
- **groups** (*int, optional*) −The number of groups into which the filter is divided. Default: 1 .

Returns

Tensor, the value that applied 3D convolution. The shape is $(N, C_{out}, D_{out}, H_{out}, W_{out})$. To see how different pad modes affect the output shape, please refer to *mindspore.nn.Conv3d* for more details.

Raises

- **TypeError** −If *out_channel* or *groups* is not an int.
- **TypeError** −If *stride*, *padding* or *dilation* is neither an int nor a tuple.
- **TypeError** −If *bias* is not a Tensor.
- **ValueError** −If the shape of *bias* is not (C_{out}).
- **ValueError** −If *stride* or *dilation* is less than 1.
- **ValueError** −If *pad_mode* is not one of 'same', 'valid' or 'pad'.
- **ValueError** −If *padding* is a tuple or list whose length is not equal to 3.
- **ValueError** −If *pad_mode* is not equal to 'pad' and *pad* is greater than 0.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.ones([16, 3, 10, 32, 32]), mindspore.float16)
>>> weight = Tensor(np.ones([32, 3, 4, 3, 3]), mindspore.float16)
>>> output = ops.conv3d(x, weight, pad_mode="same", padding=0, stride=1, dilation=1,␣
↪groups=1)
>>> print(output.shape)
(16, 32, 10, 32, 32)
>>> output = ops.conv3d(x, weight, pad_mode="valid", padding=0, stride=1, dilation=1,␣
↪groups=1)
>>> print(output.shape)
(16, 32, 7, 30, 30)
>>> output = ops.conv3d(x, weight, pad_mode="pad", padding=(2, 1, 1), stride=1, dilation=1,␣
↪groups=1)
>>> print(output.shape)
(16, 32, 11, 32, 32)
```

mindspore.ops.deformable_conv2d

mindspore.ops.**deformable_conv2d**(*x*, *weight*, *offsets*, *kernel_size*, *strides*, *padding*, *bias=None*, *dilations=(1, 1, 1, 1)*, *groups=1*, *deformable_groups=1*, *modulated=True*)

Given 4D tensor inputs *x*, *weight* and *offsets*, compute a 2D deformable convolution. The deformable convolution operation can be expressed as follow:

Deformable Convolution v1:

$$y(p) = \sum_{k=1}^{K} w_k \cdot x(p + p_k + \Delta p_k)$$

Deformable Convolution v2:

$$y(p) = \sum_{k=1}^{K} w_k \cdot x(p + p_k + \Delta p_k) \cdot \Delta m_k$$

Where Δp_k and Δm_k are the learnable offset and modulation scalar for the k-th location. For details, please refer to Deformable ConvNets v2: More Deformable, Better Results and Deformable Convolutional Networks.

Parameters

- **x** (Tensor) −A 4D tensor of input image. With the format "NCHW", the shape is $(N, C_{in}, H_{in}, W_{in})$. Dtype: float16 or float32.
- **weight** (Tensor) −A 4D tensor of learnable filters. Must have the same type as *x*. The shape is $(C_{out}, C_{in}/groups, H_f, W_f)$.
- **offsets** (Tensor) −A 4D tensor of x-y coordinates offset and mask. With the format "NCHW", the shape is $(batch, 3 * deformable\_groups * H_f * W_f, H_{out}, W_{out})$. Note the C dimension is stored in the order of (offset_x, offset_y, mask). Must have the same type as *x*.
- **kernel_size** (*tuple[int]*) −A tuple of 2 integers. The size of kernel.
- **strides** (*tuple[int]*) −A tuple of 4 integers. The stride of the sliding window for each dimension of input. The dimension order is interpreted according to the data format of *x*. The N and C dimensions must be set to 1.
- **padding** (*tuple[int]*) −A tuple of 4 integers. The number of pixels to add to each (top, bottom, left, right) side of the input.

- **bias** (*Tensor, optional*) – An 1D tensor of additive biases to the filter outputs. The shape is (C_{out}). Default: `None`.
- **dilations** (*tuple[int], optional*) – A tuple of 4 integers. The dilation factor for each dimension of input. The dimension order is interpreted according to the data format of *x*. The N and C dimensions must be set to 1. Default: `(1, 1, 1, 1)`.
- **groups** (*int, optional*) – An integer of type int32. The number of blocked connections from input channels to output channels. In_channels and out_channels must both be divisible by *groups*. Default: `1`.
- **deformable_groups** (*int, optional*) – An integer of type int32. The number of deformable group partitions. In_channels must be divisible by *deformable_groups*. Default: `1`.
- **modulated** (*bool, optional*) – Specifies version of DeformableConv2D, True means v2, False means v1, currently only supports v2. Default: `True`.

Returns

Tensor, A 4D Tensor of output feature map. With the same type as *x*. With the format "NCHW", the shape is $(N, C_{out}, H_{out}, W_{out})$.

$$
\begin{aligned}
H_{out} &= \left\lfloor \frac{H_{in}+padding[0]+padding[1]-(H_f-1)\times \text{dilations}[2]-1}{\text{stride}[0]} + 1 \right\rfloor \\
W_{out} &= \left\lfloor \frac{W_{in}+padding[2]+padding[3]-(W_f-1)\times \text{dilations}[3]-1}{\text{stride}[1]} + 1 \right\rfloor
\end{aligned}
$$

Raises

- **TypeError** – If *strides*, *padding*, *kernel_size* or *dilations* is not a tuple with integer elements.
- **TypeError** – If *modulated* is not a bool.
- **ValueError** – If the tuple size of *strides*, *padding*, *kernel_size* or *dilations* is not expected.
- **ValueError** – The N or C dimensions of *strides* or *dilations* is not set to 1.
- **ValueError** – If *modulated* is not set to True.

Warning: This is an experimental API that is subject to change or deletion.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor(np.ones((4, 3, 10, 10)), mstype.float32)
>>> kh, kw = 3, 3
>>> weight = Tensor(np.ones((5, 3, kh, kw)), mstype.float32)
>>> offsets = Tensor(np.ones((4, 3 * kh * kw, 8, 8)), mstype.float32)
>>> output = ops.deformable_conv2d(x, weight, offsets, (kh, kw), (1, 1, 1, 1), (0, 0, 0, 0))
>>> print(output.shape)
(4, 5, 8, 8)
```

mindspore.ops.dense

mindspore.ops.**dense**(*input*, *weight*, *bias=None*)

Applies the dense connected operation to the *input*. The dense function is defined as:

$$output = input * weight^T + bias$$

Warning:

- This is an experimental API that is subject to change or deletion.
- On the Ascend platform, if *bias* is not 1D, the *input* cannot be greater than 6D in PYNATIVE or KBK mode.

Parameters

- **input** (Tensor) –Input Tensor of shape $(*, in\_channels)$, where $*$ means any number of additional dimensions.
- **weight** (Tensor) –The weight applied to the input. The shape is $(out\_channels, in\_channels)$ or $(in\_channels)$.
- **bias** (Tensor, *optional*) –Additive biases to the output. The shape is $(out\_channels)$ or (). Defaults: None, the *bias* is 0.

Returns

Output whose shape is determined by the shape of the input and the weight.

Raises

- **TypeError** –If *input* is not Tensor.
- **TypeError** –If *weight* is not Tensor.
- **TypeError** –If *bias* is not Tensor.
- **RuntimeError** –On the Ascend platform, if *bias* is not 1D and *input* is greater than 6D in PYNATIVE or KBK mode.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> input = Tensor([[-1., 1., 2.], [-3., -3., 1.]], mindspore.float32)
>>> weight = Tensor([[-2., -2., -2.], [0., -1., 0.]], mindspore.float32)
>>> bias = Tensor([0., 1.], mindspore.float32)
>>> output = ops.dense(input, weight, bias)
>>> print(output)
[[-4.  0.]
 [10.  4.]]
```

mindspore.ops.dropout

mindspore.ops.**dropout**(*input*, *p=0.5*, *training=True*, *seed=None*)

During training, randomly zeroes some of the elements of the input tensor with probability *p* from a Bernoulli distribution. It plays the role of reducing neuron correlation and avoid overfitting. And the return will be multiplied by $\frac{1}{1-p}$ during training. During the reasoning, this operation returns the same Tensor as the *x*.

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **input** (Tensor) –The input Tensor of shape $(*, N)$, with data type of float16, float32 or float64.
- **p** (*float, optional*) –The dropping rate, between 0 and 1, e.g. p = 0.1, means dropping out 10% of input units. Default: 0.5 .
- **training** (*bool, optional*) –Apply dropout if is True. Default: True.
- **seed** (*int, optional*) –Seed is used as entropy source for Random number engines generating pseudo-random numbers. Default: None , which will be treated as 0 .

Returns

- **output** (Tensor) - Zeroed tensor, with the same shape and data type as *input*.

Raises

- **TypeError** –If *p* is not a float.
- **TypeError** –If dtype of *input* is not float16, float32 or float64.
- **TypeError** –If *input* is not a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> input = Tensor(((20, 16), (50, 50)), mindspore.float32)
>>> output = ops.dropout(input, p=0.5)
>>> print(output.shape)
(2, 2)
```

mindspore.ops.dropout1d

mindspore.ops.**dropout1d**(*input*, *p=0.5*, *training=True*)

During training, randomly zeroes some channels of the input tensor with probability *p* from a Bernoulli distribution(For a 3-dimensional tensor with a shape of NCL, the channel feature map refers to a 1-dimensional feature map with the shape of L).

For example, the *j_th* channel of the *i_th* sample in the batched input is a to-be-processed *1D* tensor input[i,j]. Each channel will be zeroed out independently on every forward call which based on Bernoulli distribution probability *p*.

The parper Dropout: A Simple Way to Prevent Neural Networks from Overfitting mentioned this technology, And it is proved that it can effectively reduce over fitting and prevent neuronal coadaptation. For more details, refer to Improving neural networks by preventing co-adaptation of feature detectors .

dropout1d can improve the independence between channel feature maps.

Parameters

- **input** (Tensor) −A tensor with shape (N, C, L) or (C, L), where N is the batch size, C is the number of channels, L is the feature length. The data type must be int8, int16, int32, int64, float16, float32 or float64.
- **p** (*float, optional*) −The dropping probability of a channel, between 0 and 1, e.g. $p = 0.8$, which means an 80% chance of clearing. Default: `0.5` .
- **training** (*bool, optional*) −Apply dropout if is True. Default: `True` .

Returns

Tensor, output, with the same shape and data type as *input*.

Raises

- **TypeError** −If *input* is not a Tensor.
- **TypeError** −If the data type of *p* is not float.
- **ValueError** −If *p* is out of the range *[0.0, 1.0]*.
- **ValueError** −If *input* shape is not *2D* or *3D*.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.random.randn(4, 3), mindspore.float32)
>>> output = ops.dropout1d(input_x, 0.5)
>>> print(output.shape)
(4, 3)
```

mindspore.ops.dropout2d

mindspore.ops.**dropout2d**(*input*, *p=0.5*, *training=True*)

During training, randomly zeroes some channels of the input tensor with probability *p* from a Bernoulli distribution(For a 4-dimensional tensor with a shape of *NCHW*, the channel feature map refers to a 2-dimensional feature map with the shape of *HW*).

For example, the *j_th* channel of the *i_th* sample in the batched input is a to-be-processed *2D* tensor input[i,j]. Each channel will be zeroed out independently on every forward call which based on Bernoulli distribution probability *p*. The parper Dropout: A Simple Way to Prevent Neural Networks from Overfitting mentioned this technology, And it is proved that it can effectively reduce over fitting and prevent neuronal coadaptation. For more details, refer to Improving neural networks by preventing co-adaptation of feature detectors .

dropout2d can improve the independence between channel feature maps.

Parameters

- **input** (Tensor) −A *4D* tensor with shape (N, C, H, W), where N is the batch size, C is the number of channels, H is the feature height, and W is the feature width. The data type must be int8, int16, int32, int64, float16, float32 or float64.
- **p** (*float*) −The dropping probability of a channel. The range is [0.0, 1.0], e.g. $p = 0.8$, which means dropping out 80% of channels. Default: `0.5` .
- **training** (*bool*) −If *training* is True, applying dropout, otherwise, not applying. Default: `True` .

Returns

Tensor, output, with the same shape and data type as *input*.

Raises

- **TypeError** −If *input* is not a Tensor.
- **TypeError** −If dtype of *input* is not int8, int16, int32, int64, float16, float32 or float64.
- **TypeError** −If the data type of *p* is not float.
- **ValueError** −If *p* is out of the range *[0.0, 1.0]*.
- **ValueError** −If *input* shape is not *4D*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.ones([2, 1, 2, 3]), mindspore.float32)
>>> output = ops.dropout2d(input, 0.5)
>>> print(output.shape)
(2, 1, 2, 3)
```

mindspore.ops.dropout3d

`mindspore.ops.`**`dropout3d`**(*input*, *p=0.5*, *training=True*)

During training, randomly zeroes some channels of the input tensor with probability *p* from a Bernoulli distribution(For a 5-dimensional tensor with a shape of $NCDHW$, the channel feature map refers to a 3-dimensional feature map with a shape of DHW).

For example, the *j_th* channel of the *i_th* sample in the batched input is a to-be-processed *3D* tensor input[i,j]. Each channel will be zeroed out independently on every forward call which based on Bernoulli distribution probability *p*.

dropout3d can improve the independence between channel feature maps.

Parameters

- **input** (Tensor) −A *5D* tensor with shape (N, C, D, H, W), where N is the batch size, C is the number of channels, D is the feature depth, H is the feature height, and W is the feature width. The data type must be int8, int16, int32, int64, float16, float32 or float64.
- **p** (*float*) −The dropping probability of a channel, between 0 and 1, e.g. $p = 0.8$, which means dropping out 80% of channels. Default: `0.5` .
- **training** (*bool*) −If *training* is True, applying dropout, otherwise, not applying. Default: `True` .

Returns

Tensor, output, with the same shape and data type as *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If dtype of *input* is not int8, int16, int32, int64, float16, float32 or float64.
- **TypeError** –If the data type of *p* is not float.
- **ValueError** –If *p* is out of the range *[0.0, 1.0]*.
- **ValueError** –If *input* shape is not 5D.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.ones([2, 1, 2, 1, 2]), mindspore.float32)
>>> output = ops.dropout3d(input, 0.5)
>>> print(output.shape)
(2, 1, 2, 1, 2)
```

mindspore.ops.embedding

`mindspore.ops.`**`embedding`**(*input*, *weight*, *padding_idx=None*, *max_norm=None*, *norm_type=2.0*, *scale_grad_by_freq=False*)

Retrieve the word embeddings in *weight* using indices specified in *input*.

> **Warning:** On Ascend, the behavior is unpredictable when the value of input is invalid.

Parameters

- **input** (`Tensor`) –The indices used to lookup in the *weight*. The data type must be mindspore.int32 or mindspore.int64, and the value should be in range *[0, weight.shape[0])*.
- **weight** (*`Union[Parameter, Tensor]`*) –The matrix where to lookup from. The shape must be 2D.
- **padding_idx** (*`int, optional`*) –If the value is not None, the corresponding row of *weight* will not be updated in training. The value should be in range *[-weight.shape[0], weight.shape[0])* if it's not `None`. Default `None`.
- **max_norm** (*`float, optional`*) –If not None, firstly get the p-norm result of the *weight* specified by *input* where p is specified by *norm_type*; if the result is larger then *max_norm*, update the *weight* with $\frac{max\_norm}{result+1e^{-7}}$ in-place. Default `None`.
- **norm_type** (*`float, optional`*) –Indicates the value of p in p-norm. Default `2.0`.
- **scale_grad_by_freq** (*`bool, optional`*) –If `True` the gradients will be scaled by the inverse of frequency of the index in *input*. Default `False`.

Returns

Tensor, has the same data type as *weight*, the shape is $(*input.shape, weight.shape[1])$.

Raises

- **ValueError** – If *padding_idx* is out of valid range.
- **ValueError** – If the shape of *weight* is invalid.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, Parameter, ops
>>> input = Tensor([[1, 0, 1, 1], [0, 0, 1, 0]])
>>> weight = Parameter(np.random.randn(3, 3).astype(np.float32))
>>> output = ops.embedding(input, weight, max_norm=0.4)
>>> print(output)
[[[ 5.49015924e-02,  3.47811311e-01, -1.89771220e-01],
  [ 2.09307984e-01, -2.24846993e-02,  3.40124398e-01],
  [ 5.49015924e-02,  3.47811311e-01, -1.89771220e-01],
  [ 5.49015924e-02,  3.47811311e-01, -1.89771220e-01]],
 [[ 2.09307984e-01, -2.24846993e-02,  3.40124398e-01],
  [ 2.09307984e-01, -2.24846993e-02,  3.40124398e-01],
  [ 5.49015924e-02,  3.47811311e-01, -1.89771220e-01],
  [ 2.09307984e-01, -2.24846993e-02,  3.40124398e-01]]]
```

mindspore.ops.flatten

mindspore.ops.**flatten**(*input*, *order='C'*, ***, *start_dim=1*, *end_dim=- 1*)

Flatten a tensor along dimensions from *start_dim* to *start_dim*.

Parameters

- **input** (Tensor) – The input Tensor.
- **order** (*str, optional*) – Only `'C'` and `'F'` are supported. `'C'` means to flatten in row-major (C-style) order. `'F'` means to flatten in column-major (Fortran-style) order. Default: `'C'` .

Keyword Arguments

- **start_dim** (int, *optional*) – The first dimension to flatten. Default: `1` .
- **end_dim** (int, *optional*) – The last dimension to flatten. Default: `-1` .

Returns

Tensor. If no dimensions are flattened, returns the original *input*, otherwise return the flattened Tensor. If *input* is a 0-dimensional Tensor, a 1-dimensional Tensor will be returned.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If *order* is not string type.
- **ValueError** – If *order* is string type, but not `'C'` or `'F'`.
- **TypeError** – If *start_dim* or *end_dim* is not int.

- **ValueError** – If *start_dim* is greater than *end_dim* after canonicalized.
- **ValueError** – If *start_dim* or *end_dim* is not in range of [-input.dim, input.dim-1].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.ones(shape=[1, 2, 3, 4]), mindspore.float32)
>>> output = ops.flatten(input_x)
>>> print(output.shape)
(1, 24)
```

mindspore.ops.fold

`mindspore.ops.`**`fold`**(*input*, *output_size*, *kernel_size*, *dilation=1*, *padding=0*, *stride=1*)

Combines an array of sliding local blocks into a large containing tensor.

Consider a batched input tensor of shape $(N, C \times \prod(\text{kernel\_size}), L)$, where N is the batch dimension, $C \times \prod(\text{kernel\_size})$ is the total number of values within each block (a block has $\prod(\text{kernel\_size})$ spatial locations each containing a C-channeled vector), and L is the total number of such blocks:

$$L = \prod_{d} \left\lfloor \frac{\text{output\_size}[d] + 2 \times \text{padding}[d] - \text{dilations}[d] \times (\text{kernel\_size}[d] - 1) - 1}{\text{strides}[d]} + 1 \right\rfloor,$$

where d is over all spatial dimensions.

Therefore, *output_size* is the spatial shape of the large containing tensor of the sliding local blocks.

The *dilation*, *padding* and *stride* arguments specify how the sliding blocks are retrieved.

Warning:

- The input must be a 3-dimensional Tensor with shape $(N, C \times \prod(\text{kernel\_size}), L)$.
- The output must be a 4-dimensional Tensor with shape $(N, C, output\_size[0], output\_size[1], ...)$.

Parameters

- **input** (`Tensor`) – 3-D Tensor, supported dtypes: float16, float32, float64, complex64 and complex128.
- **output_size** (`Tensor`) – 1D tensor with *2* elements of data type int.
- **kernel_size** (*`Union[int, tuple[int], list[int]]`*) – The size of the kernel, should be two int for height and width. If type is int, it means that height equal with width. Must be specified.
- **dilation** (*`Union[int, tuple[int], list[int]], optional`*) – The size of the dilation, should be two int for height and width. If type is int, it means that height equal with width. Default: `1` .
- **padding** (*`Union[int, tuple[int], list[int]], optional`*) – The size of the padding, should be two int for height and width. If type is int, it means that height equal with width. Default: `0` .

- **stride** (*Union[int, tuple[int], list[int]], optional*) – The size of the stride, should be two int for height and width. If type is int, it means that height equal with width. Default: `1` .

Returns

A Tensor, with same type as *input* . And its shape is as described above.

Raises

- **TypeError** – If *output_size*, *kernel_size*, *stride*, *dilation*, *padding* data type is not int, tuple or list.
- **ValueError** – If *output_size*, *kernel_size*, *dilation*, *stride* value is not greater than zero or elements number more than *2*.
- **ValueError** – If *padding* value is less than zero or elements number more than *2*.
- **ValueError** – If *input.shape[1] != kernel_size[0] * kernel_size[1]*
- **ValueError** – If *input.shape[2]* does not match the calculated number of sliding blocks.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor(input_data=np.random.rand(16, 64, 25), dtype=mstype.float32)
>>> output_size = Tensor(input_data=[8, 8], dtype=mstype.int32)
>>> output = ops.fold(x, output_size, [2, 2], [2, 2], [2, 2], [2, 2])
>>> print(output.shape)
(16, 16, 8, 8)
```

mindspore.ops.fractional_max_pool3d

mindspore.ops.**fractional_max_pool3d**(*input*, *kernel_size*, *output_size=None*, *output_ratio=None*, *return_indices=False*, *_random_samples=None*)

Applies the 3D FractionalMaxPool operation over *input*. The output Tensor shape can be determined by either *output_size* or *output_ratio*, and the step size is determined by *_random_samples*. *output_size* will take effect when *output_size* and *output_ratio* are set at the same time. And *output_size* and *output_ratio* can not be `None` at the same time.

Refer to the paper Fractional MaxPooling by Ben Graham for more details.

The input and output data format can be "NCDHW". N is the batch size, C is the number of channels, D the feature depth, H is the feature height, and W is the feature width.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (`Tensor`) – The input of FractionalMaxPool3d, which is a 4D or 5D tensor. Tensor of data type: float16, float32, double. Supported shape $(N, C, D_{in}, H_{in}, W_{in})$ or $(C, D_{in}, H_{in}, W_{in})$.

- **kernel_size** (*Union[int, tuple[int]]*) −The size of kernel used to take the maximum value, is an int number that represents depth, height and width of the kernel, or a tuple of three int numbers that represent depth, height and width respectively. The value must be a positive integer.
- **output_size** (*Union[int, tuple[int]], optional*) −The shape of the target *output_size*, is an int number that represents depth, height and width, or a tuple of three int numbers that represent depth, height and width respectively. The value must be a positive integer. Default: `None` .
- **output_ratio** (*Union[float, tuple[float]], optional*) −The ratio of target output shape to input shape. Specifying the size of the output tensor by using a ratio of the input size. Data type: float16, float32, double, and value is between (0, 1). Default: `None` .
- **return_indices** (*bool, optional*) −Whether to return the indices of max value. Default: `False` .
- **_random_samples** (`Tensor, optional`) −The random step of fractional_max_pool3d, which is a 3D tensor. Tensor of data type: float16, float32, double, and value is between [0, 1). Supported shape $(N, C, 3)$ or $(1, C, 3)$. Default: `None`, the values of *_random_samples* will be randomly distributed using uniform distribution over an interval [0,1).

Returns

- **y** (Tensor) - A tensor, the output of FractionalMaxPool3d. Has the same data type with *input*. Has the shape $(N, C, D_{out}, H_{out}, W_{out})$ or $(C, D_{out}, H_{out}, W_{out})$, where $(D_{out}, H_{out}, W_{out})$ = *output_size* or $(D_{out}, H_{out}, W_{out})$ = *output_ratio* * (D_{in}, H_{in}, W_{in}) .
- **argmax** (Tensor) - The indices along with the outputs, which is a Tensor, with the same shape as the *y* and int32 data type. It will output only when *return_indices* is True.

Raises

- **TypeError** −If *input* is not a 4D or 5D tensor.
- **TypeError** −If *_random_samples* is not a 3D tensor.
- **TypeError** −If data type of *input* is not float16, float32, double, int32, int64.
- **TypeError** −If dtype of *_random_samples* is not float16, float32, double.
- **TypeError** −If dtype of *argmax* is not int32, int64.
- **TypeError** −if _random_samples to have the different dtypes as input.
- **ValueError** −If *output_size* is a tuple and if *output_size* length is not 3.
- **ValueError** −If *kernel_size* is a tuple and if *kernel_size* length is not 3.
- **ValueError** −If numbers in *output_size* or *kernel_size* is not positive.
- **ValueError** −if *output_size* and *output_ratio* are None at the same time.
- **ValueError** −If the first dimension size of *input* and *_random_samples* is not equal.
- **ValueError** −If the second dimension size of *input* and *_random_samples* is not equal.
- **ValueError** −If the third dimension size of *_random_samples* is not 3.

Supported Platforms:

`GPU CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor(np.array([1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16])
...            .reshape([1, 1, 2, 2, 4]), mstype.float32)
>>> _random_samples = Tensor(np.array([0.7, 0.7, 0.7]).reshape([1, 1, 3]), mstype.float32)
>>> output, argmax = ops.fractional_max_pool3d(x, kernel_size=(1, 1, 1), output_size=(1, 1,␣
↪3),
...                                            _random_samples=_random_samples, return_
↪indices=True)
>>> print(output)
[[[[[13. 14. 16.]]]]]
>>> print(argmax)
[[[[[12 13 15]]]]]
>>> output, argmax = ops.fractional_max_pool3d(x, kernel_size=(1, 1, 1), output_ratio=(0.5,␣
↪0.5, 0.5),
...                                            _random_samples=_random_samples, return_
↪indices=True)
>>> print(output)
[[[[[13. 16.]]]]]
>>> print(argmax)
[[[[[12 15]]]]]
```

mindspore.ops.fused_infer_attention_score

mindspore.ops.**fused_infer_attention_score**(*query*, *key*, *value*, ***, *pse_shift=None*, *atten_mask=None*, *actual_seq_lengths=None*, *actual_seq_lengths_kv=None*, *dequant_scale1=None*, *quant_scale1=None*, *dequant_scale2=None*, *quant_scale2=None*, *quant_offset2=None*, *antiquant_scale=None*, *antiquant_offset=None*, *key_antiquant_scale=None*, *key_antiquant_offset=None*, *value_antiquant_scale=None*, *value_antiquant_offset=None*, *block_table=None*, *query_padding_size=None*, *kv_padding_size=None*, *key_shared_prefix=None*, *value_shared_prefix=None*, *actual_shared_prefix_len=None*, *num_heads=1*, *scale=1.0*, *pre_tokens=2147483647*, *next_tokens=2147483647*, *input_layout='BSH'*, *num_key_value_heads=0*, *sparse_mode=0*, *inner_precise=1*, *block_size=0*, *antiquant_mode=0*, *key_antiquant_mode=0*, *value_antiquant_mode=0*, *softmax_lse_flag=False*)

This is a FlashAttention function designed for both incremental and full inference scenarios. It supports full inference scenarios (PromptFlashAttention) as well as incremental inference scenarios (IncreFlashAttention). When the S dimension of the query tensor (Q_S) equals 1, it enters the IncreFlashAttention branch; otherwise, it enters the PromptFlashAttention branch.

$$Attention(Q, K, V) = Softmax(\frac{QK^T}{\sqrt{d}})V$$

Warning:

- This is an experimental API that is subject to change or deletion.
- For Ascend, only the Atlas A2 training series products and Atlas 800I A2 inference products are currently supported.

Note:

- The data layout formats of query, key and value can be interpreted from multiple dimensions, as shown below:
  - B, Batch size. Represents the batch size of the input samples.
  - S, Sequence length. Represents the sequence length of the input samples. S1 represents the sequence length of the query, and S2 represents the sequence length of the key/value.
  - H, Head size. Represents the size of the hidden layer.
  - N, Head nums. Represents the number of attention heads.
  - D, Head dims. Represents the smallest unit size of the hidden layer, satisfying $D = H/N$.

Parameters

- **query** (Tensor) –The query input of the attention structure, with data type of float16, bfloat16 or int8. Input tensor of shape (B, S, H), (B, N, S, D), or (B, S, N, D).
- **key** (*Union[Tensor, tuple[Tensor], list[Tensor]]*) –The key input of the attention structure, with data type of float16, bfloat16 or int8. Input tensor of shape (B, S, H), (B, N, S, D), or (B, S, N, D).
- **value** (*Union[Tensor, tuple[Tensor], list[Tensor]]*) –The value input of the attention structure, with data type of float16, bfloat16 or int8. Input tensor of shape (B, S, H), (B, N, S, D), or (B, S, N, D).

Keyword Arguments

- **pse_shift** (Tensor, *optional*) –The padding mask tensor with data type of float16 or bfloat16. Default: None.
  - When Q_S is not 1, if pse_shift is of type float16, the query must be of type float16 or int8. If pse_shift is of type bfloat16, the query must also be of type bfloat16. The input shape must be either (B, N, Q_S, KV_S) or $(1, N, Q\_S, KV\_S)$, where Q_S corresponds to the S dimension of the query shape, and KV_S corresponds to the S dimension of the key and value shapes. For scenarios where the KV_S of pse_shift is not 32-aligned, it is recommended to pad it to 32 bytes to improve performance. The padding values for the extra portions are not restricted.
  - When Q_S is 1, if pse_shift is of type float16, the query must also be of type float16. If pse_shift is of type bfloat16, the query must be of type bfloat16. The input shape must be $(B, N, 1, KV\_S)$ or $(1, N, 1, KV\_S)$, where KV_S corresponds to the S dimension of the key/value shapes. For scenarios where the KV_S of pse_shift is not 32-aligned, it is recommended to pad it to 32 bytes to improve performance. The padding values for the extra portions are not restricted.
- **atten_mask** (Tensor, *optional*) –The attention mask tensor for the result of query*key with data type of int8, uint8 or bool. For each element, 0 indicates retention and 1 indicates discard. Default: None.
  - When Q_S is not 1, the recommended input shapes are Q_S,KV_S; B,Q_S,KV_S; 1,Q_S,KV_S; B,1,Q_S,KV_S or 1,1,Q_S,KV_S.
  - When Q_S is 1, the recommended input shapes are B,KV_S; B,1,KV_S or B,1,1,KV_S.
- **actual_seq_lengths** (*Union[tuple[int], list[int], Tensor], optional*) –Describe actual sequence length of the query with data type of int64. If this parameter is not specified, it can be set to None, indicating that it matches the S dimension of the query shape. Constraint: The effective sequence length for each batch in this parameter should not exceed the corresponding batch's sequence length in the query. When Q_S is 1, this parameter is ignored. Default: None.
- **actual_seq_lengths_kv** (*Union[tuple[int], list[int], Tensor], optional*) –Describe actual sequence length of the key and value with data type of int64. If this parameter is not specified, it can be set to None, indicating that it matches the S dimension of the key and value shape. Constraint: The effective sequence length

for each batch in this parameter should not exceed the corresponding batch's sequence length in the key and value. Default: `None`.

- **dequant_scale1** (`Tensor, optional`) –Quantization factors for inverse quantization after BMM1 with data type of uint64. Supports per-tensor mode. If not used, set it to None. Default: `None`.
- **quant_scale1** (`Tensor, optional`) –Quantization factors for quantization before BMM2 with data type of float32. Supports per-tensor mode. If not used, set it to None. Default: `None`.
- **dequant_scale2** (`Tensor, optional`) –Quantization factors for inverse quantization after BMM2 with data type of uint64. Supports per-tensor mode. If not used, set it to None. Default: `None`.
- **quant_scale2** (`Tensor, optional`) –Quantization factors for output quantization with data type of float32, bfloat16. Supports per-tensor and per-channel modes. If not used, set it to None. Default: `None`.
- **quant_offset2** (`Tensor, optional`) –Quantization offset for output quantization with data type of float32, bfloat16. Supports per-tensor and per-channel modes. If not used, set it to None. Default: `None`.

  For scenarios where the input is int8 and the output is int8: the parameters dequant_scale1, quant_scale1, dequant_scale2, and quant_scale2 must all be provided. The parameter quant_offset2 is optional and defaults to 0 if not specified.

  – When the output is int8 and quant_scale2 and quant_offset2 are per-channel, left padding, Ring Attention, or D-axis misalignment (not 32-aligned) scenarios are not supported.

  – When the output is int8, scenarios with sparse_mode as band and pre_tokens/next_tokens being negative are not supported.

  – When the output is int8, if quant_offset2 is not None and empty tensor, and the sparse_mode, pre_tokens, and next_tokens meet the following conditions, certain rows of the matrix may not participate in calculations, leading to errors. This scenario will be intercepted (solution: if this scenario should not be intercepted, quantization should be performed outside the FIA interface, not enabled inside the FIA interface):

    * sparse_mode = 0, if atten_mask is a not None and each batch's actual_seq_lengths - actual_seq_lengths_kv - pre_tokens > 0 or next_tokens < 0, it will meet the interception condition.
    * sparse_mode = 1 or 2, no interception condition will occur.
    * sparse_mode = 3, if each batch's actual_seq_lengths - actual_seq_lengths_kv < 0, it will meet the interception condition.
    * sparse_mode = 4, if pre_tokens < 0 or each batch's next_tokens + actual_seq_lengths - actual_seq_lengths_kv < 0, it will meet the interception condition.

  For scenarios where the input is int8 and the output is float16: the parameters dequant_scale1, quant_scale1, and dequant_scale2 must all be provided.

  For scenarios where the input is entirely float16 or bfloat16 and the output is int8: the parameter quant_scale2 must be provided. The parameter quant_offset2 is optional and defaults to 0 if not specified.

  The parameters quant_scale2 and quant_offset2 support both per-tensor and per-channel modes and two data types: float32 and bfloat16. If quant_offset2 is provided, its type and shape must match those of quant_scale2. When the input is bfloat16, both float32 and bfloat16 are supported; otherwise, only float32 is supported. For per-channel mode: When the output layout is BSH, the product of all dimensions in quant_scale2 must equal H. For other layouts, the product must equal N * D. When the output layout is BSH, it is recommended to set the shape of quant_scale2 as $(1, 1, H)$ or (H). When the output layout is BNSD, it is recommended to set the shape as $(1, N, 1, D)$ or (N, D). When the output layout is BSND, it is recommended to set the shape as $(1, 1, N, D)$ or (N, D).

- **antiquant_scale** (`Tensor, optional`) –Inverse quantization factors with data type of float16, float32 or bfloat16. Only support float16 when Q_S > 1. Supports per-tensor, per-channel and per-token modes. Default: `None`.
- **antiquant_offset** (`Tensor, optional`) –Inverse quantization offset with data type of float16, float32 or bfloat16. Only support float16 when Q_S > 1. Supports per-tensor, per-channel and per-token modes. Default: `None`.

Constraints for antiquant_scale and antiquant_offset parameters:

- Supports three modes: per-channel, per-tensor, and per-token:
  - Per-channel mode: The shape of both parameters in the BNSD layout is $(2, N, 1, D)$, the shape in the BSND layout is $(2, N, D)$, and the shape in the BSH layout is $(2, H)$, where 2 corresponds to the key and value, and N represents num_key_value_heads. The parameter data type is the same as the query data type, and antiquant_mode should be set to 0.
  - Per-tensor mode: The shape of both parameters is (2), the data type is the same as the query data type, and antiquant_mode should be set to 0.
  - Per-token mode: The shape of both parameters is $(2, B, S)$, the data type is fixed to float32, and antiquant_mode should be set to 1.
- Supports both symmetric and asymmetric quantization:
  - Asymmetric quantization mode: Both antiquant_scale and antiquant_offset must be provided.
  - Symmetric quantization mode: antiquant_offset can be empty (`None`). If antiquant_offset is empty, symmetric quantization is performed. If antiquant_offset is provided, asymmetric quantization is performed.

- **key_antiquant_scale** (*Tensor, optional*) – Inverse quantization factors for the key, with data type of float16, float32 or bfloat16, when the KV fake quantization parameters are separated. Supports per-tensor, per-channel and per-token modes. Default: `None`. Invalid when Q_S > 1.
- **key_antiquant_offset** (*Tensor, optional*) – Inverse quantization offset for the key, with data type of float16, float32 or bfloat16, when the KV fake quantization parameters are separated. Supports per-tensor, per-channel and per-token modes. Default: `None`. Invalid when Q_S > 1.
- **value_antiquant_scale** (*Tensor, optional*) – Inverse quantization factors for the value, with data type of float16, float32 or bfloat16, when the KV fake quantization parameters are separated. Supports per-tensor, per-channel and per-token modes. Default: `None`. Invalid when Q_S > 1.
- **value_antiquant_offset** (*Tensor, optional*) – Inverse quantization offset for the value, with data type of float16, float32 or bfloat16, when the KV fake quantization parameters are separated. Supports per-tensor, per-channel and per-token modes. Default: `None`. Invalid when Q_S > 1.
- **block_table** (*Tensor, optional*) – Block mapping table in KV cache for PageAttention, with data type of int32. If not used, set it to None. Default: `None`. Invalid when Q_S > 1.
- **query_padding_size** (*Tensor, optional*) – The query padding size with data type of int64. Indicates whether the data in each batch of the query is right-aligned, and how many elements are right-aligned. Default: `None`. Invalid when Q_S is 1.
- **kv_padding_size** (*Tensor, optional*) – The key and value padding size with data type of int64. Indicates whether the data in each batch of the key and value is right-aligned, and how many elements are right-aligned. Default: `None`. Invalid when Q_S is 1.
- **key_shared_prefix** (*Tensor, optional*) – Shared prefix of the key. This is a reserved parameter and is not yet enabled. Default: `None`.
- **value_shared_prefix** (*Tensor, optional*) – Shared prefix of the value. This is a reserved parameter and is not yet enabled. Default: `None`.
- **actual_shared_prefix_len** (*Union[tuple[int], list[int], Tensor], optional*) – Describe the actual length of shared prefix. This is a reserved parameter and is not yet enabled. Default: `None`.
- **num_heads** (*int, optional*) – The number of heads in the query, equal to N when input_layout is BNSD. Default: `1`.
- **scale** (*double, optional*) – The scale value indicating the scale coefficient, which serves as the scalar value for the Muls in the calculation. Generally, the value is $1.0/\sqrt{d}$. Default: `1.0`.

- **pre_tokens** (int, *optional*) −Parameter for sparse computation, represents how many tokens are counted forward. Default: 2147483647. Invalid when Q_S is 1.
- **next_tokens** (int, *optional*) −Parameter for sparse computation, represents how many tokens are counted backward. Default: 2147483647. Invalid when Q_S is 1.
- **input_layout** (*str*, *optional*) −Specifies the layout of input query, key and value. BSH, BNSD, BSND or BNSD_BSND is supported. When the layout is BNSD_BSND, it means the input is in the BNSD format and the output is in the BSND format, this is only supported when Q_S > 1. Default: BSH.
- **num_key_value_heads** (int, *optional*) −Head numbers of key/value which are used in GQA (Grouped-Query Attention) scenario. Default: 0. A value of 0 means it is equal to the number of key/value heads. The num_heads must be divisible by num_key_value_heads, and the ratio of num_heads to num_key_value_heads must not be greater than 64. When the layout is BNSD, the num_key_value_heads must also equals to the N dimension of the key/value shapes, otherwise, an execution error will occur.
- **sparse_mode** (int, *optional*) −Indicates sparse mode. Default 0. Invalid when Q_S is 1.
  - 0: Indicates the defaultMask mode. If atten_mask is not passed, the mask operation is not performed, and pre_tokens and next_tokens(internally assigned as INT_MAX) are ignored. If passed in, the complete atten_mask matrix (S1 * S2) also must be passed in, indicating that the part between pre_tokens and next_tokens needs to be calculated.
  - 1: Represents allMask. The complete atten_mask matrix (S1 * S2) is required.
  - 2: Represents the mask in leftUpCausal mode. The optimized atten_mask matrix (2048*2048) is required.
  - 3: Represents the mask in rightDownCausal mode, corresponding to the lower triangular scenario divided by the right vertex. The optimized atten_mask matrix (2048*2048) is required.
  - 4: Represents the mask in band mode, that is, the part between counting pre_tokens and next_tokens. The optimized atten_mask matrix (2048*2048) is required.
  - 5: Represents the prefix scenario, not implemented yet.
  - 6: Represents the global scenario, not implemented yet.
  - 7: Represents the dilated scenario, not implemented yet.
  - 8: Represents the block_local scenario, not implemented yet.
- **inner_precise** (int, *optional*) −There are four modes: 0, 1, 2, and 3, represented by 2 bits: bit 0 (bit0) represents the choice for high precision or high performance, and bit 1 (bit1) indicates whether row-wise invalidity correction is applied.
  - 0: Enable high-precise mode, without row-wise invalidity correction.
  - 1: High-performance mode, without row-wise invalidity correction.
  - 2: Enable high-precise mode, with row-wise invalidity correction.
  - 3: High-performance mode, with row-wise invalidity correction.

  When Q_S > 1, if sparse_mode is 0 or 1 and a user-defined mask is provided, it is recommended to enable row-wise invalidity correction. Only support 0 and 1 when Q_S is 1. Default: 1.

  High-precise and high-performance are only effective for float16 inputs; Row invalidity correction is effective for float16, bfloat16, and int8 inputs. Currently, 0 and 1 are reserved configuration values. If there is a situation where an entire row in the "mask portion involved in computation" is all 1s, precision may degrade. In such cases, you can try setting this parameter to 2 or 3 to enable row invalidity correction for improved precision. However, this configuration will result in decreased performance. If the function can detect the presence of invalid row scenarios, e.g. in cases where sparse_mode is 3 and S_q > S_kv, it will automatically enable row invalidity computation.

- **block_size** (int, *optional*) −Maximum number of tokens per block in the KV cache block for PageAttention. Default: 0. Invalid when Q_S > 1.
- **antiquant_mode** (int, *optional*) −Fake-quantization mode, 0: per-channel (per-channel includes per-tensor), 1: per-token. The per-channel and per-tensor modes can be distinguished by the dimension of the input shape. When the dimension is 1, it runs in per-tensor mode; otherwise, it runs in per-channel mode. Default: 0. Invalid when Q_S > 1.
- **key_antiquant_mode** (int, *optional*) −Fake-quantization mode for the key. 0: per-channel (per-channel includes per-tensor), 1: per-token. Default: 0. Invalid when Q_S > 1.
- **value_antiquant_mode** (int, *optional*) −Fake-quantization mode for the value. 0: per-channel (per-channel includes per-tensor), 1: per-token. Default: 0. Invalid when Q_S > 1.
- **softmax_lse_flag** (bool, *optional*) −Whether to output softmax_lse. Default: False.

Returns

attention_out (Tensor), the attention score with data type of float16, bfloat16 or int8. When the input_layout is BNSD_BSND, the shape is (B, S, N, D). In all other cases, the shape is consistent with the input query shape.

softmax_lse (Tensor), the softmax_lse with data type of float32, obtained by taking the lse (log, sum and exp) of the result of query*key. Specifically, the Ring Attention algorithm first takes the max of the result of query*key, obtaining softmax_max. The result of query*key is then subtracted by softmax_max, followed by taking exp, and then the sum is computed to obtain softmax_sum. Finally, the log of softmax_sum is taken, and softmax_max is added to obtain softmax_lse. The softmax_lse is only calculated when softmax_lse_flag is True, and the shape would be $(B, N, Q\_S, 1)$. If softmax_lse_flag is False, then a tensor with shape (1) filled with zeros would be returned. In graph mode with JitConfig set to O2, please ensure that the softmax_lse_flag is enabled before using softmax_lse; otherwise, an exception will occur.

Constraints:

- Full Inference Scenario (Q_S > 1):
  - Query, key, and value inputs functional usage restrictions:
    - The B axis supports values less than or equal to 65535. If the input type includes int8, or if the input type is float16 or bfloat16 and the D axis is not 16-aligned, the B axis is only supported up to 128.
    - The N axis supports values less than or equal to 256, and the D axis supports values less than or equal to 512.
    - The S axis supports values less than or equal to 20,971,520 (20M). In some long sequence scenarios, if the computation load is too large, it may cause a timeout in the PFA operator (AICore error type with errorStr: "timeout or trap error"). In this case, it is recommended to perform an S split. Note: The computational load is affected by B, S, N, D, etc.; the larger the values, the greater the computational load. Typical long sequence timeout scenarios (where the product of B, S, N, and D is large) include, but are not limited to:
      1. B=1, Q_N=20, Q_S=2097152, D=256, KV_N=1, KV_S=2097152;
      2. B=1, Q_N=2, Q_S=20971520, D=256, KV_N=2, KV_S=20971520;
      3. B=20, Q_N=1, Q_S=2097152, D=256, KV_N=1, KV_S=2097152;
      4. B=1, Q_N=10, Q_S=2097152, D=512, KV_N=1, KV_S=2097152.
    - When the query, key, value, or attention_out type includes int8, the D axis must be 32-aligned. If all types are float16 or bfloat16, the D axis must be 16-aligned.
  - The sparse_mode parameter currently only supports values 0, 1, 2, 3, and 4. Using any other values will result in an error.
    - When sparse_mode = 0, if the atten_mask is None, or if the atten_mask is provided in the left padding scenario, the input parameters pre_tokens and next_tokens are ignored.

    - When sparse_mode = 2, 3, or 4, the shape of the atten_mask must be S,S or 1,S,S or 1,1,S,S, where S must be fixed at 2048, and the user must ensure the atten_mask is a lower triangular matrix. If no atten_mask is provided or if the shape is incorrect, an error will occur.
    - In sparse_mode = 1, 2, 3 scenarios, the pre_tokens and next_tokens inputs are ignored and assigned according to the relevant rules.
  - The KV cache de-quantization only supports queries of type float16, where int8 keys and values are de-quantized to float16. The data range of the input key/value and the antiquant_scale must have a product within the range of (-1, 1). High-performance mode can guarantee precision; otherwise, high-precision mode should be enabled to ensure accuracy.
  - Query left padding scenario:
    - In the query left padding scenario, the formula for calculating the starting point of the query transport is: Q_S - query_padding_size - actual_seq_lengths. The formula for the ending point of the query transport is: Q_S - query_padding_size. The query transport starting point must not be less than 0, and the ending point must not exceed Q_S; otherwise, the results will be incorrect.
    - If the kv_padding_size in the query left padding scenario is less than 0, it will be set to 0.
    - The query left padding scenario must be enabled together with the actual_seq_lengths parameter, otherwise, the default is the query right padding scenario.
    - The query left padding scenario does not support PageAttention and cannot be enabled together with the block_table parameter.
  - KV left padding scenario:
    - In the KV left padding scenario, the formula for calculating the starting point of the key and value transport is: KV_S - kv_padding_size - actual_seq_lengths_kv. The formula for the ending point of the key and value transport is: KV_S - kv_padding_size. The key and value transport starting point must not be less than 0, and the ending point must not exceed KV_S; otherwise, the results will be incorrect.
    - If the kv_padding_size in the KV left padding scenario is less than 0, it will be set to 0.
    - The KV left padding scenario must be enabled together with the actual_seq_lengths_kv parameter, otherwise, the default is the KV right padding scenario.
    - The KV left padding scenario does not support PageAttention and cannot be enabled together with the block_table parameter.
  - pse_shift functional usage restrictions:
    - This function is supported when the query data type is float16, bfloat16, or int8.
    - If the query data type is float16 and pse_shift is enabled, it will force high-precision mode, inheriting the limitations of high-precision mode.
    - Q_S must be greater than or equal to the length of the query S, and KV_S must be greater than or equal to the length of the key S.
  - KV fake quantization parameter separation is not currently supported.
- Incremental Inference Scenario (Q_S is 1):
  - Query, key, and value inputs functional usage restrictions:
    - The B axis supports values less than or equal to 65,536.
    - The N axis supports values less than or equal to 256.
    - The D axis supports values less than or equal to 512.
    - Scenarios where the input types of query, key, and value are all int8 are not supported.

- Page attention scenario:
  - The necessary condition to enable page attention is that the block_table exists and is valid. The key and value are arranged in contiguous memory according to the indices in the block_table. The key and value dtypes supported are float16, bfloat16, and int8. In this scenario, the input_layout parameter for key and value is invalid.
  - block_size is a user-defined parameter, and its value will affect the performance of page attention. When enabling page attention, a non-zero value for block_size must be provided, and the maximum value for block_size is 512.
  - If the input types of key and value are float16 or bfloat16, they must be 16-aligned. If the input types are int8, they must be 32-aligned, with 128 being recommended. In general, page attention can increase throughput but may lead to a performance decrease.
  - In the page attention enabled scenario, when the KV cache layout is (blocknum, block_size, H) and num_key_value_heads * D exceeds 64K, an error will be reported due to hardware instruction constraints. This can be resolved by enabling GQA (reducing num_key_value_heads) or adjusting the KV cache layout to (blocknum, num_key_value_heads, block_size, D).
  - The product of all dimensions of the shape of the key and value tensors in the page attention scenario must not exceed the representable range of int32.
- In the page attention enabled scenario, the input S must be greater than or equal to max_block_num_per_seq * block_size.
  - Enabling attention mask (e.g., mask shape = (B, 1, 1, S))
  - Enabling pse_shift (e.g., pse_shift shape = (B, N, 1, S))
  - Enabling fake quantization in per-token mode (e.g., antiquant_scale and antiquant_offset shapes = (2, B, S)) are also supported.
- KV left padding scenario:
  - In the KV left padding scenario, the formula for calculating the starting point of the KV cache transport is: KV_S - kv_padding_size - actual_seq_lengths. The formula for the endpoint of the KV cache transport is: KV_S - kv_padding_size. If the starting point or endpoint of the KV cache is less than 0, the returned data result will be all zeros.
  - If kv_padding_size is less than 0 in the KV left padding scenario, it will be set to 0.
  - The KV left padding scenario must be enabled together with the actual_seq_lengths parameter, otherwise, it defaults to the KV right padding scenario.
  - The KV left padding scenario must be enabled together with the atten_mask parameter, and the atten_mask must be correctly applied to hide invalid data. Otherwise, accuracy issues may arise.
- pse_shift functional usage restrictions:
  - The data type of pse_shift must match the data type of the query.
  - Only the D axis alignment is supported, meaning the D axis must be divisible by 16.
- KV fake quantization parameter separation:
  - key_antiquant_mode and value_antiquant_mode must be consistent.
  - key_antiquant_scale and value_antiquant_scale must either both be empty or both non-empty.
  - key_antiquant_offset and value_antiquant_offset must either both be empty or both non-empty.
  - When both key_antiquant_scale and value_antiquant_scale are non-empty, their shapes must be consistent.
  - When both key_antiquant_offset and value_antiquant_offset are non-empty, their shapes must be consistent.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import ops
>>> from mindspore import Tensor
>>> import numpy as np
>>> B, N, S, D = 1, 8, 1024, 128
>>> query = Tensor(np.random.rand(B, N, S, D).astype(np.float16))
>>> key = Tensor(np.random.rand(B, N, S, D).astype(np.float16))
>>> value = Tensor(np.random.rand(B, N, S, D).astype(np.float16))
>>> out = ops.fused_infer_attention_score(query, key, value, num_heads=N, input_layout='BNSD
↪')
>>> print(out[0].shape)
(1, 8, 1024, 128)
```

mindspore.ops.speed_fusion_attention

mindspore.ops.**speed_fusion_attention**(*query*, *key*, *value*, *head_num*, *input_layout*, ***, *pse=None*, *padding_mask=None*, *atten_mask=None*, *scale=1.0*, *keep_prob=1.0*, *pre_tokens=2147483647*, *next_tokens=2147483647*, *inner_precise=0*, *prefix=None*, *actual_seq_qlen=None*, *actual_seq_kvlen=None*, *sparse_mode=0*, *gen_mask_parallel=True*, *sync=False*, *pse_type=1*, *q_start_idx=None*, *kv_start_idx=None*)

The interface is used for self-attention fusion computing. If *pse_type* is `1` , calculation formula is:

$$attention\_out = Dropout(Softmax(Mask(scale * (pse + query * key^T), atten\_mask)), keep\_prob) * value$$

If *pse_type* is other valid value, calculation formula is:

$$attention\_out = Dropout(Softmax(Mask(scale * (query * key^T) + pse, atten\_mask)), keep\_prob) * value$$

- B: Batch size. Value range 1 to 2k.
- S1: Sequence length of query. Value range 1 to 512k.
- S2: Sequence length of key and value. Value range 1 to 512k.
- N1: Num heads of query. Value range 1 to 256.
- N2: Num heads of key and value, and N2 must be a factor of N1.
- D: Head size. The value ranges is a multiple of 16, with the max value of 512.
- H1: Hidden size of query, which equals to N1 * D.
- H2: Hidden size of key and value, which equals to N2 * D.

Warning:

- This is an experimental API that is subject to change or deletion.
- Only support on Atlas A2 training series.

Note: This interface is not supported in graph mode (mode=mindspore.GRAPH_MODE).

Parameters

- **query** (Tensor) −The query tensor. Input tensor of shape $(B, S1, H1)$, $(B, N1, S1, D)$, $(S1, B, H1)$, $(B, S1, N1, D)$ or $(T1, N1, D)$.
- **key** (Tensor) −The key tensor. Input tensor of shape $(B, S2, H2)$, $(B, N2, S2, D)$, $(S2, B, H2)$, $(B, S2, N2, D)$ or $(T2, N2, D)$.
- **value** (Tensor) −The value tensor. Input tensor of shape $(B, S2, H2)$, $(B, N2, S2, D)$, $(S2, B, H2)$, $(B, S2, N2, D)$ or $(T2, N2, D)$. The *key* and *value* should have the same shape.
- **head_num** (*int*) −The head num of query, equal to N1.
- **input_layout** (*str*) −Specifies the layout of input *query*, *key* and *value*. The value can be "BSH" , "BNSD" , "SBH" , "BSND" or "TND" . "TND" is an experimental format. When *input_layout* is "TND" , the following restrictions must be met. There are two lists that represent the length of the input sequence: list_seq_q and list_seq_k. Each value in the list indicates the length of the sequence in the batch. For example, list_seq_q = [4, 2, 6], list_seq_k = [10, 3, 9]. The element of list indicate S. T1 is sum(list_seq_q) = 12, T2 is sum(list_seq_k) = 22. max_seqlen_q = max(list_seq_q), max_seqlen_k = max(list_seq_k). qk_pointer = sum(list_seq_q * list_seq_k), which is the sum of the element multiplication.
  - The lengths of two lists are the same, and size of list is batch. batch is less than or equal to 1024.
  - When *input_layout* is "TND" , *actual_seq_qlen* and *actual_seq_kvlen* must be not None . Otherwise, they are None .
  - The *actual_seq_qlen* and *actual_seq_kvlen* are the cumulative sum of sequence of key/value, so they must be non-decreasing.
  - If *pse* is not None , list_seq_q and list_seq_k must be same. The maximum value of list_seq_q and list_seq_k is greater than 1024. *pse* should be $(B, N1, 1024, S2)$ and $(1, N1, 1024, S2)$, and S2 is equal to max_seqlen_k.
  - *atten_mask* must be a lower trianglar matrix, so *sparse_mode* should be 2 or 3. The shape of *atten_mask* should be $(2048, 2048)$.
  - Prefix is None .
  - *next_tokens* is 0, and *pre_tokens* is not less than max_seqlen_q.
  - When *sparse_mode* is 3, S1 of each batch should be less than or equal to S2.
  - 0 should not exist in list_seq_k.

Keyword Arguments

- **pse** (Tensor, *optional*) −The position embedding code, dtype is same as *query*. Default: None . If S is greater than 1024 and the mask of the lower triangle is used, enter only the inverse 1024 lines of the lower triangle for memory optimization. Input tensor of shape $(B, N1, S1, S2)$, $(1, N1, S1, S2)$, $(B, N1, 1024, S2)$, $(1, N1, 1024, S2)$.
  - ALiBi scenario: *pse* must meet the ALiBi rule, and *sparse_mode* is 2 or 3 for the lower triangle. In this scenario, *pse* is $(B, N1, 1024, S2)$, $(1, N1, 1024, S2)$.
  - Non-ALiBi scenario: *pse* is $(B, N1, S1, S2)$, $(1, N1, S1, S2)$.
  - The shape of *pse* should be $(B, N1, 1024, S2)$ and $(1, N1, 1024, S2)$ when *input_layout* is "TND" .
  - If *pse_type* is 2 or 3, dtype of *pse* must be float32, and shape of *pse* should be $(B, N1)$ or $(N1,)$.
- **padding_mask** (Tensor, *optional*) −Reserved parameter. Not implemented yet. Default: None .
- **atten_mask** (Tensor, *optional*) −The attention mask tensor. For each element, 0/False indicates retention and 1/True indicates discard. Input tensor of shape $(B, N1, S1, S2)$, $(B, 1, S1, S2)$, $(S1, S2)$ or $(2048, 2048)$. Default: None .
  - In compression scenario, *sparse_mode* is 2, 3, or 4, *atten_mask* must be $(2048, 2048)$.

  - When *sparse_mode* is 5, *atten_mask* must be $(B, N1, S1, S2)$, $(B, 1, S1, S2)$.
  - When *sparse_mode* is 0 and 1, *atten_mask* should be $(B, N1, S1, S2)$, $(B, 1, S1, S2)$, $(S1, S2)$.

- **scale** (float, *optional*) –The scale factor of score. Generally, the value is 1.0 / (D ** 0.5). Default: `1.0` .
- **keep_prob** (float, *optional*) –The keep probability of dropout. Value range is (0.0, 1.0]. Default: `1.0` .
- **pre_tokens** (int, *optional*) –Parameter for sparse computation, represents how many tokens are counted forward. When *sparse_mode* is set to 1, 2, 3, or 5, this parameter does not take effect. Default: `2147483647` .
- **next_tokens** (int, *optional*) –Parameter for sparse computation, represents how many tokens are counted backward. When *sparse_mode* is set to 1, 2, 3, or 5, this parameter does not take effect. Default: `2147483647` . The value of pre_tokens corresponds to S1, and the value of next_tokens corresponds to S2. They define the valid area on the *atten_mask* matrix. It must ensure that the band is not empty. The following values are not allowed:
  - pre_tokens < 0 and next_tokens < 0.
  - (pre_tokens < 0 and next_tokens >= 0) and (next_tokens < abs(pre_tokens) or abs(pre_tokens) >= S2).
  - (pre_tokens >= 0 and next_tokens < 0) and (abs(next_tokens) > pre_tokens or abs(next_tokens) >= S1).
- **inner_precise** (int, *optional*) –The parameter is reserved and not implemented yet. Default: `0` .
- **prefix** (*Union[tuple[int], list[int]], optional*) –N value of each Batch in the prefix sparse calculation scenario. Input tensor of shape $(B,)$. B max value 32. Not none only when sparse_mode is 5. If S1 > S2, N ranges from 0 to S2. If S1 <= S2, N ranges from S2 - S1 to S2. Default: `None` .
- **actual_seq_qlen** (*Union[tuple[int], list[int]], optional*) –Size of query corresponding to each batch, array with increasing values and the last value equal to T1. Default: `None` .
- **actual_seq_kvlen** (*Union[tuple[int], list[int]], optional*) –Size of key and value corresponding to each batch, array with increasing values and the last value equal to T2. Default: `None` .
- **sparse_mode** (int, *optional*) –Indicates sparse mode. Default `0` .
  - 0: Indicates the defaultMask mode. If *atten_mask* is not passed, the mask operation is not performed, and preTokens and nextTokens(internally assigned as INT_MAX) are ignored. If passed in, the full *atten_mask* matrix (S1 * S2) needs to be passed in, indicating that the part between preTokens and nextTokens needs to be calculated.
  - 1: Represents allMask, that is, passing in the complete *atten_mask* matrix.
  - 2: Representing the leftUpCausal mode corresponds to the lower triangle scenario divided by the left vertex, and the optimized *atten_mask* matrix (2048*2048) is required.
  - 3: Representing the rightDownCausal model corresponds to the lower triangle scene divided by the lower right vertex, and the optimized *atten_mask* matrix (2048*2048) is required.
  - 4: Represents the band scenario, that is, the part between counting preTokens and nextTokens, and the optimized *atten_mask* matrix (2048*2048) is required.
  - 5: Represents the prefix scenario, that is, on the basis of rightDownCasual, a matrix with length S1 and width N is added to the left side. The value of N is obtained by the new input prefix, and the N value of each Batch axis is different. Currently not enabled.
  - 6: Represents the global scenario. Currently not enabled.
  - 7: Represents the dilated scenario. Currently not enabled.
  - 8: Represents the block_local scenario. Currently not enabled.
- **gen_mask_parallel** (bool, *optional*) –Debug parameter, a switch to control dropout_gen_mask execution method. If `True` , dropout_gen_mask is executed in parallel. If `False` , execution is serial. Not implemented yet. Default: `True` .

- **sync** (bool, *optional*) –Debug parameter, a switch to control dropout_gen_mask execution method. If `True` , dropout_gen_mask is executed synchronously. If `False` , execution is asynchronous. Not implemented yet. Default: `False` .
- **pse_type** (int, *optional*) –Indicates how to use *pse*. Default `1` .
  - 0: *pse* is passed from outside, and the calculation process is to first mul *scale* and then add *pse*.
  - 1: *pse* is passed from outside, and the calculation process is to add *pse* first and then mul *scale*.
  - 2: *pse* is generated internally and generates standard alibi position information. The internally generated alibi matrix 0 line is aligned with the upper left corner of $query * key^T$.
  - 3: *pse* is generated internally, and the generated alibi position information is based on the standard and then the square root of sqrt is done. The internally generated alibi matrix 0 line is aligned with the upper left corner of $query * key^T$.
- **q_start_idx** (*Union[tuple[int], list[int]], optional*) –Int array with length 1. Default: `None` . When pse_type is configured as `2` or `3` , it indicates the number of cells that the internally generated alibi code is offset in the S1 direction. A positive number indicates that 0 moves diagonally upward.
- **kv_start_idx** (*Union[tuple[int], list[int]], optional*) –Int array with length 1. Default: `None` . When pse_type is configured as `2` or `3` , it indicates the number of cells that the internally generated alibi code is offset in the S2 direction. A positive number indicates that 0 moves diagonally upward.

Returns

A tuple of tensors containing *attention_out*, *softmax_max*, *softmax_sum*, *softmax_out*, *seed*, *offset* and *numels* .

- *attention_out* is the output of attention, it's shape, and data type are the same as the query.
- *softmax_max* is the max intermediate result calculated by Softmax, used for grad calculation.
- *softmax_sum* is the sum intermediate result calculated by Softmax, used for grad calculation.
- *softmax_out* is a reserved parameter.
- *seed* is generated seed, used for Dropout.
- *offset* is generated offset, used for Dropout.
- *numels* is the length of generated dropout_mask.

Raises

- **TypeError** –*query*, *key* and *value* don't have the same dtype.
- **TypeError** –Dtype of *atten_mask* is not bool or uint8.
- **TypeError** –*scale* or *keep_prob* is not a float number.
- **TypeError** –*input_layout* is not a string.
- **TypeError** –*head_num* is not an int.
- **TypeError** –*sparse_mode* is not an int.
- **TypeError** –*pse* is not Tensor type.
- **TypeError** –*padding_mask* is not Tensor type.
- **TypeError** –*atten_mask* is not Tensor type.
- **TypeError** –*pse_type* is not an int.
- **ValueError** –*input_layout* is a string but not valid.

- **ValueError** –The specified value of *sparse_mode* is invalid.
- **ValueError** –The specified value of *pse_type* is invalid.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import mindspore.common.dtype as mstype
>>> import numpy as np
>>> from mindspore import ops, Tensor
>>> query = Tensor(np.ones([2, 4, 64]), dtype=mstype.float16)
>>> key = Tensor(np.ones([2, 4, 64]), dtype=mstype.float16)
>>> value = Tensor(np.ones([2, 4, 64]), dtype=mstype.float16)
>>> head_num = 4
>>> input_layout = "BSH"
>>> output = ops.speed_fusion_attention(query, key, value, head_num, input_layout)
>>> print(output[0].shape)
(2, 4, 64)
```

mindspore.ops.group_norm

`mindspore.ops.`**`group_norm`**(*input*, *num_groups*, *weight=None*, *bias=None*, *eps=1e-5*)

Group Normalization over a mini-batch of inputs.

Group Normalization is widely used in recurrent neural networks. It applies normalization on a mini-batch of inputs for each single training case as described in the paper Group Normalization. Group Normalization divides the channels into groups and computes within each group the mean and variance for normalization, and it performs very stable over a wide range of batch size. γ and β are trainable scale and shift. It can be described using the following formula:

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

where γ is *weight*, β is *bias*, ϵ is *eps*.

Parameters

- **input** (`Tensor`) –The input feature with shape $(N, C, *)$ where $*$ means, any number of additional dimensions.
- **num_groups** (*int*) –The number of groups to be divided along the channel dimension.
- **weight** (`Tensor, optional`) –The shape $(C,)$, Default: `None`, has the same data type with *input*.
- **bias** (`Tensor, optional`) –The shape $(C,)$, Default: `None`, has the same data type with *input*.
- **eps** (*float, optional*) –A value added to the denominator for numerical stability. Default: `1e-5` .

Returns

Tensor, the normalized and scaled offset tensor, has the same shape and data type as the *input*.

Raises

- **TypeError** –If *num_groups* is not an int.
- **TypeError** –If *eps* is not a float.
- **ValueError** –If *num_groups* is less than 1.

- **ValueError** –If *C* (the second parameter of dimensions of *input*) is not divided by *num_groups*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import ops
>>> x = ms.Tensor(np.ones([1, 2, 4, 4], np.float32))
>>> output = ops.group_norm(x, 2)
>>> print(output)
[[[[0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]]
  [[0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]]]]
```

mindspore.ops.layer_norm

`mindspore.ops.`**`layer_norm`**(*input*, *normalized_shape*, *weight=None*, *bias=None*, *eps=1e-5*)

Applies the Layer Normalization on the mini-batch input.

Layer normalization is widely used in recurrent neural networks. Apply normalization to the mini-batch input of a single training case. LayerNorm is described in the paper Layer Normalization.

Unlike batch normalization, layer normalization performs the exact same calculations at training and test time. Applies to all channels and pixels, even batch_size=1. The formula is as follows:

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

where γ is the weight value learned through training, β is the bias value learned through training.

Parameters

- **input** (`Tensor`) –The shape of input is *(N, *)*, where * represents any additional dimension.
- **normalized_shape** (*`Union(int, tuple[int], list[int])`*) –The normalized shape of *input* for LayerNorm. *normalized_shape* equal to *input_shape[begin_norm_axis:]*, where *begin_norm_axis* represents the axis where normalization begins.
- **weight** (`Tensor, optional`) –Learnable parameter γ . Tensor of shape *normalized_shape*. Default: `None`, has the same data type with *input*. Initialized to `1` when *weight* is None.
- **bias** (`Tensor, optional`) –Learnable parameter β . Tensor of shape *normalized_shape*. Default: `None`, has the same data type with *input*. Initialized to `0` when *bias* is None.
- **eps** (*`float, optional`*) –A value added to the denominator for numerical stability(ϵ). Default: `1e-5` .

Returns

Tensor. The normalized tensor, has the same type and shape as the *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *normalized_shape* is not an integer, a list or a tuple.
- **TypeError** –If *eps* is not a float.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[1, 2, 3], [1, 2, 3]]), mindspore.float32)
>>> normalized_shape = (3,)
>>> gamma = Tensor(np.ones(normalized_shape), mindspore.float32)
>>> beta = Tensor(np.zeros(normalized_shape), mindspore.float32)
>>> eps = 1e-7
>>> output = ops.layer_norm(input_x, normalized_shape, gamma, beta, eps)
>>> print(output)
[[-1.2247448 0. 1.2247448]
 [-1.2247448 0. 1.2247448]]
```

mindspore.ops.lp_pool1d

mindspore.ops.**lp_pool1d**(*x*, *norm_type*, *kernel_size*, *stride=None*, *ceil_mode=False*)

Applying 1D LPPooling operation on an input Tensor can be regarded as forming a 1D input plane.

Typically the input is of shape (N, C, L_{in}) or (C, L_{in}), the output is of shape (N, C, L_{out}) or (C, L_{out}).

$$L_{out} = \left\lfloor \frac{L_{in} - \text{kernel\_size}}{\text{stride}} + 1 \right\rfloor$$

The operation is as follows.

$$f(X) = \sqrt[p]{\sum_{x \in X} x^p}$$

Note: This interface currently does not support Atlas A2 training series products.

Parameters

- **x** (Tensor) –Tensor of shape (N, C, L_{in}) or (C, L_{in}).
- **norm_type** (*Union[int, float]*) –Type of normalization, represents p in the formula, can not be 0,
  - if p = 1, the result obtained is the sum of elements in the pool nucleus(Proportional to average pooling).
  - if p = ∞, the result is the result of maximum pooling.
- **kernel_size** (*int*) –The size of kernel window.

- **stride** (*int*) −The distance of kernel moving, an int number that represents the width of movement is stride. Default: `None` , which indicates the moving step is *kernel_size* .
- **ceil_mode** (*bool*) −Whether to use ceil or floor to calculate output shape. Default: `False` .

Returns

- **output** (Tensor) - LPPool1d result, with shape (N, C, L_{out}) or (C, L_{out}), It has the same data type as x, where

$$L_{out} = \left\lfloor \frac{L_{in} - \text{kernel\_size}}{\text{stride}} + 1 \right\rfloor$$

Raises

- **TypeError** −If x is not a Tensor.
- **TypeError** −If *kernel_size* or *stride* is not an int.
- **TypeError** −If *ceil_mode* is not a bool.
- **TypeError** −If *norm_type* is neither float nor int.
- **ValueError** −If *norm_type* is equal to 0.
- **ValueError** −If *kernel_size* or *stride* is less than 1.
- **ValueError** −If length of shape of x is not equal to 2 or 3.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import ops
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.arange(2 * 3 * 4).reshape((2, 3, 4)), dtype=ms.float32)
>>> out = ops.lp_pool1d(x, norm_type=1, kernel_size=3, stride=1, ceil_mode=False)
>>> print(out)
[[[ 3.  6.]
  [15. 18.]
  [27. 30.]]
 [[39. 42.]
  [51. 54.]
  [63. 66.]]]
```

mindspore.ops.lp_pool2d

`mindspore.ops.`**lp_pool2d**(*x*, *norm_type*, *kernel_size*, *stride=None*, *ceil_mode=False*)

Applying 2D LPPooling operation on an input Tensor can be regarded as forming a 2D input plane.

Typically the input is of shape (N, C, H_{in}, W_{in}), the output is of shape (N, C, H_{in}, W_{in}), with the same shape as input, the operation is as follows.

$$f(X) = \sqrt[p]{\sum_{x \in X} x^p}$$

Note: This interface currently does not support Atlas A2 training series products.

Parameters

- **x** (Tensor) −Tensor of shape (N, C, H_{in}, W_{in}).
- **norm_type** (*Union[int, float]*) −Type of normalization, represents p in the formula, can not be 0,
  - if p = 1, the result obtained is the sum of elements in the pool nucleus(Proportional to average pooling).
  - if p = ∞, the result is the result of maximum pooling.
- **kernel_size** (*Union[int, tuple[int]]*) −The size of kernel window. The data type of kernel_size must be int and the value represents the height and width, or a tuple of two int numbers that represent height and width respectively.
- **stride** (*Union[int, tuple[int]]*) −The distance of kernel moving, an int number that represents the height and width of movement are both strides, or a tuple of two int numbers that represent height and width of movement respectively. Default: None , which indicates the moving step is *kernel_size* .
- **ceil_mode** (*bool*) −Whether to use ceil or floor to calculate output shape. Default: False .

Returns

- **output** (Tensor) - LPPool2d result, with shape (N, C, H_{in}, W_{in}), It has the same data type as *x*, where

$$H_{out} = \left\lfloor \frac{H_{in} - \text{kernel\_size}[0]}{\text{stride}[0]} + 1 \right\rfloor$$

$$W_{out} = \left\lfloor \frac{W_{in} - \text{kernel\_size}[1]}{\text{stride}[1]} + 1 \right\rfloor$$

Raises

- **TypeError** −If *x* is not a Tensor.
- **TypeError** −If *kernel_size* or *stride* is neither int nor tuple.
- **TypeError** −If *ceil_mode* is not a bool.
- **TypeError** −If *norm_type* is neither float nor int.
- **ValueError** −If *norm_type* is equal to 0.
- **ValueError** −If *kernel_size* or *stride* is less than 1.
- **ValueError** −If *kernel_size* or *stride* is a tuple whose length is not equal to *2*.
- **ValueError** −If length of shape of *x* is not equal to 4.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import ops
>>> from mindspore import Tensor
>>> import numpy as np
>>> x = Tensor(np.arange(2 * 3 * 4 * 5).reshape((2, 3, 4, 5)), dtype=ms.float32)
>>> out = ops.lp_pool2d(x, norm_type=1, kernel_size=3, stride=1, ceil_mode=False)
>>> print(out)
[[[[  54.   63.   72.]
   [  99.  108.  117.]]

```

mindspore.ops.lrn

mindspore.ops.**lrn**(*x*, *depth_radius=5*, *bias=1.0*, *alpha=1.0*, *beta=0.5*, *norm_region='ACROSS_CHANNELS'*)

Local Response Normalization.

> **Warning:** lrn is deprecated on Ascend due to potential accuracy problem. It's recommended to use other normalization methods, e.g. *mindspore.ops.batch_norm*.

$$b_c = a_c \left(k + \frac{\alpha}{n} \sum_{c'=\max(0,c-n/2)}^{\min(N-1,c+n/2)} a_{c'}^2 \right)^{-\beta}$$

where the a_c indicates the specific value of the pixel corresponding to c in feature map; where the $n/2$ indicates the *depth_radius*; where the k indicates the *bias*; where the α indicates the *alpha*; where the β indicates the *beta*.

Parameters

- **depth_radius** (*int*) –Half-width of the 1-D normalization window with the shape of 0-D. Default: `5` .
- **bias** (*float*) –An offset (usually positive to avoid dividing by 0). Default: `1.0` .
- **alpha** (*float*) –A scale factor, usually positive. Default: `1.0` .
- **beta** (*float*) –An exponent. Default: `0.5` .
- **norm_region** (*str*) –Specifies normalization region. Options: `"ACROSS_CHANNELS"` . Default: `"ACROSS_CHANNELS"` .
- **x** (Tensor) –A 4-D Tensor with float16 or float32 data type.

Returns

Tensor, with the same shape and data type as *x*.

Raises

- **TypeError** –If *depth_radius* is not an int.
- **TypeError** –If *bias*, *alpha* or *beta* is not a float.
- **TypeError** –If *norm_region* is not a str.
- **TypeError** –If *x* is not a Tensor.

Supported Platforms:

`GPU CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[[[0.1], [0.2]],
...                            [[0.3], [0.4]]]]), mindspore.float32)
>>> output = ops.lrn(input_x)
>>> print(output)
[[[[0.09534626]
   [0.1825742 ]]
  [[0.2860388 ]
   [0.3651484 ]]]]
```

mindspore.ops.max_pool2d

mindspore.ops.**max_pool2d**(*x*, *kernel_size*, *stride=None*, *padding=0*, *dilation=1*, *return_indices=False*, *ceil_mode=False*)

Performs a 2D max pooling on the input Tensor.

Typically, the input is a Tensor with shape $(N_{in}, C_{in}, H_{in}, W_{in})$, outputs regional maximum in the (H_{in}, W_{in})-dimension. Given *kernel_size* $ks = (h_{ker}, w_{ker})$ and *stride* $s = (s_0, s_1)$, the operation is as follows:

$$\text{output}(N_i, C_j, h, w) = \max_{m=0,\ldots,h_{ker}-1} \max_{n=0,\ldots,w_{ker}-1} \text{input}(N_i, C_j, s_0 \times h + m, s_1 \times w + n)$$

Parameters

- **x** (Tensor) –Tensor of shape $(N_{in}, C_{in}, H_{in}, W_{in})$ with data type of int8, int16, int32, int64, uint8, uint16, uint32, uint64, float16, float32 or float64 in CPU or GPU while that of uint16 in Ascend.
- **kernel_size** (*Union[int, tuple[int]]*) –The size of kernel used to take the maximum value and arg value, is an int number that represents height and width of the kernel, or a tuple of two int numbers that represent height and width respectively.
- **stride** (*Union[int, tuple[int]]*) –The distance of kernel moving, an int number that represents the height and width of movement are both stride, or a tuple of two int numbers that represent height and width of movement respectively. Default: `None` , which indicates the moving step is *kernel_size* .
- **padding** (*Union[int, tuple[int]]*) –An int number that represents the height and width of movement are both strides, or a tuple of two int numbers that represent height and width of movement respectively. Default: `0` .
- **dilation** (*Union[int, tuple[int]]*) –Control the stride of elements in the kernel. Default: `1` .
- **return_indices** (*bool*) –Whether to output the indices of max value. Default: `False` .
- **ceil_mode** (*bool*) –Whether to use ceil instead of floor to calculate output shape. Default: `False` .

Returns

If *return_indices* is `False` , return a Tensor *output*, else return a tuple (*output*, *argmax*).

- **output** (Tensor) - Maxpooling result, with shape $(N_{out}, C_{out}, H_{out}, W_{out})$. It has the same data type as x.

$$H_{out} = \left\lfloor \frac{H_{in} + 2 * \text{padding}[0] - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) - 1}{\text{stride}[0]} + 1 \right\rfloor$$

$$W_{out} = \left\lfloor \frac{W_{in} + 2 * \text{padding}[1] - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) - 1}{\text{stride}[1]} + 1 \right\rfloor$$

- **argmax** (Tensor) - Index corresponding to the maximum value. In CPU and GPU, data type is int64 while that is uint16 in Ascend. It will be return only when *return_indices* is True.

Raises

- **TypeError** – If x is not a Tensor.
- **ValueError** – If length of shape of x is not equal to 4.
- **TypeError** – If *kernel_size* , *stride* , *padding* or *dilation* is not int or tuple.
- **ValueError** – If *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** – If *padding* is less than 0.
- **ValueError** – If *padding* is more than half of *kernel_size*.
- **TypeError** – If *ceil_mode* is not bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.arange(20 * 16 * 50 * 32).reshape((20, 16, 50, 32)), mindspore.float32)
>>> output_tensor, argmax = ops.max_pool2d(x, kernel_size=(3, 2), stride=(2, 1), return_
↪indices=True)
>>> print(output_tensor.shape)
(20, 16, 24, 31)
>>> print(argmax.shape)
(20, 16, 24, 31)
```

mindspore.ops.max_pool3d

`mindspore.ops.`**`max_pool3d`**(*x*, *kernel_size*, *stride=None*, *padding=0*, *dilation=1*, *ceil_mode=False*, *return_indices=False*)

Performs a 3D max pooling on the input Tensor.

Typically the input is a Tensor with shape $(N_{in}, C_{in}, D_{in}, H_{in}, W_{in})$, outputs regional maximum in the (D_{in}, H_{in}, W_{in})-dimension. Given *kernel_size* $ks = (d_{ker}, h_{ker}, w_{ker})$ and *stride* $s = (s_0, s_1, s_2)$, the operation is as follows:

$$\text{output}(N_i, C_j, d, h, w) = \max_{l=0,\ldots,d_{ker}-1} \max_{m=0,\ldots,h_{ker}-1} \max_{n=0,\ldots,w_{ker}-1} \text{input}(N_i, C_j, s_0 \times d + l, s_1 \times h + m, s_2 \times w + n)$$

Parameters

- **x** (Tensor) −Tensor of shape $(N_{in}, C_{in}, D_{in}, H_{in}, W_{in})$ with data type of int8, int16, int32, int64, uint8, uint16, uint32, uint64, float16, float32 or float64.
- **kernel_size** (*Union[int, tuple[int]]*) −The size of kernel used to take the maximum value and arg value, is an int number that represents depth, height and width of the kernel, or a tuple of three int numbers that represent depth, height and width respectively.
- **stride** (*Union[int, tuple[int]]*) −The distance of kernel moving, an int number that represents the depth, height and width of movement are both stride, or a tuple of three int numbers that represent depth, height and width of movement respectively. Default: None , which indicates the moving step is *kernel_size* .
- **padding** (*Union[int, tuple[int]]*) −An int number that represents the depth, height and width of movement are both strides, or a tuple of three int numbers that represent depth, height and width of movement respectively. Default: 0 .
- **dilation** (*Union[int, tuple[int]]*) −Control the stride of elements in the kernel. Default: 1 .
- **ceil_mode** (*bool*) −Whether to use ceil instead of floor to calculate output shape. Default: False .
- **return_indices** (*bool*) −Whether to output the indices of max value. Default: False .

Returns

If *return_indices* is False, return a Tensor *output*, else return a tuple (*output*, *argmax*).

- **output** (Tensor) - Maxpooling result, with shape $(N_{out}, C_{out}, D_{out}, H_{out}, W_{out})$. It has the same data type as *x*.

$$D_{out} = \left\lfloor \frac{D_{in} + 2 \times \text{padding}[0] - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) - 1}{\text{stride}[0]} + 1 \right\rfloor$$

$$H_{out} = \left\lfloor \frac{H_{in} + 2 \times \text{padding}[1] - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) - 1}{\text{stride}[1]} + 1 \right\rfloor$$

$$W_{out} = \left\lfloor \frac{W_{in} + 2 \times \text{padding}[2] - \text{dilation}[2] \times (\text{kernel\_size}[2] - 1) - 1}{\text{stride}[2]} + 1 \right\rfloor$$

- **argmax** (Tensor) - Index corresponding to the maximum value. Data type is int64. It will be returned only when *return_indices* is True .

Raises

- **TypeError** −If *x* is not a Tensor.
- **ValueError** −If length of shape of *x* is not equal to 5.
- **TypeError** −If *kernel_size* , *stride* , *padding* or *dilation* is not int or tuple.
- **ValueError** −If *kernel_size* or *stride* is less than 1.
- **ValueError** −If *padding* is less than 0.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.arange(2 * 1 * 2 * 2 * 2).reshape((2, 1, 2, 2, 2)), mindspore.float32)
>>> output_tensor, argmax = ops.max_pool3d(x, kernel_size=2, stride=1, padding=1, return_
↪indices=True)
>>> print(output_tensor.shape)
(2, 1, 3, 3, 3)
>>> print(argmax.shape)
(2, 1, 3, 3, 3)
```

mindspore.ops.max_unpool1d

mindspore.ops.**max_unpool1d**(*x*, *indices*, *kernel_size*, *stride=None*, *padding=0*, *output_size=None*)

Computes the inverse of *max_pool1d*.

max_unpool1d keeps the maximal value and set all position of non-maximal values to zero. Typically the input is of shape (N, C, H_{in}) or (C, H_{in}), and the output is of shape (N, C, H_{out}) or (C, H_{out}). The operation is as follows.

$$H_{out} = (H_{in} - 1) \times stride[0] - 2 \times padding[0] + kernel\_size[0]$$

Parameters

- **x** (Tensor) –The input Tensor to invert. Tensor of shape (N, C, H_{in}) or (C, H_{in}).
- **indices** (Tensor) –Index of maximum value. Tensor of shape must be same with input 'x'. Values of indices must belong to $[0, H_{in} - 1]$. Data type must be in int32 or int64.
- **kernel_size** (*Union[int, tuple[int]]*) –The size of kernel used to take the maximum value.
- **stride** (*Union[int, tuple[int]]*) –The distance of kernel moving, If stride is 0, (0) or None , then stride equal to kernel_size. Default: None , which indicates the moving step is *kernel_size* .
- **padding** (*Union[int, tuple[int]]*) –The pad value to be filled. Default: 0 .
- **output_size** (*tuple[int], optional*) –The output shape. Default: None . If output_size == (), then the shape of output computed by *kernel_size*, *stride* and *padding*. If output_size != (), then output_size must be (N, C, H) , (C, H) or (H) and output_size must belong to $[(N, C, H_{out} - stride[0]), (N, C, H_{out} + stride[0])]$.

Returns

Tensor, with shape (N, C, H_{out}) or (C, H_{out}), with the same data type with *x*.

Raises

- **TypeError** –If data type of *x* or *indices* is not supported.
- **TypeError** –If *kernel_size*, *stride* or *padding* is neither an int nor a tuple.
- **ValueError** –If numbers in *stride*, *padding* (also support 0 and (0)) or *kernel_size* is not positive.
- **ValueError** –If the shapes of *x* and *indices* are not equal.
- **ValueError** –If *x* whose length is not 2 or 3.
- **ValueError** –If type of *output_size* is not tuple.
- **ValueError** –If *output_size* whose length is not 0, 2 or 3.
- **ValueError** –If *output_size* is not close to output size computed by attr *kernel_size*, *stride*, *padding*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[2, 4, 6, 8]]).astype(np.float32))
>>> indices = Tensor(np.array([[1, 3, 5, 7]]).astype(np.int64))
>>> output = ops.max_unpool1d(x, indices, kernel_size =2, stride=2, padding=0)
>>> print(output.asnumpy())
[[0. 2. 0. 4. 0. 6. 0. 8.]]
```

mindspore.ops.max_unpool2d

mindspore.ops.**max_unpool2d**(*x*, *indices*, *kernel_size*, *stride=None*, *padding=0*, *output_size=None*)

Computes the inverse of *max_pool2d*.

max_unpool2d keeps the maximal value and set all position of non-maximal values to zero. Typically the input is of shape (N, C, H_{in}, W_{in}) or (C, H_{in}, W_{in}), and the output is of shape (N, C, H_{out}, W_{out}) or (C, H_{out}, W_{out}). The operation is as follows.

$$H_{out} = (Hin - 1) \times stride[0] - 2 \times padding[0] + kernel\_size[0]$$
$$W_{out} = (Win - 1) \times stride[1] - 2 \times padding[1] + kernel\_size[1]$$

Parameters

- **x** (Tensor) – The input Tensor to invert. Tensor of shape (N, C, H_{in}, W_{in}) or (C, H_{in}, W_{in}).
- **indices** (Tensor) – Max values' index represented by the indices. Tensor of shape must be same with input 'x'. Values of indices must belong to $[0, H_{in} \times W_{in} - 1]$. Data type must be in int32 or int64.
- **kernel_size** (*Union[int, tuple[int]]*) – The size of kernel used to take the maximum value, an int number that represents height and width of the kernel, or a tuple of two int numbers that represent height and width respectively.
- **stride** (*Union[int, tuple[int]]*) – The distance of kernel moving, an int number that represents the height and width of movement are both stride, or a tuple of two int numbers that represent height and width of movement respectively. Default: `None` , which indicates the moving step is *kernel_size* .
- **padding** (*Union[int, tuple[int]]*) – The pad value to be filled. Default: `0` . If *padding* is an integer, the paddings of height and width are the same, equal to padding. If *padding* is a tuple of two integers, the padding of height and width equal to padding[0] and padding[1] correspondingly.
- **output_size** (*tuple[int], optional*) – The target output size. Default: `None` . If output_size == (), then the shape of output computed by *kernel_size*, *stride* and *padding*. If output_size != (), then output_size must be (N, C, H, W) , (C, H, W) or (H, W) and output_size must belong to $[(N, C, H_{out} - stride[0], W_{out} - stride[1]), (N, C, H_{out} + stride[0], W_{out} + stride[1])]$.

Returns

Tensor, with shape (N, C, H_{out}, W_{out}) or (C, H_{out}, W_{out}), with the same data type with *x*.

Raises

- **TypeError** – If data type of *x* or *indices* is not supported.
- **TypeError** – If *kernel_size*, *stride* or *padding* is neither an int nor a tuple.
- **ValueError** – If numbers in *stride*, *padding* (also support 0 and (0, 0)) or *kernel_size* is not positive.

- **ValueError** –If the shape of *x* and *indices* are not equal.
- **ValueError** –If *kernel_size*, *stride* or *padding* is a tuple whose length is not equal to 2.
- **ValueError** –If *x* whose length is not 3 or 4.
- **ValueError** –If *output_size* whose type is not tuple.
- **ValueError** –If *output_size* whose length is not 0, 3 or 4.
- **ValueError** –If *output_size* is not close to output size computed by attr *kernel_size*, *stride*, *padding*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[[[0, 1], [8, 9]]]]).astype(np.float32))
>>> indices = Tensor(np.array([[[[0, 1], [2, 3]]]]).astype(np.int64))
>>> output = ops.max_unpool2d(x, indices, kernel_size=1, stride=1, padding=0)
>>> print(output.asnumpy())
[[[[0. 1.]
   [8. 9.]]]]
```

mindspore.ops.max_unpool3d

mindspore.ops.**max_unpool3d**(*x*, *indices*, *kernel_size*, *stride=None*, *padding=0*, *output_size=None*)

Computes the inverse of *mindspore.ops.max_pool3d()*.

max_unpool3d keeps the maximal value and set all position of non-maximal values to zero. Typically the input is of shape $(N, C, D_{in}, H_{in}, W_{in})$ or $(C, D_{in}, H_{in}, W_{in})$, and the output is of shape $(N, C, D_{out}, H_{out}, W_{out})$ or $(C, D_{out}, H_{out}, W_{out})$. The operation is as follows.

$$
\begin{aligned}
D_{out} &= (Din - 1) \times stride[0] - 2 \times padding[0] + kernel\_size[0] \\
H_{out} &= (Hin - 1) \times stride[1] - 2 \times padding[1] + kernel\_size[1] \\
W_{out} &= (Win - 1) \times stride[2] - 2 \times padding[2] + kernel\_size[2]
\end{aligned}
$$

Parameters

- **x** (Tensor) –The input Tensor to invert. Tensor of shape $(N, C, D_{in}, H_{in}, W_{in})$ or $(C, D_{in}, H_{in}, W_{in})$.
- **indices** (Tensor) –Max values' index represented by the indices. Tensor of shape must be same with input 'x'. Values of indices must belong to $[0, D_{in} \times H_{in} \times W_{in} - 1]$. Data type must be in int32 or int64.
- **kernel_size** (*Union[int, tuple[int]]*) –The size of kernel used to take the maximum value, an int number that represents depth, height and width of the kernel, or a tuple of three int numbers that represent depth, height and width respectively.
- **stride** (*Union[int, tuple[int]]*) –The distance of kernel moving, an int number that represents the depth, height and width of movement are both stride, or a tuple of three int numbers that represent depth, height and width of movement respectively. Default: `None` , which indicates the moving step is *kernel_size* .
- **padding** (*Union[int, tuple[int]]*) –The pad value to be filled. Default: `0` . If *padding* is an integer, the paddings of depth, height and width are the same, equal to padding. If *padding* is a tuple of three integers, the padding of depth, height and width equal to padding[0], padding[1] and padding[2] correspondingly.

- **output_size** (*tuple[int], optional*) – The output size. Default: `None`. If output_size == (), then the shape of output computed by *kernel_size*, *stride* and *padding*. If output_size != (), then output_size must be (N, C, D, H, W) or (C, D, H, W) or (D, H, W) and output_size must belong to $[(N, C, D_{out} - stride[0], H_{out} - stride[1], W_{out} - stride[2]), (N, C, D_{out} + stride[0], H_{out} + stride[1], W_{out} + stride[2])]$.

Returns

Tensor, with shape $(N, C, D_{out}, H_{out}, W_{out})$ or $(C, D_{out}, H_{out}, W_{out})$, with the same data type with *x*.

Raises

- **TypeError** – If data type of *x* or *indices* is not supported.
- **TypeError** – If *kernel_size*, *stride* or *padding* is neither an int nor a tuple.
- **ValueError** – If numbers in *stride* or *padding* (also support 0 and (0, 0, 0)) or *kernel_size* is not positive.
- **ValueError** – If the shape of *x* and *indices* are not equal.
- **ValueError** – If *kernel_size*, *stride* or *padding* is a tuple whose length is not equal to 3.
- **ValueError** – If *x* whose length is not 4 or 5.
- **ValueError** – If *output_size* whose length is not 0, 4 or 5.
- **ValueError** – If *output_size* whose type is not tuple.
- **ValueError** – If *output_size* is not close to output size computed by attr *kernel_size*, *stride*, *padding*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[[[[0, 1], [8, 9]]]]]).astype(np.float32))
>>> indices= Tensor(np.array([[[[[0, 1], [2, 3]]]]]).astype(np.int64))
>>> output = ops.max_unpool3d(x, indices, kernel_size=2, stride=1, padding=0)
>>> print(output)
[[[[[0. 1. 8.]
    [9. 0. 0.]
    [0. 0. 0.]]
   [[0. 0. 0.]
    [0. 0. 0.]
    [0. 0. 0.]]]]]
```

mindspore.ops.moe_token_permute

mindspore.ops.**moe_token_permute**(*tokens*, *indices*, *num_out_tokens=None*, *padded_mode=False*)

Permute the *tokens* based on the *indices*. Token with the same index will be grouped together.

Warning:

- It is only supported on Atlas A2 Training Series Products.
- The input *tokens* only supports the bfloat16 data type in the current version.

- When *indices* is 2-D, the size of the second dim must be less than or equal to 512.

Parameters

- **tokens** (Tensor) −The input token tensor to be permuted. The dtype is bfloat16. The shape is $(num\_tokens, hidden\_size)$, where *num_tokens* and *hidden_size* are positive integers.
- **indices** (Tensor) −The tensor specifies indices used to permute the tokens. The dtype is int32 or int64. The shape is $(num\_tokens, topk)$ or $(num\_tokens,)$, where *num_tokens* and *topk* are positive integers. If the shape is the latter case, *topk* is implied to be 1.
- **num_out_tokens** (*int, optional*) −The effective output token count, when enabling the capacity factor, should equal the number of tokens not dropped. It should be non-negative integer. Default: None, meaning no tokens are dropped.
- **padded_mode** (*bool, optional*) −If True, indicating the indices are padded to denote selected tokens per expert. It can only be False currently. Default: False .

Returns

tuple (Tensor), tuple of 2 tensors, containing the permuted tokens and sorted indices.

- **permuted_tokens** (Tensor) - The permuted tensor of the same dtype as *tokens*.
- **sorted_indices** (Tensor) - The indices Tensor of dtype int32, corresponds to permuted tensor.

Raises

- **TypeError** −If *tokens* or *indices* is not a Tensor.
- **TypeError** −If dtype of *tokens* is not bfloat16.
- **TypeError** −If dtype of *indices* is not int32 or int64.
- **TypeError** −If specified *num_out_tokens* is not an integer.
- **TypeError** −If specified *padded_mode* is not a bool.
- **ValueError** −If second dim of *indices* is greater than 512 when exists.
- **ValueError** −If *padded_node* is set to True.
- **ValueError** −If *tokens* is not 2-D or *indices* is not 1-D or 2-D Tensor.
- **RuntimeError** −If first dimensions of *tokens* and *indices* are not consistent.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> tokens = Tensor([[1, 1, 1],
...                  [7, 7, 7],
...                  [2, 2, 2],
...                  [1, 1, 1],
...                  [2, 2, 2],
...                  [3, 3, 3]], dtype=mindspore.bfloat16)
>>> indices = Tensor([5, 0, 3, 1, 2, 4], dtype=mindspore.int32)
>>> out = ops.moe_token_permute(tokens, indices)
>>> print(out)
(Tensor(shape=[6, 3], dtype=BFloat16, value=
[[7, 7, 7],
 [1, 1, 1],
 [2, 2, 2],
 [2, 2, 2],
 [3, 3, 3],
 [1, 1, 1]]), Tensor(shape=[6], dtype=Int32, value= [5, 0, 3, 1, 2, 4]))
```

mindspore.ops.moe_token_unpermute

mindspore.ops.**moe_token_unpermute**(*permuted_tokens*, *sorted_indices*, *probs=None*, *padded_mode=False*, *restore_shape=None*)

Unpermute a tensor of permuted tokens based on sorted indices, and optionally merge the tokens with their corresponding probabilities.

Warning:

- It is only supported on Atlas A2 Training Series Products.
- The inputs *permuted_tokens* and *probs* only support the bfloat16 data type in the current version.
- *sorted_indices* must not have duplicate values, otherwise the result is undefined.

Parameters

- **permuted_tokens** (Tensor) –The tensor of permuted tokens to be unpermuted. The shape is $[num\_tokens * topk, hidden\_size]$, where *num_tokens*, *topk* and *hidden_size* are positive integers.
- **sorted_indices** (Tensor) –The tensor of sorted indices used to unpermute the tokens. The shape is $[num\_tokens * topk,]$, where *num_tokens* and *topk* are positive integers. It only supports the int32 data type.
- **probs** (Tensor, *optional*) –The tensor of probabilities corresponding to the permuted tokens. If provided, the unpermuted tokens will be merged with their respective probabilities. The shape is $[num\_tokens, topk]$, where *num_tokens* and *topk* are positive integers. Default: None .
- **padded_mode** (*bool*, *optional*) –If True, indicating the indices are padded to denote selected tokens per expert. Default: False .
- **restore_shape** (*Union[tuple[int], list[int]]*, *optional*) –The input shape before permutation, only used in padding mode. Default: None .

Returns

Tensor, with the same dtype as *permuted_tokens*. If *padded_mode* is `False`, the shape will be [*num_tokens*, *hidden_size*]. If *padded_mode* is `True`, the shape will be specified by *restore_shape*.

Raises

- **TypeError** –If *permuted_tokens* is not a Tensor.
- **ValueError** –Only supported when *padded_mode* is `False`.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> permuted_token = Tensor([
...                          [1, 1, 1],
...                          [0, 0, 0],
...                          [0, 0, 0],
...                          [3, 3, 3],
...                          [2, 2, 2],
...                          [1, 1, 1],
...                          [2, 2, 2],
...                          [3, 3, 3]], dtype=mindspore.bfloat16)
>>> sorted_indices = Tensor([0, 6, 7, 5, 3, 1, 2, 4], dtype=mindspore.int32)
>>> out = ops.moe_token_unpermute(permuted_token, sorted_indices)
>>> out.shape
(8, 3)
```

mindspore.ops.incre_flash_attention

mindspore.ops.**incre_flash_attention**(*query*, *key*, *value*, *attn_mask=None*, *actual_seq_lengths=None*, *pse_shift=None*, *dequant_scale1=None*, *quant_scale1=None*, *dequant_scale2=None*, *quant_scale2=None*, *quant_offset2=None*, *antiquant_scale=None*, *antiquant_offset=None*, *block_table=None*, *num_heads=1*, *input_layout='BSH'*, *scale_value=1.0*, *num_key_value_heads=0*, *block_size=0*, *inner_precise=1*, *kv_padding_size=None*)

The interface for incremental inference.

- B: Batch size
- N: Num of attention heads
- kvN: Num of *key* / *value* heads
- S: Sequence length
- D: Head dim
- H: Hidden layer size
- kvH: Hidden size of *key* / *value*

where $H = N \times D$, $kvH = kvN \times D$.

Self attention constructs an attention model based on the relationship between input samples themselves. The principle is to assume that there is a length of the input sample sequence x of n, and each element of x is a d dimensional vector, which can be viewed as

a token embedding. This sequence can be transformed through 3 weight matrices to obtain 3 matrices with dimensions of $n \times d$. The self attention calculation formula is defined as:

$$Attention(Q, K, V) = Softmax(\frac{QK^T}{\sqrt{d}})V$$

where the product of Q and K^T represents the attention of input x. To avoid the value becoming too large, it is usually scaled by dividing it by the square root of d and perform softmax normalization on each row, yields a matrix of $n \times d$ after multiplying V.

Note:

- If there is no input parameter and no default value, `None` needs to be passed.
- The shape of the tensor corresponding to the *key* and *value* parameters needs to be completely consistent.
- *N* of parameter *query* is equal with *num_heads*. *N* of parameter *key* and parameter *value* is equal with *num_key_value_heads*. *num_heads* is a multiple of *num_key_value_heads*.
- Quantization
  - When the data type of *query*, *key*, and *value* is float16 and the data type of output is int8, the input parameter *quant_scale2* is required and *quant_offset2* is optional.
  - When *antiquant_scale* exists, *key* and *value* need to be passed by int8. *antiquant_offset* is optional.
  - The data type of *antiquant_scale* and *antiquant_offset* should be consistenct with that of *query*.
- *pse_shift*
  - The *pse_shift* data type needs to be consistent with *query*, and only supports D-axis alignment, which means that the D-axis can be divided by 16.
- Page attention:
  - The necessary condition for enabling page attention is that the *block_table* exists, and the *key* and *value* are arranged in a contiguous memory according to the index in the *block_table*. The support dtype for *key* and *value* is float16/bfloat16/int8.
  - In the enabling scenario of page attention, 16 alignment is required when input types of *key* and *value* are float16/bfloat16, and 32 alignment is required when input dtype of *key* and *value* is int8. It is recommended to use 128.
  - The maximum max_block_num_per_seq currently supported by blocktable is 16k, and exceeding 16k will result in interception and error messages; If you encounter *S* being too large and causing max_block_num_per_seq to exceed 16k, you can increase the *block_size* to solve the problem.
  - The multiplication of all dimensions of the shape of the parameters *key* and *value* in the page attention scenario cannot exceed the representation range of int32.
  - When performing per-channel post quantization, page attention cannot be enabled simultaneously.
- *kv_padding_size*:
  - The calculation formula for the starting point of KV cache transfer is $S - kv\_padding\_size - actual\_seq\_lengths$. The calculation formula for the transfer endpoint of KV cache is $S - kv\_padding\_size$. When the starting or ending point of the KV cache transfer is less than 0, the returned data result is all 0.
  - When *kv_padding_size* is less than 0, it will be set to 0.
  - *kv_padding_size* needs to be enabled together with the *actual_seq_lengths* parameter, otherwise it is considered as the KV right padding scene.
  - It needs to be enabled together with the atten_mask parameter and ensure that the meaning of atten_mask is correct, that is, it can correctly hide invalid data. Otherwise, it will introduce accuracy issues.

– *kv_padding_size* does not support page attention scenarios.

Warning: Only support on Atlas A2 training series.

Parameters

- **query** (Tensor) –The query tensor with data type of float16 or bfloat16. The shape is $(B, 1, H)$ / $(B, N, 1, D)$.
- **key** (*Union[tuple, list]*) –The key tensor with data type of float16 or bfloat16 or int8. The shape is (B, S, kvH) / (B, kvN, S, D).
- **value** (*Union[tuple, list]*) –The value tensor with data type of float16 or bfloat16 or int8. The shape is (B, S, kvH) / (B, kvN, S, D).
- **attn_mask** (Tensor, *optional*) –The attention mask tensor with data type of bool or int8 or uint8. The shape is (B, S) / $(B, 1, S)$ / $(B, 1, 1, S)$. Default: None.
- **actual_seq_lengths** (*Union[Tensor, tuple[int], list[int]], optional*) –Describe actual sequence length of each input with data type of int64. The shape is $(B,)$. Default: None.
- **pse_shift** (Tensor, *optional*) –The position encoding tensor with data type of float16 or bfloat16. Input tensor of shape $(1, N, 1, S)$ / $(B, N, 1, S)$. Default: None.
- **dequant_scale1** (Tensor, *optional*) –Quantitative parametor, the tensor with data type of uint64 or float32. It is disable now. Default: None.
- **quant_scale1** (Tensor, *optional*) –Quantitative parametor, the tensor with data type of float32. It is disable now. Default: None.
- **dequant_scale2** (Tensor, *optional*) –Quantitative parametor, the tensor with data type of uint64 or float32. It is disable now. Default: None.
- **quant_scale2** (Tensor, *optional*) –Post Quantitative parametor, the tensor with data type of float32. The shape is $(1,)$. Default: None.
- **quant_offset2** (Tensor, *optional*) –Post Quantitative parametor, the tensor with data type of float32. The shape is $(1,)$. Default: None.
- **antiquant_scale** (Tensor, *optional*) –Pseudo Quantitative parametor, the tensor with data type of float16 or bfloat16. The shape is $(2, kvN, 1, D)$ when input_layout is 'BNSD' or $(2, kvH)$ when input_layout is 'BSH'. Default: None.
- **antiquant_offset** (Tensor, *optional*) –Pseudo Quantitative parametor, the tensor with data type of float16 or bfloat16. The shape is $(2, kvN, 1, D)$ when input_layout is 'BNSD' or $(2, kvH)$ when input_layout is 'BSH'. Default: None.
- **block_table** (Tensor, *optional*) –The tensor with data type of int32. The shape is $(B, max\_block\_num\_per\_seq)$, where $max\_block\_num\_per\_seq = ceil(\frac{max(actual\_seq\_length)}{block\_size})$. Default: None.
- **num_heads** (*int, optional*) –The number of heads. Default: 1.
- **input_layout** (*str, optional*) –The data layout of the input qkv, support 'BSH' and 'BNSD'. Default 'BSH'.
- **scale_value** (*double, optional*) –The scale value indicating the scale coefficient, which is used as the scalar of Muls in the calculation. Default: 1.0.
- **num_key_value_heads** (*int, optional*) –Head numbers of *key*/*value* which are used in GQA algorithm. The value 0 indicates if the *key* and *value* have the same head nums, use numHeads. Default: 0.

- **block_size** (*int, optional*) –The maximum number of tokens stored in each block of KV in page attention. Default: `0`.
- **inner_precise** (*int, optional*) –An int number from {0, 1} indicates computing mode. `0` for high precision mode for float16 dtype. `1` for high performance mode. Default: `1`.
- **kv_padding_size** (`Tensor, optional`) –The tensor with data type of int64. The range of values is $0 \leq kv\_padding\_size \leq S - max(actual\_seq\_length)$. The shape is () or (1,). Default: `None`.

Returns

attention_out (Tensor), the shape is $(B, 1, H)$ / $(B, N, 1, D)$.

Raises

- **TypeError** –dtype of *query* is not float16 or bfloat16.
- **TypeError** –*key* and *value* don't have the same dtype.
- **TypeError** –dtype of *attn_mask* is not bool, int8 or uint8.
- **TypeError** –dtype of *pse_shift* is not bfloat16 or float16.
- **TypeError** –*scale_value* is not a double number.
- **TypeError** –*input_layout* is not a string.
- **TypeError** –*num_key_value_heads* or *num_heads* is not an int.
- **TypeError** –*inner_precise* is not an int.
- **TypeError** –*quant_scale1* is not Tensor of type float32.
- **TypeError** –*quant_scale2* is not Tensor of type float32.
- **TypeError** –*quant_offset2* is not Tensor of type float32.
- **ValueError** –size of *actual_seq_lengths* is not 1 or B.
- **ValueError** –*input_layout* is a string but of *(BSH)* or *(BNSD)*.
- **ValueError** –*num_heads* is not divisible by Q_H.
- **ValueError** –*num_heads* is not divisible by *num_key_value_heads*.
- **RuntimeError** –*num_heads* is not greater than 0.
- **RuntimeError** –*attn_mask* shape is not valid.

Supported Platforms:

`Ascend`

Tensor(shape=[1, 1, 512], dtype=Float16, value=
[[[ 1.6104e+00,  7.3438e-01,  1.0684e+00 ... -8.7891e-01,  1.7695e+00,  1.0264e+00]]])
```

mindspore.ops.prompt_flash_attention

mindspore.ops.**prompt_flash_attention**(*query*, *key*, *value*, *attn_mask=None*, *actual_seq_lengths=None*, *actual_seq_lengths_kv=None*, *pse_shift=None*, *deq_scale1=None*, *quant_scale1=None*, *deq_scale2=None*, *quant_scale2=None*, *quant_offset2=None*, *num_heads=1*, *scale_value=1.0*, *pre_tokens=2147483647*, *next_tokens=0*, *input_layout='BSH'*, *num_key_value_heads=0*, *sparse_mode=0*, *inner_precise=1*)

The interface for fully inference.

- B: Batch size
- N: Num of attention heads
- S: Sequence length
- D: Head dim
- H: Hidden layer size

Self attention constructs an attention model based on the relationship between input samples themselves. The principle is to assume that there is an input sample sequence x of length n, and each element of x is a d dimensional vector, which can be viewed as a token embedding. This sequence can be transformed through 3 weight matrices to obtain 3 matrices with dimensions of $n \times d$.

The self attention calculation formula is defined as:

$$Attention(Q, K, V) = Softmax(\frac{QK^T}{\sqrt{d}})V$$

where the product of Q and K^T represents the attention of input x. To avoid the value becoming too large, it is usually scaled by dividing it by the square root of d and perform softmax normalization on each row, yields a matrix of $n \times d$ after multiplying V.

Warning:

- Support dtype of float16 for *attn_mask* will be deprecated in the future.
- When *sparse_mode* is 2, 3 or 4, the shape of *attn_mask* must be $(2048, 2048)$ / $(B, 1, 2048, 2048)$ / $(1, 1, 2048, 2048)$.

Note:

- Maximum Support for each axis
  - Supports B-axis values less than or equal to 65536 (64k). When the input type includes int8 with D-axis not aligned to 32, or the input type is float16 or bfloat16 with D-axis not aligned to 16, the B-axis supports up to 128 only.
  - Supports N-axis values less than or equal to 256.
  - Supports S-axis values less than or equal to 20971520 (20M).
  - Supports D-axis values less than or equal to 512.
- Quantization

  - int8 Input, int8 Output: Parameters *deq_scale1*, *quant_scale1*, *deq_scale2*, and *quant_scale2* must all be provided. *quant_offset2* is optional (default is 0 if not provided).
  - int8 Input, float16 Output: Parameters *deq_scale1*, *quant_scale1*, and *deq_scale2* must all be provided. If *quant_offset2* or *quant_scale2* is provided (i.e., not null), it will result in an error.
  - float16 or bfloat16 Input, int8 Output: Parameter *quant_scale2* must be provided. *quant_offset2* is optional (default is 0 if not provided). If *deq_scale1*, *quant_scale1*, or *deq_scale2* is provided (i.e., not null), it will result in an error.
  - int8 Output:
    * *quant_scale2* and *quant_offset2* in per-channel format do not support scenarios with left padding, Ring Attention, or non-32-byte aligned D-axis.
    * In GE mode: *quant_scale2* and *quant_offset2* in per-tensor format do not support scenarios with non-32-byte aligned D-axis.
    * Does not support sparse as band and *pre_tokens*/*next_tokens* being negative.
  - *quant_scale2* and *quant_offset2* can be bfloat16 only when *query* is bfloat16.

- Other Usage Caveats:
  - *N* of parameter *query* must be equal to *num_heads*. *N* of parameter *key* and parameter *value* must be equal to *num_key_value_heads*.
  - *num_heads* must be divisible by *num_key_value_heads* and *num_heads* divided by *num_key_value_heads* can not be greater than 64.
  - When *query* dtype is bfloat16, D axis should align with 16.
  - Each element of *actual_seq_lengths* must not exceed q_S and element of *actual_seq_lengths_kv* must not exceed kv_S.

Warning: Only support on Atlas A2 training series.

Parameters

- **query** (Tensor) −The query tensor with data type of int8, float16 or bfloat16. The shape is (B, q_S, q_H) / *(B, q_N, q_S, q_D)*.
- **key** (Tensor) −The key tensor with the same dtype as *query*. The shape is (B, kv_S, kv_H) / *(B, kv_N, kv_S, kv_D)*.
- **value** (Tensor) −The value tensor with the same dtype as *query*. The shape is (B, kv_S, kv_H) / *(B, kv_N, kv_S, kv_D)*.
- **attn_mask** (Tensor, *optional*) −For each element, 0/False indicates retention and 1/True indicates discard. If *sparse_mode* is 0 or 1: the shape is (q_S, kv_S) / (B, q_S, kv_S) / $(1, q_S, kv_S)$ / $(B, 1, q_S, kv_S)$ / $(1, 1, q_S, kv_S)$. If *sparse_mode* is 2, 3 or 4, the shape is $(2048, 2048)$ / $(1, 2048, 2048)$ / $(1, 1, 2048, 2048)$. Default: None.
- **actual_seq_lengths** (*Union[Tensor, tuple[int], list[int]], optional*) −Describe actual sequence length of each batch of *query* with data type of int64. The shape is $(B,)$ and every element should be positive integer. Default: None.
- **actual_seq_lengths_kv** (*Union[Tensor, tuple[int], list[int]], optional*) −Describe actual sequence length of each batch of *key* or *value* with data type of int64. The shape is $(B,)$ and every element should be positive integer. Default: None.
- **pse_shift** (Tensor, *optional*) −The position encoding tensor with data type of float16 or bfloat16. Input tensor of shape (B, N, q_S, kv_S) / $(1, N, q_S, kv_S)$. Default: None.

  - q_S must be greater than or equal to the query's S length, and kv_S must be greater than or equal to the key's S length.'
  - If *pse_shift* has dtype float16, *query* should have dtype float16 or int8, in which case high precision mode is enabled automatically.
  - If *pse_shift* has dtype bfloat16, *query* should have dtype bfloat16.
- **deq_scale1** (Tensor, *optional*) –Quantitative parametor, the tensor with data type of uint64 or float32. Input Tensor of shape $(1,)$. Default: None.
- **quant_scale1** (Tensor, *optional*) –Quantitative parametor, the tensor with data type of float32. Input Tensor of shape $(1,)$. Default: None.
- **deq_scale2** (Tensor, *optional*) –Quantitative parametor, input Tensor of shape $(1,)$ and it has the same dtype as *deq_scale1*. Default: None.
- **quant_scale2** (Tensor, *optional*) –Quantitative parametor, the tensor with data type of float32 or bfloat16. The suggested shape is $(1,)$ / $(1, 1, q_H)$ / $(q_H,)$ when output layout is BSH, $(1,)$ / $(1, q_N, 1, D)$ / $(q_N, D) when layout is BNSD. Default$:.
- **quant_offset2** (Tensor, *optional*) –Quantitative parametor, the tensor with data type of float32 or bfloat16. It has the same dtype and shape as *quant_scale2*. Default: None.
- **num_heads** (*int*, *optional*) –The number of heads. It is an integer in range [0, 256]. Default: 1.
- **scale_value** (*double*, *optional*) –The scale value indicating the scale coefficient, which is used as the scalar of Muls in the calculation. Default: 1.0.
- **pre_tokens** (*int*, *optional*) –For sparse cumputing, indicating the number of previous tokens Attention needs to associated with. Default: 2147483647.
- **next_tokens** (*int*, *optional*) –For sparse cumputing, indicating the number of next tokens Attention needs to associated with. Default: 0.
- **input_layout** (*str*, *optional*) –the data layout of the input qkv, support *(BSH)* and *(BNSD)*. Default BSH.
- **num_key_value_heads** (*int*, *optional*) –An int indicates head numbers of key/value which are used in GQA algorithm. The value 0 indicates if the key and value have the same head nums, use *num_heads*. It it is specified(not 0), it must be a factor of *num_heads* and it must be equal to kv_n. Default: 0.
- **sparse_mode** (*int*, *optional*) –An int specifies sparse mode, can be int from {0, 1, 2, 3, 4}. Default: 0.
  - sparseMode = 0: If *attn_mask* is a null pointer, *pre_tokens* and *next_tokens* inputs are ignored (internally set to INT_MAX).
  - sparseMode = 2, 3, 4: *attn_mask* shape must be (S, S) or $(1, S, S)$ or $(1, 1, S, S)$, with S fixed at 2048. User must ensure that *attn_mask* is lower triangular. If not provided or incorrect shape, it will result in an error.
  - sparseMode = 1, 2, 3: Ignores *pre_tokens*, *next_tokens* inputs and sets values according to specific rules.
  - sparseMode = 4: *pre_tokens* and *next_tokens* must be non-negative.
- **inner_precise** (*int*, *optional*) –An int number from {0, 1} indicates computing mode. 0 for high precision mode for float16 dtype. 1 for high performance mode. Default: 1.

Returns

attention_out (Tensor) - Output tensor, has the same shape as *query* of (B, q_S, q_H) / (B, q_N, q_S, q_D). Output dtype is determined by multiple factors, please refer to Note above for details.

Raises

- **TypeError** –Dtype of *query* is not int8, float16 or bfloat16.
- **TypeError** –*query*, *key* and *value* don't have the same dtype.

- **TypeError** – Dtype of *attn_mask* is not bool, int8 or uint8.
- **TypeError** – Dtype of *pse_shift* is not bfloat16 or float16.
- **TypeError** – *scale_value* is not a double number.
- **TypeError** – *input_layout* is not a string.
- **TypeError** – *num_key_value_heads* is not an int.
- **TypeError** – *sparse_mode* is not an int.
- **TypeError** – *sparse_inner_precisemode* is not an int.
- **TypeError** – *quant_scale1* is not Tensor of type float32.
- **TypeError** – *deq_scale1* is not Tensor of type uint64 or float32.
- **TypeError** – *quant_scale2* is not Tensor of type float32.
- **TypeError** – *deq_scale2* is not Tensor of type uint64 or float32.
- **TypeError** – *quant_offset2* is not Tensor of type float32.
- **ValueError** – *input_layout* is a string but of *(BSH)* or *(BNSD)*.
- **RuntimeError** – *num_heads* is not divisible by *num_key_value_heads*.
- **RuntimeError** – *num_heads* is not greater than 0.
- **RuntimeError** – *num_key_value_heads* is not greater than or equal to 0.
- **RuntimeError** – kv_n is not equal to *num_key_value_heads*.
- **RuntimeError** – *attn_mask* shape is not valid.
- **RuntimeError** – *sparse_mode* is specified but is not 0, 1, 2, 3 or 4.
- **RuntimeError** – *query* dtype is bfloat16 and D axis is not aligned with 16.
- **RuntimeError** – *input_layout* is BSH and kv_h is not divisible by *num_key_value_heads*.
- **RuntimeError** – D-axis of *query*, *key* and *value* is not the same.
- **RuntimeError** – In post quant per-channel scenario, D-axis is not 32 Byte aligned.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor, ops
>>> import numpy as np
>>> B = 1
>>> N = 16
>>> S = 256

```

mindspore.ops.flash_attention_score

mindspore.ops.**flash_attention_score**(*query*, *key*, *value*, *head_num*, *real_shift=None*, *drop_mask=None*, *padding_mask=None*, *attn_mask=None*, *prefix=None*, *actual_seq_qlen=None*, *actual_seq_kvlen=None*, *keep_prob=1.0*, *scalar_value=1.0*, *pre_tokens=2147483647*, *next_tokens=2147483647*, *inner_precise=0*, *input_layout='BSH'*, *sparse_mode=0*)

Implement self-attention calculations in training scenarios.

- B: Batch size. Value range 1 to 2k.
- S1: Sequence length of *query*. Value range 1 to 512k.
- S2: Sequence length of *key* and *value*. Value range 1 to 512k.
- N1: Num heads of *query*. Value range 1 to 256.
- N2: Num heads of *key* and *value*, and N2 must be a factor of N1.
- D: Head size. The value ranges is a multiple of 16, with the max value of 512.
- H1: Hidden size of *query*, which equals to N1 * D.
- H2: Hidden size of *key* and *value*, which equals to N2 * D.

The self attention calculation formula is defined as:

$$\text{attention\_out} = \text{Dropout}\left(\text{Softmax}\left(\text{Mask}(\text{scale} * \left(\text{query} * \text{key}^{\top}\right) + \text{pse}\right), \text{atten\_mask}), \text{keep\_prob}\right) * \text{value}$$

Warning:

- This is an experimental API that is subject to change or deletion.
- Only support on Atlas A2 training series.

Parameters

- **query** (Tensor) −The query tensor. Input tensor of shape $(B, S1, H1)$, $(B, N1, S1, D)$, $(S1, B, H1)$, $(B, S1, N1, D)$ or $(T1, N1, D)$. The supported dtype is float16 and bfloat16.
- **key** (Tensor) −The key tensor with the same dtype as *query*. Supported shape: $(B, S2, H2)$, $(B, N2, S2, D)$, $(S2, B, H2)$, $(B, S2, N2, D)$ or $(T2, N2, D)$.
- **value** (Tensor) −The value tensor with the same dtype and shape as *key*.
- **head_num** (*int*) −The head num of *query*, equal to N1.
- **real_shift** (Tensor, *optional*) −The position embedding code which is also known as pse, it has the same dtype as *query*. Default: None. If S is greater than 1024 and the mask of the lower triangle is used, only the inverse 1024 lines of the lower triangle is used for memory optimization. Input tensor of shape $(B, N1, S1, S2)$, $(1, N1, S1, S2)$, $(B, N1, 1024, S2)$, $(1, N1, 1024, S2)$.
  - ALiBi scenario: *real_shift* must meet the ALiBi rule, and sparse_mode is 2 or 3 for the lower triangle. In this scenario, *real_shift* is $(B, N1, 1024, S2)$, $(1, N1, 1024, S2)$.

  - Non-ALiBi scenario: *real_shift* is $(B, N1, S1, S2)$, $(1, N1, S1, S2)$.
  - input_layout is TND: shape should be $(B, N1, 1024, S2)$ and $(1, N1, 1024, S2)$.

- **drop_mask** (Tensor, *optional*) –The dropout mask tensor of uint8. Input tensor of shape $(B, N1, S1, S2//8) or None$. *S2* is a multiple of 8 when not None. Default: None.
- **padding_mask** (Tensor, *optional*) –Reserved parameter. Not implemented yet. Default: None.
- **attn_mask** (Tensor, *optional*) –The attention mask tensor of bool or uint8. For each element, 0/False indicates retention and 1/True indicates discard. Input tensor of shape $(B, N1, S1, S2)$, $(B, 1, S1, S2)$, $(S1, S2)$ or $(2048, 2048)$. Default: None.
  - In compression scenario, *sparse_mode* is 2, 3, or 4, *attn_mask* must be $(2048, 2048)$.
  - When *sparse_mode* is 5, *attn_mask* should be $(B, N1, S1, S2)$, $(B, 1, S1, S2)$.
  - When *sparse_mode* is 0 and 1, *attn_mask* should be $(B, N1, S1, S2)$, $(B, 1, S1, S2)$, $(S1, S2)$.
- **prefix** (*Union[Tensor, tuple[int], list[int]], optional*) –N value of each Batch in the prefix sparse calculation scenario. Input tensor of shape $(B,)$. B max value 32. Not none only when *sparse_mode* is 5. Default: None. If S1 > S2, N ranges from 0 to S2. If S1 <= S2, N ranges from S2 - S1 to S2.
- **actual_seq_qlen** (*Union[Tensor, tuple[int], list[int]], optional*) –Size of query corresponding to each batch, array with increasing values and the last value equal to T1. Default: None.
- **actual_seq_kvlen** (*Union[Tensor, tuple[int], list[int]], optional*) –Size of key and value corresponding to each batch, array with increasing values and the last value equal to T2. Default: None.
- **keep_prob** (*double, optional*) –The keep probability of dropout. Value range is (0.0, 1.0]. When *keep_prob* is 1.0, *drop_mask* should be None. Default: 1.0.
- **scalar_value** (*double, optional*) –The scale factor of score. Generally, the value is 1.0 / (D ** 0.5). Default: 1.0.
- **pre_tokens** (*int, optional*) –Parameter for sparse computation, represents how many tokens are counted forward. When *sparse_mode* is set to 1, 2, 3, or 5, this parameter does not take effect. Default: 2147483647.
- **next_tokens** (*int, optional*) –Parameter for sparse computation, represents how many tokens are counted backward. When *sparse_mode* is set to 1, 2, 3, or 5, this parameter does not take effect. Default: 2147483647. The value of *pre_tokens* corresponds to S1, and the value of *next_tokens* corresponds to S2. They define the valid area on the *attn_mask* matrix. It must ensure that the band is not empty. The following values are not allowed:
  - pre_tokens < 0 and next_tokens < 0.
  - (pre_tokens < 0 and next_tokens >= 0) and (next_tokens < abs(pre_tokens) or abs(pre_tokens) >= S2).
  - (pre_tokens >= 0 and next_tokens < 0) and (abs(next_tokens) > pre_tokens or abs(next_tokens) >= S1).
- **inner_precise** (*int, optional*) –The parameter is reserved and not implemented yet. Default:0.
- **input_layout** (*str, optional*) –Specifies the layout of input *query*, *key* and *value*. The value can be "BSH", "BNSD", "SBH", "BSND" or "TND". "TND" is an experimental format. Default: "BSH". When input_layout is "TND", the following restrictions must be met. Assume there are two lists that represent the length of the input sequence: list_seq_q and list_seq_k. Each value in the list indicates the length of the sequence in the batch. For example, list_seq_q = [4, 2, 6], list_seq_k = [10, 3, 9]. The element of list indicate S. T1 is sum(list_seq_q) = 12, T2 is sum(list_seq_k) = 22. max_seqlen_q = max(list_seq_q), max_seqlen_k = max(list_seq_k). qk_pointer = sum(list_seq_q * list_seq_k), which is the sum of the element multiplication.
  - The lengths of two lists must be the same, and size of list is batch. batch is less than or equal to 1024.
  - When *input_layout* is "TND", *actual_seq_qlen* and *actual_seq_kvlen* must be not none. Otherwise, they are none.
  - The *actual_seq_qlen* and *actual_seq_kvlen* are the cumulative sum of sequence of key/value, so they must be non-decreasing.

  - If *real_shift* is not none, list_seq_q and list_seq_k must be same. The maximum value of list_seq_q and list_seq_k is greater than 1024. *real_shift* should be $(B, N1, 1024, S2)$ and $(1, N1, 1024, S2)$, and S2 is equal to max_seqlen_k.
  - *attn_mask* must be a lower trianglar matrix, so *sparse_mode* should be 2 or 3. The shape of *attn_mask* should be $(2048, 2048)$.
  - The shape of *drop_mask* is $(qk\_pointer * N1//8,)$.
  - *prefix* is none.
  - *next_tokens* is 0, and *pre_tokens* is not less than max_seqlen_q.
  - When *sparse_mode* is 3, S1 of each batch should be less than or equal to S2.
  - 0 should not exist in list_seq_k.
- **sparse_mode** (*int, optional*) –Indicates sparse mode. Default: `0`.
  - 0: Indicates the defaultMask mode. If *attn_mask* is not passed, the mask operation is not performed, *next_tokens* and *pre_tokens* (internally assigned as INT_MAX) are ignored. If passed in, the full *attn_mask* matrix (S1 * S2) needs to be passed in, indicating that the part between *next_tokens* and *pre_tokens* needs to be calculated.
  - 1: Represents allMask, that is, passing in the complete *attn_mask* matrix.
  - 2: Representing the leftUpCausal mode corresponds to the lower triangle scenario divided by the left vertex, and the optimized *attn_mask* matrix (2048*2048) is required.
  - 3: Representing the rightDownCausal model corresponds to the lower triangle scene divided by the lower right vertex, and the optimized *attn_mask* matrix (2048*2048) is required.
  - 4: Represents the band scenario, that is, the part between counting *next_tokens* and *pre_tokens*, and the optimized *attn_mask* matrix (2048*2048) is required.
  - 5: Represents the prefix scenario, that is, on the basis of rightDownCasual, a matrix with length S1 and width N is added to the left side. The value of N is obtained by the new input prefix, and the N value of each Batch axis is different, not implemented yet.
  - 6: Represents the global scenario, not implemented yet.
  - 7: Represents the dilated scenario, not implemented yet.
  - 8: Represents the block_local scenario, not implemented yet.

Returns

attention_out (Tensor) - The output of attention, it has the same shape and dtype as *query*.

Raises

- **TypeError** –Dtype of *query* is not float16 or bfloat16.
- **TypeError** –*query*, *key* and *value* don't have the same dtype.
- **TypeError** –Dtype of *attn_mask* is not bool or uint8.
- **TypeError** –Dtype of *real_shift* has a different dtype as *query*.
- **TypeError** –*scalar_value* or *keep_prob* is not a double number.
- **TypeError** –*input_layout* is not a string.
- **TypeError** –*num_key_value_heads* is not an int.
- **TypeError** –*sparse_mode* is not an int.
- **TypeError** –*real_shift* is not Tensor type.
- **TypeError** –*drop_mask* is not Tensor type.

- **TypeError** – *padding_mask* is not Tensor type.
- **TypeError** – *attn_mask* is not Tensor type.
- **ValueError** – *input_layout* is a string but not valid.
- **RuntimeError** – *head_num* is not divisible by *N2*.
- **RuntimeError** – *head_num* is not greater than 0.
- **RuntimeError** – *attn_mask* shape is not valid.
- **RuntimeError** – The specified value of *sparse_mode* is invalid.
- **RuntimeError** – D-axis of *query*, *key* and *value* is not the same.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import mindspore.common.dtype as mstype
>>> import numpy as np
>>> from mindspore import ops, Tensor
>>> query = Tensor(np.ones([2, 4, 64]), dtype=mstype.float16)
>>> key = Tensor(np.ones([2, 4, 64]), dtype=mstype.float16)
>>> value = Tensor(np.ones([2, 4, 64]), dtype=mstype.float16)
>>> head_num = 4
>>> output = ops.flash_attention_score(query, key, value, head_num)
>>> print(output.shape)
(2, 4, 64)
```

mindspore.ops.rms_norm

mindspore.ops.**rms_norm**(*x*, *gamma*, *epsilon=1e-6*)

The RmsNorm(Root Mean Square Layer Normalization) operator is a normalization operation. Compared to LayerNorm, it retains scaling invariance and removes translation invariance. Its formula is:

$$y = \frac{x_i}{\sqrt{\frac{1}{n}\sum_{i=1}^{n} x_i^2 + \varepsilon}}\gamma_i$$

Warning: This is an experimental API that is subject to change or deletion. This API is only supported in Atlas A2 training series for now.

Parameters

- **x** (Tensor) – Input data of RmsNorm. Support data type: float16, float32, bfloat16.
- **gamma** (Tensor) – Learnable parameter γ . Support data type: float16, float32, bfloat16.
- **epsilon** (*float, optional*) – A float number ranged in (0, 1] to prevent division by 0. Default value is *1e-6*.

Returns

- Tensor, denotes the normalized result, has the same type and shape as *x*.

- Tensor, with the float data type, denotes the reciprocal of the input standard deviation, used by gradient calculation.

Raises

- **TypeError** –If data type of *x* is not one of the following: float16, float32, bfloat16.
- **TypeError** –If data type of *gamma* is not one of the following: float16, float32, bfloat16.
- **TypeError** –If data type of *x* is not the same with the data type of *gamma*.
- **ValueError** –If *epsilon* is not a float between 0 and 1.
- **ValueError** –If the rank of *gamma* is lagger than the rank of *x*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[1, 2, 3], [1, 2, 3]]), mindspore.float32)
>>> gamma = Tensor(np.ones([3]), mindspore.float32)
>>> y, rstd = ops.rms_norm(x, gamma)
>>> print(y)
[[0.46290997  0.92581993  1.3887299]
 [0.46290997  0.92581993  1.3887299]]
>>> print(rstd)
[[0.46290997]
 [0.46290997]]
```

mindspore.ops.unfold

mindspore.ops.**unfold**(*input*, *kernel_size*, *dilation=1*, *padding=0*, *stride=1*)

Extracts sliding local blocks from a batched input tensor.

Consider a batched input tensor of shape $(N, C, *)$, where N is the batch dimension, C is the channel dimension, and $*$ represent arbitrary spatial dimensions. This operation flattens each sliding *Kernel_size*- sized block within the spatial dimensions of input x into a column (i.e., last dimension) of a 3-D output tensor of shape $(N, C \times \prod(\text{kernel\_size}), L)$, where $C \times \prod(\text{kernel\_size})$ is the total number of values within each block (a block has $\prod(\text{kernel\_size})$ spatial locations, each containing a C-channeled vector), and L is the total number of such blocks:

$$L = \prod_{d} \left\lfloor \frac{\text{spatial\_size}[d] + 2 \times \text{pads}[d] - \text{dilations}[d] \times (\text{kernel\_size}[d] - 1) - 1}{\text{strides}[d]} + 1 \right\rfloor,$$

where spatial_size is formed by the spatial dimensions of input x ($*$ above), and d is over all spatial dimensions.

Therefore, indexing *output* at the last dimension (column dimension) gives all values within a certain block.

The *dilation*, *padding* and *stride* arguments specify how the sliding blocks are retrieved.

Warning:

- The output is a 3-dimensional Tensor whose shape is $(N, C \times \prod(\text{kernel\_size}), L)$.
- This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –4-D Tensor, supported dtypes: float16, float32, float64, complex64 and complex128.
- **kernel_size** (*Union[int, tuple[int], list[int]]*) –The size of the kernel, should be two int for height and width. If type is int, it means that height equal with width.
- **dilation** (*Union[int, tuple[int], list[int]], optional*) –The dilation of the window, should be two int for height and width. If type is int, it means that height equal with width. Default: 1 .
- **padding** (*Union[int, tuple[int], list[int]], optional*) –The pad of the window, that must be a tuple/list of one or two *int* for height and width. Default: 0 .
  - If one int, pad_height = pad_width.
  - If two int, pad_height = padding[0], pad_width = padding[1].
- **stride** (*Union[int, tuple[int], list[int]], optional*) –The stride of the window, should be two int for height and width. If type is int, it means that height equal with width. Default: 1 .

Returns

A Tensor, with same type as *input* . And its shape is as described above.

Raises

- **TypeError** –If any data type of *kernel_size*, *stride*, *dilation*, *padding* is not int, tuple or list.
- **ValueError** –If *kernel_size*, *dilation*, *stride* value is not greater than zero or elements number more than *2*.
- **ValueError** –If *padding* value is less than zero.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.random.rand(4, 4, 32, 32), mindspore.float64)
>>> output = ops.unfold(x, kernel_size=3, dilation=1, stride=1)
>>> print(output.shape)
(4, 36, 900)
```

2.3.2 Loss Functions

API Name	Description	Supported Platforms
mindspore.ops.binary_cross_entropy	Computes the binary cross entropy(Measure the difference information between two probability distributions) between predictive value *logits* and target value *labels*.	Ascend GPU CPU
mindspore.ops.binary_cross_entropy_with_logits	Adds sigmoid activation function to input *input* as logits, and uses the given logits to compute binary cross entropy between the *input* and the *target*.	Ascend GPU CPU

continues on next page

Table 12 – continued from previous page

mindspore.ops.cosine_embedding_loss	CosineEmbeddingLoss creates a criterion to measure the similarity between two tensors using cosine distance.	Ascend GPU CPU
mindspore.ops.cross_entropy	The cross entropy loss between input and target.	Ascend GPU CPU
mindspore.ops.ctc_loss	Calculates the CTC (Connectionist Temporal Classification) loss and the gradient.	Ascend GPU CPU
mindspore.ops.gaussian_nll_loss	Gaussian negative log likelihood loss.	Ascend GPU CPU
mindspore.ops.hinge_embedding_loss	Measures Hinge Embedding Loss given an input Tensor *intputs* and a labels Tensor *targets* (containing 1 or -1).	Ascend GPU CPU
mindspore.ops.huber_loss	Calculates the error between the predicted value and the target value, which has the best of both the loss of mindspore.ops.l1_loss() and the loss of mindspore.ops.mse_loss().	Ascend GPU CPU
mindspore.ops.kl_div	Computes the Kullback-Leibler divergence between the logits and the labels.	Ascend GPU CPU
mindspore.ops.l1_loss	Calculate the mean absolute error between the *input* value and the *target* value.	Ascend GPU CPU
mindspore.ops.margin_ranking_loss	MarginRankingLoss creates a criterion that measures the loss.	Ascend GPU CPU
mindspore.ops.mse_loss	Calculates the mean squared error between the predicted value and the label value.	Ascend GPU CPU
mindspore.ops.multi_margin_loss	Hinge loss for optimizing a multi-class classification.	Ascend GPU CPU
mindspore.ops.multilabel_margin_loss	Hinge loss for optimizing a multi-label classification.	Ascend GPU
mindspore.ops.multilabel_soft_margin_loss	Calculates the MultiLabelSoftMarginLoss.	Ascend GPU CPU
mindspore.ops.nll_loss	Gets the negative log likelihood loss between inputs and target.	Ascend GPU CPU
mindspore.ops.smooth_l1_loss	Computes smooth L1 loss, a robust L1 loss.	Ascend GPU CPU
mindspore.ops.soft_margin_loss	Calculate the soft margin loss of input and target.	Ascend GPU
mindspore.ops.triplet_margin_loss	TripletMarginLoss operation.	GPU

mindspore.ops.binary_cross_entropy

mindspore.ops.**binary_cross_entropy**(*logits*, *labels*, *weight=None*, *reduction='mean'*)

Computes the binary cross entropy(Measure the difference information between two probability distributions) between predictive value *logits* and target value *labels*.

Set *logits* as x, *labels* as y, output as $\ell(x, y)$, the weight of nth batch of binary cross entropy is w_n. Let,

$$L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -w_n \left[y_n \cdot \log x_n + (1 - y_n) \cdot \log(1 - x_n) \right]$$

In which, L indicates the loss of all *batch_size*, l indicates the loss of one *batch_size*, and n indicates one *batch_size* in the $1 - N$ range. Then,

$$\ell(x, y) = \begin{cases} L, & \text{if reduction = 'none';} \\ \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Warning:

- The value of *logits* must range from *0* to *1*.

Parameters

- **logits** (Tensor) –The predictive value whose data type must be float16 or float32.
- **labels** (Tensor) –The target value which has the same shape and data type as *logits*. And the data type is float16 or float32.
- **weight** (Tensor, *optional*) –A rescaling weight applied to the loss of each batch element. Its shape must be able to broadcast to that of *logits* and *labels*. And it must have the same shape and data type as *logits*. Default: None . If set to None , the loss function will not consider any sample weights, and each sample will be treated as having equal importance when calculating the loss.
- **reduction** (*str*, *optional*) –Apply specific reduction method to the output: 'none' , 'mean' , 'sum' . Default: 'mean' .
  - 'none': no reduction will be applied.
  - 'mean': compute and return the weighted mean of elements in the output.
  - 'sum': the output elements will be summed.

Returns

Tensor or Scalar. Returns Tensor that has the same dtype and shape as *logits* if *reduction* is 'none'. Otherwise, returns a scalar Tensor.

Raises

- **TypeError** –If *logits*, *labels* or *weight* is not a Tensor.
- **TypeError** –If dtype of *logits*, *labels* or *weight* (if given) is neither float16 nor float32.
- **ValueError** –If *reduction* is not one of 'none', 'mean' or 'sum'.
- **ValueError** –If shape of *labels* is not the same as *logits* or *weight* (if given).

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> logits = Tensor(np.array([0.2, 0.7, 0.1]), mindspore.float32)
>>> labels = Tensor(np.array([0., 1., 0.]), mindspore.float32)
>>> weight = Tensor(np.array([1, 2, 2]), mindspore.float32)
>>> output = ops.binary_cross_entropy(logits, labels, weight)
>>> print(output)
0.38240486
```

mindspore.ops.binary_cross_entropy_with_logits

mindspore.ops.**binary_cross_entropy_with_logits**(*input*, *target*, *weight=None*, *pos_weight=None*, *reduction='mean'*)

Adds sigmoid activation function to input *input* as logits, and uses the given logits to compute binary cross entropy between the *input* and the *target*.

Sets input *input* as X, input *target* as Y, input *weight* as W, output as L. Then,

$$
\begin{aligned}
p_{ij} &= sigmoid(X_{ij}) = \frac{1}{1+e^{-X_{ij}}} \\
L_{ij} &= -[Y_{ij}log(p_{ij}) + (1 - Y_{ij})log(1 - p_{ij})]
\end{aligned}
$$

i indicates the i^{th} sample, j indicates the category. Then,

$$
\ell(x, y) = \begin{cases} L, & \text{if reduction = 'none';} \\ \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}
$$

ℓ indicates the method of calculating the loss. There are three methods: the first method is to provide the loss value directly, the second method is to calculate the average value of all losses, and the third method is to calculate the sum of all losses.

This operator will multiply the output by the corresponding weight. The tensor $weight$ assigns different weights to each piece of data in the batch, and the tensor pos_weight adds corresponding weights to the positive examples of each category.

In addition, it can trade off recall and precision by adding weights to positive examples. In the case of multi-label classification the loss can be described as:

$$
\begin{aligned}
p_{ij,c} &= sigmoid(X_{ij,c}) = \frac{1}{1+e^{-X_{ij,c}}} \\
L_{ij,c} &= -[P_c Y_{ij,c} * log(p_{ij,c}) + (1 - Y_{ij,c})log(1 - p_{ij,c})]
\end{aligned}
$$

where c is the class number (c>1 for multi-label binary classification, c=1 for single-label binary classification), n is the number of the sample in the batch and P_c is the weight of the positive answer for the class c. $P_c > 1$ increases the recall, $P_c < 1$ increases the precision.

Parameters

- **input** (Tensor) −Input *input*. Data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported).
- **target** (Tensor) −Ground truth label, has the same shape as *input*. Data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported).
- **weight** (Tensor, *optional*) −A rescaling weight applied to the loss of each batch element. It can be broadcast to a tensor with shape of *input*. Data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported). Default: None, it equals to *weight* is a Tensor whose value is 1.
- **pos_weight** (Tensor, *optional*) −A weight of positive examples. Must be a vector with length equal to the number of classes. It can be broadcast to a tensor with shape of *input*. Data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported). Default: None, it equals to *pos_weight* is a Tensor whose value is 1.
- **reduction** (*str, optional*) −Apply specific reduction method to the output: 'none' , 'mean' , 'sum' . Default: 'mean' .
  - 'none': no reduction will be applied.
  - 'mean': compute and return the weighted mean of elements in the output.
  - 'sum': the output elements will be summed.

Returns

Tensor or Scalar, if *reduction* is `'none'`, it's a tensor with the same shape and type as input *input*. Otherwise, the output is a scalar.

Raises

- **TypeError** –If input *input*, *target*, *weight*, *pos_weight* is not Tensor.
- **TypeError** –If data type of input *input*, *target*, *weight*, *pos_weight* is not float16, float32 or bfloat16.
- **TypeError** –If data type of input *reduction* is not string.
- **ValueError** –If *weight* or *pos_weight* can not be broadcast to a tensor with shape of *input*.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'` or `'sum'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.array([[-0.8, 1.2, 0.7], [-0.1, -0.4, 0.7]]), mindspore.float32)
>>> target = Tensor(np.array([[0.3, 0.8, 1.2], [-0.6, 0.1, 2.2]]), mindspore.float32)
>>> weight = Tensor(np.array([1.0, 1.0, 1.0]), mindspore.float32)
>>> pos_weight = Tensor(np.array([1.0, 1.0, 1.0]), mindspore.float32)
>>> output = ops.binary_cross_entropy_with_logits(input, target, weight, pos_weight)
>>> print(output)
0.3463612
```

mindspore.ops.cosine_embedding_loss

`mindspore.ops.`**`cosine_embedding_loss`**(*input1*, *input2*, *target*, *margin=0.0*, *reduction='mean'*)

CosineEmbeddingLoss creates a criterion to measure the similarity between two tensors using cosine distance.

Given two tensors $input1$, $input2$, and a Tensor label $target$ with values 1 or -1:

$$loss(input1, input2, target) = \begin{cases} 1 - cos(input1, input2), & \text{if } target = 1 \\ max(0, cos(input1, input2) - margin), & \text{if } target = -1 \end{cases}$$

Parameters

- **input1** (Tensor) –Tensor of shape $(N, *)$ where $*$ means, any number of additional dimensions.
- **input2** (Tensor) –Tensor of shape $(N, *)$, same shape and dtype as *input1*.
- **target** (Tensor) –Contains value 1 or -1. Suppose the shape of *input1* is $(x_1, x_2, x_3, ..., x_R)$, then the shape of *target* must be $(x_1, x_3, x_4, ..., x_R)$.
- **margin** (*float, optional*) –Should be in [-1.0, 1.0]. Default: `0.0`.
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.

- `'sum'`: the output elements will be summed.

Returns

Tensor or Scalar, if *reduction* is `"none"`, its shape is the same as *target*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** – If *margin* is not a float.
- **ValueError** – If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.
- **ValueError** – If *margin* is not in range [-1.0, 1.0].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> intput1 = Tensor(np.array([[0.3, 0.8], [0.4, 0.3]]), mindspore.float32)
>>> intput2 = Tensor(np.array([[0.4, 1.2], [-0.4, -0.9]]), mindspore.float32)
>>> target = Tensor(np.array([1, -1]), mindspore.int32)
>>> output = ops.cosine_embedding_loss(intput1, intput2, target)
>>> print(output)
0.0003425479
```

mindspore.ops.cross_entropy

`mindspore.ops.`**`cross_entropy`**(*input*, *target*, *weight=None*, *ignore_index=- 100*, *reduction='mean'*, *label_smoothing=0.0*)

The cross entropy loss between input and target.

The cross entropy support two kind of targets:

- Class indices (int) in the range $[0, C)$ where C is the number of classes, the loss with reduction=none can be described as:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -w_{y_n} \log \frac{\exp(x_{n,y_n})}{\sum_{c=1}^{C} \exp(x_{n,c})} \cdot \mathbb{1}\{y_n \neq \text{ignore\_index}\}$$

  where x is the inputs, y is the target, w is the weight, N is the batch size, c belonging to $[0, C-1]$ is class index, where C is the number of classes.

  If *reduction* is not `None` (default `'mean'`), then

$$\ell(x, y) = \begin{cases} \sum_{n=1}^{N} \frac{1}{\sum_{n=1}^{N} w_{y_n} \cdot \mathbb{1}\{y_n \neq \text{ignore\_index}\}} l_n, & \text{if reduction = 'mean',} \\ \sum_{n=1}^{N} l_n, & \text{if reduction = 'sum'.} \end{cases}$$

- Probabilities (float) for each class, useful when labels beyond a single class per minibatch item are required, the loss with reduction=none can be described as:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -\sum_{c=1}^{C} w_c \log \frac{\exp(x_{n,c})}{\sum_{i=1}^{C} \exp(x_{n,i})} y_{n,c}$$

  where x is the inputs, y is the target, w is the weight, N is the batch size, c belonging to $[0, C-1]$ is class index, where C is the number of classes.

If *reduction* is not `None` (default `'mean'`), then

$$\ell(x, y) = \begin{cases} \frac{\sum_{n=1}^{N} l_n}{N}, & \text{if reduction = 'mean',} \\ \sum_{n=1}^{N} l_n, & \text{if reduction = 'sum'.} \end{cases}$$

Parameters

- **input** (Tensor) −(N) or (N, C) where C = *number of classes* or (N, C, H, W) in case of 2D Loss, or $(N, C, d_1, d_2, ..., d_K)$. *input* is expected to be log-probabilities, data type must be float16 or float32.
- **target** (Tensor) −For class indices, tensor of shape (), (N) or $(N, d_1, d_2, ..., d_K)$, data type must be int32. For probabilities, tensor of shape $(C,)$, (N, C) or $(N, C, d_1, d_2, ..., d_K)$, data type must be float16 or float32 or float64.
- **weight** (Tensor) −A rescaling weight applied to the loss of each batch element. If not None, the shape is $(C,)$, data type must be float16 or float32. Default: `None` .
- **ignore_index** (*int*) −Specifies a target value that is ignored and does not contribute to the input gradient. Default: `-100` .
- **reduction** (*str, optional*) −Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **label_smoothing** (*float*) −Label smoothing values, a regularization tool used to prevent the model from overfitting when calculating Loss. The value range is [0.0, 1.0]. Default value: `0.0` .

Returns

Tensor, the computed loss value.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> # Case 1: Indices labels
>>> inputs = ms.Tensor(np.random.randn(3, 5), ms.float32)
>>> target = ms.Tensor(np.array([1, 0, 4]), ms.int32)
>>> output = ms.ops.cross_entropy(inputs, target)
>>> # Case 2: Probability labels
>>> inputs = ms.Tensor(np.random.randn(3, 5), ms.float32)
>>> target = ms.Tensor(np.random.randn(3, 5), ms.float32)
>>> output = ms.ops.cross_entropy(inputs, target)
```

mindspore.ops.ctc_loss

mindspore.ops.**ctc_loss**(*log_probs*, *targets*, *input_lengths*, *target_lengths*, *blank=0*, *reduction='mean'*, *zero_infinity=False*)

Calculates the CTC (Connectionist Temporal Classification) loss and the gradient.

CTC is a loss function in sequence labeling problems, which is mainly used to deal with the alignment of input and output labels in sequence labeling problems. While traditional sequence labeling algorithms require the input and output symbols to be perfectly aligned at each moment, CTC expands the label collection and adds empty elements. After labeling the sequence using the extended label set, all the prediction sequences that can be converted into real sequences by the mapping function are correct prediction results, that is, the predicted sequence can be obtained without data alignment processing. Its objective function is to maximize the sum of probabilities of all correct prediction sequences.

The CTC algorithm is proposed in Connectionist Temporal Classification: Labeling Unsegmented Sequence Data with Recurrent Neural Networks.

Parameters

- **log_probs** (Tensor) – A tensor of shape (T, N, C), where T is input length, N is batch size and C is number of classes (including blank).
- **targets** (Tensor) – Target sequences. A tensor of shape (N, S), where S is max target length.
- **input_lengths** (*Union(tuple, Tensor)*) – Lengths of the input. A tuple or Tensor of shape (N).
- **target_lengths** (*Union(tuple, Tensor)*) – Lengths of the target. A tuple or Tensor of shape (N).
- **blank** (*int, optional*) – The blank label. Default: `0` .
- **reduction** (*str, optional*) – Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **zero_infinity** (*bool, optional*) – Whether to set infinite loss and correlation gradient to 0. Default: `False` .

Returns

neg_log_likelihood (Tensor), A loss value with shape (N) , which is differentiable with respect to each input node.

log_alpha (Tensor), The probability of possible trace of input to target with shape $(N, T, 2 * S + 1)$.

Raises

- **TypeError** – If *zero_infinity* is not a bool, *reduction* is not string.
- **TypeError** – If the dtype of *log_probs* is not float or double.
- **TypeError** – If the dtype of *targets*, *input_lengths* or *target_lengths* is not int32 or int64.
- **ValueError** – If the rank of *log_probs* is not 3.
- **ValueError** – If the rank of *targets* is not 2.
- **ValueError** – If the shape of *input_lengths* does not match N. N is batch size of *log_probs* .
- **ValueError** – If the shape of *target_lengths* does not match N. N is batch size of *log_probs* .
- **ValueError** – If the value of *blank* is not in range [0, num_labels|C). C is number of classes of *log_probs* .
- **RuntimeError** – If any value of *input_lengths* is larger than T. T is the length of *log_probs*.

- **RuntimeError** –If any target_lengths[i] is not in range [0, input_length[i]].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> log_probs = Tensor(np.array([[[0.3, 0.6, 0.6]],
...                              [[0.9, 0.4, 0.2]]]).astype(np.float32))
>>> targets = Tensor(np.array([[0, 1]]), mstype.int32)
>>> input_lengths = Tensor(np.array([2]), mstype.int32)
>>> target_lengths = Tensor(np.array([1]), mstype.int32)
>>> loss, log_alpha = ops.ctc_loss(log_probs, targets, input_lengths,
...                                target_lengths, 0, 'mean', True)
>>> print(loss)
-2.2986124
>>> print(log_alpha)
[[[0.3       0.3             -inf      -inf      -inf]
  [1.2       1.8931472 1.2             -inf      -inf]]]
```

mindspore.ops.gaussian_nll_loss

mindspore.ops.**gaussian_nll_loss**(*x*, *target*, *var*, *full=False*, *eps=1e-6*, *reduction='mean'*)

Gaussian negative log likelihood loss.

The target values are considered to be samples from a Gaussian distribution, where the expectation and variance are predicted by a neural network. For *labels* modeled on a Gaussian distribution, *logits* to record expectations, and the variance *var* (elements are all positive), the calculated loss is:

$$\text{loss} = \frac{1}{2}\left(\log\left(\max\left(\text{var},\ \text{eps}\right)\right) + \frac{\left(\text{x} - \text{target}\right)^2}{\max\left(\text{var},\ \text{eps}\right)}\right) + \text{const.}$$

where eps is used for stability of log. When $full = True$, a constant will be added to the loss. If the shape of var and $logits$ are not the same (due to a homoscedastic assumption), their shapes must allow correct broadcasting.

Parameters

- **x** (Tensor) –Tensor of shape $(N, *)$ or $(*)$ where $*$ means any number of additional dimensions.
- **target** (Tensor) –Tensor of shape $(N, *)$ or $(*)$, same shape as the x, or same shape as the x but with one dimension equal to 1 (to allow broadcasting).
- **var** (Tensor) –Tensor of shape $(N, *)$ or $(*)$, same shape as x, or same shape as the x but with one dimension equal to 1, or same shape as the x but with one fewer dimension (to allow for broadcasting).
- **full** (*bool, optional*) –Include the constant term in the loss calculation. When $full = True$, the constant term will be $const = 0.5 * log(2\pi)$. Default: `False`.
- **eps** (*float, optional*) –Used to improve the stability of log function must be greater than 0. Default: `1e-6` .
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.

- `'mean'`: compute and return the mean of elements in the output.
- `'sum'`: the output elements will be summed.

Returns

Tensor or Tensor scalar, the computed loss depending on $reduction$.

Raises

- **TypeError** – If *x*, *target* or *var* is not a Tensor.
- **TypeError** – If *full* is not a bool.
- **TypeError** – If *eps* is not a float.
- **ValueError** – If *eps* is not a float within (0, inf).
- **ValueError** – If *reduction* is not one of `"none"` , `"mean"` , `"sum"` .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> import mindspore.common.dtype as mstype
>>> arr1 = np.arange(8).reshape((4, 2))
>>> arr2 = np.array([2, 3, 1, 4, 6, 4, 4, 9]).reshape((4, 2))
>>> x = Tensor(arr1, mstype.float32)
>>> var = Tensor(np.ones((4, 1)), mstype.float32)
>>> target = Tensor(arr2, mstype.float32)
>>> output = ops.gaussian_nll_loss(x, target, var)
>>> print(output)
1.4374993
```

mindspore.ops.hinge_embedding_loss

`mindspore.ops.`**`hinge_embedding_loss`**(*inputs*, *targets*, *margin=1.0*, *reduction='mean'*)

Measures Hinge Embedding Loss given an input Tensor *intputs* and a labels Tensor *targets* (containing 1 or -1).

The loss function for n-th sample in the mini-batch is

$$l_n = \begin{cases} x_n, & \text{if } y_n = 1, \\ \max\{0, \Delta - x_n\}, & \text{if } y_n = -1, \end{cases}$$

and the total loss functions is

$$\ell(x, y) = \begin{cases} \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

where $L = \{l_1, \ldots, l_N\}^\top$.

Parameters

- **inputs** (Tensor) –Predicted values, represented as *x* in the formula.
- **targets** (Tensor) –Label values, represented as *y* in the formula. Has the same shape as *inputs*, contains -1 or 1.
- **margin** (*float, int*) –Threshold defined by Hinge Embedding Loss *margin*. Represented as Δ in the formula. Default: `1.0`.
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'mean'`.
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Returns

Tensor or Tensor scalar, the computed loss depending on *reduction*.

Raises

- **TypeError** –If *inputs* is not a Tensor.
- **TypeError** –If *targets* is not a Tensor.
- **TypeError** –If *margin* is not a float or int.
- **ValueError** –If *targets* does not have the same shape as *inputs* or they could not broadcast to each other.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import numpy as np
>>> import mindspore.common.dtype as mstype
>>> from mindspore import ops
>>> from mindspore import Tensor
>>> arr1 = np.array([0.9, -1.2, 2, 0.8, 3.9, 2, 1, 0, -1]).reshape((3, 3))
>>> arr2 = np.array([1, 1, -1, 1, -1, 1, -1, 1, 1]).reshape((3, 3))
>>> logits = Tensor(arr1, mstype.float32)
>>> labels = Tensor(arr2, mstype.float32)
>>> loss = ops.hinge_embedding_loss(logits, labels, margin=1.0, reduction='mean')
>>> print(loss)
0.16666666
```

mindspore.ops.huber_loss

mindspore.ops.**huber_loss**(*input*, *target*, *reduction='mean'*, *delta=1.0*)

Calculates the error between the predicted value and the target value, which has the best of both the loss of *mindspore.ops.l1_loss()* and the loss of *mindspore.ops.mse_loss()*.

Assuming that the x and y are 1-D Tensor, length N, the *reduction* parameter is set to `'none'` then calculate the loss of x and y without dimensionality reduction. The formula is as follows:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top$$

with

$$l_n = \begin{cases} 0.5 * (x_n - y_n)^2, & \text{if } |x_n - y_n| < delta; \\ delta * (|x_n - y_n| - 0.5 * delta), & \text{otherwise.} \end{cases}$$

where N is the batch size.

If *reduction* is "mean" or "sum", then:

$$\ell(x, y) = \begin{cases} \text{mean}(L), & \text{if reduction = "mean";} \\ \text{sum}(L), & \text{if reduction = "sum".} \end{cases}$$

Parameters

- **input** (Tensor) –Predicted value, Tensor of any dimension.
- **target** (Tensor) –Target value, has same dtype and shape as the *input* in common cases. However, when the shape of *target* is different from the shape of *input*, and they should be broadcasted to each other.
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'mean'`.
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **delta** (*Union[int, float]*) –The threshold to change between two type of loss. The value must be greater than zero. Default: `1.0`.

Returns

Tensor or Scalar, if *reduction* is `'none'`, return a Tensor with same shape and dtype as *input*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** –If *input* or *target* is not a Tensor.
- **TypeError** –If dtype of *delta* is neither float nor int.
- **ValueError** –If *delta* is less than or equal to 0.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.
- **ValueError** –If *input* and *target* have different shapes and cannot be broadcasted to each other.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> x = Tensor([1, 2, 10, 2], mindspore.float32)
>>> target = Tensor([1, 5, 1, 20], mindspore.float32)
>>> output = ops.huber_loss(x, target, reduction="mean", delta=2)
>>> print(output)
13.5
```

mindspore.ops.kl_div

mindspore.ops.**kl_div**(*logits*, *labels*, *reduction='mean'*)

Computes the Kullback-Leibler divergence between the logits and the labels.

For input tensors x and $target$ with the same shape, the updating formulas of KLDivLoss algorithm are as follows,

$$L(x, target) = target \cdot (\log target - x)$$

Then,

$$\ell(x, target) = \begin{cases} L(x, target), & \text{if reduction = 'none';} \\ \text{mean}(L(x, target)), & \text{if reduction = 'mean';} \\ \text{sum}(L(x, target))/x.\text{shape}[0], & \text{if reduction = 'batchmean';} \\ \text{sum}(L(x, target)), & \text{if reduction = 'sum'.} \end{cases}$$

where x represents *logits*. $target$ represents *labels*. $\ell(x, target)$ represents *output*.

Note:

- Currently it does not support float64 input on *Ascend*.
- The output aligns with the mathematical definition of Kullback-Leibler divergence only when *reduction* is set to `'batchmean'`.

Parameters

- **logits** (Tensor) −The input Tensor. The data type must be float16, float32 or float64.
- **labels** (Tensor) −The label Tensor which has the same shape and data type as *logits*.
- **reduction** (*str*) −Specifies the reduction to be applied to the output. Its value must be one of `'none'`, `'mean'`, `'batchmean'` or `'sum'`. Default: `'mean'`.
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.
  - `'batchmean'`: the summed output elements divided by batch size.

Returns

Tensor or Scalar, if *reduction* is `'none'`, then output is a tensor and has the same shape as *logits*. Otherwise, it is a scalar.

Raises

- **TypeError** –If *reduction* is not a str.
- **TypeError** –If neither *logits* nor *labels* is a Tensor.
- **TypeError** –If dtype of *logits* or *labels* is not the supported type.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> logits = Tensor(np.array([0.2, 0.7, 0.1]), mindspore.float32)
>>> labels = Tensor(np.array([0., 1., 0.]), mindspore.float32)
>>> output = mindspore.ops.kl_div(logits, labels, 'mean')
>>> print(output)
-0.23333333
```

mindspore.ops.l1_loss

`mindspore.ops.`**`l1_loss`**(*input*, *target*, *reduction='mean'*)

Calculate the mean absolute error between the *input* value and the *target* value.

Assuming that the x and y (predicted and target value) are 1-D Tensor, length N, *reduction* is set to `'none'`, then calculate the loss of x and y without dimensionality reduction.

The formula is as follows:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad \text{with } l_n = |x_n - y_n|,$$

where N is the batch size.

If *reduction* is set to `'mean'` or `'sum'` , then:

$$\ell(x, y) = \begin{cases} \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Parameters

- **input** (Tensor) –Predicted value, Tensor of any dimension.
- **target** (Tensor) –Target value, usually has the same shape as the *input*. If *input* and *target* have different shape, make sure they can broadcast to each other.
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Returns

Tensor or Scalar, if *reduction* is `'none'`, return a Tensor with same shape and dtype as *input*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If *target* is not a Tensor.
- **ValueError** – If *reduction* is not one of `'none'`, `'mean'` or `'sum'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor([[1, 2, 3], [4, 5, 6]], mstype.float32)
>>> target = Tensor([[6, 5, 4], [3, 2, 1]], mstype.float32)
>>> output = ops.l1_loss(x, target, reduction="mean")
>>> print(output)
3.0
```

mindspore.ops.margin_ranking_loss

`mindspore.ops.`**`margin_ranking_loss`**(*input1*, *input2*, *target*, *margin=0.0*, *reduction='mean'*)

MarginRankingLoss creates a criterion that measures the loss.

Given two tensors $input1$, $input2$ and a Tensor label $target$ with values 1 or -1, the operation is as follows:

$$\text{loss}(input1, input2, target) = \max(0, -target * (input1 - input2) + \text{margin})$$

Parameters

- **input1** (`Tensor`) – Tensor of shape $(N, *)$ where $*$ means, any number of additional dimensions.
- **input2** (`Tensor`) – Tensor of shape $(N, *)$, same shape and dtype as *input1*.
- **target** (`Tensor`) – Contains value 1 or -1. Suppose the shape of *input1* is $(x_1, x_2, x_3, ..., x_R)$, then the shape of *target* must be $(x_1, x_2, x_3, ..., x_R)$.
- **margin** (*`float, optional`*) – Specify the adjustment factor of the operation. Default: `0.0` .
- **reduction** (*`str, optional`*) – Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Returns

Tensor or Scalar. if *reduction* is `'none'`, its shape is the same as *input1*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** – If *margin* is not a float.
- **TypeError** – If *input1*, *input2* or *target* is not a Tensor.
- **TypeError** – If the types of *input1* and *input2* are inconsistent.

- **TypeError** –If the types of *input1* and *target* are inconsistent.
- **ValueError** –If the shape of *input1* and *input2* are inconsistent.
- **ValueError** –If the shape of *input1* and *target* are inconsistent.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, ops
>>> import numpy as np
>>> input1 = Tensor(np.array([0.3864, -2.4093, -1.4076]), ms.float32)
>>> input2 = Tensor(np.array([-0.6012, -1.6681, 1.2928]), ms.float32)
>>> target = ops.Sign()(Tensor(np.array([-2, -2, 3]), ms.float32))
>>> output = ops.margin_ranking_loss(input1, input2, target)
>>> print(output)
1.2293333
```

mindspore.ops.mse_loss

`mindspore.ops.`**`mse_loss`**(*input*, *target*, *reduction='mean'*)

Calculates the mean squared error between the predicted value and the label value.

For detailed information, please refer to *mindspore.nn.MSELoss*.

Parameters

- **input** (Tensor) –Tensor of any dimension.
- **target** (Tensor) –The input label. Tensor of any dimension, same shape as the *input* in common cases. However, it supports that the shape of *input* is different from the shape of *target* and they should be broadcasted to each other.
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'mean'`.
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Returns

Tensor, loss of type float, the shape is zero if *reduction* is `'mean'` or `'sum'`, while the shape of output is the broadcasted shape if *reduction* is `'none'`.

Raises

- **ValueError** –If *reduction* is not one of `'none'`, `'mean'` or `'sum'`.
- **ValueError** –If *input* and *target* have different shapes and cannot be broadcasted.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([[1, 1, 1], [1, 2, 2]]), mindspore.float32)
>>> output = ops.mse_loss(logits, labels, reduction='none')
>>> print(output)
[[0. 1. 4.]
 [0. 0. 1.]]
```

mindspore.ops.multi_margin_loss

mindspore.ops.**multi_margin_loss**(*input*, *target*, *p=1*, *margin=1*, *weight=None*, *reduction='mean'*)

Hinge loss for optimizing a multi-class classification.

Optimizes a multi-class classification hinge loss (margin-based loss) between input and output.

For each mini-batch sample, the loss in terms of the 1D input x and scalar output y is:

$$\text{loss}(x, y) = \frac{\sum_i \max(0, \text{margin} - x[y] + x[i])^p}{\text{x.size}(0)}$$

where $i \in \{0, , x.size(0) - 1\}$ and $i \neq y$.

Parameters

- **input** (Tensor) –Input , with shape (N, C). Data type only support float32, float16 or float64. It is x in the above formula.
- **target** (Tensor) –Ground truth labels, with shape $(N,)$. Data type only support int64. The value of target should be non-negative, less than C. It is y in the above formula.
- **p** (*int, optional*) –The norm degree for pairwise distance. Should be 1 or 2. Default: `1` .
- **margin** (*int, optional*) –A parameter to change pairwise distance. Default: `1` .
- **weight** (Tensor, *optional*) –The rescaling weight to each class with shape $(C,)$. Data type only support float16, float32 or float64. Default: `None` .
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Returns

- **outputs** - Tensor. If *reduction* is `'none'`, returns a Tensor with the same shape as *target*. Otherwise, it is a scalar.

Raises

- **TypeError** –If dtype of *p* or *target* is not int.
- **TypeError** –If dtype of *margin* is not int.
- **TypeError** –If dtype of *reduction* is not str.
- **TypeError** –If dtype of *input* is not float16, float or float64.

- **TypeError** –If dtype of *weight* and *input* is not the same.
- **ValueError** –If *p* is not 1 or 2.
- **ValueError** –If *reduction* is not one of {'none','sum','mean'}.
- **ValueError** –If shape[0] of *input* is not equal to shape[0] of *target*.
- **ValueError** –If shape[1] of *input* is not equal to shape[0] of *weight*.
- **ValueError** –If rank of *weight* is not 1 or rank of *target* is not 1 or *input* is not 2.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> inputs = Tensor(np.ones(shape=[3, 3]), mindspore.float32)
>>> target = Tensor(np.array([1, 2, 1]), mindspore.int64)
>>> weight = Tensor(np.array([1, 1, 1]), mindspore.float32)
>>> output = ops.multi_margin_loss(inputs, target, weight=weight)
>>> print(output)
0.6666667
```

mindspore.ops.multilabel_margin_loss

`mindspore.ops.`**`multilabel_margin_loss`**(*input*, *target*, *reduction='mean'*)

Hinge loss for optimizing a multi-label classification.

Creates a criterion that optimizes a multi-label multi-classification hinge loss (margin-based loss) between input x (a 2D mini-batch *Tensor*) and output y (which is a 2D *Tensor* of target class indices). For each sample in the mini-batch:

$$\text{loss}(x, y) = \sum_{ij} \frac{\max(0, 1 - (x[y[j]] - x[i]))}{\text{x.size}(0)}$$

where $x \in \{0, \cdots, \text{x.size}(0) - 1\}$, $y \in \{0, \cdots, \text{y.size}(0) - 1\}$, $0 \leq y[j] \leq \text{x.size}(0) - 1$, and $i \neq y[j]$ for all i and j. y and x must have the same size. The criterion only considers a contiguous block of non-negative targets that starts at the front. This allows for different samples to have variable amounts of target classes.

Parameters

- **input** (`Tensor`) –Predict data, x in the formula above. Tensor of shape (C) or (N, C), where N is the batch size and C is the number of classes. Data type must be float16 or float32.
- **target** (`Tensor`) –Ground truth data, y in the formula above, with the same shape as *input*, data type must be int32 and label targets padded by -1.
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Returns

- **outputs** (Union[Tensor, Scalar]) - The loss of MultilabelMarginLoss. If *reduction* is `"none"`, its shape is (N). Otherwise, a scalar value will be returned.

Raises

- **TypeError** –If *input* or *target* is not a Tensor.
- **TypeError** –If dtype of *input* is neither float16 nor float32.
- **TypeError** –If dtype of *target* is not int32.
- **ValueError** –If length of shape of *input* is neither 1 nor 2.
- **ValueError** –If shape of *input* is not the same as *target*.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> inputs = Tensor(np.array([[0.1, 0.2, 0.4, 0.8], [0.2, 0.3, 0.5, 0.7]]), mindspore.
↪float32)
>>> target = Tensor(np.array([[1, 2, 0, 3], [2, 3, -1, 1]]), mindspore.int32)
>>> output = ops.multilabel_margin_loss(inputs, target)
>>> print(output)
0.325
```

mindspore.ops.multilabel_soft_margin_loss

mindspore.ops.**multilabel_soft_margin_loss**(*input*, *target*, *weight=None*, *reduction='mean'*)

Calculates the MultiLabelSoftMarginLoss. The multi-label soft margin loss is a commonly used loss function in multi-label classification tasks where an input sample can belong to multiple classes. Given an input $input$ and binary labels $output$ of size (N, C), where N denotes the number of samples and C denotes the number of classes.

$$loss\left(input, output\right) = -\frac{1}{N}\frac{1}{C}\sum_{i=1}^{N}\sum_{j=1}^{C}\left(output_{ij}\log\frac{1}{1+e^{-input_{ij}}} + \left(1-output_{ij}\right)\log\frac{e^{-input_{ij}}}{1+e^{-input_{ij}}}\right)$$

where $input_{ij}$ represents the predicted score of sample i for class j. $output_{ij}$ represents the binary label of sample i for class j, where sample i belongs to class j if $output_{ij} = 1$, and sample i does not belong to class j if $output_{ij} = 0$. For a multi-label classification task, each sample may have multiple labels with a value of 1 in the binary label $output$. *weight* will multiply to the loss of each class if given.

Parameters

- **input** (Tensor) –A tensor of shape (N, C) , where N is batch size and C is number of classes.
- **target** (Tensor) –The label target Tensor which has the same shape as *input*.
- **weight** (*Union[Tensor, int, float], optional*) –The manual rescaling weight given to each class. Default: `None`.

- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Returns

Tensor, the data type is the same as input, if the *reduction* is `'none'`, its shape is (N) , otherwise it is zero.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor, ops
>>> input = Tensor([[0.3, 0.6, 0.6], [0.9, 0.4, 0.2]])
>>> target = Tensor([[0.0, 0.0, 1.0], [0.0, 0.0, 1.0]])
>>> loss = ops.multilabel_soft_margin_loss(input, target, reduction='mean')
>>> print(loss.asnumpy())
0.84693956
```

mindspore.ops.nll_loss

`mindspore.ops.`**`nll_loss`**(*inputs*, *target*, *weight=None*, *ignore_index=- 100*, *reduction='mean'*, *label_smoothing=0.0*)

Gets the negative log likelihood loss between inputs and target.

The nll loss with reduction=none can be described as:

$$\ell(x,t) = L = \{l_1,\dots,l_N\}^\top, \quad l_n = -w_{t_n} x_{n,t_n}, \quad w_c = \text{weight}\,[c] \cdot \mathbb{1}\{c \neq \text{ignore\_index}\},$$

where x is the inputs, t is the target, w is the weight, N is the batch size, c belonging to $[0, C-1]$ is class index, where C is the number of classes.

If *reduction* is not `'None'` (default `'mean'`), then

$$\ell(x,t) = \begin{cases} \sum_{n=1}^{N} \frac{1}{\sum_{n=1}^{N} w_{tn}} l_n, & \text{if reduction} = \text{'mean'}, \\ \sum_{n=1}^{N} l_n, & \text{if reduction} = \text{'sum'} \end{cases}$$

Parameters

- **inputs** (`Tensor`) –(N, C) where C = *number of classes* or (N, C, H, W) in case of 2D Loss, or $(N, C, d_1, d_2, ..., d_K)$. *inputs* is expected to be log-probabilities, data type must be float16 or float32.
- **target** (`Tensor`) –(N) or $(N, d_1, d_2, ..., d_K)$ for high-dimensional loss, data type must be int32.
- **weight** (`Tensor`) –A rescaling weight applied to the loss of each batch element. If not None, the shape is $(C,)$. The data type must be float16 or float32. Default: `None` .
- **ignore_index** (*int*) –Specifies a target value that is ignored and does not contribute to the input gradient. Default: `-100` .
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .

  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **label_smoothing** (*float*) –Label smoothing values, a regularization tool used to prevent the model from overfitting when calculating Loss. The value range is [0.0, 1.0]. Default value: `0.0`.

Returns

Tensor, the computed loss value.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> inputs = mindspore.Tensor(np.random.randn(3, 5), mindspore.float32)
>>> target = mindspore.Tensor(np.array([1, 0, 4]), mindspore.int32)
>>> output = ops.nll_loss(inputs, target)
```

mindspore.ops.smooth_l1_loss

`mindspore.ops.`**smooth_l1_loss**(*input*, *target*, *beta=1.0*, *reduction='none'*)

Computes smooth L1 loss, a robust L1 loss.

SmoothL1Loss is a Loss similar to MSELoss but less sensitive to outliers as described in the Fast R-CNN by Ross Girshick.

Given two input x, y of length N, the unreduced SmoothL1Loss can be described as follows:

$$L_i = \begin{cases} \frac{0.5(x_i - y_i)^2}{\text{beta}}, & \text{if } |x_i - y_i| < \text{beta} \\ |x_i - y_i| - 0.5 * \text{beta}, & \text{otherwise.} \end{cases}$$

If *reduction* is not *none*, then:

$$L = \begin{cases} \text{mean}(L_i), & \text{if reduction = 'mean';} \\ \text{sum}(L_i), & \text{if reduction = 'sum'.} \end{cases}$$

Here beta controls the point where the loss function changes from quadratic to linear. beta > 0, its default value is `1.0`. N is the batch size.

> **Warning:** This API has poor performance on CPU and it is recommended to run it on the Ascend/GPU.

Parameters

- **input** (`Tensor`) –Tensor of shape $(N, *)$ where $*$ means, any number of additional dimensions.Supported dtypes:
  - Ascend: float16, float32, bfloat16.
  - CPU/GPU: float16, float32, float64.
- **target** (`Tensor`) –Ground truth data, tensor of shape $(N, *)$.

  - CPU/Ascend: has the same shape as the *input*, *target* and *input* comply with the implicit type conversion rules to make the data types consistent.
  - GPU: has the same shape and dtype as the *input*.
- **beta** (*number, optional*) – A parameter used to control the point where the function will change between L1 to L2 loss. Default: `1.0`.
  - Ascend: The value should be equal to or greater than zero.
  - CPU/GPU: The value should be greater than zero.
- **reduction** (*str, optional*) – Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'none'`.
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Returns

Tensor, if *reduction* is `'none'`, then output is a tensor with the same shape as *input*. Otherwise, the shape of output tensor is ().

Raises

- **TypeError** – If input *input*, *target* is not Tensor.
- **RuntimeError** – If dtype of *input* or *target* is not one of float16, float32, float64, bfloat16.
- **ValueError** – If shape of *input* is not the same as *target*.
- **ValueError** – If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.
- **TypeError** – If *beta* is not a float, int or bool.
- **RuntimeError** – If *beta* is less than or equal to 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([1, 2, 2]), mindspore.float32)
>>> output = ops.smooth_l1_loss(logits, labels)
>>> print(output)
[0.  0.  0.5]
```

mindspore.ops.soft_margin_loss

mindspore.ops.**soft_margin_loss**(*input*, *target*, *reduction='mean'*)

Calculate the soft margin loss of input and target.

Creates a criterion that optimizes a two-class classification logistic loss between input tensor x and target tensor y (containing 1 or -1).

$$\text{loss}(x, y) = \sum_i \frac{\log(1 + \exp(-y[i] * x[i]))}{\text{x.nelement()}}$$

where $x.nelement()$ is the number of elements of x.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) −Predict data. Data type must be float16, float32, bfloat16 (Atlas training series products are not supported).
- **target** (Tensor) −Ground truth data, with the same shape as *input*. In GE mode, the data type should be the same as *input*.
- **reduction** (*str, optional*) −Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Returns

Tensor or Scalar. If *reduction* is `'none'`, its shape is the same as *input*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** −If *input* or *target* is not a Tensor.
- **TypeError** −If dtype of *input* or *target* is not float16, float32, bfloat16 (Atlas training series products are not supported).
- **ValueError** −If shape of *input* is not the same as that of *target*.
- **ValueError** −If *reduction* is not one of `'none'`, `'mean'` or `'sum'`.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> logits = Tensor(np.array([[0.3, 0.7], [0.5, 0.5]]), mindspore.float32)
>>> labels = Tensor(np.array([[-1, 1], [1, -1]]), mindspore.float32)
>>> output = ops.soft_margin_loss(logits, labels)
>>> print(output)
0.6764238
```

mindspore.ops.triplet_margin_loss

mindspore.ops.**triplet_margin_loss**(*anchor*, *positive*, *negative*, *margin=1.0*, *p=2*, *eps=1e-06*, *swap=False*, *reduction='mean'*)

TripletMarginLoss operation. See *mindspore.nn.TripletMarginLoss* for details.

Parameters

- **anchor** (Tensor) – A sample randomly selected from the training set. Data type must be BasicType.
- **positive** (Tensor) – A sample belonging to the same category as *anchor*, with the same type and shape as *anchor*.
- **negative** (Tensor) – A sample belonging to the different class from *anchor*, with the same type and shape as *anchor*.
- **margin** (*float, optional*) – Make a margin between the positive pair and the negative pair. The shape of margin must be 0. Default: 1.0 .
- **p** (*int, optional*) – The degree of norm for pairwise distance. Default: 2 .
- **eps** (*float, optional*) – Add small value to avoid division by zero. Default: 1e-06.
- **swap** (*bool, optional*) – The distance swap change the negative distance to the distance between positive sample and negative sample. Default: False .
- **reduction** (*str, optional*) – Apply specific reduction method to the output: 'none' , 'mean' , 'sum' . Default: 'mean' .
  - 'none': no reduction will be applied.
  - 'mean': compute and return the mean of elements in the output.
  - 'sum': the output elements will be summed.

Returns

Tensor. If *reduction* is "none", its shape is (N). Otherwise, a scalar value will be returned.

Raises

- **TypeError** – If *anchor* or *positive* or *negative* is not a Tensor.
- **TypeError** – If dtype of *anchor*, *positive* and *negative* is not the same.
- **TypeError** – If *margin* is not a float.
- **TypeError** – If *p* is not an int.
- **TypeError** – If *eps* is not a float.
- **TypeError** – If *swap* is not a bool.
- **ValueError** – If dimensions of input *anchor*, *positive* and *negative* are less than or equal to 1 at the same time.

- **ValueError** – If the dimension of input *anchor* or *positive* or *negative* is bigger than or equal to 8.
- **ValueError** – If shape of *anchor*, *positive* and *negative* cannot broadcast.
- **ValueError** – If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`GPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> anchor = Tensor(np.array([[0.3, 0.7], [0.5, 0.5]]), mindspore.float32)
>>> positive = Tensor(np.array([[0.4, 0.6], [0.4, 0.6]]), mindspore.float32)
>>> negative = Tensor(np.array([[0.2, 0.9], [0.3, 0.7]]), mindspore.float32)
>>> output = ops.triplet_margin_loss(anchor, positive, negative)
>>> print(output)
0.8881968
```

2.3.3 Activation Functions

API Name	Description	Supported Platforms
mindspore.ops.celu	celu activation function, computes celu (Continuously differentiable exponential linear units) of input tensors element-wise.	Ascend GPU CPU
mindspore.ops.elu	Exponential Linear Unit activation function.	Ascend GPU CPU
mindspore.ops.fast_gelu	Fast Gaussian Error Linear Units activation function.	Ascend GPU CPU
mindspore.ops.gelu	Gaussian Error Linear Units activation function.	Ascend GPU CPU
mindspore.ops.glu	Computes GLU (Gated Linear Unit activation function) of input tensors.	Ascend GPU CPU
mindspore.ops.gumbel_softmax	Returns the samples from the Gumbel-Softmax distribution and optionally discretizes.	Ascend GPU CPU
mindspore.ops.hardshrink	Hard Shrink activation function.	Ascend GPU CPU
mindspore.ops.hardsigmoid	Hard Sigmoid activation function.	Ascend GPU CPU
mindspore.ops.hardswish	Hard Swish activation function.	Ascend GPU CPU
mindspore.ops.hardtanh	Applies the hardtanh activation function element-wise.	Ascend GPU CPU
mindspore.ops.leaky_relu	leaky_relu activation function.	Ascend GPU CPU
mindspore.ops.log_softmax	Applies the Log Softmax function to the input tensor on the specified axis.	Ascend GPU CPU
mindspore.ops.logsigmoid	Applies LogSigmoid activation element-wise.	Ascend GPU CPU
mindspore.ops.mish	Computes MISH(A Self Regularized Non-Monotonic Neural Activation Function) of input tensors element-wise.	Ascend GPU CPU
mindspore.ops.prelu	Parametric Rectified Linear Unit activation function.	Ascend GPU CPU

continues on next page

Table 13 – continued from previous page

mindspore.ops.relu	Computes ReLU (Rectified Linear Unit activation function) of input tensors element-wise.	Ascend GPU CPU
mindspore.ops.relu6	Computes ReLU (Rectified Linear Unit) upper bounded by 6 of input tensors element-wise.	Ascend GPU CPU
mindspore.ops.rrelu	Randomized Leaky ReLU activation function.	Ascend GPU CPU
mindspore.ops.selu	Activation function SeLU (Scaled exponential Linear Unit).	Ascend GPU CPU
mindspore.ops.sigmoid	Computes Sigmoid of input element-wise.	Ascend GPU CPU
mindspore.ops.silu	Computes Sigmoid Linear Unit of input element-wise, also known as Swish function.	Ascend GPU CPU
mindspore.ops.softmax	Applies the Softmax operation to the input tensor on the specified axis.	Ascend GPU CPU
mindspore.ops.softmin	Applies the Softmin operation to the input tensor on the specified axis.	Ascend GPU CPU
mindspore.ops.softshrink	Soft Shrink activation function.	Ascend GPU CPU
mindspore.ops.softsign	SoftSign activation function.	Ascend GPU CPU
mindspore.ops.swiglu	Computes SwiGLU (Swish-Gated Linear Unit activation function) of input tensor.	Ascend
mindspore.ops.tanh	Computes hyperbolic tangent of input element-wise.	Ascend GPU CPU
mindspore.ops.threshold	Returns each element of *input* after thresholding by *thr* as a Tensor.	Ascend GPU CPU

mindspore.ops.celu

mindspore.ops.**celu**(*x*, *alpha=1.0*)

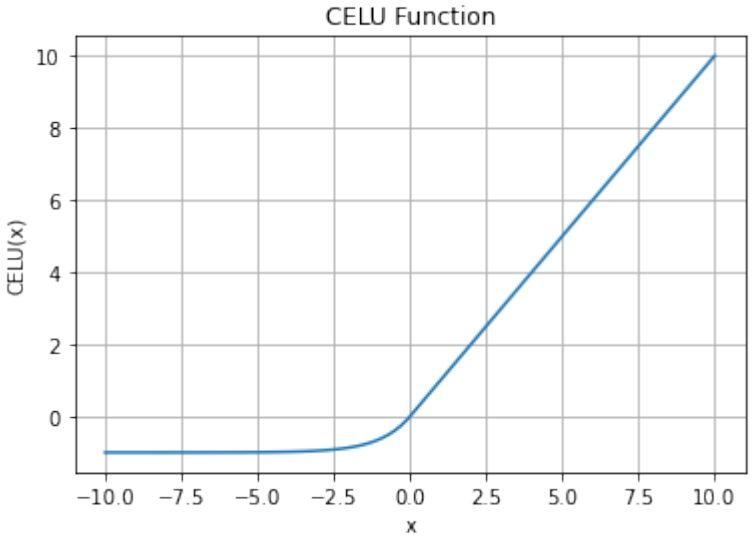
celu activation function, computes celu (Continuously differentiable exponential linear units) of input tensors element-wise. The formula is defined as follows:

$$\text{CeLU}(x) = \max(0, x) + \min(0, \alpha * (\exp(x/\alpha) - 1))$$

For more details, please refer to celu.

Warning: This is an experimental API that is subject to change or deletion.

CELU Activation Function Graph:



Parameters

- **x** (Tensor) −The input of celu with data type of float16 or float32.
- **alpha** (*float, optional*) −The α value for the Celu formulation. Default: 1.0

Returns

Tensor, has the same data type and shape as the input.

Raises

- **TypeError** −If *alpha* is not a float.
- **TypeError** −If *x* is not a Tensor.
- **TypeError** −If dtype of *x* is neither float16 nor float32.
- **ValueError** −If *alpha* has the value of 0.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([-2.0, -1.0, 1.0, 2.0]), mindspore.float32)
>>> output = ops.celu(x, alpha=1.0)
>>> print(output)
[-0.86466473 -0.63212055  1.          2.        ]
```

mindspore.ops.elu

mindspore.ops.**elu**(*input_x*, *alpha=1.0*)

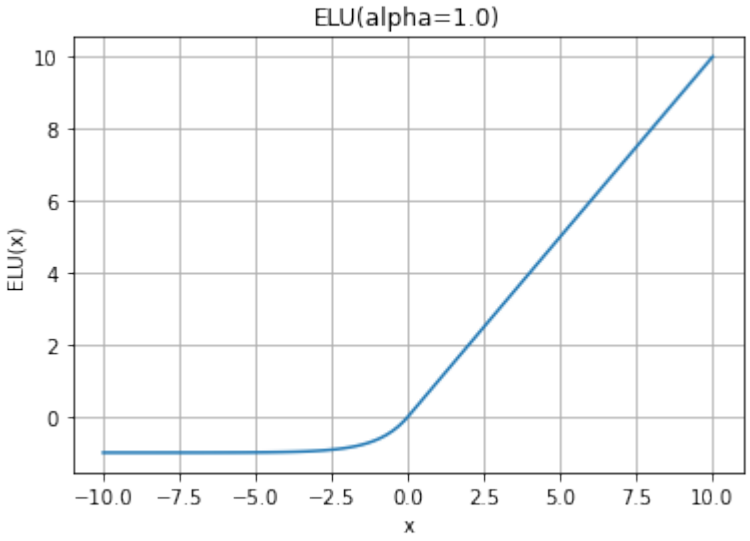
Exponential Linear Unit activation function.

Applies the exponential linear unit function element-wise. The activation function is defined as:

$$\text{ELU}(x) = \begin{cases} \alpha(e^x - 1) & \text{if } x \leq 0 \\ x & \text{if } x > 0 \end{cases}$$

Where x is the element of input Tensor *input_x*, α is param *alpha*, it determines the smoothness of ELU.

ELU function graph:



Parameters

- **input_x** (Tensor) −The input of ELU is a Tensor of any dimension with data type of float16 or float32.
- **alpha** (*float, optional*) −The alpha value of ELU, the data type is float. Only support `1.0` currently. Default: `1.0`.

Returns

Tensor, has the same shape and data type as *input_x*.

Raises

- **TypeError** −If *alpha* is not a float.
- **TypeError** −If dtype of *input_x* is neither float16 nor float32.
- **ValueError** −If *alpha* is not equal to 1.0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> output = ops.elu(x)
>>> print(output)
[[-0.63212055  4.         -0.99966455]
 [ 2.         -0.99326205  9.        ]]
```

mindspore.ops.fast_gelu

mindspore.ops.**fast_gelu**(*x*)

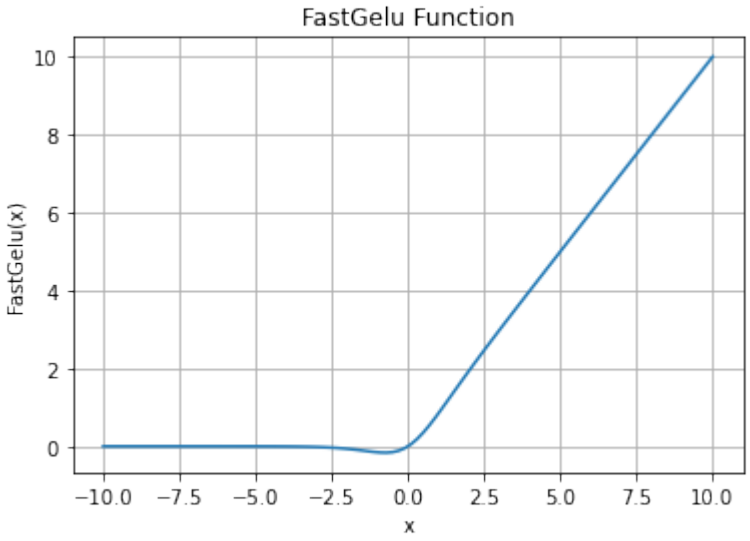
Fast Gaussian Error Linear Units activation function.

FastGeLU is defined as follows:

$$\text{output} = \frac{x}{1 + \exp(-1.702 * |x|)} * \exp(0.851 * (x - |x|)),$$

where x is the element of the input.

FastGelu function graph:



Parameters

x (Tensor) – Input to compute the FastGeLU with data type of float16 or float32.

Returns

Tensor, with the same type and shape as x.

Raises

TypeError – If dtype of x is neither float16 nor float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> output = ops.fast_gelu(x)
>>> print(output)
[[-1.5418735e-01  3.9921875e+00 -9.7473649e-06]
 [ 1.9375000e+00 -1.0052517e-03  8.9824219e+00]]
```

mindspore.ops.gelu

mindspore.ops.**gelu**(*input*, *approximate='none'*)

Gaussian Error Linear Units activation function.

GeLU is described in the paper Gaussian Error Linear Units (GELUs). And also please refer to BERT: Pre-training of Deep Bidirectional Transformers for Language Understanding.

When *approximate* argument is *none*, GeLU is defined as follows:

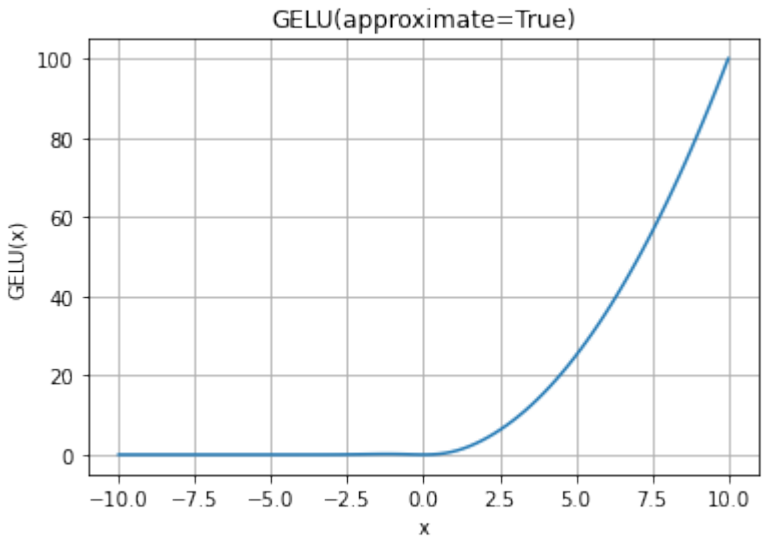
$$GELU(x_i) = x_i * P(X < x_i),$$

where P is the cumulative distribution function of the standard Gaussian distribution, x_i is the input element.

When *approximate* argument is *tanh*, GeLU is estimated with:

$$GELU(x_i) = 0.5 * x_i * (1 + \tanh(\sqrt{(2/\pi)} * (x_i + 0.044715 * x_i^3)))$$

GELU Activation Function Graph:



Parameters

- **input** (Tensor) –The input of the activation function GeLU, the data type is float16, float32 or float64.
- **approximate** (*str, optional*) –the gelu approximation algorithm to use. Acceptable vaslues are 'none' and 'tanh'. Default: 'none'.

Returns

Tensor, with the same type and shape as *input*.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If dtype of *input* is not bfloat16, float16, float32 or float64.
- **ValueError** – If *approximate* value is neither *none* nor *tanh*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> x = Tensor([1.0, 2.0, 3.0], mindspore.float32)
>>> result = ops.gelu(x, approximate='none')
>>> print(result)
[0.8413447 1.9544997 2.9959505]
```

mindspore.ops.glu

`mindspore.ops.`**`glu`**(*x*, *axis=- 1*)

Computes GLU (Gated Linear Unit activation function) of input tensors.

$$GLU(a, b) = a \otimes \sigma(b)$$

where a is the first half of the input matrices and b is the second half.

Here σ is the sigmoid function, and $\otimes$ is the Hadamard product. See Language Modeling with Gated Convluational Networks.

Parameters

- **x** (`Tensor`) – Tensor to be split. Its dtype is Number, and shape is $(*_1, N, *_2)$ where * means, any number of additional dimensions.
- **axis** (*int, optional*) – the axis to split the input. It must be int. Default: `-1` , the last axis of x.

Returns

Tensor, the same dtype as the x, with the shape $(*_1, M, *_2)$ where $M = N/2$.

Raises

- **TypeError** – If dtype of x is not Number.
- **TypeError** – If x is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor, ops
>>> input = Tensor([[0.1,0.2,0.3,0.4],[0.5,0.6,0.7,0.8]])
>>> output = ops.glu(input)
>>> print(output)
[[0.05744425 0.11973753]
 [0.33409387 0.41398472]]
```

mindspore.ops.gumbel_softmax

mindspore.ops.**gumbel_softmax**(*logits*, *tau=1.0*, *hard=False*, *dim=- 1*)

Returns the samples from the Gumbel-Softmax distribution and optionally discretizes. If *hard* is `True`, the returned samples will be one-hot, otherwise it will be probability distributions that sum to 1 across *dim*.

Parameters

- **logits** (Tensor) –Unnormalized log probabilities. The data type must be float16 or float32.
- **tau** (*float, optional*) –The scalar temperature, which is a positive number. Default: `1.0` .
- **hard** (*bool, optional*) –If `True`, the returned samples will be discretized as one-hot vectors, but will be differentiated as if it is the soft sample in autograd. Default: `False` .
- **dim** (*int, optional*) –Dim for softmax to compute. Default: `-1` .

Returns

Tensor, has the same dtype and shape as *logits*.

Raises

- **TypeError** –If *logits* is not a Tensor.
- **TypeError** –If dtype of *logits* is not one of: float16, float32.
- **TypeError** –If *tau* is not a float.
- **TypeError** –If *hard* is not a bool.
- **TypeError** –If *dim* is not an int.
- **ValueError** –If If *tau* is not positive.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]), mindspore.float32)
>>> output = ops.gumbel_softmax(input_x, 1.0, True, -1)
>>> print(output.shape)
(2, 3)
```

mindspore.ops.hardshrink

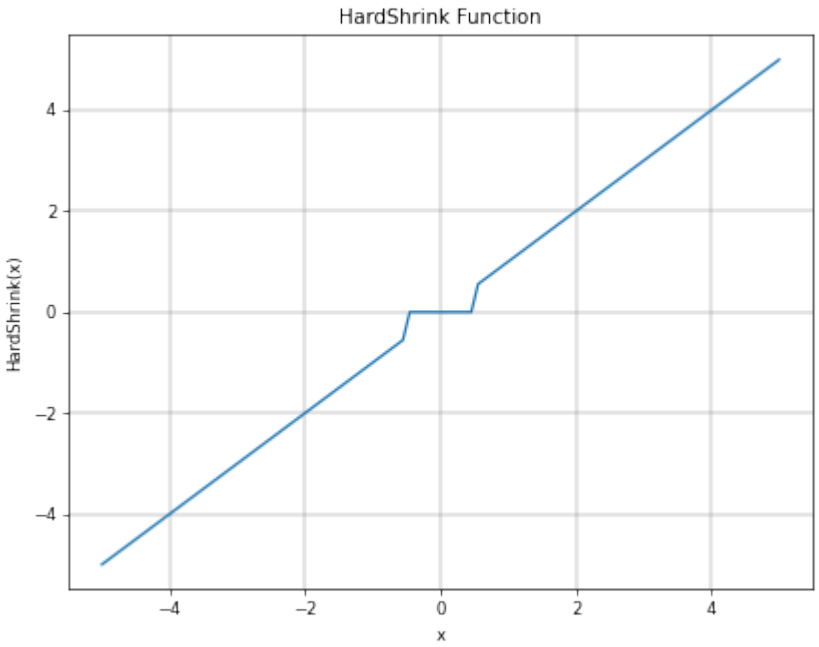
mindspore.ops.**hardshrink**(*input*, *lambd=0.5*)

Hard Shrink activation function. Calculates the output according to the input elements.

The formula is defined as follows:

$$\text{HardShrink}(x) = \begin{cases} x, & \text{if } x > \lambda \\ x, & \text{if } x < -\lambda \\ 0, & \text{otherwise} \end{cases}$$

HardShrink Activation Function Graph:



Parameters

- **input** (Tensor) – The input of Hard Shrink. Supported dtypes:
  - Ascend: float16, float32, bfloat16.
  - CPU/GPU: float16, float32.
- **lambd** (*number, optional*) – The threshold λ defined by the Hard Shrink formula. Default: 0.5 .

Returns

Tensor, has the same data type and shape as the input *input*.

Raises

- **TypeError** – If *lambd* is not a float, int or bool.
- **TypeError** – If *input* is not a tensor.
- **TypeError** – If dtype of *input* is not float16, float32 or bfloat16.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.array([[0.5, 1, 2.0], [0.0533, 0.0776, -2.1233]]), mindspore.float32)
>>> output = ops.hardshrink(input)
>>> print(output)
[[ 0.      1.      2.    ]
 [ 0.      0.     -2.1233]]
```

mindspore.ops.hardsigmoid

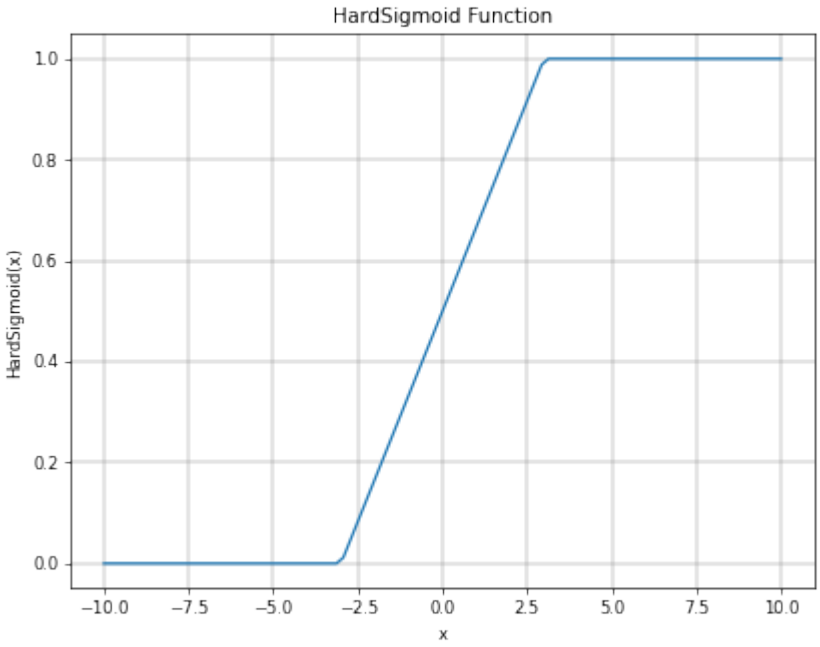
mindspore.ops.**hardsigmoid**(*input*)

Hard Sigmoid activation function. Calculates the output according to the input elements.

Hard Sigmoid is defined as:

$$\text{HardSigmoid}(input) = \begin{cases} 0, & \text{if } input \leq -3, \\ 1, & \text{if } input \geq +3, \\ input/6 + 1/2, & \text{otherwise} \end{cases}$$

HardSigmoid Activation Function Graph:



Parameters

input (Tensor) – The input Tensor.

Returns

Tensor, with the same type and shape as the *input*.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If *input* is neither int nor float.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> output = ops.hardsigmoid(input)
>>> print(output)
[0.3333 0.1666 0.5    0.8335 0.6665]
```

mindspore.ops.hardswish

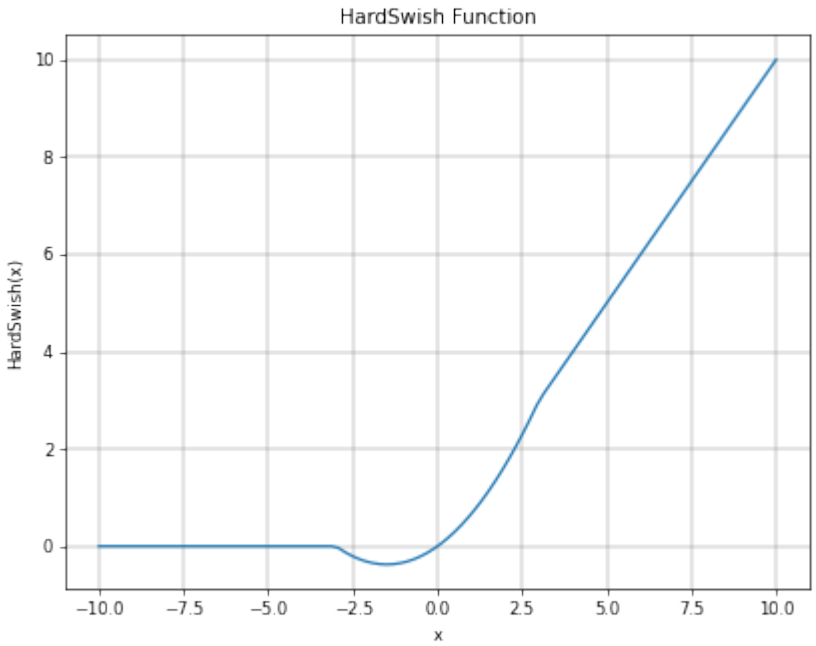
`mindspore.ops.`**`hardswish`**(*input*)

Hard Swish activation function. The input is a Tensor with any valid shape.

Hard swish is defined as:

$$\text{HardSwish}(input) = \begin{cases} 0, & \text{if } input \leq -3, \\ input, & \text{if } input \geq +3, \\ input * (input + 3)/6, & \text{otherwise} \end{cases}$$

HardSwish Activation Function Graph:



Parameters

input (Tensor) –The input Tensor.

Returns

Tensor, with the same type and shape as the *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *input* is neither int nor float.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> output = ops.hardswish(input)
>>> print(output)
[-0.3333  -0.3333  0  1.667  0.6665]
```

mindspore.ops.hardtanh

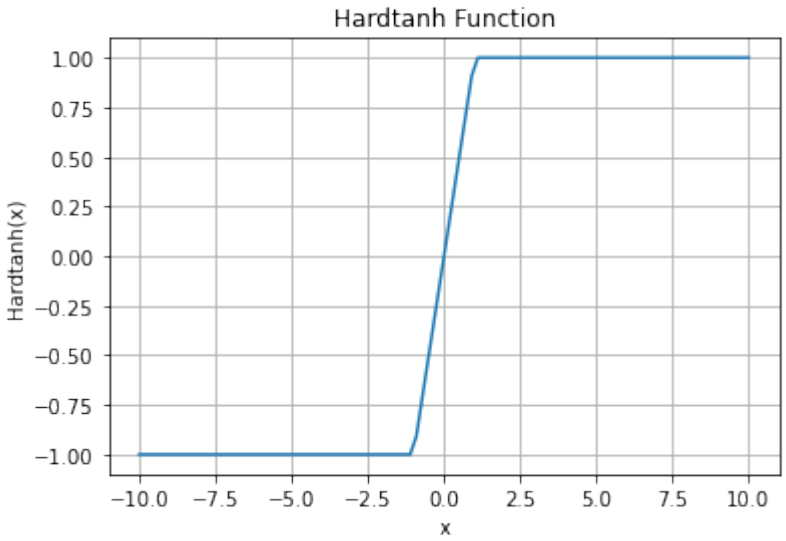
mindspore.ops.**hardtanh**(*input*, *min_val=- 1.0*, *max_val=1.0*)

Applies the hardtanh activation function element-wise. The activation function is defined as:

$$\text{hardtanh}(input) = \begin{cases} max\_val, & \text{if } input > max\_val \\ min\_val, & \text{if } input < min\_val \\ input, & \text{otherwise.} \end{cases}$$

Linear region range $[min\_val, max\_val]$ can be adjusted using *min_val* and *max_val*.

Hardtanh Activation Function Graph:



Parameters

- **input** (Tensor) – Input Tensor.
- **min_val** (*Union[int, float], optional*) – Minimum value of the linear region range. Default: `-1.0`.
- **max_val** (*Union[int, float], optional*) – Maximum value of the linear region range. Default: `1.0`.

Returns

Tensor, with the same dtype and shape as *input*.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If dtype of *min_val* is neither float nor int.
- **TypeError** – If dtype of *max_val* is neither float nor int.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> x = Tensor([-1, -2, 0, 2, 1], mindspore.float16)
>>> output = ops.hardtanh(x, min_val=-1.0, max_val=1.0)
>>> print(output)
[-1. -1.  0.  1.  1.]
```

mindspore.ops.leaky_relu

mindspore.ops.**leaky_relu**(*input*, *alpha=0.2*)

leaky_relu activation function. The element of *input* less than 0 times *alpha* .

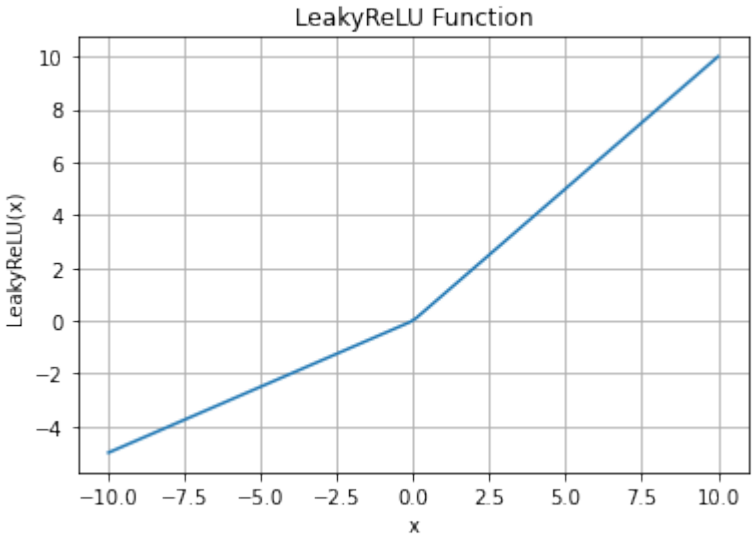
The activation function is defined as:

$$\text{leaky\_relu}(input) = \begin{cases} input, & \text{if } input \geq 0; \\ \alpha * input, & \text{otherwise.} \end{cases}$$

where α represents the *alpha* parameter.

For more details, see Rectifier Nonlinearities Improve Neural Network Acoustic Models.

LeakyReLU Activation Function Graph:



Parameters

- **input** (Tensor) – The input of leaky_relu is a Tensor of any dimension.
- **alpha** (*Union[int, float], optional*) – Slope of the activation function when the element of *input* is less than 0. Default: 0.2 .

Returns

Tensor, has the same type and shape as the *input*.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If *alpha* is not a float or an int.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> print(ops.leaky_relu(x, alpha=0.2))
[[-0.2  4.  -1.6]
 [ 2.  -1.   9. ]]
```

mindspore.ops.log_softmax

mindspore.ops.**log_softmax**(*logits*, *axis=- 1*)

Applies the Log Softmax function to the input tensor on the specified axis. Supposes a slice in the given axis, x for each element x_i, the Log Softmax function is shown as follows:

$$\text{output}(x_i) = \log\left(\frac{\exp(x_i)}{\sum_{j=0}^{N-1}\exp(x_j)}\right),$$

where N is the length of the Tensor.

Parameters

- **logits** (Tensor) –The input Tensor, which is the x in the formula above, it's shape is $(N, *)$, where $*$ means, any number of additional dimensions, with float16 or float32 data type.
- **axis** (*int*) –The axis to perform the Log softmax operation. Default: `-1` .

Returns

Tensor, with the same type and shape as the logits.

Raises

- **TypeError** –If *axis* is not an int.
- **TypeError** –If dtype of *logits* is neither float16 nor float32.
- **ValueError** –If *axis* is not in range [-len(logits.shape), len(logits.shape)).
- **ValueError** –If dimension of *logits* is less than 1.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> logits = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> output = ops.log_softmax(logits)
>>> print(output)
[-4.4519143 -3.4519143 -2.4519143 -1.4519144 -0.4519144]
```

mindspore.ops.logsigmoid

mindspore.ops.**logsigmoid**(*x*)

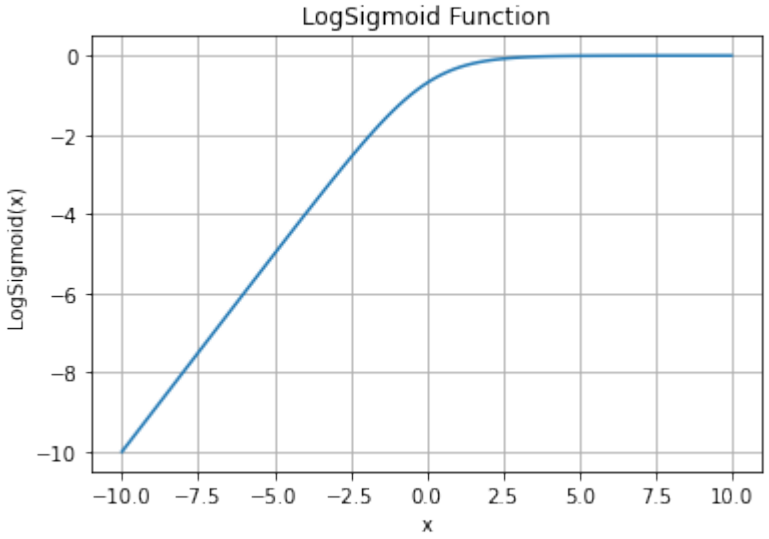
Applies LogSigmoid activation element-wise. The input is a Tensor with any valid shape.

Logsigmoid is defined as:

$$\text{logsigmoid}(x_i) = \log(\frac{1}{1 + \exp(-x_i)}),$$

where x_i is the element of the input.

LogSigmoid Activation Function Graph:



Parameters

x (Tensor) −The input of LogSigmoid with data type of float16 or float32. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.

Returns

Tensor, with the same type and shape as the *x*.

Raises

TypeError −If dtype of *x* is neither float16 nor float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([1.0, 2.0, 3.0]), mindspore.float32)
>>> output = ops.logsigmoid(x)
>>> print(output)
[-0.31326166 -0.12692806 -0.04858734]
```

mindspore.ops.mish

mindspore.ops.**mish**(*x*)

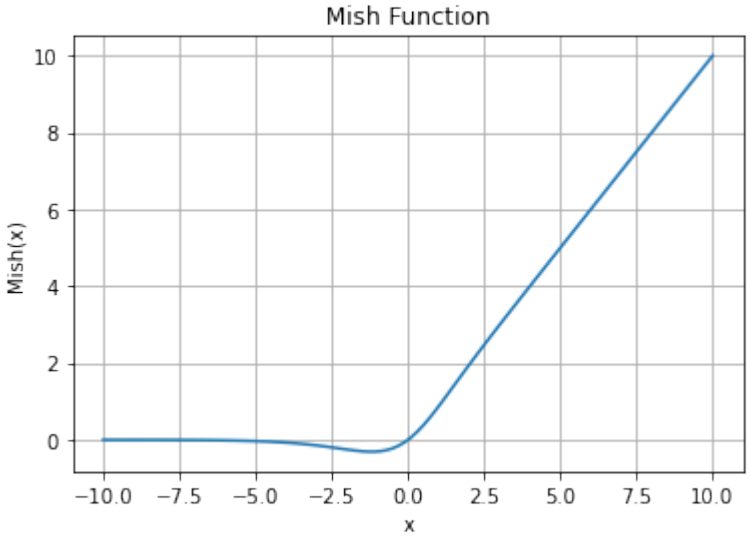
Computes MISH(A Self Regularized Non-Monotonic Neural Activation Function) of input tensors element-wise.

The function is shown as follows:

$$\text{output} = x * \tanh(\log(1 + \exp(x)))$$

See more details in A Self Regularized Non-Monotonic Neural Activation Function.

Mish Activation Function Graph:



Parameters

x (Tensor) −The input Tensor. Supported dtypes:

- GPU/CPU: float16, float32, float64.
- Ascend: float16, float32.

Returns

Tensor, with the same type and shape as the *x*.

Raises

TypeError −If dtype of *x* is not float16, float32 or float64.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> output = ops.mish(input_x)
>>> print(output)
[[-3.0340147e-01  3.9974129e+00 -2.68311895e-03]
 [ 1.9439590e+00  -3.3576239e-02 8.99999990e+00]]
>>> input_x = Tensor(2.1, mindspore.float32)
>>> output = ops.mish(input_x)
>>> print(output)
2.050599
```

mindspore.ops.prelu

mindspore.ops.**prelu**(*input*, *weight*)

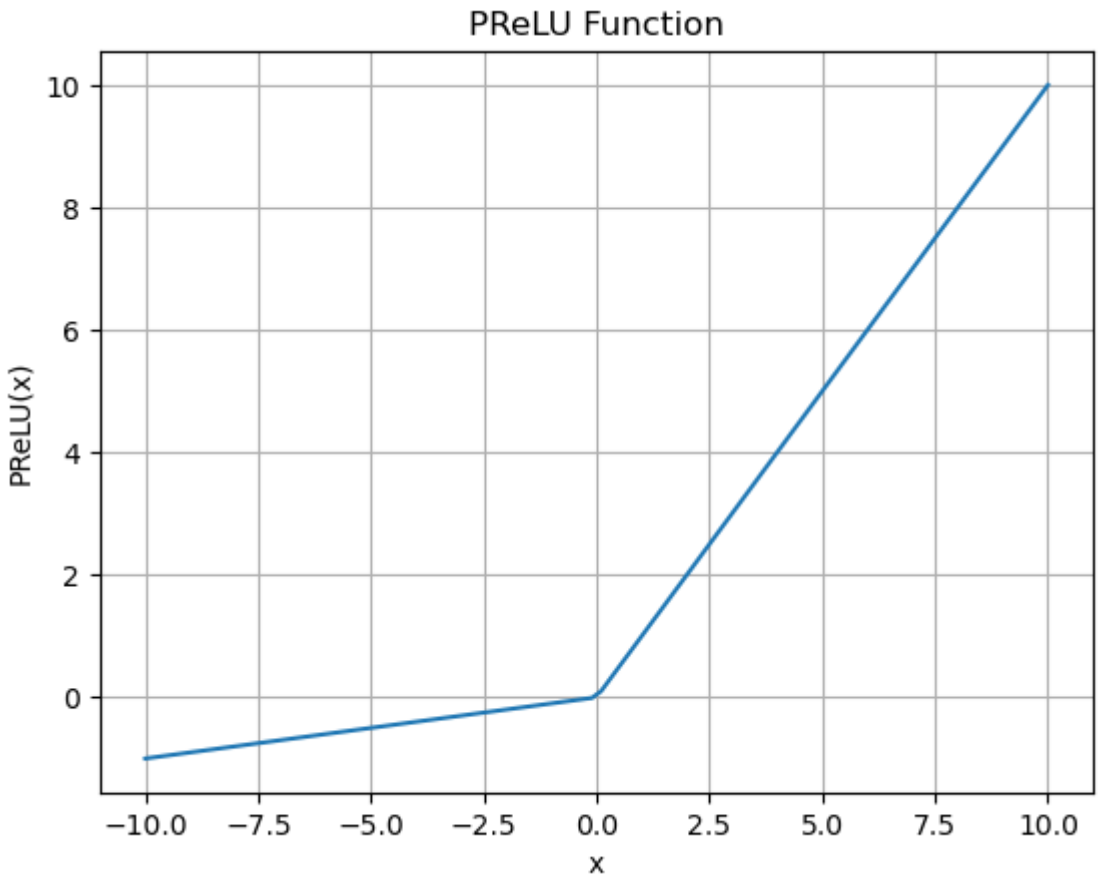
Parametric Rectified Linear Unit activation function.

PReLU is described in the paper Delving Deep into Rectifiers: Surpassing Human-Level Performance on ImageNet Classification. Defined as follows:

$$prelu(x_i) = \max(0, x_i) + \min(0, w * x_i),$$

where x_i is an element of a channel of the input, w is the weight of the channel.

PReLU Activation Function Graph:



Note: Channel dim is the 2nd dim of input. When input has dims < 2, then there is no channel dim and the number of channels = 1.

Parameters

- **input** (Tensor) −The input Tensor of the activation function.
- **weight** (Tensor) −Weight Tensor. The size of the weight should be 1 or the number of channels at Tensor *input*.

Returns

Tensor, with the same shape and dtype as *input*. For detailed information, please refer to *mindspore.mint.nn.PReLU*.

Raises

- **TypeError** −If the *input* or the *weight* is not a Tensor.
- **ValueError** −If the *weight* is not a 0-D or 1-D Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.arange(-6, 6).reshape((2, 3, 2)), mindspore.float32)
>>> weight = Tensor(np.array([0.1, 0.6, -0.3]), mindspore.float32)
>>> output = ops.prelu(x, weight)
>>> print(output)
[[[-0.60 -0.50]
  [-2.40 -1.80]
  [ 0.60  0.30]]
 [[ 0.00  1.00]
  [ 2.00  3.00]
  [ 4.0   5.00]]]
```

mindspore.ops.relu

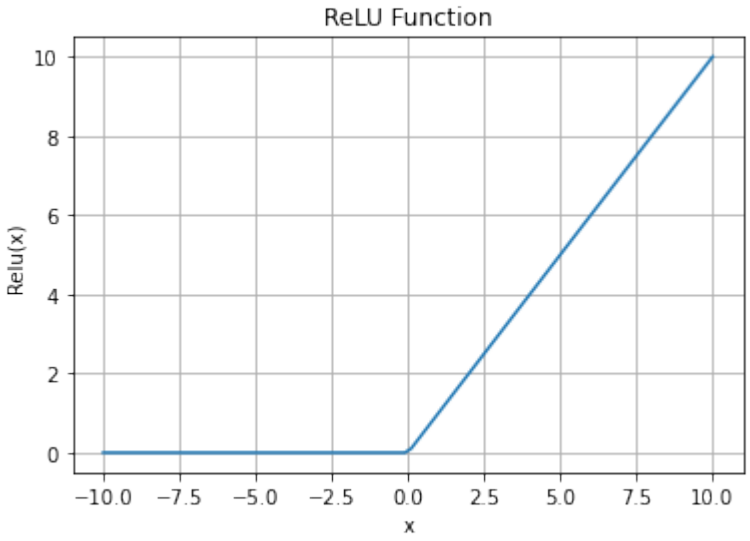
mindspore.ops.**relu**(*input*, *inplace=False*)

Computes ReLU (Rectified Linear Unit activation function) of input tensors element-wise.

It returns $\max(input,\ 0)$ element-wise. Specially, the neurons with the negative output will be suppressed and the active neurons will stay the same.

$$ReLU(input) = (input)^+ = \max(0, input)$$

ReLU Activation Function Graph:



Parameters

- **input** (Tensor) −The input Tensor.
- **inplace** (*bool, optional*) −Whether to use inplace mode, Defaults to False.

Returns

Tensor, with the same dtype and shape as the *input*.

Raises

- **TypeError** –If dtype of *input* is not Number type.
- **TypeError** –If *input* is not a Tensor.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> output = ops.relu(input)
>>> print(output)
[[0. 4. 0.]
 [2. 0. 9.]]
```

mindspore.ops.relu6

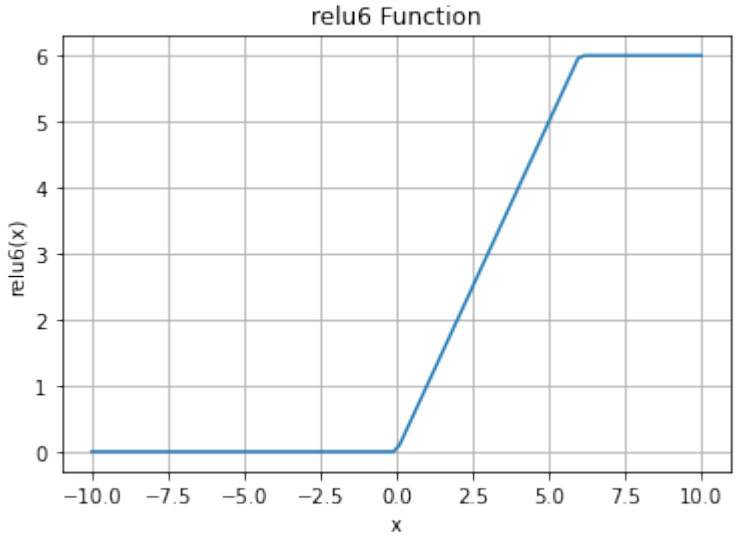
`mindspore.ops.`**`relu6`**`(x)`

Computes ReLU (Rectified Linear Unit) upper bounded by 6 of input tensors element-wise.

$$\text{ReLU6}(x) = \min(\max(0, x), 6)$$

It returns $\min(\max(0, x), 6)$ element-wise.

ReLU6 Activation Function Graph:



Parameters

x (`Tensor`) –Tensor of shape $(N, *)$, where $*$ means any number of additional dimensions. Data type must be float16, float32.

Returns

Tensor, with the same dtype and shape as the *x*.

Raises

- **TypeError** – If dtype of *x* is neither float16 nor float32.
- **TypeError** – If *x* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> result = ops.relu6(x)
>>> print(result)
[[0. 4. 0.]
 [2. 0. 6.]]
```

mindspore.ops.rrelu

`mindspore.ops.`**`rrelu`**(*input*, *lower=1.0 / 8*, *upper=1.0 / 3*)

Randomized Leaky ReLU activation function.

The activation function is defined as:

$$\text{rrelu}(input_{ji}) = \begin{cases} input_{ji}, & \text{if } input_{ji} \geq 0; \\ \alpha_{ji} * input_{ji}, & \text{otherwise.} \end{cases}$$

where $\alpha_{ji} \sim U(l, u), l \leq u$.

Applies the rrelu function elementally, as described in the paper: Empirical Evaluation of Rectified Activations in Convolution Network .

Parameters

- **input** (`Tensor`) – The input of rrelu is a Tensor of any dimension.
- **lower** (*`Union[int, float]`*) – Slope of the activation function at data of *input* is less than 0. Default: `1.0 / 8`.
- **upper** (*`Union[int, float]`*) – Slope of the activation function at data of *input* is less than 0. Default: `1.0 / 3`.

Returns

Tensor, after rrelu, has the same type and shape as the *input*.

Raises

- **TypeError** – If *lower* is not a float or an int.
- **TypeError** – If *upper* is not a float or an int.
- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If *input* is not a Tensor of mindspore.float16 or mindspore.float32.
- **ValueError** – If *lower* is greater than upper.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[-1.0, 4.0], [2.0, 0]]), mindspore.float32)
>>> output = ops.rrelu(x)
>>> print(output)
[[-0.31465699  4.        ]
 [ 2.          0.        ]]
```

mindspore.ops.selu

`mindspore.ops.`**`selu`**(*input_x*)

Activation function SeLU (Scaled exponential Linear Unit).

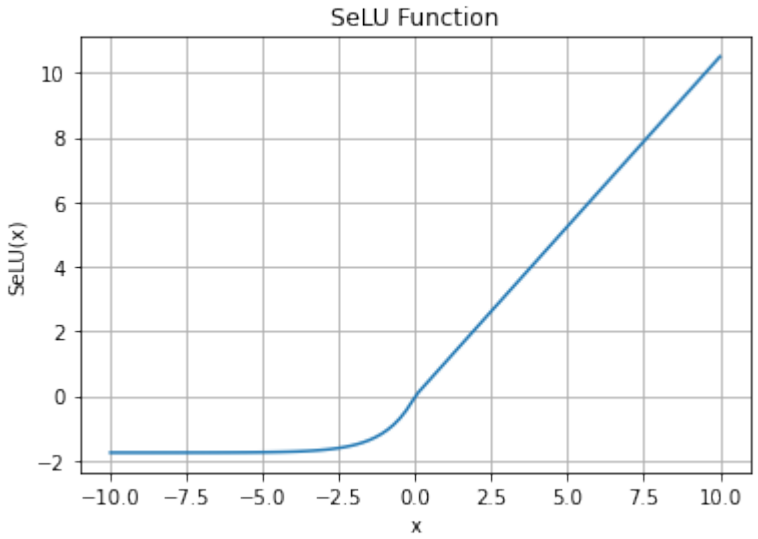
The activation function is defined as:

$$E_i = scale * \begin{cases} x_i, & \text{if } x_i \geq 0; \\ \text{alpha} * (\exp(x_i) - 1), & \text{otherwise.} \end{cases}$$

where $alpha$ and $scale$ are pre-defined constants($alpha = 1.67326324$ and $scale = 1.05070098$).

See more details in Self-Normalizing Neural Networks.

SeLU Activation Function Graph:



Parameters

`input_x` (`Tensor`) −Tensor of any dimension, the data type is int8, int32, float16, float32, or float64 (CPU, GPU only).

Returns

Tensor, with the same type and shape as the *input_x*.

Raises

TypeError – If dtype of *input_x* is not int8, int32, float16, float32, or float64.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> output = ops.selu(input_x)
>>> print(output)
[[-1.1113307 4.202804 -1.7575096]
[ 2.101402 -1.7462534 9.456309 ]]
```

mindspore.ops.sigmoid

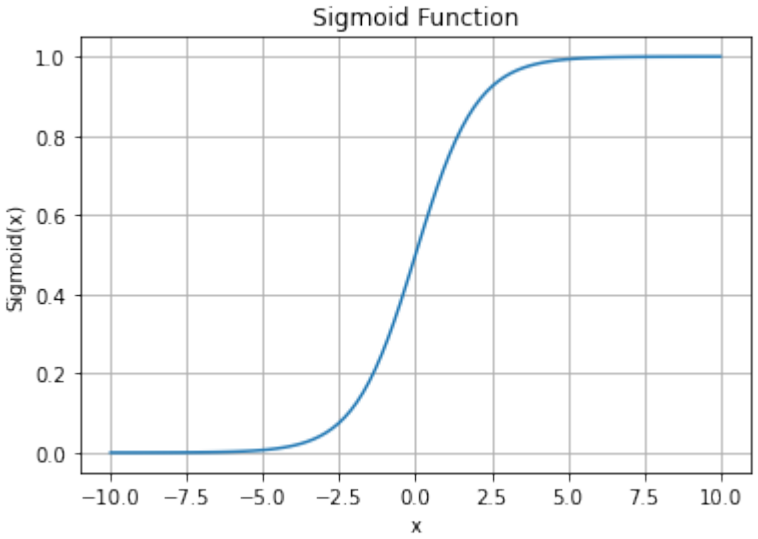
`mindspore.ops.`**`sigmoid`**(*input*)

Computes Sigmoid of input element-wise. The Sigmoid function is defined as:

$$\text{sigmoid}(x_i) = \frac{1}{1 + \exp(-x_i)}$$

where x_i is an element of x.

Sigmoid Function Graph:



Parameters

input (Tensor) – *input* is x in the preceding formula. Tensor of any dimension, the data type is float16, float32, float64, complex64 or complex128.

Returns

Tensor, with the same type and shape as the input.

Raises

- **TypeError** – If dtype of *input* is not float16, float32, float64, complex64 or complex128.
- **TypeError** – If *input* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> output = ops.sigmoid(input)
>>> print(output)
[0.7310586  0.880797   0.95257413 0.98201376 0.9933072 ]
```

mindspore.ops.silu

`mindspore.ops.`**`silu`**(*input*)

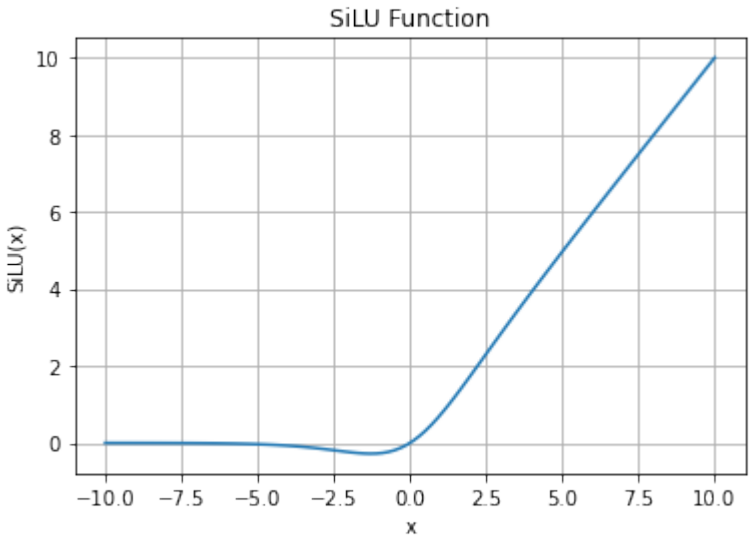
Computes Sigmoid Linear Unit of input element-wise, also known as Swish function. The SiLU function is defined as:

$$\text{SiLU}(x) = x * \sigma(x),$$

where x is an element of the input, $\sigma(x)$ is Sigmoid function.

$$\text{sigma}(x_i) = \frac{1}{1 + \exp(-x_i)},$$

SiLU Function Graph:



Parameters

input (Tensor) – *input* is x in the preceding formula. Input with the data type float16 or float32.

Returns

Tensor, with the same type and shape as the *input*.

Raises

TypeError – If dtype of *input* is neither float16 nor float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> import numpy as np
>>> input = Tensor(np.array([-1, 2, -3, 2, -1]), mindspore.float16)
>>> output = ops.silu(input)
>>> print(output)
[-0.269  1.762  -0.1423  1.762  -0.269]
```

mindspore.ops.softmax

mindspore.ops.**softmax**(*input*, *axis=- 1*, ***, *dtype=None*)

Applies the Softmax operation to the input tensor on the specified axis. Suppose a slice in the given axis *axis*, then for each element $input_i$, the Softmax function is shown as follows:

$$\text{output}(input_i) = \frac{\exp(input_i)}{\sum_{j=0}^{N-1}\exp(input_j)},$$

where N is the length of the tensor.

Parameters

- **input** (Tensor) – Tensor of shape $(N, *)$, where $*$ means, any number of additional dimensions, with float16 or float32 data type.
- **axis** (*int, optional*) – The axis to perform the Softmax operation. Default: `-1` .

Keyword Arguments

dtype (*mindspore.dtype*, optional) – When set, *input* will be converted to the specified type, *dtype*, before execution, and dtype of returned Tensor will also be *dtype*. Default: `None` .

Returns

Tensor, with the same type and shape as the *input*.

Raises

TypeError – If *axis* is not an int.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> output = ops.softmax(input)
>>> print(output)
[0.01165623 0.03168492 0.08612854 0.23412167 0.6364086 ]
```

mindspore.ops.softmin

mindspore.ops.**softmin**(*x*, *axis=- 1*, ***, *dtype=None*)

Applies the Softmin operation to the input tensor on the specified axis. Suppose a slice in the given axis x, then for each element x_i, the Softmin function is shown as follows:

$$\text{output}(x_i) = \frac{\exp(-x_i)}{\sum_{j=0}^{N-1}\exp(-x_j)},$$

where N is the length of the tensor.

Parameters

- **axis** (*Union[int, tuple[int]], optional*) – The axis to perform the Softmin operation. Default: `-1` .
- **x** (`Tensor`) – Tensor of shape $(N, *)$, where $*$ means, any number of additional dimensions, with float16 or float32 data type.

Keyword Arguments

dtype (*mindspore.dtype*, optional) – When set, x will be converted to the specified type, *dtype*, before execution, and dtype of returned Tensor will also be *dtype*. Default: `None` .

Returns

Tensor, with the same type and shape as x.

Raises

- **TypeError** – If *axis* is not an int or a tuple.
- **TypeError** – If dtype of x is neither float16 nor float32.
- **ValueError** – If *axis* is a tuple whose length is less than 1.
- **ValueError** – If *axis* is a tuple whose elements are not all in range [-len(logits.shape), len(logits.shape)).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> output = ops.softmin(x)
>>> print(output)
[0.2341  0.636  0.0862  0.01165  0.03168 ]
```

mindspore.ops.softshrink

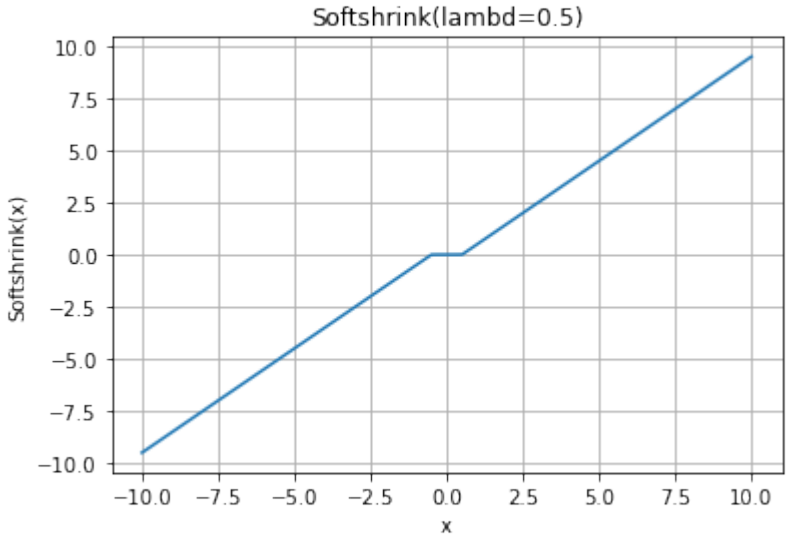
mindspore.ops.**softshrink**(*input*, *lambd=0.5*)

Soft Shrink activation function. Calculates the output according to the input elements.

The formula is defined as follows:

$$\text{SoftShrink}(x) = \begin{cases} x - \lambda, & \text{if } x > \lambda \\ x + \lambda, & \text{if } x < -\lambda \\ 0, & \text{otherwise} \end{cases}$$

SoftShrink Activation Function Graph:



Parameters

- **input** (Tensor) – The input of Soft Shrink. Supported dtypes:
  - Ascend: float16, float32, bfloat16.
  - CPU/GPU: float16, float32.
- **lambd** (*number, optional*) – The threshold λ defined by the Soft Shrink formula. It should be greater than or equal to 0, default: 0.5 .

Returns

Tensor, has the same data type and shape as the input *input*.

Raises

- **TypeError** – If *lambd* is not a float, int or bool.
- **TypeError** – If *input* is not a tensor.
- **TypeError** – If dtype of *input* is not float16, float32 or bfloat16.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> import numpy as np
>>> x = Tensor(np.array([[ 0.5297,  0.7871,  1.1754], [ 0.7836,  0.6218, -1.1542]]),␣
↪mindspore.float32)
>>> output = ops.softshrink(x)
>>> print(output)
[[ 0.02979  0.287    0.676  ]
[ 0.2837   0.1216  -0.6543 ]]
```

mindspore.ops.softsign

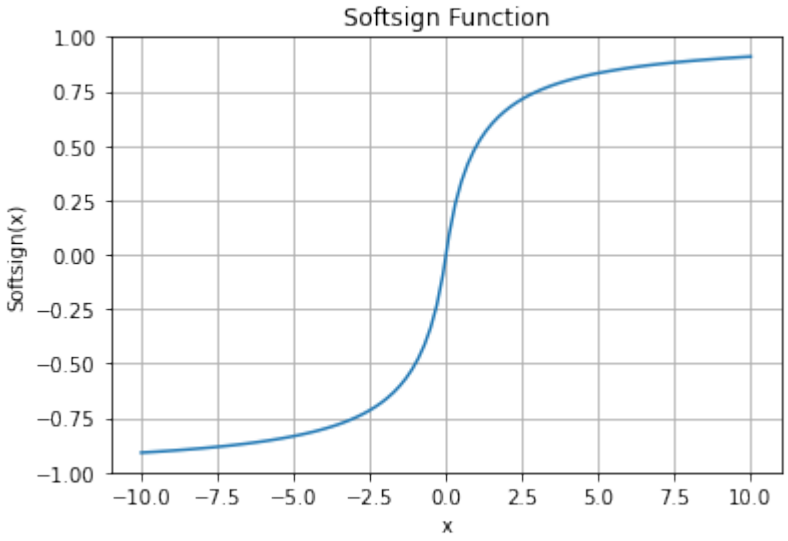
mindspore.ops.**softsign**(*x*)

SoftSign activation function.

The function is shown as follows:

$$\text{SoftSign}(x) = \frac{x}{1 + |x|}$$

Softsign Activation Function Graph:



Parameters

x (Tensor) – Tensor of shape $(N, *)$, where $*$ means, any number of additional dimensions, with float16 or float32 data type.

Returns

Tensor, with the same type and shape as the *x*.

Raises

- **TypeError** –If *x* is not a Tensor.
- **TypeError** –If dtype of *x* is neither float16 nor float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([0, -1, 2, 30, -30]), mindspore.float32)
>>> output = ops.softsign(x)
>>> print(output)
[ 0.        -0.5         0.6666667  0.9677419 -0.9677419]
```

mindspore.ops.swiglu

mindspore.ops.**swiglu**(*input*, *dim=- 1*)

Computes SwiGLU (Swish-Gated Linear Unit activation function) of input tensor. SwiGLU is a variant of the *mindspore.ops.GLU* activation function, it is defined as:

> **Warning:** This is an experimental API that is subject to change or deletion.

$$SwiGLU(a, b) = Swish(a) \otimes b$$

where a is the first half of the *input* matrices and b is the second half, Swish(a)=a σ (a), σ is the *mindspore.ops.sigmoid()* activation function and $\otimes$ is the Hadamard product.

Parameters

- **input** (Tensor) –Tensor to be split. It has shape $(*_1, N, *_2)$ where * means, any number of additional dimensions. N must be divisible by 2.
- **dim** (*int, optional*) –the axis to split the input. It must be int. Default: `-1` , the last axis of *input*.

Returns

Tensor, the same dtype as the *input*, with the shape $(*_1, M, *_2)$ where $M = N/2$.

Raises

- **TypeError** –If dtype of *input* is not float16, float32 or bfloat16.
- **TypeError** –If *input* is not a Tensor.
- **RuntimeError** –If the dimension specified by *dim* is not divisible by 2.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> input = Tensor([[-0.12, 0.123, 31.122], [2.1223, 4.1212121217, 0.3123]], dtype=mindspore.
↪float32)
>>> output = ops.swiglu(input, 0)
>>> print(output)
[[-0.11970687 0.2690224 9.7194 ]]
```

mindspore.ops.tanh

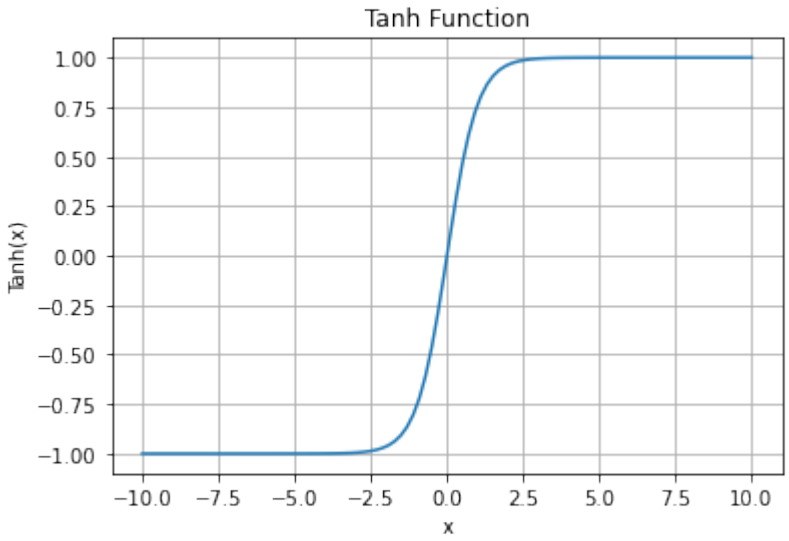
`mindspore.ops.`**`tanh`**(*input*)

Computes hyperbolic tangent of input element-wise. The Tanh function is defined as:

$$tanh(x_i) = \frac{\exp(x_i) - \exp(-x_i)}{\exp(x_i) + \exp(-x_i)} = \frac{\exp(2x_i) - 1}{\exp(2x_i) + 1},$$

where x_i is an element of the input Tensor.

Tanh Activation Function Graph:



Parameters

`input` (`Tensor`) – Input of Tanh.

Returns

Tensor, with the same type and shape as the *input*.

Raises

`TypeError` – If *input* is not a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> output = ops.tanh(input)
>>> print(output)
[0.7615941 0.9640276 0.9950547 0.9993293 0.9999092]
```

mindspore.ops.threshold

mindspore.ops.**threshold**(*input*, *thr*, *value*)

Returns each element of *input* after thresholding by *thr* as a Tensor.

The formula is defined as follows:

$$y = \begin{cases} input, & \text{if } input > \text{thr} \\ \text{value}, & \text{otherwise} \end{cases}$$

Parameters

- **input** (Tensor) –The input of threshold with data type of float16 or float32.
- **thr** (*Union[int, float]*) –The value of the threshold.
- **value** (*Union[int, float]*) –The value to replace with when element is less than threshold.

Returns

Tensor, the same shape and data type as the input.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *thr* is not a float or an int.
- **TypeError** –If *value* is not a float or an int.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> inputs = mindspore.Tensor([0.0, 2, 3], mindspore.float32)
>>> outputs = ops.threshold(inputs, 1, 100)
>>> print(outputs)
[100.   2.   3.]
```

2.3.4 Distance Functions

API Name	Description	Supported Platforms
mindspore.ops.cdist	Computes p-norm distance between each pair of row vectors of two input Tensors.	Ascend GPU CPU
mindspore.ops.dist	Computes batched the *p*-norm distance between each pair of the two collections of row vectors.	Ascend GPU CPU
mindspore.ops.pdist	Calculates the distance between every pair of row vectors in the input using the p-norm.	GPU CPU

mindspore.ops.cdist

mindspore.ops.**cdist**(*x1*, *x2*, *p=2.0*)

Computes p-norm distance between each pair of row vectors of two input Tensors.

Note:

- On Ascend, the supported dtypes are float16 and float32.
- On CPU, the supported dtypes are float16 and float32.
- On GPU, the supported dtypes are float32 and float64.

Parameters

- **x1** (Tensor) −Input tensor of shape (B, P, M). Letter B represents 0 or positive int number. When B is equal to 0, it means this dimension can be ignored, i.e. shape of the tensor is (P, M).
- **x2** (Tensor) −Input tensor of shape (B, R, M), has the same dtype as *x1*.
- **p** (*float, optional*) −P value for the p-norm distance to calculate between each vector pair, P >= 0. Default: 2.0.

Returns

Tensor, p-norm distance, has the same dtype as *x1*, its shape is (B, P, R).

Raises

- **TypeError** −If *x1* or *x2* is not Tensor.
- **TypeError** −If dtype of *x1* or *x2* is not listed in the "Note" above.
- **TypeError** −If *p* is not float32.
- **ValueError** −If *p* is negative.
- **ValueError** −If dimension of *x1* is not the same as *x2*.
- **ValueError** −If dimension of *x1* or *x2* is neither 2 nor 3.
- **ValueError** −If the batch dim of *x1* and *x2* can not broadcast.
- **ValueError** −If the number of columns of *x1* is not the same as that of *x2*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[[1.0, 1.0], [2.0, 2.0]]]).astype(np.float32))
>>> y = Tensor(np.array([[[3.0, 3.0], [3.0, 3.0]]]).astype(np.float32))
>>> output = ops.cdist(x, y, 2.0)
>>> print(output)
[[[2.8284273 2.8284273]
  [1.4142137 1.4142137]]]
```

mindspore.ops.dist

mindspore.ops.**dist**(*input*, *other*, *p=2*)

Computes batched the *p*-norm distance between each pair of the two collections of row vectors.

Note: Since only normalization for integer *p*-normal form is supported in MindSpore, a type error will be raised if *p* is not an integer.

Parameters

- **input** (Tensor) –The first input tensor. The dtype must be float16 or float32.
- **other** (Tensor) –The second input tensor. The dtype must be float16 or float32.
- **p** (*int, optional*) –The order of norm. *p* is greater than or equal to 0. Default: 2 .

Returns

Tensor, has the same dtype as *input*, which shape is (1).

Raises

- **TypeError** –If *input* or *other* is not a Tensor.
- **TypeError** –If dtype of *input* or *other* is neither float16 nor float32.
- **TypeError** –If *p* is not a non-negative integer.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import Tensor, ops
>>> input_x = Tensor([[[1.0, 1.0], [2.0, 2.0]]])
>>> input_y = Tensor([[[3.0, 3.0], [3.0, 3.0]]])
>>> out = ops.dist(input_x, input_y)
>>> print(out.asnumpy())
3.1622777
```

mindspore.ops.pdist

mindspore.ops.**pdist**(*input*, *p=2.0*)

Calculates the distance between every pair of row vectors in the input using the p-norm. If the input *input* is a 2D Tensor with shape (N, M), the *output* must be a 1D Tensor with shape $(N * (N-1)/2,)$.

$$y[n] = \sqrt[p]{| x_i - x_j |^p}$$

where x_i, x_j are two different row vectors in the input.

Parameters

- **input** (Tensor) –Input tensor. dtype: float16, float32 or float64.
- **p** (*float*) –The order of norm distance, p [0,). Default: 2.0 .

Returns

Tensor, has the same dtype as *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If dtype of *input* is not float16, float32 or float64.
- **TypeError** –If *p* is not a float.
- **ValueError** –If *p* is a negative float.
- **ValueError** –If dimension of *input* is less than 2.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[1.0, 1.0], [2.0, 2.0], [3.0, 3.0]]).astype(np.float32))
>>> y = ops.pdist(x, p=2.0)
>>> print(y)
[1.4142135 2.828427 1.4142135]
```

2.3.5 Sampling Functions

API Name	Description	Supported Platforms
mindspore.ops.choice_with_mask	Generates a random sample as index tensor with a mask tensor from a given tensor.	Ascend GPU CPU
mindspore.ops.random_categorical	Generates random samples from a given categorical distribution tensor.	Ascend GPU CPU
mindspore.ops.log_uniform_candidate_sampler	Generates random labels with a log-uniform distribution for sampled_candidates.	Ascend CPU
mindspore.ops.uniform_candidate_sampler	Uniform candidate sampler.	Ascend GPU CPU

mindspore.ops.choice_with_mask

mindspore.ops.**choice_with_mask**(*input_x*, *count=256*, *seed=None*)

Generates a random sample as index tensor with a mask tensor from a given tensor.

The *input_x* must be a tensor whose dimension is not less than 1. If its dimension is greater than or equal to 2, the first dimension specifies the number of samples. The returned index tensor denotes the index of the nonzero sample, the mask tensor denotes which elements in the index tensor are valid.

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **input_x** (*Tensor[bool]*) – The input tensor. The input tensor rank must be greater than or equal to 1 and less than or equal to 5.
- **count** (*int, optional*) – Number of items expected to get and the number must be greater than 0. Default: 256 .
- **seed** (*int, optional*) – Seed is used as entropy source for Random number engines generating pseudo-random numbers. Default: None .

Returns

Two tensors, the first one is the index tensor and the other one is the mask tensor.

- **index** (Tensor) - The output shape is 2-D.
- **mask** (Tensor) - The output shape is 1-D.

Raises

- **TypeError** – If *count* is not an int.
- **TypeError** – If *seed* is not an int.
- **TypeError** – If *input_x* is not a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.ones(shape=[240000, 4]).astype(np.bool_))
>>> output_y, output_mask = ops.choice_with_mask(input_x)
>>> result = output_y.shape
>>> print(result)
(256, 2)
>>> result = output_mask.shape
>>> print(result)
(256,)
```

mindspore.ops.random_categorical

mindspore.ops.**random_categorical**(*logits*, *num_sample*, *seed=0*, *dtype=mstype.int64*)

Generates random samples from a given categorical distribution tensor.

> **Warning:** The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **logits** (Tensor) –The input tensor. 2-D Tensor with shape $(batch\_size, num\_classes)$.
- **num_sample** (*int*) –Number of sample to be drawn. Only constant values is allowed.
- **seed** (*int*) –Random seed. Only constant values is allowed. Default: `0` .
- **dtype** (mindspore.dtype) –The type of output. Its value must be one of mindspore.int16, mindspore.int32 and mindspore.int64. Default: `mstype.int64` .

Returns

Tensor, The output Tensor with shape $(batch\_size, num\_samples)$.

Raises

- **TypeError** –If *dtype* is not one of the following: mindspore.int16, mindspore.int32, mindspore.int64.
- **TypeError** –If *logits* is not a Tensor.
- **TypeError** –If neither *num_sample* nor *seed* is an int.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import ops
>>> from mindspore import Tensor
>>> import mindspore.common.dtype as mstype
>>> import numpy as np
>>> logits = Tensor(np.random.random((10, 5)).astype(np.float32), mstype.float32)
>>> net = ops.random_categorical(logits, 8)
>>> result = net.shape
>>> print(result)
(10, 8)
```

mindspore.ops.log_uniform_candidate_sampler

mindspore.ops.**log_uniform_candidate_sampler**(*true_classes*, *num_true=1*, *num_sampled=5*, *unique=True*, *range_max=5*, *seed=0*)

Generates random labels with a log-uniform distribution for sampled_candidates.

Randomly samples a tensor of sampled classes from the range of integers [0, range_max).

> **Warning:** The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **true_classes** (Tensor) –The target classes. With data type of int64 and shape $(batch\_size, num\_true)$.
- **num_true** (*int, optional*) –The number of target classes per training example. Default: `1` .
- **num_sampled** (*int, optional*) –The number of classes to randomly sample. Default: `5` .
- **unique** (*bool, optional*) –Determines whether sample with rejection. If *unique* is `True` , all sampled classes in a batch are unique. Default: `True` .
- **range_max** (*int, optional*) –The number of possible classes. When *unique* is `True` , *range_max* must be greater than or equal to *num_sampled*. Default: `5` .
- **seed** (*int, optional*) –Random seed, must be non-negative. Default: `0` .

Returns

Tuple of 3 Tensors.

- **sampled_candidates** (Tensor) - A Tensor with shape $(num\_sampled,)$ and the same type as *true_classes*.
- **true_expected_count** (Tensor) - A Tensor with the same shape as *true_classes and* type float32.
- **sampled_expected_count** (Tensor) - A Tensor with the same shape as *sampled_candidates* and type float32.

Raises

- **TypeError** –If neither *num_true* nor *num_sampled* is an int.
- **TypeError** –If *unique* is not a bool.
- **TypeError** –If neither *range_max* nor *seed* is an int.
- **TypeError** –If *true_classes* is not a Tensor.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> output1, output2, output3 = ops.log_uniform_candidate_sampler(
... Tensor(np.array([[1, 7], [0, 4], [3, 3]])), 2, 5, True, 5)
>>> print(output1, output2, output3)
[3 2 0 4 1]
[[0.92312991 0.49336370]
 [0.99248987 0.65806371]
 [0.73553443 0.73553443]]
[0.73553443 0.82625800 0.99248987 0.65806371 0.92312991]
```

mindspore.ops.uniform_candidate_sampler

mindspore.ops.**uniform_candidate_sampler**(*true_classes*, *num_true*, *num_sampled*, *unique*, *range_max*, *seed=0*, *remove_accidental_hits=False*)

Uniform candidate sampler.

This function samples a set of classes(sampled_candidates) from [0, range_max-1] based on uniform distribution. If unique=True, candidates are drawn without replacement, else unique=False with replacement.

Warning:

- The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.
- The Ascend backend does not support dynamic shape scenarios currently.

Parameters

- **true_classes** (Tensor) −A Tensor. The target classes with a Tensor shape of $(batch\_size, num\_true)$. The value range of the elements must be $[0, range\_max)$.
- **num_true** (*int*) −The number of target classes in each training example.
- **num_sampled** (*int*) −The number of classes to randomly sample. The sampled_candidates will have a shape of num_sampled. If unique=True, num_sampled must be less than or equal to range_max.
- **unique** (*bool*) −Whether all sampled classes in a batch are unique.
- **range_max** (*int*) −The number of possible classes, must be positive.
- **seed** (*int*) −Used for random number generation, must be non-negative. If seed has a value of 0, the seed will be replaced with a randomly generated value. Default: `0` .
- **remove_accidental_hits** (*bool*) −Whether accidental hit is removed. Accidental hit is when one of the true classes matches one of the sample classes. Set `True` to remove which accidentally sampling the true class as sample class. Default: `False` .

Returns

- **sampled_candidates** (Tensor) - The sampled_candidates is independent of the true classes. shape: $(num\_sampled,)$.
- **true_expected_count** (Tensor) - The expected counts under the sampling distribution of each of true_classes. shape: $(batch\_size, num\_true)$.
- **sampled_expected_count** (Tensor) - The expected counts under the sampling distribution of each of sampled_candidates. shape: $(num\_sampled,)$.

Raises

- **TypeError** −If neither *num_true* nor *num_sampled* is an int.
- **TypeError** −If neither *unique* nor *remove_accidental_hits* is a bool.
- **TypeError** −If neither *range_max* nor *seed* is an int.
- **TypeError** −If *true_classes* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> data = Tensor(np.array([[1], [3], [4], [6], [3]], dtype=np.int64))
>>> output1, output2, output3 = ops.uniform_candidate_sampler(data, 1, 3, False, 4, 1)
>>> print(output1.shape)
(3,)
>>> print(output2.shape)
(5, 1)
>>> print(output3.shape)
(3,)
```

2.3.6 Image Functions

API Name	Description	Supported Platforms
mindspore.ops.affine_grid	Returns a 2D or 3D flow field (sampling grid) based on *theta*, a batch of affine matrices.	Ascend GPU CPU
mindspore.ops.bounding_box_decode	Decode the bounding box locations, calculate the offset, and convert the offset into a Bbox, which is used to mark the target in the subsequent images, etc.	Ascend GPU CPU
mindspore.ops.bounding_box_encode	Encode the bounding box locations, calculate the offset between the predicted bounding boxes and the real bounding boxes, and the offset will be used as a variable for the loss.	Ascend GPU CPU
mindspore.ops.col2im	Combines an array of sliding local blocks into a large containing tensor.	Ascend GPU CPU
mindspore.ops.check_valid	Checks whether the bounding box is in the image.	Ascend GPU CPU
mindspore.ops.crop_and_resize	Extracts crops from the input image Tensor and resizes them.	Ascend GPU CPU
mindspore.ops.grid_sample	Given an *input* and a flow-field *grid*, computes the *output* using *input* values and pixel locations from *grid*.	Ascend GPU CPU
mindspore.ops.interpolate	Samples the input Tensor to the given size or scale_factor by using one of the interpolate algorithms.	Ascend GPU CPU
mindspore.ops.iou	Calculates intersection over union for boxes.	Ascend GPU CPU
mindspore.ops.pad	Pads the input tensor according to the padding.	Ascend GPU CPU
mindspore.ops.padding	Extends the last dimension of the input tensor from 1 to pad_dim_size, by filling with 0.	Ascend GPU CPU
mindspore.ops.pixel_shuffle	Applies the PixelShuffle operation over input *input* which implements sub-pixel convolutions with stride $1/r$.	Ascend GPU CPU
mindspore.ops.pixel_unshuffle	Applies the PixelUnshuffle operation over input *input* which is the inverse of PixelShuffle.	Ascend GPU CPU
mindspore.ops.rotary_position_embedding	Implements the Rotary Position Embedding algorithm.	Ascend
mindspore.ops.rotated_iou	Calculate the overlap area between rotated rectangles.	Ascend

continues on next page

Table 16 – continued from previous page

mindspore.ops.upsample	Alias for *mindspore.ops.interpolate()*.	Ascend GPU CPU

mindspore.ops.affine_grid

mindspore.ops.**affine_grid**(*theta*, *size*, *align_corners=False*)

Returns a 2D or 3D flow field (sampling grid) based on *theta*, a batch of affine matrices.

Parameters

- **theta** (Tensor) –The input tensor of flow field whose dtype is float16, float32. Input batch of affine matrices with shape $(N, 2, 3)$ for 2D grid or $(N, 3, 4)$ for 3D grid.
- **size** (*tuple[int]*) –The target output image size. The value of target output with format (N, C, H, W) for 2D grid or (N, C, D, H, W) for 3D grid.
- **align_corners** (*bool, optional*) –Geometrically, each pixel of input is viewed as a squqre instead of dot. If True , consider extremum -1 and 1 referring to the centers of the pixels rather than pixel corners. The default value is False , extremum -1 and 1 refer to the corners of the pixels, so that sampling is irrelevant to resolution of the image. Default: False .

Returns

Tensor, a tensor whose data type is same as 'theta', and the shape is $(N, H, W, 2)$ for 2D grid or $(N, D, H, W, 3)$ for 3D grid.

Raises

- **TypeError** –If *theta* is not a Tensor or *size* is not a tuple.
- **ValueError** –If the shape of *theta* is not $(N, 2, 3)$ or $(N, 3, 4)$.
- **ValueError** –If the size of *size* is not 4 or 5.
- **ValueError** –If the shape of *theta* is $(N, 2, 3)$, the size of *size* is not 4; If the shape of *theta* is $(N, 3, 4)$, the size of *size* is not 5.
- **ValueError** –If the size[0] is not equal to the shape[0] of theta.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> theta = Tensor([[[0.8, 0.5, 0],[-0.5, 0.8, 0]]], mindspore.float32)
>>> out_size = (1, 3, 2, 3)
>>> output = ops.affine_grid(theta, out_size, False)
>>> print(output)
[[[[-0.78333336 -0.06666666]
[-0.25       -0.4       ]
[ 0.28333336 -0.73333335]]
[[-0.28333336  0.73333335]
[ 0.25        0.4       ]
[ 0.78333336  0.06666666]]]]
```

mindspore.ops.bounding_box_decode

mindspore.ops.**bounding_box_decode**(*anchor_box*, *deltas*, *max_shape*, *means=(0.0, 0.0, 0.0, 0.0)*, *stds=(1.0, 1.0, 1.0, 1.0)*, *wh_ratio_clip=0.016*)

Decode the bounding box locations, calculate the offset, and convert the offset into a Bbox, which is used to mark the target in the subsequent images, etc.

Parameters

- **anchor_box** (Tensor) –Anchor boxes. The shape of *anchor_box* must be $(n, 4)$.
- **deltas** (Tensor) –Delta of boxes. Which has the same shape with *anchor_box*.
- **max_shape** (*tuple*) –The max size limit for decoding box calculation.
- **means** (*tuple, optional*) –The means of *deltas* calculation. Default: `(0.0, 0.0, 0.0, 0.0)`.
- **stds** (*tuple, optional*) –The standard deviations of *deltas* calculation. Default: `(1.0, 1.0, 1.0, 1.0)`.
- **wh_ratio_clip** (*float, optional*) –The limit of width and height ratio for decoding box calculation. Default: `0.016`.

Returns

Tensor, decoded boxes. It has the same data type and shape as *anchor_box*.

Raises

- **TypeError** –If *means*, *stds* or *max_shape* is not a tuple.
- **TypeError** –If *wh_ratio_clip* is not a float.
- **TypeError** –If *anchor_box* or *deltas* is not a Tensor.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> anchor_box = Tensor([[4, 1, 2, 1], [2, 2, 2, 3]], mindspore.float32)
>>> deltas = Tensor([[3, 1, 2, 2], [1, 2, 1, 4]], mindspore.float32)
>>> output = ops.bounding_box_decode(anchor_box, deltas, max_shape=(768, 1280), means=(0.0,␣
↪0.0, 0.0, 0.0),
...                                  stds=(1.0, 1.0, 1.0, 1.0), wh_ratio_clip=0.016)
>>> print(output)
[[ 4.1953125  0.         0.         5.1953125]
 [ 2.140625   0.         3.859375  60.59375  ]]
```

mindspore.ops.bounding_box_encode

mindspore.ops.**bounding_box_encode**(*anchor_box*, *groundtruth_box*, *means=(0.0, 0.0, 0.0, 0.0)*, *stds=(1.0, 1.0, 1.0, 1.0)*)

Encode the bounding box locations, calculate the offset between the predicted bounding boxes and the real bounding boxes, and the offset will be used as a variable for the loss.

Parameters

- **anchor_box** (Tensor) – Anchor boxes. The shape of *anchor_box* must be $(n, 4)$.
- **groundtruth_box** (Tensor) – Ground truth boxes. Which has the same shape with *anchor_box*.
- **means** (*tuple, optional*) – Means for encoding bounding boxes calculation. Default: `(0.0, 0.0, 0.0, 0.0)`.
- **stds** (*tuple, optional*) – The standard deviations of deltas calculation. Default: `(1.0, 1.0, 1.0, 1.0)`.

Returns

Tensor, encoded bounding boxes. It has the same data type and shape as input *anchor_box*.

Raises

- **TypeError** – If *means* or *stds* is not a tuple.
- **TypeError** – If *anchor_box* or *groundtruth_box* is not a Tensor.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> anchor_box = Tensor([[2, 2, 2, 3], [2, 2, 2, 3]], mindspore.float32)
>>> groundtruth_box = Tensor([[1, 2, 1, 4], [1, 2, 1, 4]], mindspore.float32)
>>> output = ops.bounding_box_encode(anchor_box, groundtruth_box, means=(0.0, 0.0, 0.0, 0.0),
...                                  stds=(1.0, 1.0, 1.0, 1.0))
>>> print(output)
[[ -1.   0.25  0.   0.40551758]
 [ -1.   0.25  0.   0.40551758]]
```

mindspore.ops.col2im

mindspore.ops.**col2im**(*input_x*, *output_size*, *kernel_size*, *dilation*, *padding_value*, *stride*)

Combines an array of sliding local blocks into a large containing tensor.

Parameters

- **input_x** (Tensor) – 4D tensor with data type float16 or float32.
- **output_size** (Tensor) – 1D tensor with 2 elements of data type int.
- **kernel_size** (*Union[int, tuple[int], list[int]]*) – The size of the kernel, should be two int for height and width. If type is int, it means that height equal with width. Must be specified.
- **dilation** (*Union[int, tuple[int], list[int]]*) – The size of the dilation, should be two int for height and width. If type is int, it means that height equal with width.

- **padding_value** (*Union[int, tuple[int], list[int]]*) –The size of the padding, should be two int for height and width. If type is int, it means that height equal with width.
- **stride** (*Union[int, tuple[int], list[int]]*) –The size of the stride, should be two int for height and width. If type is int, it means that height equal with width.

Returns

A 4D Tensor, with same type as *input_x*.

Raises

- **TypeError** –If `kernel_size`, *dilation*, *padding_value*, *stride* data type is not in Union[int, tuple[int], list[int]].
- **ValueError** –If `kernel_size`, *dilation*, *padding_value*, *stride* value is not greater than zero or elements number more than 2.
- **ValueError** –If `padding_value` value is less than zero or elements number more than 2.
- **ValueError** –If input_x.shape[2] != kernel_size[0] * kernel_size[1].
- **ValueError** –If input_x.shape[3] does not match the calculated number of sliding blocks.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor(input_data=np.random.rand(16, 16, 4, 25), dtype=mstype.float32)
>>> output_size = Tensor(input_data=[8, 8], dtype=mstype.int32)
>>> output = ops.col2im(x, output_size, [2, 2], [2, 2], [2, 2], [2, 2])
>>> print(output.shape)
(16, 16, 8, 8)
```

mindspore.ops.check_valid

mindspore.ops.**check_valid**(*bboxes*, *img_metas*)

Checks whether the bounding box is in the image.

bboxes contain several sets of bounding boxes, each represented by two abscissa points $(x0, x1)$ and two ordinate points $(y0, y1)$. *img_metas* provides information about the original image, including three parameters $(height, width, ratio)$, which specify the valid boundary of the image.

when the following conditions are met:

$x0 >= 0$

$y0 >= 0$

$x1 <= width * ratio - 1$

$y1 <= height * ratio - 1$

the bounding box is considered to be within the image.

Warning: The bounding box specified by *bboxes* and the image information specified by *img_metas* need to be valid, i.e.: $x0 <= x1$, $y0 <= y1$, and $(height, width, ratio)$ are all positive.

Parameters

- **bboxes** (Tensor) −Bounding boxes tensor with shape $(N, 4)$. N indicates the number of bounding boxes, the value *4* indicates four coordinate points $(x0, y0, x1, y1)$. Data type must be float16 or float32.
- **img_metas** (Tensor) −Raw image size information with the format of $(height, width, ratio)$, specifying the valid boundary $(height * ratio - 1, width * ratio - 1)$. Data type must be float16 or float32.

Returns

Tensor, with shape of $(N,)$ and dtype of bool, specifying whether the bounding boxes is in the image. *True* indicates valid, while *False* indicates invalid.

Raises

- **TypeError** −If *bboxes* or *img_metas* is not a Tensor.
- **TypeError** −If dtype of *bboxes* or *img_metas* is neither float16 nor float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bboxes = Tensor(np.linspace(0, 6, 12).reshape(3, 4), mindspore.float32)
>>> img_metas = Tensor(np.array([2, 1, 3]), mindspore.float32)
>>> output = ops.check_valid(bboxes, img_metas)
>>> print(output)
[ True False False]
```

mindspore.ops.crop_and_resize

mindspore.ops.**crop_and_resize**(*image*, *boxes*, *box_indices*, *crop_size*, *method='bilinear'*, *extrapolation_value=0.0*)

Extracts crops from the input image Tensor and resizes them.

Note: In case that the output shape depends on crop_size, the crop_size must be constant. For now, the backward of the operator only supports bilinear method, for other methods, will return 0.

Parameters

- **image** (Tensor) −A 4-D Tensor representing a batch of images. It has shape $(batch, image\_height, image\_width, depth)$.
- **boxes** (Tensor) −A 2-D Tensor with shape $(num\_boxes, 4)$ representing the normalized coordinates of the boxes to be cropped. The coordinates are specified in the form $[y1, x1, y2, x2]$, where $(y1, x1)$ is the first corner and $(y2, x2)$ is the second corner of the box. If $y1 > y2$, the sampled crop is inverted upside down, the width dimensionis treated

similarly when $x1 > x2$. If normalized coordinates are not in range $[0, 1]$, extrapolated input image values are used instead. Supported data type: float32.

- **box_indices** (Tensor) −A 1-D Tensor of shape (*num_boxes*) representing the batch index for each box. Supported type: int32.
- **crop_size** (*Tuple[int]*) −A tuple of two elements: (crop_height, crop_width), representing the output size of the cropped and resized images. Only positive values are supported. Supported type: int32.
- **method** (*str, optional*) −An optional string that specifies the sampling method for resizing. It can be `"bilinear"`, `"nearest"` or `"bilinear_v2"`. Default: `"bilinear"`.
  - `"nearest"`: Nearest neighbor interpolation. Each output pixel is assigned the value of the nearest input pixel. This method is simple and fast but can result in blocky or pixelated outputs.
  - `"bilinear"`: Bilinear interpolation. Each output pixel is a weighted average of the four nearest input pixels, computed using bilinear interpolation. This method produces smoother results compared to nearest neighbor interpolation.
  - `"bilinear_v2"`: The optimized variant of `"bilinear"`, it may achieve better result(higher precision and speed) in some cases.
- **extrapolation_value** (*float, optional*) −An optional float value used extrapolation, if applicable. Default: `0.0`.

Returns

A 4-D tensor of shape ($num\_boxes, crop\_height, crop\_width, depth$) with type(float32).

Raises

- **TypeError** −If *image* or *boxes* or *box_indices* is not a Tensor.
- **TypeError** −If *crop_size* is not a Tuple with two int32 elements.
- **TypeError** −If dtype of *boxes* is not float or that of *box_indices* is not int32.
- **TypeError** −If *method* is not a str.
- **TypeError** −If *extrapolation_value* is not a float.
- **ValueError** −If the shape rank of *image* is not 4.
- **ValueError** −If the shape rank of *boxes* is not 2.
- **ValueError** −If the second dim of *boxes* is not 4.
- **ValueError** −If the shape rank of *box_indices* is not 1.
- **ValueError** −If the first dim of *box_indices* is not equal to that of *boxes*.
- **ValueError** −If existing element in *box_indices* is out of range *[0, batch)*.
- **ValueError** −If the data of *crop_size* is not positive.
- **ValueError** −If *method* is not one of 'bilinear', 'nearest', 'bilinear_v2'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import ops, Tensor
>>> BATCH_SIZE = 1
>>> NUM_BOXES = 5
>>> IMAGE_HEIGHT = 256
>>> IMAGE_WIDTH = 256
>>> CHANNELS = 3
>>> image = np.random.normal(size=[BATCH_SIZE, IMAGE_HEIGHT, IMAGE_WIDTH, CHANNELS]).
↪astype(np.float32)
>>> boxes = np.random.uniform(size=[NUM_BOXES, 4]).astype(np.float32)
>>> box_indices = np.random.uniform(size=[NUM_BOXES], low=0, high=BATCH_SIZE).astype(np.
↪int32)
>>> crop_size = (24, 24)
>>> output = ops.crop_and_resize(Tensor(image), Tensor(boxes), Tensor(box_indices), crop_
↪size)
>>> print(output.shape)
(5, 24, 24, 3)
```

mindspore.ops.grid_sample

mindspore.ops.**grid_sample**(*input*, *grid*, *mode='bilinear'*, *padding_mode='zeros'*, *align_corners=False*)

Given an *input* and a flow-field *grid*, computes the *output* using *input* values and pixel locations from *grid*. Only spatial (4-D) and volumetric (5-D) *input* is supported.

In the spatial (4-D) case, for *input* with shape (N, C, H_{in}, W_{in}) and *grid* with shape $(N, H_{out}, W_{out}, 2)$, the *output* will have shape (N, C, H_{out}, W_{out}).

For each output location *output[n, :, h, w]*, the size-2 vector *grid[n, h, w]* specifies *input* pixel locations x and y, which are used to interpolate the output value *output[n, :, h, w]*. In the case of 5D inputs, *grid[n, d, h, w]*, specifies the x, y, z pixel locations for interpolating *output[n, :, d, h, w]*. And *mode* argument specifies "nearest" or "bilinear" ("bicubic" is not supported yet) interpolation method to sample the input pixels.

grid specifies the sampling pixel locations normalized by the *input* spatial dimensions. Therefore, it should have most values in the range of $[-1, 1]$.

If *grid* has values outside the range of $[-1, 1]$, the corresponding outputs are handled as defined by *padding_mode*. If *padding_mode* is set to be "zeros", use 0 for out-of-bound grid locations. If *padding_mode* is set to be "border", use border values for out-of-bound grid locations. If *padding_mode* is set to be "reflection", use values at locations reflected by the border for out-of-bound grid locations. For location far away from the border, it will keep being reflected until becoming in bound.

Parameters

- **input** (Tensor) – input with shape of (N, C, H_{in}, W_{in}) (4-D case) or $(N, C, D_{in}, H_{in}, W_{in})$ (5-D case) and dtype of float32 or float64.
- **grid** (Tensor) – flow-field with shape of $(N, H_{out}, W_{out}, 2)$ (4-D case) or $(N, D_{out}, H_{out}, W_{out}, 3)$ (5-D case) and same dtype as *input*.
- **mode** (*str, optional*) – An optional string specifying the interpolation method. The optional values are `'bilinear'`, `'nearest'`. Default: `'bilinear'` . Note: *bicubic* is not supported yet. When *mode="bilinear"* and the input is 5-D, the interpolation mode used internally will actually be trilinear. However, when the input is 4-D, the interpolation mode will legistimately be bilinear. Default: `'bilinear'` .
  - `'nearest'`: Nearest neighbor interpolation. Each output pixel is assigned the value of the nearest input pixel. This method is simple and fast but can result in blocky or pixelated outputs.

  - `'bilinear'`: Bilinear interpolation. Each output pixel is a weighted average of the four nearest input pixels, computed using bilinear interpolation. This method produces smoother results compared to nearest neighbor interpolation.
  - `'trilinear'`: Trilinear interpolation. This is an extension of bilinear interpolation to 3D data. It performs bilinear interpolation in the two spatial dimensions and linear interpolation along the third dimension. It is commonly used for volume or 3D image interpolation.

- **padding_mode** (*str, optional*) – An optional string specifying the pad method. The optional values are "zeros", "border" or "reflection". Default: `'zeros'` .
- **align_corners** (*bool, optional*) – If set to *True*, the extrema (-1 and 1) are considered as referring to the center points of the input's corner pixels. If set to *False*, they are instead considered as referring to the corner points of the input's corner pixels, making the sampling more resolution agnostic. Default: `False` .

Returns

Tensor, dtype is the same as *input* and whose shape is (N, C, H_{out}, W_{out}) (4-D) and $(N, C, D_{out}, H_{out}, W_{out})$ (5-D).

Raises

- **TypeError** – If *input* or *grid* is not a Tensor.
- **TypeError** – If the dtypes of *input* and *grid* are inconsistent.
- **TypeError** – If the dtype of *input* or *grid* is not a valid type.
- **TypeError** – If *align_corners* is not a boolean value.
- **ValueError** – If the rank of *input* or *grid* is not equal to 4(4-D case) or 5(5-D case).
- **ValueError** – If the first dimension of *input* is not equal to that of *grid*.
- **ValueError** – If the last dimension of *grid* is not equal to 2(4-D case) or 3(5-D case).
- **ValueError** – If *mode* is not "bilinear", "nearest" or a string value.
- **ValueError** – If *padding_mode* is not "zeros", "border", "reflection" or a string value.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.arange(16).reshape((2, 2, 2, 2)).astype(np.float32))
>>> grid = Tensor(np.arange(0.2, 1, 0.1).reshape((2, 2, 1, 2)).astype(np.float32))
>>> output = ops.grid_sample(input_x, grid, mode='bilinear', padding_mode='zeros',
...                          align_corners=True)
>>> print(output)
[[[[ 1.9       ]
   [ 2.1999998]]
  [[ 5.9       ]
   [ 6.2       ]]]
 [[[10.5       ]
   [10.8       ]]
  [[14.5       ]
   [14.8       ]]]]
```

mindspore.ops.interpolate

mindspore.ops.**interpolate**(*input*, *size=None*, *scale_factor=None*, *mode='nearest'*, *align_corners=None*, *recompute_scale_factor=None*)

Samples the input Tensor to the given size or scale_factor by using one of the interpolate algorithms.

Parameters

- **input** (Tensor) –Tensor to be resized. Input tensor must be a 3-D, 4-D, or 5-D tensor with shape $(N, C, [optionalD], [optionalH], W)$, with data type of float.
- **size** (*Union[int, tuple[int], list[int]], optional*) –The target size. If size is a tuple or list, its length should be the same as the number of dimensions in input after removing the first two dimensions N, C. One and only one of size and scale_factor can be set to None. Default: None .
- **scale_factor** (*Union[float, tuple[float], list[float]], optional*) –The scale factor of new size of the tensor. If scale_factor is a tuple or list, its length should be the same as the number of dimensions in input after removing the first two dimensions N, C. One and only one of size and scale_factor can be set to None. Default: None .
- **mode** (*str, optional*) –The sampling algorithm. Default: "nearest" . One of the following sampling methods can be used:
  - 'nearest': the nearest neighbours interpolation.
  - 'linear': Linear interpolation, 3D only.
  - 'bilinear': Bilinear interpolation, 4D only.
  - 'trilinear': Trilinear interpolation, 5D only.
  - 'bicubic': Double trilinear interpolation, 4D only.
  - 'area': area interpolation.
  - 'nearest-exact': matches Scikit-Image and PIL nearest neighbours interpolation algorithms and fixes knows issues with *nearest*, for 3D and 4D.
- **align_corners** (*bool, optional*) –Whether to use corner alignment for coordinate mapping. Assuming a transformation is applied to the input Tensor along the x-axis, the specific calculation formula is as follows:

```
ori_i = new_length != 1 ? new_i * (ori_length - 1) / (new_length - 1) : 0   # 'align_
↪corners' = True

ori_i = new_length > 1 ? (new_i + 0.5) * ori_length / new_length - 0.5 : 0  # 'align_
↪corners' = False
```

  Among them, *ori_length* and *new_length* represent the length of the Tensor before and after transformation along the x-axis respectively; *new_i* represents the coordinate of the i-th element along the x-axis after transformation; *ori_i* represents the corresponding coordinate of the original data along the x-axis.

  This is only valid for 'linear', 'bilinear', or 'bicubic' modes. Default: False .
- **recompute_scale_factor** (*bool, optional*) –Recalculate *scale_factor*.
  - If True, the parameter *size* will be calculated using the value of the *scale_factor*, and finally scaled using the value of *size*.
  - If False, the value of *size* or *scale_factor* will be used for direct interpolation. Default: None .

Note: The 'nearest-exact' mode is the same as the nearest-neighbor interpolation algorithm used in scikit-image and PIL. The 'nearest' mode produces the same results as the INTER_NEAREST interpolation algorithm used in OpenCV.

Args Support List and Supported Platforms:

mode	input.dim	align_corners	scale_factor	device
nearest	3	-	×	Ascend,GPU,CPU
	4	-	×	Ascend,GPU,CPU
	5	-	√	Ascend,GPU,CPU
linear	3	√	×	Ascend,GPU,CPU
bilinear	4	√	×	Ascend,GPU,CPU
bicubic	4	√	×	Ascend,GPU,CPU
area	3	-	√	Ascend,GPU,CPU
	4	-	√	Ascend,GPU,CPU
	5	-	√	Ascend,GPU,CPU
nearest-exact	3	-	×	Ascend,CPU
	4	-	×	Ascend,CPU
trilinear	5	√	√	Ascend,GPU,CPU

- \- indicates that there is no such parameter.
- × indicates that this parameter is not currently supported.
- √ indicates that this parameter is supported.

Returns

Tensor, resized, whose dimensions and dtype are the same as *input*.

Raises

- **TypeError** – *input* is not a Tensor.
- **ValueError** – Both *size* and *scale_factor* are not empty.
- **ValueError** – Both *size* and *scale_factor* are empty.
- **ValueError** – When *size* is a tuple or list, its length is not equal to *input.ndim - 2*.
- **ValueError** – When *scale_factor* is a tuple or list, its length is not equal to *input.ndim - 2*.
- **ValueError** – *mode* is not in the list of supported modes.
- **ValueError** – *input.ndim* is not in the list of supported dimensions for the corresponding mode.
- **ValueError** – *size* is not empty, *recompute_scale_factor* is not empty.
- **ValueError** – *scale_factor* is not in the corresponding list of supported values.
- **ValueError** – *align_corners* is not in the corresponding list of supported values.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> input = Tensor([[[1, 2, 3], [4, 5, 6]]], mindspore.float32)
>>> output = ops.interpolate(input, size=(6,), mode='nearest')
>>> print(output)
[[[1. 1. 2. 2. 3. 3.]
  [4. 4. 5. 5. 6. 6.]]]
```

mindspore.ops.iou

mindspore.ops.**iou**(*anchor_boxes*, *gt_boxes*, *mode='iou'*)

Calculates intersection over union for boxes.

Computes the intersection over union (IOU) or the intersection over foreground (IOF) based on the ground-truth and predicted regions.

$$\text{IOU} = \frac{\text{Area of Overlap}}{\text{Area of Union}}$$

$$\text{IOF} = \frac{\text{Area of Overlap}}{\text{Area of Ground Truth}}$$

Warning: In Ascend, only computation of float16 data is supported. To avoid overflow, the input length and width are scaled by 0.2 internally.

Parameters

- **anchor_boxes** (Tensor) – Anchor boxes, tensor of shape $(N, 4)$. N indicates the number of anchor boxes, and the value 4 refers to four boundary coordinates of the predicted area "x0", "y0", "x1", and "y1". Data type must be either float16, float32 or float64.
- **gt_boxes** (Tensor) – Ground truth boxes, tensor of shape $(M, 4)$. M indicates the number of ground truth boxes, and the value 4 refers to four boundary coordinates of the truth area "x0", "y0", "x1", and "y1". Data type must be either float16, float32 or float64.
- **mode** (*str*) – The mode is used to specify the calculation method, now supporting 'iou' (intersection over union) or 'iof' (intersection over foreground) mode. Default: 'iou' .

Returns

Tensor, the IOU/IOF values, tensor of shape (M, N) , with the same data type as *anchor_boxes*.

Raises

KeyError – When *mode* is not 'iou' or 'iof'.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> anchor_boxes = Tensor(np.random.randint(1.0, 5.0, [3, 4]), mindspore.float16)
>>> gt_boxes = Tensor(np.random.randint(1.0, 5.0, [3, 4]), mindspore.float16)
>>> mode = 'iou'
>>> output = ops.iou(anchor_boxes, gt_boxes, mode)
>>> print(output.shape)
(3, 3)
```

mindspore.ops.pad

mindspore.ops.**pad**(*input_x*, *padding*, *mode='constant'*, *value=None*)

Pads the input tensor according to the padding.

Parameters

- **input_x** (Tensor) –Tensor of shape $(N, *)$, where $*$ means, any number of additional dimensions which is required to be no more than 5 in Ascend.
- **padding** (*Union[tuple[int], list[int], Tensor]*) –Filling position of pad where the negative value is not supported while running in Ascend. $\left\lfloor \frac{\text{len(padding)}}{2} \right\rfloor$ dimensions of *input_x* will be padded.

  Example: to pad only the last dimension of the input tensor, then *padding* has the form (padding_left, padding_right);

  Example: to pad the last 2 dimensions of the input tensor, then use (padding_left, padding_right, padding_top, padding_bottom);

  Example: to pad the last 3 dimensions, use (padding_left, padding_right, padding_top, padding_bottom, padding_front, padding_ba
  and so on.
- **mode** (*str, optional*) –Pad filling mode, 'constant', 'reflect', 'replicate' or 'circular'. Default: 'constant'.

  For 'constant' mode, please refer to *mindspore.nn.ConstantPad1d* as an example to understand this filling pattern and extend the padding pattern to n dimensions.

  For 'reflect' mode, please refer to *mindspore.nn.ReflectionPad1d* as an example to understand this filling pattern. The reflect mode is used to pad the last two dimensions of 3D or 4D input, or the last dimension of 2D or 3D input.

  For 'replicate' mode, please refer to *mindspore.nn.ReplicationPad1d* as an example to understand this filling pattern. The replicate mode is used to pad the last three dimensions of 4D or 5D input, the last two dimensions of 3D or 4D input, or the last dimension of 2D or 3D input.

  For 'circular' mode, the pixels from one edge of the image are wrapped around to the opposite edge, such that the pixel on the right edge of the image is replaced with the pixel on the left edge, and the pixel on the bottom edge is replaced with the pixel on the top edge. The circular mode is used to pad the last three dimensions of 4D or 5D input, the last two dimensions of 3D or 4D input, or the last dimension of 2D or 3D input.
- **value** (*Union[int, float, None], optional*) –Valid only in 'constant' mode. Set the padding value in 'constant' mode. If the value is None, 0 is used as the default padding value. Default: None.

Returns

Tensor, the tensor after padding.

Raises

- **TypeError** –If *padding* is not an int of tuple or int of list.
- **TypeError** –If *input_x* is not a Tensor.
- **ValueError** –If length of *padding* is not even.
- **ValueError** –If length of *padding* is greater than 6.
- **ValueError** –If *mode* is not `'constant'` and *value* not `None`.
- **ValueError** –If rank of *input_x* is more than 5 while running in Ascend.
- **ValueError** –If *paddings* contains negative value while running in Ascend.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import ops
>>> import numpy as np
>>> x = ms.Tensor(np.arange(1 * 2 * 2 * 2).reshape((1, 2, 2, 2)), dtype=ms.float64)
>>> output = ops.pad(x, [1, 0, 0, 1], mode='constant', value=6.0)
>>> print(output)
[[[[6. 0. 1.]
   [6. 2. 3.]
   [6. 6. 6.]]
  [[6. 4. 5.]
   [6. 6. 7.]
   [6. 6. 6.]]]]
>>> output1 = ops.pad(x, (1, 0, 0, 1), mode='reflect')
>>> print(output1)
[[[[1. 0. 1.]
   [3. 2. 3.]
   [1. 0. 1.]]
  [[5. 4. 5.]
   [7. 6. 7.]
   [5. 4. 5.]]]]
>>> output2 = ops.pad(x, (1, 1, 2, 1), mode='replicate')
>>> print(output2)
[[[[0. 0. 1. 1.]

```

mindspore.ops.padding

mindspore.ops.**padding**(*x*, *pad_dim_size=8*)

Extends the last dimension of the input tensor from 1 to pad_dim_size, by filling with 0.

Parameters

- **x** (Tensor) −The shape of tensor is $(x_1, x_2, ..., x_R)$. The rank of *x* must be at least 2. The last dimension of *x* must be 1. The data type is Number.
- **pad_dim_size** (*int*) −The value of the last dimension of *x* to be extended, which must be positive. Default: 8 .

Returns

Tensor, has the same type and shape as input shape value.

Raises

- **TypeError** −If *pad_dim_size* is not an int.
- **ValueError** −If *pad_dim_size* is less than 1.
- **ValueError** −If last dim of *x* is not equal to 1.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[8], [10]]), mindspore.float32)
>>> pad_dim_size = 4
>>> output = ops.padding(x, pad_dim_size)
>>> print(output)
[[ 8.  0.  0.  0.]
 [10.  0.  0.  0.]]
```

mindspore.ops.pixel_shuffle

mindspore.ops.**pixel_shuffle**(*input*, *upscale_factor*)

Applies the PixelShuffle operation over input *input* which implements sub-pixel convolutions with stride $1/r$. For more details, refer to Real-Time Single Image and Video Super-Resolution Using an Efficient Sub-Pixel Convolutional Neural Network .

Typically, the *input* is of shape $(*, C \times r^2, H, W)$, and the output is of shape $(*, C, H \times r, W \times r)$, where r is an upscale factor and * is zero or more batch dimensions.

Parameters

- **input** (Tensor) –Tensor of shape $(*, C \times r^2, H, W)$. The dimension of *input* is larger than 2, and the length of third to last dimension can be divisible by *upscale_factor* squared.
- **upscale_factor** (*int*) –factor to shuffle the input Tensor, and is a positive integer. *upscale_factor* is the above-mentioned r.

Returns

- **output** (Tensor) - Tensor of shape $(*, C, H \times r, W \times r)$.

Raises

- **ValueError** –If *upscale_factor* is not a positive integer.
- **ValueError** –If the length of third to last dimension is not divisible by *upscale_factor* squared.
- **ValueError** –If the dimension of *input* is less than 3.
- **TypeError** –If *input* is not a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import ops
>>> input_x = np.arange(3 * 2 * 9 * 4 * 4).reshape((3, 2, 9, 4, 4))
>>> input_x = mindspore.Tensor(input_x, mindspore.dtype.int32)
>>> output = ops.pixel_shuffle(input_x, 3)
>>> print(output.shape)
(3, 2, 1, 12, 12)
```

mindspore.ops.pixel_unshuffle

mindspore.ops.**pixel_unshuffle**(*input*, *downscale_factor*)

Applies the PixelUnshuffle operation over input *input* which is the inverse of PixelShuffle. For more details, refer to Real-Time Single Image and Video Super-Resolution Using an Efficient Sub-Pixel Convolutional Neural Network .

Typically, the input is of shape $(*, C, H \times r, W \times r)$, and the output is of shape $(*, C \times r^2, H, W)$, where r is a downscale factor and * is zero or more batch dimensions.

Parameters

- **input** (Tensor) –Tensor of shape $(*, C, H \times r, W \times r)$. The dimension of *input* is larger than 2, and the length of second to last dimension or last dimension can be divisible by *downscale_factor* .

- **downscale_factor** (*int*) –factor to unshuffle the input Tensor, and is a positive integer. *downscale_factor* is the above-mentioned r.

Returns

- **output** (Tensor) - Tensor of shape $(*, C \times r^2, H, W)$.

Raises

- **ValueError** –If *downscale_factor* is not a positive integer.
- **ValueError** –If the length of second to last dimension or last dimension is not divisible by *downscale_factor* .
- **ValueError** –If the dimension of *input* is less than 3.
- **TypeError** –If *input* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = np.arange(8 * 8).reshape((1, 1, 8, 8))
>>> input_x = mindspore.Tensor(input_x, mindspore.dtype.int32)
>>> output = ops.pixel_unshuffle(input_x, 2)
>>> print(output.shape)
(1, 4, 4, 4)
```

mindspore.ops.rotary_position_embedding

mindspore.ops.**rotary_position_embedding**(*x*, *cos*, *sin*, *mode=0*)

Implements the Rotary Position Embedding algorithm. Refer to paper Enhanced Transformer with Rotary Position Embedding.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **x** (Tensor) –4D tensor, with float16, bfloat16 or float32 data type.
- **cos** (Tensor) –4D constant, has the same type as *x* , in range of [-1, 1].
- **sin** (Tensor) –Same with *cos* .
- **mode** (*int*) –An optional attribute. Used to select a calculation mode. 0: rotate_half(GPT-NeoX style); 1: rotate_interleaved(GPT-J style). Defaults to `0` .

Table 17: Config layout constraints

Args	RotateHalf(mode:0)	RotateInterleaved(mode:1)
x	Supported layout: 11SD, B1SD, BNSD; D < 896 and D is an Even. B, N < 1000;	Supported layout: 11SD, B1SD, BNSD; D < 896 and D is an Even. B, N < 1000;
cos	Support layout for different values of *x*: *x* is BNSD: 11SD, B1SD, BNSD; *x* is BSND: 1S1D, BS1D, BSND; *x* is SBND: S11D, SB1D, SBND	Support layout for different values of *x*: *x* is BNSD: 11SD; *x* is BSND: 1S1D; *x* is SBND: S11D
sin	Same with *cos* .	Same with *cos* .

Note: When the layout is BNSD, B * N > 8S and D is 32-bytes alignment, the performance is poor. Therefore, this interface cannot be called.

Returns

Tensor, has the same dtype and shape as the *x*.

Raises

- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If *cos* is not a Tensor.
- **TypeError** – If *sin* is not a Tensor.
- **TypeError** – If *mode* is not an int.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.random.uniform(-2, 2, (4, 8192, 4, 128)))
>>> cos = Tensor(np.random.uniform(-1, 1, (1, 8192, 1, 128)))
>>> sin = Tensor(np.random.uniform(-1, 1, (1, 8192, 1, 128)))
>>> output = ops.rotary_position_embedding(x, cos, sin, 0)
>>> print(output.shape)
(4, 8192, 4, 128)
```

mindspore.ops.rotated_iou

mindspore.ops.**rotated_iou**(*boxes*, *query_boxes*, *trans=False*, *mode=0*, *is_cross=True*, *v_threshold=0.0*, *e_threshold=0.0*)

Calculate the overlap area between rotated rectangles.

> **Warning:** This is an experimental API that is subject to change or deletion.

Note: The input data types supported by the Ascend platform include bfloat16, float16, float32.

Parameters

- **boxes** (Tensor) –The first set of rectangles which has a shape of $(B, N, 5)$.
- **query_boxes** (Tensor) –The second set of rectangles which has a shape of $(B, K, 5)$.
- **trans** (*bool, optional*) –Distinguish the rectangles representations of boxes and query_boxes. If `True`, the format of boxes and query_boxes is `'xyxyt'`, else the format is `'xywht'`. The default value is `False`.
- **mode** (*int, optional*) –Distinguish the calculation mode. If the value is `1`, the calculation mode is `'iof'`, else the calculation mode is `'iou'`. The default value is `0`.
- **is_cross** (*bool, optional*) –If `True`, use cross-calculation, else use one-to-one calculation. The default value is `True`.
- **v_threshold** (*float, optional*) –Tolerance threshold for vertex determination. The default value is `0.0`.
- **e_threshold** (*float, optional*) –Tolerance threshold for edge intersection determination. The default value is `0.0`.

Returns

Tensor, the shape is (B, N, K).

Raises

- **TypeError** –If *boxes* is not a Tensor.
- **TypeError** –If *query_boxes* is not a Tensor.
- **ValueError** –If *boxes* and *query_boxes* do not has same first dim.
- **ValueError** –If the third dimension of *boxes* or *query_boxes* is not `5`.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> a = np.random.uniform(0,1,(2,2,5)).astype(np.float16)
>>> b = np.random.uniform(0,1,(2,3,5)).astype(np.float16)
>>> box1 = Tensor(a)
>>> box2 = Tensor(b)
>>> output = ops.rotated_iou(box1, box2, trans=False, mode=0, is_cross=True)
```

mindspore.ops.upsample

mindspore.ops.**upsample**(*input*, *size=None*, *scale_factor=None*, *mode='nearest'*, *align_corners=None*, *recompute_scale_factor=None*)

Alias for *mindspore.ops.interpolate()*.

Supported Platforms:

Ascend GPU CPU

2.4 Parameter Operation Functions

API Name	Description	Supported Platforms
mindspore.ops.assign	Assigns a parameter or tensor with a value.	Ascend GPU CPU
mindspore.ops.assign_add	Updates a parameter or tensor by adding a value to it.	Ascend GPU CPU
mindspore.ops.assign_sub	Updates a parameter or tensor by subtracting a value from it.	Ascend GPU CPU
mindspore.ops.scatter_add	Perform an addition update on *input_x* based on the specified indices and update values.	Ascend GPU CPU
mindspore.ops.scatter_div	Perform a division update on *input_x* based on the specified indices and update values.	Ascend GPU CPU
mindspore.ops.scatter_min	Perform a minimum update on *input_x* based on the specified indices and update values.	Ascend GPU CPU
mindspore.ops.scatter_max	Perform a maximum update on *input_x* based on the specified indices and update values.	Ascend GPU CPU
mindspore.ops.scatter_mul	Perform a multiplication update on *input_x* based on the specified indices and update values.	Ascend GPU CPU
mindspore.ops.scatter_nd_add	Perform a sparse addition update on *input_x* based on the specified indices and update values.	Ascend GPU CPU
mindspore.ops.scatter_nd_div	Perform a sparse division update on *input_x* based on the specified indices and update values.	GPU CPU
mindspore.ops.scatter_nd_max	Perform a sparse maximum update on *input_x* based on the specified indices and update values.	Ascend GPU CPU
mindspore.ops.scatter_nd_min	Perform a sparse minimum update on *input_x* based on the specified indices and update values.	Ascend GPU CPU
mindspore.ops.scatter_nd_mul	Perform a sparse multiplication update on *input_x* based on the specified indices and update values.	GPU CPU
mindspore.ops.scatter_nd_sub	Perform a sparse subtraction update on *input_x* based on the specified indices and update values.	Ascend GPU CPU
mindspore.ops.scatter_update	Updates the input tensor values using the given input indices and update values.	Ascend GPU CPU

2.4.1 mindspore.ops.assign

mindspore.ops.**assign**(*variable*, *value*)

Assigns a parameter or tensor with a value.

Support implicit type conversion and type promotion.

Parameters

- **variable** (*Union[Parameter, Tensor]*) –The input parameter or tensor.
- **value** (Tensor) –The value to be assigned.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> value = mindspore.tensor([2.0], mindspore.float32)
>>> variable = mindspore.Parameter(mindspore.tensor([1.0], mindspore.float32), name="variable
↪")
>>> mindspore.ops.assign(variable, value)
>>> print(variable.asnumpy())
[2.]
```

2.4.2 mindspore.ops.assign_add

mindspore.ops.**assign_add**(*variable*, *value*)

Updates a parameter or tensor by adding a value to it.

Support implicit type conversion and type promotion.

Parameters

- **variable** (*Union[Parameter, Tensor]*) –The input parameter or tensor.
- **value** (*Union[Tensor, Number]*) –The value to be added to the *variable*.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> variable = mindspore.Parameter([1], name="global_step")
>>> value = mindspore.tensor([100], dtype=mindspore.int32)
>>> mindspore.ops.assign_add(variable, value)
>>> print(variable.asnumpy())
[101]
```

2.4.3 mindspore.ops.assign_sub

mindspore.ops.**assign_sub**(*variable*, *value*)

Updates a parameter or tensor by subtracting a value from it.

Support implicit type conversion and type promotion.

Parameters

- **variable** (*Union[Parameter, Tensor]*) – The input parameter or tensor.
- **value** (Tensor) – The value to be subtracted from the *variable*.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> variable = mindspore.Parameter([1], name="global_step")
>>> value = mindspore.tensor([100], dtype=mindspore.int32)
>>> mindspore.ops.assign_sub(variable, value)
>>> print(variable.asnumpy())
[-99]
```

2.4.4 mindspore.ops.scatter_add

mindspore.ops.**scatter_add**(*input_x*, *indices*, *updates*)

Perform an addition update on *input_x* based on the specified indices and update values.

$$\text{input\_x}[\text{indices}[i, ..., j], :] \mathrel{+}= \text{updates}[i, ..., j, :]$$

Note:

- Support implicit type conversion and type promotion.
- Since Parameter objects do not support type conversion, an exception will be thrown when *input_x* is of a low-precision data type.
- The shape of *updates* is *indices.shape* + *input_x.shape[1:]*.

Parameters

- **input_x** (*Union[Parameter, Tensor]*) –The input parameter or tensor.
- **indices** (Tensor) –The specified indices.
- **updates** (Tensor) –The update values.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.Parameter(mindspore.tensor([[0.0, 0.0, 0.0], [0.0, 0.0, 0.0]],
...                               mindspore.float32), name="x")
>>> indices = mindspore.tensor([[0, 1], [1, 1]], mindspore.int32)
>>> updates = mindspore.tensor([[[1.0, 1.0, 1.0], [3.0, 3.0, 3.0]],
...                             [[7.0, 7.0, 7.0], [9.0, 9.0, 9.0]]], mindspore.float32)
>>> output = mindspore.ops.scatter_add(input_x, indices, updates)
>>> print(output)
[[ 1.  1.  1.]
 [19. 19. 19.]]
```

2.4.5 mindspore.ops.scatter_div

mindspore.ops.**scatter_div**(*input_x*, *indices*, *updates*)

Perform a division update on *input_x* based on the specified indices and update values.

$$\text{input\_x}[\text{indices}[i, ..., j], :] \ /= \text{updates}[i, ..., j, :]$$

Note:

- Support implicit type conversion and type promotion.
- Since Parameter objects do not support type conversion, an exception will be thrown when *input_x* is of a low-precision data type.
- The shape of *updates* is *indices.shape* + *input_x.shape[1:]*.

Parameters

- **input_x** (*Union[Parameter, Tensor]*) –The input parameter or tensor.
- **indices** (Tensor) –The specified indices.
- **updates** (Tensor) –The update values.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input_x = mindspore.Parameter(mindspore.tensor([[6.0, 6.0, 6.0], [2.0, 2.0, 2.0]],
...                               mindspore.float32), name="x")
>>> indices = mindspore.tensor([0, 1], mindspore.int32)
>>> updates = mindspore.tensor([[2.0, 2.0, 2.0], [2.0, 2.0, 2.0]], mindspore.float32)
>>> output = mindspore.ops.scatter_div(input_x, indices, updates)
>>> print(output)
[[3. 3. 3.]
 [1. 1. 1.]]
>>> # for input_x will be updated after the operation is completed. input_x need to be re-
 ↪initialized.
>>> input_x = mindspore.Parameter(mindspore.tensor([[105.0, 105.0, 105.0],
...                                                 [315.0, 315.0, 315.0]], mindspore.
 ↪float32), name="x")
>>> # for indices = [[0, 1], [1, 1]]
>>> # step 1: [0, 1]
>>> # input_x[0] = [105.0, 105.0, 105.0] / [1.0, 1.0, 1.0] = [105.0, 105.0, 105.0]
>>> # input_x[1] = [315.0, 315.0, 315.0] / [3.0, 3.0, 3.0] = [105.0, 105.0, 105.0]
>>> # step 2: [1, 1]
>>> # input_x[1] = [105.0, 105.0, 105.0] / [5.0, 5.0, 5.0] = [21.0, 21.0, 21.0]
>>> # input_x[1] = [21.0, 21.0, 21.0] / [7.0, 7.0, 7.0] = [3.0, 3.0, 3.0]
>>> indices = mindspore.tensor([[0, 1], [1, 1]], mindspore.int32)
>>> updates = mindspore.tensor([[[1.0, 1.0, 1.0], [3.0, 3.0, 3.0]],
...                             [[5.0, 5.0, 5.0], [7.0, 7.0, 7.0]]], mindspore.float32)
>>> output = mindspore.ops.scatter_div(input_x, indices, updates)
>>> print(output)
[[105. 105. 105.]
 [  3.   3.   3.]]
>>> # for input_x will be updated after the operation is completed. input_x need to be re-
 ↪initialized.
>>> input_x = mindspore.Parameter(mindspore.tensor([[105.0, 105.0, 105.0],
...                                                 [315.0, 315.0, 315.0]], mindspore.
 ↪float32), name="x")
>>> # for indices = [[1, 0], [1, 1]]
>>> # step 1: [1, 0]
>>> # input_x[0] = [105.0, 105.0, 105.0] / [3.0, 3.0, 3.0] = [35.0, 35.0, 35.0]
>>> # input_x[1] = [315.0, 315.0, 315.0] / [1.0, 1.0, 1.0] = [315.0, 315.0, 315.0]
>>> # step 2: [1, 1]
>>> # input_x[1] = [315.0, 315.0, 315.0] / [5.0, 5.0, 5.0] = [63.0 63.0 63.0]
>>> # input_x[1] = [63.0 63.0 63.0] / [7.0, 7.0, 7.0] = [9.0, 9.0, 9.0]
>>> indices = mindspore.tensor([[1, 0], [1, 1]], mindspore.int32)
>>> updates = mindspore.tensor([[[1.0, 1.0, 1.0], [3.0, 3.0, 3.0]],
...                             [[5.0, 5.0, 5.0], [7.0, 7.0, 7.0]]], mindspore.float32)
>>> output = mindspore.ops.scatter_div(input_x, indices, updates)
>>> print(output)
[[35. 35. 35.]
 [ 9.  9.  9.]]
```

2.4.6 mindspore.ops.scatter_min

mindspore.ops.**scatter_min**(*input_x*, *indices*, *updates*)

Perform a minimum update on *input_x* based on the specified indices and update values.

$$\text{input\_x}[\text{indices}[i, ..., j], :] = \min(\text{input\_x}[\text{indices}[i, ..., j], :], \text{updates}[i, ..., j, :])$$

Note:

- Support implicit type conversion and type promotion.
- Since Parameter objects do not support type conversion, an exception will be thrown when *input_x* is of a low-precision data type.
- The shape of *updates* is *indices.shape* + *input_x.shape[1:]*.

Parameters

- **input_x** (*Union[Parameter, Tensor]*) –The input parameter or tensor.
- **indices** (Tensor) –The specified indices.
- **updates** (Tensor) –The update values.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.Parameter(mindspore.tensor(mindspore.ops.zeros((2, 3)),
...                               mindspore.float32), name="input_x")
>>> indices = mindspore.tensor([1, 0], mindspore.int32)
>>> update = mindspore.tensor(mindspore.ops.arange(0, 6).reshape((2, 3)), mindspore.float32)
>>> output = mindspore.ops.scatter_min(input_x, indices, update)
>>> print(output)
[[0. 0. 0.]
 [0. 0. 0.]]
```

2.4.7 mindspore.ops.scatter_max

mindspore.ops.**scatter_max**(*input_x*, *indices*, *updates*)

Perform a maximum update on *input_x* based on the specified indices and update values.

$$\text{input\_x}[\text{indices}[i, ..., j], :] = \max(\text{input\_x}[\text{indices}[i, ..., j], :], \text{updates}[i, ..., j, :])$$

Note:

- Support implicit type conversion and type promotion.
- Since Parameter objects do not support type conversion, an exception will be thrown when *input_x* is of a low-precision data type.
- The shape of *updates* is *indices.shape* + *input_x.shape[1:]*.

Parameters

- **input_x** (*Union[Parameter, Tensor]*) –The input parameter or tensor.
- **indices** (Tensor) –The specified indices.
- **updates** (Tensor) –The update values.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input_x = mindspore.Parameter(mindspore.tensor([[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]],
...                               mindspore.float32), name="input_x")
>>> indices = mindspore.tensor([[0, 0], [1, 1]], mindspore.int32)
>>> updates = mindspore.tensor(mindspore.ops.ones([2, 2, 3]) * 88, mindspore.float32)
>>> output = mindspore.ops.scatter_max(input_x, indices, updates)
>>> print(output)
[[88. 88. 88.]
 [88. 88. 88.]]
```

2.4.8 mindspore.ops.scatter_mul

`mindspore.ops.`**`scatter_mul`**(*input_x*, *indices*, *updates*)

Perform a multiplication update on *input_x* based on the specified indices and update values.

$$\text{input\_x}[\text{indices}[i, ..., j], :] \mathrel{*}= \text{updates}[i, ..., j, :]$$

Note:

- Support implicit type conversion and type promotion.
- Since Parameter objects do not support type conversion, an exception will be thrown when *input_x* is of a low-precision data type.
- The shape of *updates* is *indices.shape* + *input_x.shape[1:]*.

Parameters

- **input_x** (*Union[Parameter, Tensor]*) –The input parameter or tensor.

- **indices** (Tensor) −The specified indices.
- **updates** (Tensor) −The update values.

Returns

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> input_x = mindspore.Parameter(mindspore.tensor([[1.0, 1.0, 1.0],
...                               [2.0, 2.0, 2.0]], mindspore.float32), name="x")
>>> indices = mindspore.tensor([0, 1], mindspore.int32)
>>> updates = mindspore.tensor([[2.0, 2.0, 2.0], [2.0, 2.0, 2.0]], mindspore.float32)
>>> output = mindspore.ops.scatter_mul(input_x, indices, updates)
>>> print(output)

2.4.9 mindspore.ops.scatter_nd_add

mindspore.ops.**scatter_nd_add**(*input_x*, *indices*, *updates*, *use_locking=False*)

Perform a sparse addition update on *input_x* based on the specified indices and update values.

$$\text{input\_x}[\text{indices}[i, ..., j]] \mathrel{+}= \text{updates}[i, ..., j]$$

Note:

- Support implicit type conversion and type promotion.
- The dimension of *indices* is at least 2, and its shape must be *indices.shape[-1] <= len(indices.shape)*.
- The shape of *updates* is *indices.shape[:-1] + input_x.shape[indices.shape[-1]:]*.

Parameters

- **input_x** (*Union[Parameter, Tensor]*) –The input parameter or tensor.
- **indices** (Tensor) –The specified indices.
- **updates** (Tensor) –The update values.
- **use_locking** (*bool, optional*) –Whether to protect the assignment by a lock. Default: False .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.Parameter(mindspore.tensor([1, 2, 3, 4, 5, 6, 7, 8],
...                               mindspore.float32), name="x")
>>> indices = mindspore.tensor([[2], [4], [1], [7]], mindspore.int32)
>>> updates = mindspore.tensor([6, 7, 8, 9], mindspore.float32)
>>> output = mindspore.ops.scatter_nd_add(input_x, indices, updates, False)
>>> print(output)
[ 1. 10.  9.  4. 12.  6.  7. 17.]
>>> input_x = mindspore.Parameter(mindspore.tensor(mindspore.ops.zeros((4, 4, 4)), mindspore.
 ↪int32))
>>> indices = mindspore.tensor([[0], [2]], mindspore.int32)
>>> updates = mindspore.tensor([[[1, 1, 1, 1], [2, 2, 2, 2], [3, 3, 3, 3], [4, 4, 4, 4]],
...                             [[5, 5, 5, 5], [6, 6, 6, 6], [7, 7, 7, 7], [8, 8, 8, 8]]],␣
 ↪mindspore.int32)
>>> output = mindspore.ops.scatter_nd_add(input_x, indices, updates, False)
>>> print(output)
[[[1 1 1 1]
  [2 2 2 2]
  [3 3 3 3]
  [4 4 4 4]]
 [[0 0 0 0]
  [0 0 0 0]
  [0 0 0 0]
  [0 0 0 0]]
 [[5 5 5 5]
  [6 6 6 6]
  [7 7 7 7]
  [8 8 8 8]]
 [[0 0 0 0]
  [0 0 0 0]
  [0 0 0 0]
  [0 0 0 0]]]
```

2.4.10 mindspore.ops.scatter_nd_div

mindspore.ops.**scatter_nd_div**(*input_x*, *indices*, *updates*, *use_locking=False*)

Perform a sparse division update on *input_x* based on the specified indices and update values.

$$\text{input\_x}[\text{indices}[i, ..., j]] \ /= \text{updates}[i, ..., j]$$

Note:

- Support implicit type conversion and type promotion.
- The dimension of *indices* is at least 2, and its shape must be *indices.shape[-1] <= len(indices.shape)*.
- The shape of *updates* is *indices.shape[:-1] + input_x.shape[indices.shape[-1]:]*.

Parameters

- **input_x** (*Union[Parameter, Tensor]*) – The input parameter or tensor.
- **indices** (Tensor) – The specified indices.

- **updates** (Tensor) −The update values.
- **use_locking** (*bool*) −Whether to protect the assignment by a lock. Default: `False` .

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.Parameter(mindspore.tensor([1, 2, 3, 4, 5, 6, 7, 8],
...                               mindspore.float32), name="x")
>>> indices = mindspore.tensor([[2], [4], [1], [7]], mindspore.int32)

```

2.4.11 mindspore.ops.scatter_nd_max

mindspore.ops.**scatter_nd_max**(*input_x*, *indices*, *updates*, *use_locking=False*)

Perform a sparse maximum update on *input_x* based on the specified indices and update values.

$$\text{input\_x}[\text{indices}[i, ..., j]] = \max(\text{input\_x}[\text{indices}[i, ..., j]], \text{updates}[i, ..., j])$$

Note:

- Support implicit type conversion and type promotion.
- The dimension of *indices* is at least 2, and its shape must be *indices.shape[-1] <= len(indices.shape)*.
- The shape of *updates* is *indices.shape[:-1] + input_x.shape[indices.shape[-1]:]*.

Parameters

- **input_x** (*Union[Parameter, Tensor]*) – The input parameter or tensor.
- **indices** (Tensor) – The specified indices.
- **updates** (Tensor) – The update values.
- **use_locking** (*bool*) – Whether to protect the assignment by a lock. Default: False .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore

```

2.4.12 mindspore.ops.scatter_nd_min

mindspore.ops.**scatter_nd_min**(*input_x*, *indices*, *updates*, *use_locking=False*)

Perform a sparse minimum update on *input_x* based on the specified indices and update values.

$$\text{input\_x}[\text{indices}[i, ..., j]] = \min(\text{input\_x}[\text{indices}[i, ..., j]], \text{updates}[i, ..., j])$$

Note:

- Support implicit type conversion and type promotion.
- The dimension of *indices* is at least 2, and its shape must be *indices.shape[-1] <= len(indices.shape)*.
- The shape of *updates* is *indices.shape[:-1] + input_x.shape[indices.shape[-1]:]*.

Parameters

- **input_x** (*Union[Parameter, Tensor]*) – The input parameter or tensor.
- **indices** (Tensor) – The specified indices.
- **updates** (Tensor) – The update values.
- **use_locking** (*bool*) – Whether to protect the assignment by a lock. Default: False .

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```

```

2.4.13 mindspore.ops.scatter_nd_mul

mindspore.ops.**scatter_nd_mul**(*input_x*, *indices*, *updates*, *use_locking=False*)

Perform a sparse multiplication update on *input_x* based on the specified indices and update values.

$$\text{input\_x}[\text{indices}[i, ..., j]] *= \text{updates}[i, ..., j]$$

Note:

- Support implicit type conversion and type promotion.
- The dimension of *indices* is at least 2, and its shape must be *indices.shape[-1] <= len(indices.shape)*.
- The shape of *updates* is *indices.shape[:-1] + input_x.shape[indices.shape[-1]:]*.

Parameters

- **input_x** (*Union[Parameter, Tensor]*) – The input parameter or tensor.
- **indices** (Tensor) – The specified indices.

- **updates** (Tensor) −The update values.
- **use_locking** (*bool*) −Whether to protect the assignment by a lock. Default: False .

Returns

Tensor

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> input_x = mindspore.Parameter(mindspore.tensor([1, 2, 3, 4, 5, 6, 7, 8],

2.4.15 mindspore.ops.scatter_update

mindspore.ops.**scatter_update**(*input_x*, *indices*, *updates*)

Updates the input tensor values using the given input indices and update values.

Note:

- Support implicit type conversion and type promotion.
- Since Parameter objects do not support type conversion, an exception will be thrown when input_x is of a low-precision data type.
- The *updates* with a shape of *indices.shape* + *input_x.shape[1:]* .

---

for each $i, \cdots, j$ in *indices.shape*:

$$\text{input\_x}[\text{indices}[i, ..., j], :] = \text{updates}[i, ..., j, :]$$

Parameters

- **input_x** (*Union[Parameter, Tensor]*) –The input parameter or tensor.
- **indices** (Tensor) –Specify the indices for update operation. If there are duplicates in indices, the order for updating is undefined.
- **updates** (Tensor) –The values to update.

Returns

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> np_x = mindspore.tensor([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]], mindspore.float32)
>>> input_x = mindspore.Parameter(np_x, name="x")
>>> indices = mindspore.tensor([0, 1], mindspore.int32)
>>> np_updates =  mindspore.tensor([[2.0, 1.2, 1.0], [3.0, 1.2, 1.0]])
>>> updates =  mindspore.tensor(np_updates, mindspore.float32)
>>> output = mindspore.ops.scatter_update(input_x, indices, updates)
>>> print(output)
[[2. 1.2  1.]
 [3. 1.2  1.]]
```

2.5 Differential Functions

API Name	Description	Supported Platforms
mindspore.ops.derivative	This function is designed to calculate the higher order differentiation of given composite function.	Ascend GPU CPU
mindspore.ops.jet	This function is designed to calculate the higher order differentiation of given composite function.	Ascend GPU CPU
mindspore.ops.stop_gradient	StopGradient is used for eliminating the effect of a value on the gradient, such as truncating the gradient propagation from an output of a function.	Ascend GPU CPU

2.5.1 mindspore.ops.derivative

mindspore.ops.**derivative**(*fn*, *primals*, *order*)

This function is designed to calculate the higher order differentiation of given composite function. To figure out *order*-th order differentiations, original inputs and order must be provided together. In particular, the value of input first order derivative is set to 1, while the other to 0.

Note: If *primals* is tensor of int type, it will be converted to tensor of float type.

Parameters

- **fn** (*Union[Cell, function]*) –Function to do TaylorOperation.
- **primals** (*Union[Tensor, tuple[Tensor]]*) –The inputs to *fn*.
- **order** (*int*) –The order of differentiation.

Returns

Tuple(out_primals, out_series)

- **out_primals** (Union[Tensor, list[Tensor]]) - The output of *fn(primals)*.
- **out_series** (Union[Tensor, list[Tensor]]) - The *order*-th order of derivative of output with respect to the inputs.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> mindspore.set_context(mode=mindspore.GRAPH_MODE)
>>> class Net(nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.sin = mindspore.ops.Sin()
...         self.exp = mindspore.ops.Exp()
...     def construct(self, x):
...         out1 = self.sin(x)
...         out2 = self.exp(out1)
...         return out2
>>>
>>> primals = mindspore.tensor([[1, 2], [3, 4]], mindspore.float32)
>>> order = 3
>>> net = Net()
>>> out_primals, out_series = mindspore.ops.derivative(net, primals, order)
>>> print(out_primals, out_series)
[[2.319777  2.4825778]
 [1.1515628 0.4691642]] [[-4.0515366   3.6724353 ]
 [ 0.5053504  -0.52061415]]
```

2.5.2 mindspore.ops.jet

mindspore.ops.**jet**(*fn*, *primals*, *series*)

This function is designed to calculate the higher order differentiation of given composite function. To figure out first to *n*-th order differentiations, original inputs and first to *n*-th order derivative of original inputs must be provided together. Generally, it is recommended to set the values of given first order derivative to 1, while the other to 0, which is like the derivative of origin input with respect to itself.

Note: If *primals* is tensor of int type, it will be converted to Tensor of float type.

Parameters

- **fn** (*Union[Cell, function]*) –Function to do TaylorOperation.
- **primals** (*Union[Tensor, tuple[Tensor]]*) –The inputs to *fn*.
- **series** (*Union[Tensor, tuple[Tensor]]*) –The original 1st to nth order derivatives of the input. The index *i* of the zeroth dimension of the tensor corresponds to the *i+1* -th order derivative of the output with respect to the input.

Returns

Tuple(out_primals, out_series)

- **out_primals** (Union[Tensor, list[Tensor]]) - The output of *fn(primals)*.
- **out_series** (Union[Tensor, list[Tensor]]) - The *1* to *i+1* -th order of derivative of output with respect to the inputs.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> mindspore.set_context(mode=mindspore.GRAPH_MODE)
>>> class Net(nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.sin = mindspore.ops.Sin()
...         self.exp = mindspore.ops.Exp()
...     def construct(self, x):
...         out1 = self.sin(x)
...         out2 = self.exp(out1)
...         return out2
>>> primals = mindspore.tensor([[1, 2], [3, 4]], mindspore.float32)
>>> series = mindspore.tensor([[[1, 1], [1, 1]], [[0, 0], [0, 0]], [[0, 0], [0, 0]]],␣
↪mindspore.float32)
>>> net = Net()
>>> out_primals, out_series = mindspore.ops.jet(net, primals, series)
>>> print(out_primals, out_series)
[[2.319777  2.4825778]
 [1.1515628 0.4691642]] [[[ 1.2533808  -1.0331168 ]
  [-1.1400385  -0.3066662 ]]
 [[-1.2748207  -1.8274734 ]
  [ 0.966121    0.55551505]]
 [[-4.0515366   3.6724353 ]
  [ 0.5053504  -0.52061415]]]
```

2.5.3 mindspore.ops.stop_gradient

mindspore.ops.**stop_gradient**(*value*)

StopGradient is used for eliminating the effect of a value on the gradient, such as truncating the gradient propagation from an output of a function. For more details, please refer to Stop Gradient.

Parameters

value (*Any*) – The value whose effect on the gradient to be eliminated.

Returns

The same as *value*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> def f1(x):
...     return x ** 2
>>> x = 3.0
>>> f1(x)
9.0
>>> mindspore.ops.grad(f1)(mindspore.tensor(x))
Tensor(shape=[], dtype=Float32, value= 6)
>>>
>>> # The same function with stop_gradient, return a zero gradient because x is effectively␣
↪treated as a constant.
>>> def f2(x):
...     return mindspore.ops.stop_gradient(x) ** 2
>>> f2(x)
9.0
>>> mindspore.ops.grad(f2)(mindspore.tensor(x))
Tensor(shape=[], dtype=Float32, value= 0)
```

2.6 Debugging Functions

API Name	Description	Supported Platforms
*mindspore.ops.print_*	Outputs the inputs to stdout.	Ascend GPU CPU
mindspore.ops.tensordump	Save tensor in npy format.	Ascend

2.6.1 mindspore.ops.print_

mindspore.ops.**print_**(**input_x*)

Outputs the inputs to stdout. The outputs are printed to screen by default. It can also be saved in a file by setting the parameter *print_file_path* in *context*. *mindspore.parse_print()* can be employed to reload the data. For more information, please refer to *mindspore.set_context()* and *mindspore.parse_print()*. In Ascend platform with graph mode, the environment variables *MS_DUMP_SLICE_SIZE* and *MS_DUMP_WAIT_TIME* can be set to solve operator execution failure when outputting big tensor or outputting tensor intensively.

Note: In pynative mode, please use python print function. In Ascend platform with graph mode, the bool, int and float would be converted into tensor to print, and str remains unchanged. This function is used for debugging.

Parameters

input_x (*Union[Tensor, bool, int, float, str, tuple, list]*) – The inputs of **print_**. Supports multiple inputs which are separated by ','.

Returns

Invalid value, should be ignored.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> x = mindspore.tensor(mindspore.ops.ones([2, 1], mindspore.int32))
>>> y = mindspore.tensor(mindspore.ops.ones([2, 2], mindspore.int32))
>>> result = mindspore.ops.print_('Print Tensor x and Tensor y:', x, y)
Print Tensor x and Tensor y:
Tensor(shape=[2, 1], dtype=Int32, value=
[[1],
 [1]])
Tensor(shape=[2, 2], dtype=Int32, value=
[[1, 1],
 [1, 1]])
```

2.6.2 mindspore.ops.tensordump

mindspore.ops.**tensordump**(*file_name*, *tensor*, *mode='out'*)

Save tensor in npy format.

Warning:

- The parameter *mode* will no longer support the value 'all'.

In Parallel situation, tensordump will dump slice of data at each rank. In Ascend platform with graph mode, Your code OpA -> OpB may compiled as OpA -> RedistributionOps -> OpB.

Note: The redistribution operator is introduced, Due to inter-device communication and shard strategies in the static graph parallel scenario.

In case of OpA -> OpB, the dump data of OpA's output is equal to OpB's input.

But in case of OpA -> RedistributionOps -> OpB, The dump data of OpA's output is not equal to OpB's input (Due to the redistribution operators). So the parameter mode is to handle this situation.

Assuming OpA's output is used as both tensordump's input parameter and OpB's input parameter. Different requirements of saving dump data can be achieved by configuring parameter *mode* :

- If the *mode* is 'out', the dump data contains only OpA's output slice.
- If the *mode* is 'in', the dump data contains only OpB's input slice.

For *mode* 'in', the input slice npy file format is: fileName_dumpMode_dtype_id.npy.

For *mode* 'out', the output slice npy file format is: fileName_dtype_id.npy.

- fileName: Value of the parameter file_name (if parameter *file_name* is a user-specified path, the value of fileName is the last level of the path).
- dumpMode: Value of the parameter *mode*.
- dtype: The original data type. Data of type bfloat16 stored in the .npy file will be converted to float32.
- id: An auto increment ID.

Note:

- In Ascend platform with graph mode, the environment variables *MS_DUMP_SLICE_SIZE* and *MS_DUMP_WAIT_TIME* can be set to solve operator execution failure when outputting big tensor or outputting tensor intensively.

- The operator of tensordump doesn't support in control flow.
- If current parallel mode is STAND_ALONE, *mode* should only be 'out'.
- This function is used for debugging.

Parameters

- **file_name** (*str*) −The path of the npy file saves.
- **tensor** (Tensor) −The tensor that user want to dump.
- **mode** (*str, optional*) −Used to control tensordump behavior, available value is one of ['in', 'out']. Default `out` .

Supported Platforms:

`Ascend`

Examples

Note: Using msrun command to run below example: msrun −worker_num=2 −local_worker_num=2 −master_port=11450 −log_dir=msrun_log −join=True −cluster_time_out=300 tensordump_example.py

↪matmul1's output slice
>>> print(f"matmul1_output_slice is loaded, shape is: {matmul1_output_slice.shape}")
>>> # matmul1_output_slice is loaded, shape is: (64, 64)
```

2.7 Sparse Functions

Warning: These are experimental APIs that are subject to change or deletion.

API Name	Description	Supported Platforms
mindspore.ops.dense_to_sparse_coo	Convert a Tensor to COOTensor.	GPU
mindspore.ops.dense_to_sparse_csr	Convert a Tensor to CSRTensor.	GPU
mindspore.ops.csr_to_coo	Converts a CSRTensor to COOTensor.	Ascend GPU CPU

2.7.1 mindspore.ops.dense_to_sparse_coo

mindspore.ops.**dense_to_sparse_coo**(*tensor:* Tensor)

Convert a Tensor to COOTensor.

Note: Only 2-D tensor is supported for now.

Parameters

tensor (Tensor) – A dense tensor, must be 2-D.

Returns

COOTensor, a sparse representation of the original dense tensor, containing the following parts.

- indices (Tensor): 2-D integer tensor, indicates the positions of *values* of the dense tensor.
- values (Tensor): 1-D tensor, indicates the non-zero values of the dense tensor.
- shape (tuple(int)): the shape of the COOTensor, is the same as the original dense tensor.

Raises

- **TypeError** – If *tensor* is not a tensor.
- **ValueError** – If *tensor* is not 2-D.

Supported Platforms:

GPU

Examples

```
>>> from mindspore import Tensor, ops
>>> import mindspore as ms
>>> x = Tensor([[1, 0], [-5, 0]], ms.float32)
>>> output = ops.dense_to_sparse_coo(x)
>>> print(output.indices)
[[0 0]
[1 0]]
>>> print(output.values)
[ 1. -5.]
>>> print(output.shape)
(2, 2)
```

2.7.2 mindspore.ops.dense_to_sparse_csr

mindspore.ops.**dense_to_sparse_csr**(*tensor:* Tensor)

Convert a Tensor to CSRTensor.

Note: Only 2-D tensor is supported for now.

Parameters

tensor (Tensor) – A dense tensor, must be 2-D.

Returns

CSRTensor, a sparse representation of the original dense tensor, containing the following parts.

- indptr (Tensor): 1-D integer tensor, indicates the start and end point for *values* in each row.
- indices (Tensor): 1-D integer tensor, indicates the column positions of all non-zero values of the input.
- values (Tensor): 1-D tensor, indicates the non-zero values of the dense tensor.
- shape (tuple(int)): the shape of the CSRTensor, is the same as the original dense tensor.

Raises

- **TypeError** – If input is not a tensor.
- **ValueError** – If input tensor is not 2-D.

Supported Platforms:

GPU

Examples

```
>>> from mindspore import Tensor, ops
>>> import mindspore as ms
>>> x = Tensor([[1, 0], [-5, 0]], ms.float32)
>>> output = ops.dense_to_sparse_csr(x)
>>> print(output.indptr)
[0 1 2]
>>> print(output.indices)
[0 0]
>>> print(output.shape)
(2, 2)
```

2.7.3 mindspore.ops.csr_to_coo

mindspore.ops.**csr_to_coo**(*tensor:* CSRTensor)

Converts a CSRTensor to COOTensor.

Note: Only 2-D CSRTensor is supported for now.

Parameters

tensor (CSRTensor) – A CSRTensor, must be 2-D.

Returns

2D COOTensor, the input tensor stored in COO format.

Raises

- **TypeError** – If input is not a COOTensor.
- **ValueError** – If input tensor is not 2-D.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import Tensor, CSRTensor
>>> indptr = Tensor([0, 1, 2]).astype("int32")
>>> indices = Tensor([0, 1]).astype("int32")
>>> values = Tensor([2, 1]).astype("float32")
>>> shape = (2, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_to_coo(x)
>>> print(output.indices)
[[0 0]
[1 1]]
```

2.7.4 COO Functions

Warning: These are experimental APIs that are subject to change or deletion.

API Name	Description	Supported Platforms
mindspore.ops.coo_abs	Returns coo_absolute value of a COOTensor element-wise.	Ascend GPU CPU
mindspore.ops.coo_acos	Computes arccosine of input coo_tensors element-wise.	Ascend GPU CPU
mindspore.ops.coo_acosh	Computes inverse hyperbolic cosine of the inputs element-wise.	Ascend GPU CPU
mindspore.ops.coo_add	Computes the sum of x1(COOTensor) and x2(COOTensor), and return a new COOTensor based on the computed result and *thresh*.	GPU CPU
mindspore.ops.coo_asin	Computes arcsine of input coo_tensors element-wise.	Ascend GPU CPU
mindspore.ops.coo_asinh	Computes inverse hyperbolic sine of the input element-wise.	Ascend GPU CPU
mindspore.ops.coo_atan	Computes the trigonometric inverse tangent of the input element-wise.	Ascend GPU CPU
mindspore.ops.coo_atanh	Computes inverse hyperbolic tangent of the input element-wise.	Ascend GPU CPU
mindspore.ops.coo_ceil	Rounds a COOTensor up to the closest integer element-wise.	Ascend GPU CPU
mindspore.ops.coo_concat	concatenates the input SparseTensor(COO format) along the specified dimension.	CPU
mindspore.ops.coo_cos	Computes cosine of input element-wise.	Ascend GPU CPU
mindspore.ops.coo_cosh	Computes hyperbolic cosine of input element-wise.	Ascend GPU CPU
mindspore.ops.coo_exp	Returns the element-wise exponential of a COOTensor.	Ascend GPU CPU
mindspore.ops.coo_expm1	Returns exponential then minus 1 of a COOTensor element-wise.	Ascend GPU CPU
mindspore.ops.coo_floor	Rounds a COOTensor down to the closest integer element-wise.	Ascend GPU CPU
mindspore.ops.coo_inv	Computes Reciprocal of input COOTensor element-wise.	Ascend GPU CPU
mindspore.ops.coo_isfinite	Determines which elements are finite for each position.	Ascend GPU CPU
mindspore.ops.coo_isinf	Determines which elements are inf or -inf for each position.	GPU CPU
mindspore.ops.coo_isnan	Determines which elements are NaN for each position.	Ascend GPU CPU
mindspore.ops.coo_log	Returns the natural logarithm of a COOTensor element-wise.	Ascend GPU CPU
mindspore.ops.coo_log1p	Returns the natural logarithm of one plus the input COOTensor element-wise.	Ascend GPU CPU
mindspore.ops.coo_neg	Returns a COOTensor with coo_negative values of the input COOTensor element-wise.	Ascend GPU CPU

continues on next page

Table 22 – continued from previous page

mindspore.ops.coo_relu	Computes ReLU (Rectified Linear Unit activation function) of input coo_tensors element-wise.	Ascend GPU CPU
mindspore.ops.coo_relu6	Computes ReLU (Rectified Linear Unit) upper bounded by 6 of input coo_tensors element-wise.	Ascend GPU CPU
mindspore.ops.coo_round	Returns half to even of a COOTensor element-wise.	Ascend GPU CPU
mindspore.ops.coo_sigmoid	Sigmoid activation function.	Ascend GPU CPU
mindspore.ops.coo_sin	Computes sine of the input element-wise.	Ascend GPU CPU
mindspore.ops.coo_sinh	Computes hyperbolic sine of the input element-wise.	Ascend GPU CPU
mindspore.ops.coo_softsign	Softsign activation function.	Ascend GPU CPU
mindspore.ops.coo_sqrt	Computes sqrt of a COOTensor element-wise.	Ascend GPU CPU
mindspore.ops.coo_square	Returns square of a COOTensor element-wise.	Ascend GPU CPU
mindspore.ops.coo_tan	Computes tangent of *x* element-wise.	Ascend GPU CPU
mindspore.ops.coo_tanh	Computes hyperbolic tangent of input element-wise.	Ascend GPU CPU

mindspore.ops.coo_abs

mindspore.ops.**coo_abs**(*x:* COOTensor)

Returns coo_absolute value of a COOTensor element-wise.

$$out_i = |x_i|$$

Parameters

x (COOTensor) – The input COOTensor.

Returns

COOTensor, has the same shape as the *x*.

Raises

TypeError – If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_abs(x)
>>> print(output.values)
[1. 2.]
```

mindspore.ops.coo_acos

mindspore.ops.**coo_acos**(*x:* COOTensor)

Computes arccosine of input coo_tensors element-wise.

$$out_i = \cos^{-1}(x_i)$$

Parameters

x (COOTensor) – Input COOTensor.

Returns

COOTensor, has the same shape and dtype as *x*.

Raises

- **TypeError** – If *x* is not a COOTensor.
- **TypeError** – If dtype of *x* is not float16, float32 or float64.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_acos(x)
>>> print(output.values)
[3.1415927       nan]
```

mindspore.ops.coo_acosh

mindspore.ops.**coo_acosh**(*x:* COOTensor)

Computes inverse hyperbolic cosine of the inputs element-wise.

$$y_i = \cosh^{-1}(x_i)$$

Warning: Given an input COOTensor x, the function computes inverse hyperbolic cosine of every element. Input range is [1, inf].

Parameters

x (COOTensor) – The input COOTensor of inverse hyperbolic cosine function.

Returns

COOTensor, has the same shape and type as *x*.

Raises

TypeError – If *x* is not a COOTensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_acosh(x)
>>> print(output.values)
[     nan 1.316958]
```

mindspore.ops.coo_add

`mindspore.ops.`**`coo_add`**(*x1:* COOTensor, *x2:* COOTensor, *thresh:* Tensor)

Computes the sum of x1(COOTensor) and x2(COOTensor), and return a new COOTensor based on the computed result and *thresh*.

Parameters

- **x1** (COOTensor) – the first COOTensor to sum.
- **x2** (COOTensor) – the second COOTensor to sum.
- **thresh** (Tensor) – A 0-D Tensor, represents the magnitude threshold that determines if an output value/index pair take place. Its dtype should match that of the values if they are real. If output's value is less than the *thresh*, it will vanish.

Returns

A COOTensor, the result of sum.

Raises

- **ValueError** – If any input(x1/x2)'s indices's dim is not equal to 2.
- **ValueError** – If any input(x1/x2)'s values's dim is not equal to 1.
- **ValueError** – If any input(x1/x2)'s shape's dim is not equal to 1.
- **ValueError** – If thresh's dim is not equal to 0.
- **TypeError** – If any input(x1/x2)'s indices's type is not equal to int64.
- **TypeError** – If any input(x1/x2)'s shape's type is not equal to int64.
- **ValueError** – If any input(x1/x2)'s indices's length is not equal to its values's length.
- **TypeError** – If any input(x1/x2)'s values's type is not equal to anf of (int8/int16/int32/int64/float32/float64/complex64/complex128).
- **TypeError** – If thresh's type is not equal to anf of (int8/int16/int32/int64/float32/float64).
- **TypeError** – If x1's indices's type is not equal to x2's indices's type.
- **TypeError** – If x1's values's type is not equal to x2's values's type.

- **TypeError** –If x1's shape's type is not equal to x2's shape's type.
- **TypeError** –If (x1/x2)'s value's type is not matched with thresh's type.

Supported Platforms:

GPU CPU

Examples

```
>>> from mindspore import Tensor, COOTensor
>>> from mindspore import dtype as mstype
>>> from mindspore import context
>>> from mindspore import ops
>>> indics0 = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values0 = Tensor([1, 2], dtype=mstype.int32)
>>> shape0 = (3, 4)
>>> input0 = COOTensor(indics0, values0, shape0)
>>> indics1 = Tensor([[0, 0], [1, 1]], dtype=mstype.int64)
>>> values1 = Tensor([3, 4], dtype=mstype.int32)
>>> shape1 = (3, 4)
>>> input1 = COOTensor(indics1, values1, shape1)
>>> thres = Tensor(0, dtype=mstype.int32)
>>> out = ops.coo_add(input0, input1, thres)
>>> print(out)
COOTensor(shape=[3, 4], dtype=Int32, indices=Tensor(shape=[4, 2], dtype=Int64, value=
[[0 0]
 [0 1]
 [1 1]
 [1 2]]), values=Tensor(shape=[4], dtype=Int32, value=[3 1 4 2]))
```

mindspore.ops.coo_asin

mindspore.ops.**coo_asin**(*x:* COOTensor)

Computes arcsine of input coo_tensors element-wise.

$$out_i = \sin^{-1}(x_i)$$

Parameters

x (COOTensor) –Input COOTensor. The shape of COOTensor is $(N, *)$, where $*$ means any number of additional dimensions. The data type should be one of the following types: float16, float32, float64, complex64, complex128.

Returns

COOTensor, has the same shape and dtype as x.

Raises

- **TypeError** –If x is not a COOTensor.
- **TypeError** –If dtype of x is not float16, float32, float64, complex64, complex128.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_asin(x)
>>> print(output.values)
[-1.5707964        nan]
```

mindspore.ops.coo_asinh

mindspore.ops.**coo_asinh**(*x:* COOTensor)

Computes inverse hyperbolic sine of the input element-wise.

$$out_i = \sinh^{-1}(input_i)$$

Parameters

x (COOTensor) – The input COOTensor of inverse hyperbolic sine function.

Returns

COOTensor, has the same shape and type as *x*.

Raises

TypeError – If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_asinh(x)
>>> print(output.values)
[-0.8813736  1.4436355]
```

mindspore.ops.coo_atan

mindspore.ops.**coo_atan**(*x:* COOTensor)

Computes the trigonometric inverse tangent of the input element-wise.

$$out_i = \tan^{-1}(x_i)$$

Parameters

x (COOTensor) –The data type should be one of the following types: float16, float32.

Returns

A COOTensor, has the same type as the input.

Raises

- **TypeError** –If *x* is not a COOTensor.
- **TypeError** –If dtype of *x* is not float16 or float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_atan(x)
>>> print(output.values)
[-0.7853982  1.1071488]
```

mindspore.ops.coo_atanh

mindspore.ops.**coo_atanh**(*x:* COOTensor)

Computes inverse hyperbolic tangent of the input element-wise.

$$out_i = \tanh^{-1}(x_i)$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

x (COOTensor) –Input COOTensor. The data type should be one of the following types: float16, float32.

Returns

A COOTensor, has the same type as the input.

Raises

- **TypeError** – If *x* is not a COOTensor.
- **TypeError** – If dtype of *x* is not float16 or float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_atanh(x)
>>> print(output.values)
[-inf  nan]
```

mindspore.ops.coo_ceil

mindspore.ops.**coo_ceil**(*x:* COOTensor)

Rounds a COOTensor up to the closest integer element-wise.

$$out_i = \lceil x_i \rceil = \lfloor x_i \rfloor + 1$$

Parameters

x (COOTensor) – The input COOTensor with a dtype of float16 or float32.

Returns

COOTensor, has the same shape as the *x*.

Raises

- **TypeError** – If *x* is not a COOTensor.
- **TypeError** – If dtype of *x* is not float16 or float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_ceil(x)
>>> print(output.values)
[-1.  2.]
```

mindspore.ops.coo_concat

mindspore.ops.**coo_concat**(*sp_input*, *concat_dim=0*)

concatenates the input SparseTensor(COO format) along the specified dimension.

> **Warning:** This is an experimental API that is subjected to change or deletion. Only supported on CPU now.

Parameters

- **sp_input** (*Union[list(COOTensor), tuple(COOTensor)]*) – for COOTensor input.
- **concat_dim** (*scalar*) – decide the dimension to concatenation along. The value must be in range [-rank, rank), where rank is the number of dimensions in each input SparseTensor. Default is 0.

Returns

- **output** (COOtensor) - the result of concatenates the input SparseTensor along the specified dimension. OutShape: OutShape[non concat_dim] is equal to InShape[non concat_dim] and OutShape[concat_dim] is all input concat_dim axis shape accumulate.

Raises

- **ValueError** – If only one sparse tensor input.
- **ValueError** – If Input COOTensor shape dim > 3. COOtensor shape dim size must be 2 now.

Supported Platforms:

CPU

Examples

```
>>> from mindspore import Tensor, ops, COOTensor
>>> from mindspore import dtype as mstype
>>> indices0 = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values0 = Tensor([1, 2], dtype=mstype.int32)
>>> shape0 = (3, 4)
>>> input0 = COOTensor(indices0, values0, shape0)
>>> indices1 = Tensor([[0, 0], [1, 1]], dtype=mstype.int64)
>>> values1 = Tensor([3, 4], dtype=mstype.int32)
>>> shape1 = (3, 4)
>>> input1 = COOTensor(indices1, values1, shape1)
>>> concat_dim = 1
>>> out = ops.coo_concat((input0, input1), concat_dim)
>>> print(out)
COOTensor(shape=[3, 8], dtype=Int32, indices=Tensor(shape=[4, 2], dtype=Int64, value=
[[0 1]
 [0 4]
 [1 2]
 [1 5]]), values=Tensor(shape=[4], dtype=Int32, value=[1 3 2 4]))
```

mindspore.ops.coo_cos

mindspore.ops.**coo_cos**(*x:* COOTensor)

Computes cosine of input element-wise.

$$out_i = \cos(x_i)$$

Warning: If use float64, there may be a problem of missing precision.

Parameters

x (COOTensor) – Input COOTensor.

Returns

COOTensor, has the same shape and dtype as *x*.

Raises

- **TypeError** – If *x* is not a COOTensor.
- **TypeError** – If dtype of *x* is not float16, float32 or float64, complex64, complex128.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_cos(x)
>>> print(output.values)
[ 0.5403023  -0.41614684]
```

mindspore.ops.coo_cosh

mindspore.ops.**coo_cosh**(*x:* COOTensor)

Computes hyperbolic cosine of input element-wise.

$$out_i = \cosh(x_i)$$

Parameters

x (COOTensor) – The input COOTensor of hyperbolic cosine function, its data type must be float16, float32, float64, complex64 or complex128.

Returns

COOTensor, has the same shape as *x*.

Raises

- **TypeError** – If the dtype of *x* is not one of the following types: float16, float32, float64, complex64, complex128.
- **TypeError** – If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_cosh(x)
>>> print(output.values)
[1.5430807 3.7621956]
```

mindspore.ops.coo_exp

mindspore.ops.**coo_exp**(*x:* COOTensor)

Returns the element-wise exponential of a COOTensor.

$$out_i = e^{x_i}$$

Parameters

x (COOTensor) – The input COOTensor.

Returns

COOTensor, has the same shape and dtype as the *x*.

Raises

TypeError – If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_exp(x)
>>> print(output.values)
[0.36787948 7.3890557 ]
```

mindspore.ops.coo_expm1

mindspore.ops.**coo_expm1**(*x:* COOTensor)

Returns exponential then minus 1 of a COOTensor element-wise.

$$out_i = e^{x_i} - 1$$

Parameters

x (COOTensor) –The input COOTensor with a dtype of float16 or float32.

Returns

COOTensor, has the same shape as the *x*.

Raises

- **TypeError** –If *x* is not a COOTensor.
- **TypeError** –If dtype of *x* is neither float16 nor float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_expm1(x)
>>> print(output.values)
[-0.63212055  6.389056  ]
```

mindspore.ops.coo_floor

mindspore.ops.**coo_floor**(*x:* COOTensor)

Rounds a COOTensor down to the closest integer element-wise.

$$out_i = \lfloor x_i \rfloor$$

Parameters

x (COOTensor) –The input COOTensor, its data type must be float16, float32 or float64.

Returns

COOTensor, has the same shape as *x*.

Raises

- **TypeError** –If *x* is not a COOTensor.
- **TypeError** –If dtype of *x* is not in [float16, float32, float64].

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_floor(x)
>>> print(output.values)
[-1.  2.]
```

mindspore.ops.coo_inv

mindspore.ops.**coo_inv**(*x:* COOTensor)

Computes Reciprocal of input COOTensor element-wise.

$$out_i = \frac{1}{x_i}$$

Parameters

x (COOTensor) – Input COOTensor. Must be one of the following types: float16, float32 or int32.

Returns

COOTensor, has the same type and shape as input shape value.

Raises

- **TypeError** – If *x* is not a COOTensor.
- **TypeError** – If dtype of *x* is not one of float16, float32, int32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_inv(x)
>>> print(output.values)
[-1.   0.5]
```

mindspore.ops.coo_isfinite

mindspore.ops.**coo_isfinite**(*x:* COOTensor)

Determines which elements are finite for each position.

$$out_i = \begin{cases} \text{if } x_i = \text{Finite}, & True \\ \text{if } x_i \neq \text{Finite}, & False \end{cases}$$

Parameters

x (COOTensor) –The input COOTensor.

Returns

COOTensor, has the same shape of input, and the dtype is bool.

Raises

TypeError –If x is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_isfinite(x)
>>> print(output.values)
[ True  True]
```

mindspore.ops.coo_isinf

mindspore.ops.**coo_isinf**(*x:* COOTensor)

Determines which elements are inf or -inf for each position.

$$out_i = \begin{cases} \text{if } x_i = \text{Inf}, & True \\ \text{if } x_i \neq \text{Inf}, & False \end{cases}$$

where Inf means infinitity or negative infinitity.

Parameters

x (COOTensor) –The input COOTensor.

Returns

COOTensor, has the same shape of input, and the dtype is bool.

Raises

TypeError –If x is not a COOTensor.

Supported Platforms:

GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_isinf(x)
>>> print(output.values)
[False False]
```

mindspore.ops.coo_isnan

mindspore.ops.**coo_isnan**(*x:* COOTensor)

Determines which elements are NaN for each position.

$$out_i = \begin{cases} True, & \text{if } x_i = \text{Nan} \\ False, & \text{if } x_i \neq \text{Nan} \end{cases}$$

where Nan means not a number.

Parameters

x (COOTensor) – The input COOTensor.

Returns

COOTensor, has the same shape of input, and the dtype is bool.

Raises

TypeError – If x is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_isnan(x)
>>> print(output.values)
[False False]
```

mindspore.ops.coo_log

mindspore.ops.**coo_log**(*x:* COOTensor)

Returns the natural logarithm of a COOTensor element-wise.

$$y_i = \log_e(x_i)$$

Warning: If the input value of operator Log is within the range (0, 0.01] or [0.95, 1.05], the output accuracy may be affacted.

Parameters

x (COOTensor) –The value must be greater than 0.

Returns

COOTensor, has the same shape and dtype as the *x*.

Raises

- **TypeError** –If *x* is not a COOTensor.
- **TypeError** –If dtype of *x* is not float16, float32 or float64 on GPU and CPU.
- **TypeError** –If dtype of *x* is not float16 or float32 on Ascend.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_log(x)
>>> print(output.values)
[       nan 0.69314575]
```

mindspore.ops.coo_log1p

mindspore.ops.**coo_log1p**(*x:* COOTensor)

Returns the natural logarithm of one plus the input COOTensor element-wise.

$$out_i = \log\_e(x_i + 1)$$

Parameters

x (COOTensor) –The input COOTensor, should have dtype of float16 or float32 and its value should be greater than -1.

Returns

COOTensor, has the same shape as the *x*.

Raises

- **TypeError** – If *x* is not a COOTensor.
- **TypeError** – If dtype of *x* is neither float16 nor float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_log1p(x)
>>> print(output.values)
[    -inf 1.0986123]
```

mindspore.ops.coo_neg

`mindspore.ops.coo_neg`(*x:* COOTensor)

Returns a COOTensor with coo_negative values of the input COOTensor element-wise.

$$out_i = -x_i$$

Parameters

x (`COOTensor`) – The input COOTensor with a dtype of Number.

Returns

COOTensor, has the same shape and dtype as input *x*.

Raises

TypeError – If *x* is not a COOTensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_neg(x)
>>> print(output.values)
[ 1. -2.]
```

mindspore.ops.coo_relu

mindspore.ops.**coo_relu**(*x:* COOTensor)

Computes ReLU (Rectified Linear Unit activation function) of input coo_tensors element-wise.

It returns $\max(x,\ 0)$ element-wise. Specially, the neurons with the negative output will be suppressed and the active neurons will stay the same.

$$ReLU(x) = (x)^+ = \max(0, x)$$

Parameters

x (COOTensor) –Input COOTensor with shape $(N, *)$, where $*$ means any number of additional dimensions. Its dtype is number.

Returns

COOTensor, has the same shape and dtype as the *x*.

Raises

- **TypeError** –If dtype of *x* is not a number.
- **TypeError** –If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_relu(x)
>>> print(output.values)
[0. 2.]
```

mindspore.ops.coo_relu6

mindspore.ops.**coo_relu6**(*x:* COOTensor)

Computes ReLU (Rectified Linear Unit) upper bounded by 6 of input coo_tensors element-wise.

$$\text{ReLU6}(x) = \min(\max(0, x), 6)$$

It returns $\min(\max(0, x), 6)$ element-wise.

Parameters

x (COOTensor) –Input COOTensor, with float16 or float32 data type.

Returns

COOTensor, with the same dtype and shape as the *x*.

Raises

- **TypeError** – If dtype of *x* is neither float16 nor float32.
- **TypeError** – If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_relu6(x)
>>> print(output.values)
[0. 2.]
```

mindspore.ops.coo_round

mindspore.ops.**coo_round**(*x:* COOTensor)

Returns half to even of a COOTensor element-wise.

$$out_i \approx x_i$$

Parameters

x (COOTensor) – The input COOTensor.

Returns

COOTensor, has the same shape and type as the *x*.

Raises

TypeError – If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_round(x)
>>> print(output.values)
[-1.  2.]
```

mindspore.ops.coo_sigmoid

mindspore.ops.**coo_sigmoid**(*x:* COOTensor)

Sigmoid activation function.

Computes Sigmoid of input element-wise. The Sigmoid function is defined as:

$$\text{coo\_sigmoid}(x_i) = \frac{1}{1 + \exp(-x_i)}$$

where x_i is an element of the x.

Parameters

x (COOTensor) –Input COOTensor, the data type is float16, float32, float64, complex64 or complex128.

Returns

COOTensor, with the same type and shape as the x.

Raises

- **TypeError** –If dtype of *x* is not float16, float32, float64, complex64 or complex128.
- **TypeError** –If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_sigmoid(x)
>>> print(output.values)
[0.26894143 0.8807971 ]
```

mindspore.ops.coo_sin

mindspore.ops.**coo_sin**(*x:* COOTensor)

Computes sine of the input element-wise.

$$out_i = \sin(x_i)$$

Parameters

x (COOTensor) –Input COOTensor.

Returns

COOTensor, has the same shape and dtype as *x*.

Raises

- **TypeError** –If *x* is not a COOTensor.

- **TypeError** – If dtype of *x* is not float16, float32 or float64, complex64, complex128.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_sin(x)
>>> print(output.values)
[-0.84147096  0.9092974 ]
```

mindspore.ops.coo_sinh

mindspore.ops.**coo_sinh**(*x:* COOTensor)

Computes hyperbolic sine of the input element-wise.

$$out_i = \sinh(x_i)$$

Parameters

x (COOTensor) – The input COOTensor of hyperbolic sine function.

Returns

COOTensor, has the same shape as *x*.

Raises

TypeError – If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_sinh(x)
>>> print(output.values)
[-1.1752012  3.6268604]
```

mindspore.ops.coo_softsign

mindspore.ops.**coo_softsign**(*x:* COOTensor)

Softsign activation function.

The function is shown as follows:

$$\text{SoftSign}(x) = \frac{x}{1 + |x|}$$

Parameters

x (COOTensor) – Input COOTensor, with float16 or float32 data type.

Returns

COOTensor, with the same type and shape as the *x*.

Raises

- **TypeError** – If *x* is not a COOTensor.
- **TypeError** – If dtype of *x* is neither float16 nor float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_softsign(x)
>>> print(output.values)
[-0.5        0.6666667]
```

mindspore.ops.coo_sqrt

mindspore.ops.**coo_sqrt**(*x:* COOTensor)

Computes sqrt of a COOTensor element-wise.

$$out_i = \sqrt{x_i}$$

Parameters

x (COOTensor) – The input COOTensor with a dtype of Number.

Returns

COOTensor, has the same shape and dtype as the *x*.

Raises

TypeError – If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_sqrt(x)
>>> print(output.values)
[      nan 1.4142135]
```

mindspore.ops.coo_square

mindspore.ops.**coo_square**(*x:* COOTensor)

Returns square of a COOTensor element-wise.

$$out_i = (x_i)^2$$

Parameters

x (COOTensor) – The input COOTensor with a dtype of Number.

Returns

COOTensor, has the same shape and dtype as the *x*.

Raises

TypeError – If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_square(x)
>>> print(output.values)
[1. 4.]
```

mindspore.ops.coo_tan

mindspore.ops.**coo_tan**(*x:* COOTensor)

Computes tangent of *x* element-wise.

$$out_i = \tan(x_i)$$

Parameters

x (COOTensor) –The input COOTensor.

Returns

COOTensor, has the same shape as *x*.

Raises

TypeError –If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_tan(x)
>>> print(output.values)
[-1.5574077 -2.1850398]
```

mindspore.ops.coo_tanh

mindspore.ops.**coo_tanh**(*x:* COOTensor)

Computes hyperbolic tangent of input element-wise. The Tanh function is defined as:

$$tanh(x_i) = \frac{\exp(x_i) - \exp(-x_i)}{\exp(x_i) + \exp(-x_i)} = \frac{\exp(2x_i) - 1}{\exp(2x_i) + 1},$$

where x_i is an element of the input COOTensor.

Parameters

x (COOTensor) –Input COOTensor, with float16 or float32 data type.

Returns

COOTensor, with the same type and shape as the *x*.

Raises

- **TypeError** –If dtype of *x* is neither float16 nor float32.
- **TypeError** –If *x* is not a COOTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, COOTensor
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mstype.int64)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = COOTensor(indices, values, shape)
>>> output = ops.coo_tanh(x)
>>> print(output.values)
[-0.7615942  0.9640276]
```

2.7.5 CSR Functions

Warning: These are experimental APIs that are subject to change or deletion.

API Name	Description	Supported Platforms
mindspore.ops.csr_abs	Returns csr_absolute value of a CSRTensor element-wise.	Ascend GPU CPU
mindspore.ops.csr_acos	Computes arccosine of input csr_tensors element-wise.	Ascend GPU CPU
mindspore.ops.csr_acosh	Computes inverse hyperbolic cosine of the inputs element-wise.	Ascend GPU CPU
mindspore.ops.csr_add	Computes the linear combination of two input CSRTensors a and b.	GPU CPU
mindspore.ops.csr_asin	Computes arcsine of input csr_tensors element-wise.	Ascend GPU CPU
mindspore.ops.csr_asinh	Computes inverse hyperbolic sine of the input element-wise.	Ascend GPU CPU
mindspore.ops.csr_atan	Computes the trigonometric inverse tangent of the input element-wise.	Ascend GPU CPU
mindspore.ops.csr_atanh	Computes inverse hyperbolic tangent of the input element-wise.	Ascend GPU CPU
mindspore.ops.csr_ceil	Rounds a CSRTensor up to the closest integer element-wise.	Ascend GPU CPU
mindspore.ops.csr_cos	Computes cosine of input element-wise.	Ascend GPU CPU
mindspore.ops.csr_cosh	Computes hyperbolic cosine of input element-wise.	Ascend GPU CPU
mindspore.ops.csr_exp	Returns csr_exponential of a CSRTensor element-wise.	Ascend GPU CPU
mindspore.ops.csr_expm1	Returns exponential then minus 1 of a CSRTensor element-wise.	Ascend GPU CPU
mindspore.ops.csr_floor	Rounds a CSRTensor down to the closest integer element-wise.	Ascend GPU CPU
mindspore.ops.csr_inv	Computes Reciprocal of input CSRTensor element-wise.	Ascend GPU CPU
mindspore.ops.csr_isfinite	Determines which elements are finite for each position.	Ascend GPU CPU
mindspore.ops.csr_isinf	Determines which elements are inf or -inf for each position.	GPU CPU

continues on next page

Table 23 – continued from previous page

mindspore.ops.csr_isnan	Determines which elements are NaN for each position.	Ascend GPU CPU
mindspore.ops.csr_log	Returns the natural logarithm of a CSRTensor element-wise.	Ascend GPU CPU
mindspore.ops.csr_log1p	Returns the natural logarithm of one plus the input CSRTensor element-wise.	Ascend GPU CPU
mindspore.ops.csr_mm	Return the matrix multiplication result of the right-multiply matrix (dense or CSRTensor) of the CSRTensor.	GPU
mindspore.ops.csr_neg	Returns a CSRTensor with csr_negative values of the input CSRTensor element-wise.	Ascend GPU CPU
mindspore.ops.csr_relu	Computes ReLU (Rectified Linear Unit activation function) of input csr_tensors element-wise.	Ascend GPU CPU
mindspore.ops.csr_relu6	Computes ReLU (Rectified Linear Unit) upper bounded by 6 of input csr_tensors element-wise.	Ascend GPU CPU
mindspore.ops.csr_round	Returns half to even of a CSRTensor element-wise.	Ascend GPU CPU
mindspore.ops.csr_sigmoid	Sigmoid activation function.	Ascend GPU CPU
mindspore.ops.csr_sin	Computes sine of the input element-wise.	Ascend GPU CPU
mindspore.ops.csr_sinh	Computes hyperbolic sine of the input element-wise.	Ascend GPU CPU
mindspore.ops.csr_softmax	Calculates the softmax of a CSRTensorMatrix.	GPU CPU
mindspore.ops.csr_softsign	Softsign activation function.	Ascend GPU CPU
mindspore.ops.csr_sqrt	Returns sqrt of a CSRTensor element-wise.	Ascend GPU CPU
mindspore.ops.csr_square	Returns square of a CSRTensor element-wise.	Ascend GPU CPU
mindspore.ops.csr_tan	Computes tangent of x element-wise.	Ascend GPU CPU
mindspore.ops.csr_tanh	Computes hyperbolic tangent of input element-wise.	Ascend GPU CPU

mindspore.ops.csr_abs

mindspore.ops.**csr_abs**(*x:* CSRTensor)

Returns csr_absolute value of a CSRTensor element-wise.

$$out_i = |x_i|$$

Parameters

x (CSRTensor) – The input CSRTensor.

Returns

CSRTensor, has the same shape as the x.

Raises

TypeError – If x is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_abs(x)
>>> print(output.values)
[1. 2.]
```

mindspore.ops.csr_acos

mindspore.ops.**csr_acos**(*x:* CSRTensor)

Computes arccosine of input csr_tensors element-wise.

$$out_i = \cos^{-1}(x_i)$$

Parameters

x (CSRTensor) – Input CSRTensor.

Returns

CSRTensor, has the same shape and dtype as *x*.

Raises

- **TypeError** – If *x* is not a CSRTensor.
- **TypeError** – If dtype of *x* is not float16, float32 or float64, complex64, complex128.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_acos(x)
>>> print(output.values)
[3.1415927       nan]
```

mindspore.ops.csr_acosh

mindspore.ops.**csr_acosh**(*x:* CSRTensor)

Computes inverse hyperbolic cosine of the inputs element-wise.

$$out_i = \cosh^{-1}(input_i)$$

Parameters

x (CSRTensor) –The input CSRTensor of inverse hyperbolic cosine function, i.e. $input_i$, its element must be in range [1, inf].

Returns

CSRTensor, has the same shape and type as *x*.

Raises

TypeError –If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_acosh(x)
>>> print(output.values)
[     nan 1.316958]
```

mindspore.ops.csr_add

mindspore.ops.**csr_add**(*a:* CSRTensor, *b:* CSRTensor, *alpha:* Tensor, *beta:* Tensor)

Computes the linear combination of two input CSRTensors a and b.

$$out = alpha * a + beta * b$$

where both a and b are CSRTensor, $alpha$ and $beta$ are both Tensor

---

Note: The user need to ensure that the input sparse matrix is legal. Otherwise, the behavior of the operator is undefined. For example, when there are multiple elements in the same position, the operator may return an error of fail execute.

Parameters

- **a** (CSRTensor) –Input sparse CSRTensor.
- **b** (CSRTensor) –Input sparse CSRTensor.
- **alpha** (Tensor) –Dense Tensor, its shape must be able to broadcast to a.

- **beta** (Tensor) –Dense Tensor, its shape must be able to broadcast to b.

Returns

CSRTensor, a CSRTensor containing the following parts.

- **indptr** - Indicates the start and end point for non-zero values in each row.
- **indices** - The column positions of all non-zero values of the input.
- **values** - The non-zero values.
- **shape** - The shape of the CSRTensor.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.common.dtype as mstype
>>> from mindspore import Tensor, CSRTensor
>>> from mindspore import ops
>>> a_indptr = Tensor([0, 1, 2], dtype=mstype.int32)
>>> a_indices = Tensor([0, 1], dtype=mstype.int32)
>>> a_values = Tensor([1, 2], dtype=mstype.float32)
>>> shape = (2, 6)
>>> b_indptr = Tensor([0, 1, 2], dtype=mstype.int32)
>>> b_indices = Tensor([0, 1], dtype=mstype.int32)
>>> b_values = Tensor([1, 2], dtype=mstype.float32)
>>> alpha = Tensor(1, mstype.float32)
>>> beta = Tensor(1, mstype.float32)
>>> csra = CSRTensor(a_indptr, a_indices, a_values, shape)
>>> csrb = CSRTensor(b_indptr, b_indices, b_values, shape)
>>> out = ops.csr_add(csra, csrb, alpha, beta)
>>> print(out)
CSRTensor(shape=[2, 6], dtype=Float32,                    indptr=Tensor(shape=[3],␣
↪dtype=Int32, value=[0 1 2]),                    indices=Tensor(shape=[2], dtype=Int32,␣
↪value=[0 1]),                    values=Tensor(shape=[2], dtype=Float32, value=[ 2.
↪00000000e+00  4.00000000e+00]))
```

mindspore.ops.csr_asin

mindspore.ops.**csr_asin**(*x:* CSRTensor)

Computes arcsine of input csr_tensors element-wise.

$$out_i = \sin^{-1}(x_i)$$

Parameters

x (CSRTensor) –Input CSRTensor. The data types should be one of the following types: float16, float32, float64.

Returns

CSRTensor, has the same shape and dtype as *x*.

Raises

- **TypeError** –If *x* is not a CSRTensor.
- **TypeError** –If dtype of *x* is not float16, float32, float64.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_asin(x)
>>> print(output.values)
[-1.5707964        nan]
```

mindspore.ops.csr_asinh

mindspore.ops.**csr_asinh**(*x:* CSRTensor)

Computes inverse hyperbolic sine of the input element-wise.

$$out_i = \sinh^{-1}(input_i)$$

Parameters

x (CSRTensor) –The input CSRTensor of inverse hyperbolic sine function, i.e. $input_i$.

Returns

CSRTensor, has the same shape and type as *x*.

Raises

TypeError –If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_asinh(x)
>>> print(output.values)
[-0.8813736  1.4436355]
```

mindspore.ops.csr_atan

mindspore.ops.**csr_atan**(*x:* CSRTensor)

Computes the trigonometric inverse tangent of the input element-wise.

$$out_i = \tan^{-1}(x_i)$$

Parameters

x (CSRTensor) – The data type should be one of the following types: float16, float32.

Returns

A CSRTensor, has the same type as the input.

Raises

- **TypeError** – If *x* is not a CSRTensor.
- **TypeError** – If dtype of *x* is not float16 or float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_atan(x)
>>> print(output.values)
[-0.7853982  1.1071488]
```

mindspore.ops.csr_atanh

mindspore.ops.**csr_atanh**(*x:* CSRTensor)

Computes inverse hyperbolic tangent of the input element-wise.

$$out_i = \tanh^{-1}(x_i)$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

x (CSRTensor) – Input CSRTensor. The shape is $(N, *)$ where $*$ means, any number of additional dimensions. The data type should be one of the following types: float16, float32.

Returns

A CSRTensor, has the same type as the input.

Raises

- **TypeError** – If x is not a CSRTensor.
- **TypeError** – If dtype of x is not float16 or float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_atanh(x)
>>> print(output.values)
[-inf  nan]
```

mindspore.ops.csr_ceil

mindspore.ops.**csr_ceil**(*x: CSRTensor*)

Rounds a CSRTensor up to the closest integer element-wise.

$$out_i = \lceil x_i \rceil = \lfloor x_i \rfloor + 1$$

Parameters

x (CSRTensor) – The input CSRTensor with a dtype of float16 or float32.

Returns

CSRTensor, has the same shape as the x.

Raises

- **TypeError** – If x is not a CSRTensor.
- **TypeError** – If dtype of x is not float16 or float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_ceil(x)
>>> print(output.values)
[-1.  2.]
```

mindspore.ops.csr_cos

mindspore.ops.**csr_cos**(*x:* CSRTensor)

Computes cosine of input element-wise.

$$out_i = \cos(x_i)$$

Warning: Currently support data types float16 and float32. If use float64, there may be a problem of missing precision.

Parameters

x (CSRTensor) – Input CSRTensor.

Returns

CSRTensor, has the same shape and dtype as *x*.

Raises

- **TypeError** – If *x* is not a CSRTensor.
- **TypeError** – If dtype of *x* is not float16, float32 or float64, complex64, complex128.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_cos(x)
>>> print(output.values)
[ 0.5403023  -0.41614684]
```

mindspore.ops.csr_cosh

mindspore.ops.**csr_cosh**(*x:* CSRTensor)

Computes hyperbolic cosine of input element-wise.

$$out_i = \cosh(x_i)$$

Parameters

x (CSRTensor) –The input CSRTensor of hyperbolic cosine function, its data type must be float16, float32, float64, complex64 or complex128.

Returns

CSRTensor, has the same shape as *x*.

Raises

- **TypeError** –If the dtype of *x* is not one of the following types: float16, float32, float64, complex64, complex128.
- **TypeError** –If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_cosh(x)
>>> print(output.values)
[1.5430807 3.7621956]
```

mindspore.ops.csr_exp

mindspore.ops.**csr_exp**(*x:* CSRTensor)

Returns csr_exponential of a CSRTensor element-wise.

$$out_i = e^{x_i}$$

Parameters

x (CSRTensor) –The input CSRTensor.

Returns

CSRTensor, has the same shape and dtype as the *x*.

Raises

TypeError –If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_exp(x)
>>> print(output.values)
[0.36787948 7.3890557 ]
```

mindspore.ops.csr_expm1

mindspore.ops.**csr_expm1**(*x: CSRTensor*)

Returns exponential then minus 1 of a CSRTensor element-wise.

$$out_i = e^{x_i} - 1$$

Parameters

x (CSRTensor) – The input CSRTensor with a dtype of float16 or float32.

Returns

CSRTensor, has the same shape as the *x*.

Raises

- **TypeError** – If *x* is not a CSRTensor.
- **TypeError** – If dtype of *x* is neither float16 nor float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_expm1(x)
>>> print(output.values)
[-0.63212055  6.389056  ]
```

mindspore.ops.csr_floor

mindspore.ops.**csr_floor**(*x:* CSRTensor)

Rounds a CSRTensor down to the closest integer element-wise.

$$out_i = \lfloor x_i \rfloor$$

Parameters

x (CSRTensor) – The input CSRTensor, its data type must be float16, float32 or float64.

Returns

CSRTensor, has the same shape as *x*.

Raises

- **TypeError** – If *x* is not a CSRTensor.
- **TypeError** – If dtype of *x* is not in [float16, float32, float64].

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_floor(x)
>>> print(output.values)
[-1.  2.]
```

mindspore.ops.csr_inv

mindspore.ops.**csr_inv**(*x:* CSRTensor)

Computes Reciprocal of input CSRTensor element-wise.

$$out_i = \frac{1}{x_i}$$

Parameters

x (CSRTensor) – Input CSRTensor. Must be one of the following types: float16, float32 or int32.

Returns

CSRTensor, has the same type and shape as input shape value.

Raises

- **TypeError** – If *x* is not a CSRTensor.
- **TypeError** – If dtype of *x* is not one of float16, float32, int32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_inv(x)
>>> print(output.values)
[-1.   0.5]
```

mindspore.ops.csr_isfinite

mindspore.ops.**csr_isfinite**(*x:* CSRTensor)

Determines which elements are finite for each position.

$$out_i = \begin{cases} \text{if } x_i = \text{Finite}, & True \\ \text{if } x_i \neq \text{Finite}, & False \end{cases}$$

Parameters

x (CSRTensor) – The input CSRTensor.

Returns

CSRTensor, has the same shape of input, and the dtype is bool.

Raises

TypeError – If x is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_isfinite(x)
>>> print(output.values)
[ True  True]
```

mindspore.ops.csr_isinf

mindspore.ops.**csr_isinf**(*x:* CSRTensor)

Determines which elements are inf or -inf for each position.

$$out_i = \begin{cases} \text{if } x_i = \text{Inf}, & True \\ \text{if } x_i \neq \text{Inf}, & False \end{cases}$$

where Inf means not a number.

Parameters

x (CSRTensor) –The input CSRTensor.

Returns

CSRTensor, has the same shape of input, and the dtype is bool.

Raises

TypeError –If x is not a CSRTensor.

Supported Platforms:

GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_isinf(x)
>>> print(output.values)
[False False]
```

mindspore.ops.csr_isnan

mindspore.ops.**csr_isnan**(*x:* CSRTensor)

Determines which elements are NaN for each position.

$$out_i = \begin{cases} True, & \text{if } x_i = \text{NaN} \\ False, & \text{if } x_i \neq \text{NaN} \end{cases}$$

where NaN means not a number.

Parameters

x (CSRTensor) –The input CSRTensor.

Returns

CSRTensor, has the same shape of input, and the dtype is bool.

Raises

TypeError –If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_isnan(x)
>>> print(output.values)
[False False]
```

mindspore.ops.csr_log

mindspore.ops.**csr_log**(*x:* CSRTensor)

Returns the natural logarithm of a CSRTensor element-wise.

$$y_i = \log_e(x_i)$$

Warning: If the input value of operator Log is within the range (0, 0.01] or [0.95, 1.05], the output accuracy may be affacted.

Parameters

x (CSRTensor) –Input CSRTensor of any dimension. If the value is smaller than 0, return nan.

Returns

CSRTensor, has the same shape and dtype as the *x*.

Raises

- **TypeError** –If *x* is not a CSRTensor.
- **TypeError** –If dtype of *x* is not float16, float32 or float64 on GPU and CPU.
- **TypeError** –If dtype of *x* is not float16 or float32 on Ascend.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_log(x)
>>> print(output.values)
[       nan 0.69314575]
```

mindspore.ops.csr_log1p

mindspore.ops.**csr_log1p**(*x: CSRTensor*)

Returns the natural logarithm of one plus the input CSRTensor element-wise.

$$out_i = \log\_e(x_i + 1)$$

Parameters

x (CSRTensor) – The input CSRTensor. With float16 or float32 data type. The value must be greater than -1.

Returns

CSRTensor, has the same shape as the *x*.

Raises

- **TypeError** – If *x* is not a CSRTensor.
- **TypeError** – If dtype of *x* is neither float16 nor float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_log1p(x)
>>> print(output.values)
[     -inf 1.0986123]
```

mindspore.ops.csr_mm

mindspore.ops.**csr_mm**(*a:* CSRTensor, *b:* CSRTensor, *trans_a:* *bool* = *False*, *trans_b:* *bool* = *False*, *adjoint_a:* *bool* = *False*, *adjoint_b:* *bool* = *False*)

Return the matrix multiplication result of the right-multiply matrix (dense or CSRTensor) of the CSRTensor. The CSRTensor with shape *[M, N]* needs to adapt the right matrix with shape *[N, K]* to get the dense matrix or CSRTensor with result *[M, K]*.

Note: If right matrix is CSRTensor, currently only supports GPU backend. If right matrix is Tensor, currently supports CPU backend with LLVM no lower than 12.0.1, and GPU backend.

Parameters

- **a** (CSRTensor) –Sparse CSR Tensor, rank should be 2.
- **b** (CSRTensor) –Sparse CSR Tensor, rank should be 2.
- **trans_a** (*bool, optional*) –whether to transpose CSRTensor a. Default: `False` .
- **trans_b** (*bool, optional*) –whether to transpose CSRTensor b. Default: `False` .
- **adjoint_a** (*bool, optional*) –whether to adjoint CSRTensor a. Default: `False` .
- **adjoint_b** (*bool, optional*) –whether to adjoint CSRTensor b. Default: `False` .

Returns

CSRTensor.

Supported Platforms:

`GPU`

Examples

```
>>> from mindspore import Tensor, CSRTensor
>>> from mindspore import dtype as mstype
>>> from mindspore import ops
>>> a_shape = (4, 5)
>>> a_indptr = Tensor([0, 1, 1, 3, 4], dtype=mstype.int32)
>>> a_indices = Tensor([0, 3, 4, 0],dtype=mstype.int32)
>>> a_values = Tensor([1.0, 5.0, -1.0, -2.0], dtype=mstype.float32)
>>> b_shape = (5, 3)
>>> b_indptr = Tensor([0, 1, 1, 3, 3, 3], dtype=mstype.int32)
>>> b_indices = Tensor([0, 0, 1],dtype=mstype.int32)
>>> b_values = Tensor([2.0, 7.0, 8.0], dtype=mstype.float32)
>>> a = CSRTensor(a_indptr, a_indices, a_values, a_shape)
>>> b = CSRTensor(b_indptr, b_indices, b_values, b_shape)
>>> c = ops.csr_mm(a, b)
>>> print(c.shape)
(4, 3)
>>> print(c.values)
[2. -4.]
>>> print(c.indptr)
[0 1 1 1 2]
>>> print(c.indices)
[0 0]
```

mindspore.ops.csr_neg

mindspore.ops.**csr_neg**(*x:* CSRTensor)

Returns a CSRTensor with csr_negative values of the input CSRTensor element-wise.

$$out_i = -x_i$$

Parameters

x (CSRTensor) – The input CSRTensor with a dtype of Number.

Returns

CSRTensor, has the same shape and dtype as input.

Raises

TypeError – If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_neg(x)
>>> print(output.values)
[ 1. -2.]
```

mindspore.ops.csr_relu

mindspore.ops.**csr_relu**(*x:* CSRTensor)

Computes ReLU (Rectified Linear Unit activation function) of input csr_tensors element-wise.

It returns max(x, 0) element-wise. Specially, the neurons with the negative output will be suppressed and the active neurons will stay the same.

$$ReLU(x) = (x)^+ = \max(0, x)$$

Parameters

x (CSRTensor) – Input CSRTensor.

Returns

CSRTensor, with the same dtype and shape as the *x*.

Raises

- **TypeError** – If dtype of *x* is not a number.
- **TypeError** – If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_relu(x)
>>> print(output.values)
[0. 2.]
```

mindspore.ops.csr_relu6

mindspore.ops.**csr_relu6**(*x:* CSRTensor)

Computes ReLU (Rectified Linear Unit) upper bounded by 6 of input csr_tensors element-wise.

$$\text{ReLU6}(x) = \min(\max(0, x), 6)$$

It returns $\min(\max(0, x), 6)$ element-wise.

Parameters

x (CSRTensor) – Input CSRTensor, with float16 or float32 data type.

Returns

CSRTensor, with the same dtype and shape as the *x*.

Raises

- **TypeError** – If dtype of *x* is neither float16 nor float32.
- **TypeError** – If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_relu6(x)
>>> print(output.values)
[0. 2.]
```

mindspore.ops.csr_round

mindspore.ops.**csr_round**(*x:* CSRTensor)

Returns half to even of a CSRTensor element-wise.

$$out_i \approx x_i$$

Parameters

x (CSRTensor) – The input CSRTensor.

Returns

CSRTensor, has the same shape and type as the *x*.

Raises

TypeError – If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_round(x)
>>> print(output.values)
[-1.  2.]
```

mindspore.ops.csr_sigmoid

mindspore.ops.**csr_sigmoid**(*x:* CSRTensor)

Sigmoid activation function.

Computes Sigmoid of input element-wise. The Sigmoid function is defined as:

$$\text{csr\_sigmoid}(x_i) = \frac{1}{1 + \exp(-x_i)}$$

where x_i is an element of the x.

Parameters

x (CSRTensor) – Input CSRTensor, the data type is float16, float32, float64, complex64 or complex128.

Returns

CSRTensor, with the same type and shape as the x.

Raises

- **TypeError** – If dtype of *x* is not float16, float32, float64, complex64 or complex128.

- **TypeError** – If *x* is not a CSRTensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_sigmoid(x)
>>> print(output.values)
[0.26894143 0.8807971 ]
```

mindspore.ops.csr_sin

`mindspore.ops.`**`csr_sin`**(*x:* CSRTensor)

Computes sine of the input element-wise.

$$out_i = \sin(x_i)$$

Parameters

x (`CSRTensor`) – Input CSRTensor.

Returns

CSRTensor, has the same shape and dtype as *x*.

Raises

- **TypeError** – If *x* is not a CSRTensor.
- **TypeError** – If dtype of *x* is not float16, float32 or float64, complex64, complex128.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_sin(x)
>>> print(output.values)
[-0.84147096  0.9092974 ]
```

mindspore.ops.csr_sinh

mindspore.ops.**csr_sinh**(*x:* CSRTensor)

Computes hyperbolic sine of the input element-wise.

$$out_i = \sinh(x_i)$$

Parameters

x (CSRTensor) –The input CSRTensor of hyperbolic sine function.

Returns

CSRTensor, has the same shape as *x*.

Raises

TypeError –If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_sinh(x)
>>> print(output.values)
[-1.1752012  3.6268604]
```

mindspore.ops.csr_softmax

mindspore.ops.**csr_softmax**(*logits:* CSRTensor, *dtype: mstype*)

Calculates the softmax of a CSRTensorMatrix.

Parameters

- **logits** (CSRTensor) –Input sparse CSRTensor.
- **dtype** (dtype) –Input data type.

Returns

CSRTensor, a CSRTensor containing

- **indptr** - Indicates the start and end point for non-zero values in each row.
- **indices** - The column positions of all non-zero values of the input.
- **values** - The non-zero values of the dense tensor.
- **shape** - The shape of the CSRTensor.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import ops
>>> import mindspore.common.dtype as mstype
>>> from mindspore import Tensor, CSRTensor
>>> logits_indptr = Tensor([0, 4, 6], dtype=mstype.int32)
>>> logits_indices = Tensor([0, 2, 3, 4, 3, 4], dtype=mstype.int32)
>>> logits_values = Tensor([1, 2, 3, 4, 1, 2], dtype=mstype.float32)
>>> shape = (2, 6)
>>> logits = CSRTensor(logits_indptr, logits_indices, logits_values, shape)
>>> out = ops.csr_softmax(logits, dtype=mstype.float32)
>>> print(out)
CSRTensor(shape=[2, 6], dtype=Float32, indptr=Tensor(shape=[3], dtype=Int32, value=[0 4 6]),
              indices=Tensor(shape=[6], dtype=Int32, value=[0 2 3 4 3 4]),
              values=Tensor(shape=[6], dtype=Float32, value=[ 3.20586003e-02  8.71443152e-
↪02  2.36882806e-01
              6.43914223e-01  2.68941432e-01  7.31058598e-01]))
```

mindspore.ops.csr_softsign

mindspore.ops.**csr_softsign**(*x:* CSRTensor)

Softsign activation function.

The function is shown as follows:

$$\text{SoftSign}(x) = \frac{x}{1 + |x|}$$

Parameters

x (CSRTensor) – Input CSRTensor, with float16 or float32 data type.

Returns

CSRTensor, with the same type and shape as the *x*.

Raises

- **TypeError** – If *x* is not a CSRTensor.
- **TypeError** – If dtype of *x* is neither float16 nor float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_softsign(x)
>>> print(output.values)
[-0.5        0.6666667]
```

mindspore.ops.csr_sqrt

mindspore.ops.**csr_sqrt**(*x:* CSRTensor)

Returns sqrt of a CSRTensor element-wise.

$$out_i = \sqrt{x_i}$$

Parameters

x (CSRTensor) – The input CSRTensor with a dtype of Number.

Returns

CSRTensor, has the same shape and dtype as the *x*.

Raises

TypeError – If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_sqrt(x)
>>> print(output.values)
[      nan 1.4142135]
```

mindspore.ops.csr_square

mindspore.ops.**csr_square**(*x:* CSRTensor)

Returns square of a CSRTensor element-wise.

$$out_i = (x_i)^2$$

Parameters

x (CSRTensor) – The input CSRTensor with a dtype of Number.

Returns

CSRTensor, has the same shape and dtype as the *x*.

Raises

TypeError – If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_square(x)
>>> print(output.values)
[1. 4.]
```

mindspore.ops.csr_tan

mindspore.ops.**csr_tan**(*x:* CSRTensor)

Computes tangent of *x* element-wise.

$$out_i = \tan(x_i)$$

Parameters

x (CSRTensor) – The input CSRTensor.

Returns

CSRTensor, has the same shape as *x*.

Raises

TypeError – If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_tan(x)
>>> print(output.values)
[-1.5574077 -2.1850398]
```

mindspore.ops.csr_tanh

mindspore.ops.**csr_tanh**(*x:* CSRTensor)

Computes hyperbolic tangent of input element-wise. The Tanh function is defined as:

$$tanh(x_i) = \frac{\exp(x_i) - \exp(-x_i)}{\exp(x_i) + \exp(-x_i)} = \frac{\exp(2x_i) - 1}{\exp(2x_i) + 1},$$

where x_i is an element of the input CSRTensor.

Parameters

x (CSRTensor) – Input CSRTensor, with float16 or float32 data type.

Returns

CSRTensor, with the same type and shape as the *x*.

Raises

- **TypeError** – If dtype of *x* is neither float16 nor float32.
- **TypeError** – If *x* is not a CSRTensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, CSRTensor
>>> indptr = Tensor([0, 1, 2, 2], dtype=mstype.int32)
>>> indices = Tensor([3, 0], dtype=mstype.int32)
>>> values = Tensor([-1, 2], dtype=mstype.float32)
>>> shape = (3, 4)
>>> x = CSRTensor(indptr, indices, values, shape)
>>> output = ops.csr_tanh(x)
>>> print(output.values)
[-0.7615942  0.9640276]
```

2.8 MC2 Functions

Warning: These are experimental APIs that are subject to change or deletion.

API Name	Description	Supported Platforms
mindspore.ops.all_gather_matmul	In the TP segmentation scenario, allgather and matmul are fused, and communication and computational pipelines are parallelized within the fusion operator.	Ascend
mindspore.ops.matmul_reduce_scatter	In the TP segmentation scenario, matmul and reducescatter are fused, and communication and computational pipelines are parallelized within the fusion operator.	Ascend

2.8.1 mindspore.ops.all_gather_matmul

mindspore.ops.**all_gather_matmul**(*input*, *x2*, *group*, *world_size*, ***, *bias=None*, *gather_index=0*, *gather_output=True*, *comm_turn=0*, *trans_input=False*, *trans_x2=False*) → *Tensor*

In the TP segmentation scenario, allgather and matmul are fused, and communication and computational pipelines are parallelized within the fusion operator.

$$output = allgather(input)@x2$$
$$gather\_out = allgather(input)$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) −The left matrix of matmul, the dtype supports float16 and bfloat16, the shape supports 2 dimensions, and the data format supports ND.
- **x2** (Tensor) −The right matrix of matmul, the dtype needs to be consistent with `input` , the shape supports 2 dimensions, and the data format supports ND.
- **group** (*str*) −Communication group name, can be created by `create_group` method, or use the default group `mindspore.communication.GlobalComm.WORLD_COMM_GROUP`.
- **world_size** (*int*) −The total number of ranks in the communication group, should be consistent with the number of devices actually running, supporting `2` , `4` , and `8` .

Keyword Arguments

- **bias** (Tensor, *optional*) −Currently only `None` is supported. Default: `None` .
- **gather_index** (int, *optional*) −Indicates the allgather operation object, `0` means gather `input` , `1` means gather `x2` . Currently only `0` is supported. Default: `0` .
- **gather_output** (bool, *optional*) −Indicates whether gather output is required. Default: `True` .
- **comm_turn** (int, *optional*) −Indicates the granularity of communication between ranks. Currently only `0` is supported. Default: `0` .

- **trans_input** (bool, *optional*) –Indicates whether input is transposed. Currently only False is supported. Default: False .
- **trans_x2** (bool, *optional*) –Indicates whether x2 is transposed. Default: False .

Returns

- output (Tensor) - The result of allgather and matmul fusion calculations.
- gather_out (Tensor) - The result of allgather. If gather_output is False , gather_out returns a tensor with shape 0.

Note:

- When using this interface, please ensure that the driver firmware package and CANN package are both the matching 8.0.RC2 version or a higher version, otherwise an error will be reported, such as BUS ERROR.
- The shape of input is (m, k), the shape of x2 is (k, n), k is required to be equal, and the value range of k is [256, 65535). The shape of output is (m * world_size, n), and the shape of gather_out is (m * world_size, k).
- The common fusion operators in a model only support the same communication group.

Raises

- **TypeError** –Any arg is of wrong type.
- **RuntimeError** –The dtype of input or x2 is neither float16 nor bfloat16.
- **RuntimeError** –The dtypes of input and x2 are different.
- **RuntimeError** –The shape of input or x2 is not two-dimensional.
- **RuntimeError** –The k axis of input shape and x2 shape are not equal.
- **RuntimeError** –k is less than 256 or greater than or equal to 65535 .
- **RuntimeError** –bias is not None.
- **RuntimeError** –group does not exist.
- **RuntimeError** –world_size is inconsistent with the actual number of running cards.
- **RuntimeError** –world_size is not equal to 2 , 4 , or 8 .
- **RuntimeError** –gather_index is not 0 .
- **RuntimeError** –trans_input is True .

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import ops
>>> ms.communication.init()
>>> rank = ms.communication.get_rank()
>>> np.random.seed(rank)
>>> input = ms.Tensor(np.random.randn(128, 256).astype(np.float32), dtype=ms.float16)
>>> x2 = ms.Tensor(np.random.randn(256, 512).astype(np.float32), dtype=ms.float16)
>>> group = ms.communication.GlobalComm.WORLD_COMM_GROUP
>>> world_size = ms.communication.get_group_size()
>>> output, gather_out = ops.all_gather_matmul(
...     input,
...     x2,
...     group,
...     world_size,
...     bias=None,
...     gather_index=0,
...     gather_output=True,
...     comm_turn=0,
...     trans_input=False,
...     trans_x2=False,
... )
>>> print(output.shape)
(256, 512)
>>> print(gather_out.shape)
(256, 256)
```

2.8.2 mindspore.ops.matmul_reduce_scatter

mindspore.ops.**matmul_reduce_scatter**(*input*, *x2*, *group*, *world_size*, *, *reduce_op='sum'*, *bias=None*, *comm_turn=0*, *trans_input=False*, *trans_x2=False*) → *Tensor*

In the TP segmentation scenario, matmul and reducescatter are fused, and communication and computational pipelines are parallelized within the fusion operator.

$$output = reducescatter(input@x2)$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) – The left matrix of matmul, the dtype supports float16 and bfloat16, the shape supports 2 dimensions, and the data format supports ND.

- **x2** (Tensor) –The right matrix of matmul, the dtype needs to be consistent with `input` , the shape supports 2 dimensions, and the data format supports ND.
- **group** (*str*) –Communication group name, can be created by `create_group` method, or use the default group `mindspore.communication.GlobalComm.WORLD_COMM_GROUP`.
- **world_size** (*int*) –The total number of ranks in the communication group, should be consistent with the number of devices actually running, supporting `2` , `4` , and `8` .

Keyword Arguments

- **reduce_op** (*str, optional*) – `'sum'` .
- **bias** (Tensor, *optional*) –Currently only `None` is supported. Default: `None` .
- **comm_turn** (int, *optional*) –Indicates the granularity of communication between ranks. Currently only `0` is supported. Default: `0` .
- **trans_input** (bool, *optional*) –Indicates whether `input` is transposed. Currently only `False` is supported. Default: `False` .
- **trans_x2** (bool, *optional*) –Indicates whether `x2` is transposed. Default: `False` .

Returns

- output (Tensor) - The result of allgather and matmul fusion calculations.

Note:

- When using this interface, please ensure that the driver firmware package and CANN package are both the matching 8.0.RC2 version or a higher version, otherwise an error will be reported, such as BUS ERROR.
- The shape of `input` is (m, k), the shape of `x2` is (k, n), k is required to be equal, and the value range of k is [256, 65535), and m is required to be an integer multiple of `world_size` . The shape of `output` is (m * world_size, n).
- The common fusion operators in a model only support the same communication group.

Raises

- **TypeError** –Any arg is of wrong type.
- **RuntimeError** –The dtype of `input` or `x2` is neither float16 nor bfloat16.
- **RuntimeError** –The dtypes of `input` and `x2` are different.
- **RuntimeError** –The shape of `input` or `x2` is not two-dimensional.
- **RuntimeError** –The k axis of `input` shape and `x2` shape are not equal.
- **RuntimeError** –k is less than `256` or greater than or equal to `65535` .
- **RuntimeError** –`bias` is not None.
- **RuntimeError** –`group` does not exist.
- **RuntimeError** –`world_size` is inconsistent with the actual number of running cards.
- **RuntimeError** –`world_size` is not equal to `2` , `4` , or `8` .
- **RuntimeError** –`reduce_op` is not `'sum'` .
- **RuntimeError** –`trans_input` is `True` .

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import mindspore as ms
>>> from mindspore import ops
>>> import numpy as np
>>> ms.communication.init()
>>> rank = ms.communication.get_rank()
>>> np.random.seed(rank)
>>> input = ms.Tensor(np.random.randn(1024, 256).astype(np.float32), dtype=ms.float16)
>>> x2 = ms.Tensor(np.random.randn(256, 512).astype(np.float32), dtype=ms.float16)
>>> group = ms.communication.GlobalComm.WORLD_COMM_GROUP
>>> world_size = ms.communication.get_group_size()
>>> reduce_op = ops.ReduceOp.SUM
>>> output = ops.matmul_reduce_scatter(
...     input,
...     x2,
...     group,
...     world_size,
...     reduce_op=reduce_op,
...     bias=None,
...     comm_turn=0,
...     trans_input=False,
...     trans_x2=False,
... )
>>> print(output.shape)
(512, 512)
```

CHAPTER

THREE

MINDSPORE.NN

Neural Network Cell

For building predefined building blocks or computational units in neural networks.

For more information about dynamic shape support status, please refer to Dynamic Shape Support Status of nn Interface .

Compared with the previous version, the added, deleted and supported platforms change information of *mindspore.nn* operators in MindSpore, please refer to the link mindspore.nn API Interface Change .

3.1 Basic Block

API Name	Description	Supported Platforms
mindspore.nn.Cell	The basic building block of neural networks in MindSpore.	Ascend GPU CPU
mindspore.nn.GraphCell	Base class for running the graph loaded from a MindIR.	Ascend GPU CPU
mindspore.nn.LossBase	Base class for other losses.	Ascend GPU CPU
mindspore.nn.Optimizer	Base class for updating parameters.	Ascend GPU CPU

3.1.1 mindspore.nn.Cell

class mindspore.nn.**Cell**(*auto_prefix=True*, *flags=None*)

The basic building block of neural networks in MindSpore. The model or neural network layer should inherit this base class.

Layers in *mindspore.nn* are also the subclass of Cell, such as *mindspore.nn.Conv2d*, and *mindspore.nn.ReLU*, etc. Cell will be compiled into a calculation graph in GRAPH_MODE (static graph mode) and used as the basic module of neural networks in PYNATIVE_MODE (dynamic graph mode).

Note: Cell is the inference mode by default. For a class that inherits a Cell, if the training and inference have different structures, the subclass performs the inference branch by default. To set the training mode, refer to *mindspore.nn.Cell.set_train()* .

Warning: In the subclass of Cell, it's not allowed to define a method named 'cast' and not allowed to define an attribute named 'phase' or 'cells', otherwise, an error will be raised.

Parameters

- **auto_prefix** (*bool, optional*) –Whether to automatically generate NameSpace for Cell and its child cells. It also affects the names of parameters in the *Cell*. If set to `True` , the parameter name will be automatically prefixed, otherwise not. In general, the backbone network should be set to `True` , otherwise the duplicate name problem will appear. The cell to train the backbone network, such as optimizer and *mindspore.nn.TrainOneStepCell*, should be set to `False` , otherwise the parameter name in backbone will be changed by mistake. Default: `True` .
- **flags** (*dict, optional*) –Network configuration information, currently it is used for the binding of network and dataset. Users can also customize network attributes by this parameter. Default: `None` .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> class MyCell(nn.Cell):
...     def __init__(self, forward_net):
...         super(MyCell, self).__init__(auto_prefix=False)
...         self.net = forward_net
...         self.relu = ops.ReLU()
...
...     def construct(self, x):
...         y = self.net(x)
...         return self.relu(y)
>>>
>>> inner_net = nn.Conv2d(120, 240, 4, has_bias=False, weight_init='normal')
>>> my_net = MyCell(inner_net)
>>> print(my_net.trainable_params())
... # If the 'auto_prefix' set to True or not set when call the '__init__' method of the␣
↪parent class,
... # the parameter's name will be 'net.weight'.
[Parameter (name=weight, shape=(240, 120, 4, 4), dtype=Float32, requires_grad=True)]
```

add_flags (***flags*)

Add customized attributes for cell.

This method is also called when the cell class is instantiated and the class parameter 'flags' is set to True.

Parameters

flags (*dict*) –Network configuration information, currently it is used for the binding of network and dataset. Users can also customize network attributes by this parameter.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.relu = nn.ReLU()
...
...     def construct(self, x):
```

(continues on next page)

(continued from previous page)

```
...         x = self.relu(x)
...         return x
>>> net = Net()
>>> net.add_flags(sink_mode=True)
>>> print(net.sink_mode)
True
```

add_flags_recursive(***flags*)

If a cell contains child cells, this method can recursively customize attributes of all cells.

Parameters

flags (*dict*) – Network configuration information, currently it is used for the binding of network and dataset. Users can also customize network attributes by this parameter.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.relu = nn.ReLU()
...
...     def construct(self, x):
...         x = self.relu(x)
...         return x
>>> net = Net()
>>> net.add_flags_recursive(sink_mode=True)
>>> print(net.sink_mode)
True
```

apply(*fn*)

Applies fn recursively to every subcell (as returned by .cells()) as well as self. Typical use includes initializing the parameters of a model.

Parameters

fn (*function*) – function to be applied to each subcell.

Returns

Cell, self.

Examples

```
>>> import mindspore.nn as nn
>>> from mindspore.common.initializer import initializer, One
>>> net = nn.SequentialCell(nn.Dense(2, 2), nn.Dense(2, 2))
>>> def func(cell):
...     if isinstance(cell, nn.Dense):
...         cell.weight.set_data(initializer(One(), cell.weight.shape, cell.weight.
↪dtype))
>>> net.apply(func)
```

(continues on next page)

(continued from previous page)

```
SequentialCell(
  (0): Dense(input_channels=2, output_channels=2, has_bias=True)
  (1): Dense(input_channels=2, output_channels=2, has_bias=True)
)
>>> print(net[0].weight.asnumpy())
[[1. 1.]
 [1. 1.]]
```

auto_cast_inputs(*inputs*)

Auto cast inputs in mixed precision scenarios.

Parameters

inputs (*tuple*) – the inputs of construct.

Returns

Tuple, the inputs after data type cast.

property bprop_debug

Get whether cell custom bprop debug is enabled.

buffers(*recurse: bool = True*)

Return an iterator over cell buffers.

Parameters

recurse (*bool, optional*) – If `True` , then yields buffers of this cell and all sub cells. Otherwise, yields only buffers that are direct members of this cell. Default `True`.

Returns

Iterator[Tensor], an iterator of buffer.

Examples

```
>>> import mindspore
...
...
>>> class NetB(mindspore.nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.register_buffer("buffer_b", mindspore.tensor([1, 2, 3]))
...
...     def construct(self, x):
...         return x + self.buffer_b
...
...
>>> class NetA(mindspore.nn.Cell):
...     def __init__(self, net_b):
...         super().__init__()
...         self.net_b = net_b
...         self.register_buffer("buffer_a", mindspore.tensor([4, 5, 6]))
...
...     def construct(self, x):
...         return self.net_b(x) + self.buffer_a
...
...
```

(continues on next page)

(continued from previous page)

```
>>> net_b = NetB()
>>> net_a = NetA(net_b)
>>>
>>> for buffer in net_a.buffers():
...     print(f'buffer is {buffer}')
buffer is [4 5 6]
buffer is [1 2 3]
```

cast_inputs(*inputs*, *dst_type*)

Cast inputs to specified type.

Parameters

- **inputs** (*tuple[Tensor]*) –The cell inputs.
- **dst_type** (mindspore.dtype) –The specified data type.

Returns

tuple[Tensor], the result with destination data type.

cast_param(*param*)

Cast parameter according to auto mix precision level in pynative mode.

This interface is currently used in the case of auto mix precision and usually needs not to be used explicitly.

Parameters

param (Parameter) –Parameters, the type of which should be cast.

Returns

Parameter, the input parameter with type automatically cast.

cells()

Returns an iterator over immediate cells.

Returns

Iteration, the immediate cells in the cell.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.dense = nn.Dense(2, 2)
...
...     def construct(self, x):
...         x = self.dense(x)
...         return x
>>> net = Net()
>>> print(net.cells())
odict_values([Dense(input_channels=2, output_channels=2, has_bias=True)])
```

cells_and_names(*cells=None*, *name_prefix=''*)

Returns an iterator over all cells in the network, including the cell's name and itself.

Parameters

- **cells** (*str*) –Cells to iterate over. Default: None .
- **name_prefix** (*str*) –Namespace. Default: '' .

Returns

Iteration, all the child cells and corresponding names in the cell.

Examples

```
>>> from mindspore import nn
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.conv = nn.Conv2d(3, 64, 3)
...     def construct(self, x):
...         out = self.conv(x)
...         return out
>>> names = []
>>> n = Net()
>>> for m in n.cells_and_names():
...     if m[0]:
...         names.append(m[0])
```

check_names()
Check the names of cell parameters.

compile(**args*, ***kwargs*)
Compile Cell as a computation graph, the input must be consistent with the input defined in construct.

Parameters

- **args** (*tuple*) –Args of the Cell object.
- **kwargs** (*dict*) –Kwargs of the Cell object.

compile_and_run(**args*, ***kwargs*)
Compile and run Cell, the input must be consistent with the input defined in construct.

Note: It is not recommended to call directly.

Parameters

- **args** (*tuple*) –Args of the Cell object.
- **kwargs** (*dict*) –Kwargs of the Cell object.

Returns

Object, the result of executing.

construct(**args*, ***kwargs*)
Defines the computation to be performed. This method must be overridden by all subclasses.

Note: It is not supported currently that inputs contain both tuple and non-tuple types at same time.

Parameters

- **args** (*tuple*) –Tuple of variable parameters.
- **kwargs** (*dict*) –Dictionary of variable keyword parameters.

Returns

Tensor, returns the computed result.

extend_repr()
Expand the description of Cell.

To print customized extended information, re-implement this method in your own cells.

flatten_weights(*fusion_size=0*)
Reset data for weight parameters so that they are using contiguous memory chunks grouped by data type.

Note: By default, parameters with same data type will using a single contiguous memory chunk. but for some models with huge number of parameters, splitting a large memory chunk into several smaller memory chunks has the potential for performance gains, if this is the case, we can use 'fusion_size' to limit the maximum memory chunk size.

Parameters

fusion_size (*int*) –Maximum memory chunk size in bytes, 0 for unlimited. Default: 0 .

generate_scope()
Generate the scope for each cell object in the network.

get_buffer(*target: str*)
Return the buffer given by *target* if it exists, otherwise throw an error.

See the docstring for *get_sub_cell* for a more detailed explanation of this method's functionality as well as how to correctly specify *target* .

Parameters

target (*str*) –The fully-qualified string name of the buffer to look for. (See *get_sub_cell* for how to specify a fully-qualified string.)

Returns

Tensor

Examples

```
>>> import mindspore
...
...
>>> class NetC(mindspore.nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.register_buffer("buffer_c", mindspore.tensor([0, 0, 0]))
...
...     def construct(self, x):
...         return x + self.buffer_c
...
...
```

(continues on next page)

(continued from previous page)

```
>>> class NetB(mindspore.nn.Cell):
...     def __init__(self, net_c):
...         super().__init__()
...         self.net_c = net_c
...         self.register_buffer("buffer_b", mindspore.tensor([1, 2, 3]))
...
...     def construct(self, x):
...         return self.net_c(x) + self.buffer_b
...
...
>>> class NetA(mindspore.nn.Cell):
...     def __init__(self, net_b):
...         super().__init__()
...         self.net_b = net_b
...         self.register_buffer("buffer_a", mindspore.tensor([4, 5, 6]))
...
...     def construct(self, x):
...         return self.net_b(x) + self.buffer_a
...
...
>>> net_c = NetC()
>>> net_b = NetB(net_c)
>>> net_a = NetA(net_b)
>>> buffer_c = net_a.get_buffer("net_b.net_c.buffer_c")
>>> print(f'buffer_c is {buffer_c}')
buffer_c is [0 0 0]
```

get_extra_state()

Return any extra state to include in the cell's state_dict.

This function is called from `state_dict`. Implement this and a corresponding `set_extra_state` for your cell if you need to store extra state.

Note that extra state should be picklable to ensure working serialization of the state_dict. Only provide backwards compatibility guarantees for serializing tensors; other objects may break backwards compatibility if their serialized pickled form changes.

Returns

object, any extra state to store in the cell's state_dict.

get_flags()

Get the self_defined attributes of the cell, which can be added by *add_flags* method.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.relu = nn.ReLU()
...
...     def construct(self, x):
...         x = self.relu(x)
```

(continues on next page)

(continued from previous page)

```
...         return x
>>> net = Net()
>>> net.add_flags(sink_mode=True)
>>> print(net.get_flags())
{'sink_mode':True}
```

get_func_graph_proto()
Return graph binary proto.

get_inputs()
Returns the dynamic_inputs of a cell object in one network.

Returns

inputs (tuple), Inputs of the Cell object.

> **Warning:** This is an experimental API that is subject to change or deletion.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import nn, Tensor
>>>
>>> class ReluNet(nn.Cell):
...     def __init__(self):
...         super(ReluNet, self).__init__()
...         self.relu = nn.ReLU()
...     def construct(self, x):
...         return self.relu(x)
>>>
>>> net = ReluNet()
>>> input_dyn = Tensor(shape=[3, None], dtype=ms.float32)
>>> net.set_inputs(input_dyn)
>>> get_inputs = net.get_inputs()
>>> print(get_inputs)
(Tensor(shape=[3, -1], dtype=Float32, value= ),)
```

get_parameters(*expand=True*)
Returns an iterator over cell parameters.

Yields parameters of this cell. If *expand* is `true` , yield parameters of this cell and all subcells. For more details about subcells, please see the example below.

Parameters

expand (*bool*) – If `true` , yields parameters of this cell and all subcells. Otherwise, only yield parameters that are direct members of this cell. Default: `True` .

Returns

Iteration, all parameters at the cell.

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn, ops, Tensor
>>> import numpy as np
>>> class TestNet(nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.my_w1 = ms.Parameter(Tensor(np.ones([4, 4]), ms.float32))
...         self.my_w2 = ms.Parameter(Tensor(np.ones([16]), ms.float32))
...     def construct(self, x):
...         x += self.my_w1
...         x = ops.reshape(x, (16,)) - self.my_w2
...         return x
>>> class TestNet2(nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.my_t1 = ms.Parameter(Tensor(np.ones([4, 4]), ms.float32))
...         # self.subcell is a subcell of TestNet2, when using expand=True, the␣
↪parameters of TestNet will
...         # also be gathered.
...         self.subcell = TestNet()
...     def construct(self, x):
...         x += self.my_w1
...         x = ops.reshape(x, (16,)) - self.my_w2
...         return x
>>> net = TestNet2()
>>> print([p for p in net.get_parameters(expand=True)])
[Parameter (name=my_t1, shape=(4, 4), dtype=Float32, requires_grad=True), Parameter␣
↪(name=subcell.my_w1,
shape=(4, 4), dtype=Float32, requires_grad=True), Parameter (name=subcell.my_w2,␣
↪shape=(16,), dtype=Float32,
requires_grad=True)]
```

get_scope()

Returns the scope of a cell object in one network.

Returns

String, scope of the cell.

get_sub_cell(*target: str*)

Return the sub cell given by *target* if it exists, otherwise throw an error.

For example, let's say you have an `nn.Cell` `A` that looks like this:

```
A(
    (net_b): NetB(
        (net_c): NetC(
            (conv): Conv2d(16, 33, kernel_size=(3, 3), stride=(2, 2))
        )
        (dense): Dense(in_features=100, out_features=200, bias=True)
    )
)
```

(The diagram shows an `nn.Cell` `A`. `A` has a nested sub cell `net_b`, which itself has two sub cells `net_c` and `dense`. `net_c` then has a sub cell `conv`.)

To check whether we have the `dense` sub cell, we would call *get_sub_cell("net_b.dense")*. To check whether we have the `conv` sub cell, we would call *get_sub_cell("net_b.net_c.conv")*.

The runtime of `get_sub_cell` is bounded by the degree of cell nesting in *target*. A query against *name_cells* achieves the same result, but it is O(N) in the number of transitive cells. So, for a simple check to see if some sub cells exist, `get_sub_cell` should always be used.

Parameters

target (*str*) –The fully-qualified string name of the sub cell to look for. (See above example for how to specify a fully-qualified string.)

Returns

Cell

Examples

```
>>> import mindspore
...
...
>>> class NetC(mindspore.nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.register_buffer("buffer_c", mindspore.tensor([0, 0, 0]))
...         self.dense_c = mindspore.nn.Dense(5, 3)
...
...     def construct(self, x):
...         return self.dense_c(x) + self.buffer_c
...
...
>>> class NetB(mindspore.nn.Cell):
...     def __init__(self, net_c):
...         super().__init__()
...         self.net_c = net_c
...         self.register_buffer("buffer_b", mindspore.tensor([1, 2, 3]))
...
...     def construct(self, x):
...         return self.net_c(x) + self.buffer_b
...
...
>>> class NetA(mindspore.nn.Cell):
...     def __init__(self, net_b):
...         super().__init__()
...         self.net_b = net_b
...         self.register_buffer("buffer_a", mindspore.tensor([4, 5, 6]))
...
...     def construct(self, x):
...         return self.net_b(x) + self.buffer_a
...
...
>>> net_c = NetC()
>>> net_b = NetB(net_c)
>>> net_a = NetA(net_b)
>>> net_c = net_a.get_sub_cell("net_b.net_c")
>>> print(f'net_c is {net_c}')
net_c is NetC(
    (dense_c): Dense(input_channels=5, output_channels=3, has_bias=True)
)
```

infer_param_pipeline_stage()
Infer pipeline stages of all parameters in the cell.

Note:

- The interface is deprecated from version 2.3 and will be removed in a future version.

Returns

The params belong to current stage in pipeline parallel.

Raises

RuntimeError –If there is a parameter does not belong to any stage.

init_parameters_data(*auto_parallel_mode=False*)
Initialize all parameters and replace the original saved parameters in cell.

Note: trainable_params() and other similar interfaces may return different parameter instance after *init_parameters_data*. It is not recommended to save these results.

Parameters

auto_parallel_mode (*bool*) –If running in auto_parallel_mode. Default: `False` .

Returns

Dict[Parameter, Parameter], returns a dict of original parameter and replaced parameter.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.dense = nn.Dense(2, 2)
...
...     def construct(self, x):
...         x = self.dense(x)
...         return x
>>> net = Net()
>>> print(net.init_parameters_data())
{Parameter (name=dense.weight, shape=(2,2), dtype=Float32, requires_grad=True):
 Parameter (name=dense.weight, shape=(2,2), dtype=Float32, requires_grad=True),
 Parameter (name=dense.bias, shape=(2,), dtype=Float32, requires_grad=True):
 Parameter (name=dense.bias, shape=(2,), dtype=Float32, requires_grad=True)}
```

insert_child_to_cell(*child_name*, *child_cell*)
Adds a child cell to the current cell with a given name.

Parameters

- **child_name** (*str*) –Name of the child cell.

- **child_cell** (Cell) –The child cell to be inserted.

Raises

- **KeyError** –Child Cell's name is incorrect or duplicated with the other child name.
- **TypeError** –If type of *child_name* is not str.
- **TypeError** –Child Cell's type is incorrect.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn
...
>>> net1 = nn.ReLU()
>>> net2 = nn.Dense(2, 2)
>>> net1.insert_child_to_cell("child", net2)
>>> print(net1)
ReLU(
  (child): Dense(input_channels=2, output_channels=2, has_bias=True)
)
```

insert_param_to_cell(*param_name*, *param*, *check_name_contain_dot=True*)

Adds a parameter to the current cell.

Inserts a parameter with given name to the cell. The method is currently used in *mindspore.nn.Cell.__setattr__*.

Parameters

- **param_name** (*str*) –Name of the parameter.
- **param** (Parameter) –Parameter to be inserted to the cell.
- **check_name_contain_dot** (*bool*) –Determines whether the name input is compatible. Default: True .

Raises

- **KeyError** –If the name of parameter is null or contains dot.
- **TypeError** –If the type of parameter is not Parameter.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn, Parameter
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.relu = nn.ReLU()
...
...     def construct(self, x):
...         x = self.relu(x)
...         return x
>>> net = Net()
>>> net.insert_param_to_cell("bias", Parameter(Tensor([1, 2, 3])))
>>> print(net.bias)
Parameter(name=bias, shape=(3,), dtype=Int64, requires_grad=True)
```

load_state_dict(*state_dict: Mapping[str, Any]*, *strict: bool = True*)

Copy parameters and buffers from *state_dict* into this cell and its descendants.

If `strict` is `True`, then the keys of *state_dict* must exactly match the keys returned by this cell's *mindspore.nn.Cell.state_dict()* function.

Parameters

- **state_dict** (*dict*) –A dict containing parameters and persistent buffers.
- **strict** (*bool, optional*) –Whether to strictly enforce that the keys in input *state_dict* match the keys returned by this cell's *mindspore.nn.Cell.state_dict()* function. Default `True` .

Returns

A namedtuple with `missing_keys` and `unexpected_keys` fields,

- *missing_keys* is a list of str containing any keys that are expected by this cell but missing from the provided `state_dict`.
- *unexpected_keys* is a list of str containing the keys that are not expected by this cell but present in the provided `state_dict`.

Note: If *strict* is `True` and a parameter or buffer is registered as `None`, but its corresponding key exists in *state_dict*, and *mindspore.nn.Cell.load_state_dict()* will raise a `RuntimeError`.

Examples

```
>>> import mindspore
>>> import os
>>> class Model(mindspore.nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.register_buffer("buffer_a", mindspore.tensor([4, 5, 6]))
...         self.param_a = mindspore.Parameter(mindspore.tensor([1, 2, 3]))
...
...     def construct(self, x):
...         return x + self.buffer_a + self.param_a
...
...
>>> model = Model()
>>> print(model.state_dict())
>>> mindspore.save_checkpoint(model.state_dict(), './model_state_dict_ckpt')
>>> new_model = Model()
>>> new_model.load_state_dict(mindspore.load_checkpoint('./model_state_dict_ckpt'))
>>> print(new_model.state_dict())
>>> os.remove('./model_state_dict_ckpt')
OrderedDict([('param_a', Parameter (name=param_a, shape=(3,), dtype=Int64, requires_
↪grad=True)), \
('buffer_a', Tensor(shape=[3], dtype=Int64, value= [4, 5, 6]))])
OrderedDict([('param_a', Parameter (name=param_a, shape=(3,), dtype=Int64, requires_
↪grad=True)), \
('buffer_a', Tensor(shape=[3], dtype=Int64, value= [4, 5, 6]))])
```

name_cells()

Returns an iterator over all immediate cells in the network.

Include name of the cell and cell itself.

Returns

Dict, all the child cells and corresponding names in the cell.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.dense = nn.Dense(2, 2)
...
...     def construct(self, x):
...         x = self.dense(x)
...         return x
>>> net = Net()
>>> print(net.name_cells())
OrderedDict([('dense', Dense(input_channels=2, output_channels=2, has_bias=True))])
```

named_buffers(*prefix: str = ''*, *recurse: bool = True*, *remove_duplicate: bool = True*)

Return an iterator over cell buffers, yielding both the name of the buffer as well as the buffer itself.

Parameters

- **prefix** (*str, optional*) – prefix to prepend to all buffer names. Default `""`.
- **recurse** (*bool, optional*) – if `True` , then yields buffers of this cell and all sub cells. Otherwise, yields only buffers that are direct members of this cell. Default `True`.
- **remove_duplicate** (*bool, optional*) – Whether to remove the duplicated buffers in the result. Default `True`.

Returns

Iterator[Tuple[str, Tensor]], an iterator of tuple containing the name and buffer.

Examples

```
>>> import mindspore
...
...
>>> class NetB(mindspore.nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.register_buffer("buffer_b", mindspore.tensor([1, 2, 3]))
...
...     def construct(self, x):
...         return x + self.buffer_b
...
...
>>> class NetA(mindspore.nn.Cell):
...     def __init__(self, net_b):
...         super().__init__()
```

(continues on next page)

(continued from previous page)

```
...         self.net_b = net_b
...         self.register_buffer("buffer_a", mindspore.tensor([4, 5, 6]))
...
...     def construct(self, x):
...         return self.net_b(x) + self.buffer_a
...
...
>>> net_b = NetB()
>>> net_a = NetA(net_b)
>>>
>>> for name, buffer in net_a.named_buffers():
...     print(f'buffer name is {name}, buffer is {buffer}')
buffer name is buffer_a, buffer is [4 5 6]
buffer name is net_b.buffer_b, buffer is [1 2 3]
```

offload(*backward_prefetch='Auto'*)

Set the cell offload. All primitive ops in the cell will be set offload. For the intermediate activations calculated by these primitive ops, we will not save them in the forward pass, but offload them and onload them in the backward pass.

Note:

- If Cell.offload is called, the mode should be set to "GRAPH_MODE".
- If Cell.offload is called, lazyinline should be enabled.

Parameters

backward_prefetch (*Union[str, int], optional*) – The timing for prefetching activations in advance in backward pass. Default: `"Auto"`. If set it to `"Auto"`, framework will start to prefetch activations one operator in advance. If set it to a positive int value, framework will start to prefetch activations `backward_prefetch` operators in advance, such as 1, 20, 100.

Examples

```
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> from mindspore.common import Tensor, Parameter
>>> from mindspore.common.lazy_inline import lazy_inline
>>>
>>> class Block(nn.Cell):
...     def __init__(self):
...         super(Block, self).__init__()
...         self.transpose1 = ops.Transpose()
...         self.transpose2 = ops.Transpose()
...         self.transpose3 = ops.Transpose()
...         self.transpose4 = ops.Transpose()
...         self.real_div1 = ops.RealDiv()
...         self.real_div2 = ops.RealDiv()
...         self.batch_matmul1 = ops.BatchMatMul()
...         self.batch_matmul2 = ops.BatchMatMul()
...         self.softmax = ops.Softmax(-1)
...         self.expand_dims = ops.ExpandDims()
...         self.sub = ops.Sub()
...         self.y = Parameter(Tensor(np.ones((1024, 128, 128)).astype(np.float32)))
```

(continues on next page)

(continued from previous page)

```
...     def construct(self, x):
...         transpose1 = self.transpose1(x, (0, 2, 1, 3))
...         real_div1 = self.real_div1(transpose1, Tensor(2.37891))
...         transpose2 = self.transpose2(x, (0, 2, 3, 1))
...         real_div2 = self.real_div2(transpose2, Tensor(2.37891))
...         batch_matmul1 = self.batch_matmul1(real_div1, real_div2)
...         expand_dims = self.expand_dims(self.y, 1)
...         sub = self.sub(Tensor([1.0]), expand_dims)
...         soft_max = self.softmax(sub)
...         transpose3 = self.transpose3(x, (0, 2, 1, 3))
...         batch_matmul2 = self.batch_matmul2(soft_max[0], transpose3)
...         transpose4 = self.transpose4(batch_matmul2, (0, 2, 1, 3))
...         return transpose4
>>>
>>> class OuterBlock(nn.Cell):
...     @lazy_inline
...     def __init__(self):
...         super(OuterBlock, self).__init__()
...         self.block = Block()
...     def construct(self, x):
...         return self.block(x)
>>>
>>> class Nets(nn.Cell):
...     def __init__(self):
...         super(Nets, self).__init__()
...         self.blocks = nn.CellList()
...         for _ in range(3):
...             b = OuterBlock()
...             b.offload()
...             self.blocks.append(b)
...     def construct(self, x):
...         out = x
...         for i in range(3):
...             out = self.blocks[i](out)
...         return out
```

property param_prefix

Param prefix is the prefix of current cell's direct child parameter.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.dense = nn.Dense(2, 2)
...
...     def construct(self, x):
...         x = self.dense(x)
...         return x
>>> net = Net()
>>> net.update_cell_prefix()
>>> print(net.dense.param_prefix)
```

(continues on next page)

(continued from previous page)

```
dense
```

property parameter_layout_dict

parameter_layout_dict represents the tensor layout of a parameter, which is inferred by shard strategy and distributed operator information.

parameters_and_names(*name_prefix=''*, *expand=True*)

Returns an iterator over cell parameters.

Includes the parameter's name and itself.

Parameters

- **name_prefix** (*str*) –Namespace. Default: `''` .
- **expand** (*bool*) –If true, yields parameters of this cell and all subcells. Otherwise, only yield parameters that are direct members of this cell. Default: `True` .

Returns

Iteration, all the names and corresponding parameters in the cell.

Examples

```
>>> from mindspore import nn
>>> n = nn.Dense(3, 4)
>>> names = []
>>> for m in n.parameters_and_names():
...     if m[0]:
...         names.append(m[0])
```

Tutorial Examples:

- Building a Network - Model Parameters

parameters_broadcast_dict(*recurse=True*)

Gets the parameters broadcast dictionary of this cell.

Parameters

recurse (*bool*) –Whether contains the parameters of subcells. Default: `True` .

Returns

OrderedDict, return parameters broadcast dictionary.

parameters_dict(*recurse=True*)

Gets the parameters dictionary of this cell.

Parameters

recurse (*bool*) –Whether contains the parameters of subcells. Default: `True` .

Returns

OrderedDict, return parameters dictionary.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn, Parameter
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.dense = nn.Dense(2, 2)
...
...     def construct(self, x):
...         x = self.dense(x)
...         return x
>>> net = Net()
>>> print(net.parameters_dict())
OrderedDict([('dense.weight', Parameter(name=dense.weight, shape=(2, 2), dtype=Float32,
requires_grad=True)), ('dense.bias', Parameter(name=dense.bias, shape=(2,),␣
↪dtype=Float32,
requires_grad=True))])
```

property pipeline_stage

pipeline_stage represents the pipeline stage of current Cell.

place(*role*, *rank_id*)

Set the label for all operators in this cell. This label tells MindSpore compiler on which process this cell should be launched. And each process's identical label consists of input *role* and *rank_id*. So by setting different cells with different labels, which will be launched on different processes, users can launch a distributed training or predicting job.

Note:

- This method is effective only after *mindspore.communication.init()* is called for dynamic cluster building.

Parameters

- **role** (*str*) – The role of the process on which this cell will be launched. Only 'MS_WORKER' is supported for now.
- **rank_id** (*int*) – The rank id of the process on which this cell will be launched. The rank is unique in processes with the same role.

Examples

```
>>> from mindspore import context
>>> import mindspore.nn as nn
>>> context.set_context(mode=context.GRAPH_MODE)
>>> fc = nn.Dense(2, 3)
>>> fc.place('MS_WORKER', 0)
```

recompute(***kwargs*)

Set the cell recomputed. All the primitive in the cell except the outputs will be set recomputed. If a primitive set recomputed feeds into some backward nodes for computing gradient, rather than storing the intermediate activation computed in forward pass, we will recompute it in backward pass.

Note:

- If the computation involves something like randomization or global variable, the equivalence is not guaranteed currently.
- If the recompute api of a primitive in this cell is also called, the recompute mode of this primitive is subject to the recompute api of the primitive.
- The interface can be configured only once. Therefore, when the parent cell is configured, the child cell should not be configured.
- The outputs of cell are excluded from recomputation by default, which is based on our configuration experience to reduce memory footprint. If a cell has only one primitive and the primitive is wanted to be set recomputed, use the recompute api of the primtive.
- When the memory remains after applying the recomputation, configuring 'mp_comm_recompute=False' to improve performance if necessary.
- When the memory still not enough after applying the recompute, configuring 'parallel_optimizer_comm_recompute=True' to save more memory if necessary. Cells in the same fusion group should have the same parallel_optimizer_comm_recompute configures.

Parameters

- **mp_comm_recompute** (*bool*) −Specifies whether the model parallel communication operators in the cell are recomputed in auto parallel or semi auto parallel mode. Default: `True` .
- **parallel_optimizer_comm_recompute** (*bool*) −Specifies whether the communication operator allgathers introduced by optimizer shard are recomputed in auto parallel or semi auto parallel mode. Default: `False` .

register_backward_hook(*hook_fn*)

Register the backward hook function.

Note:

- The *register_backward_hook(hook_fn)* does not work in graph mode or functions decorated with 'jit'.
- The 'hook_fn' must be defined as the following code. *cell* is the registered Cell object. *grad_input* is the gradient computed and passed to the next Cell or primitive, which can be return a new gradient or None. *grad_output* is the gradient passed to the Cell.
- The 'hook_fn' should have the following signature: hook_fn(cell, grad_input, grad_output) -> New grad_input gradient or none.
- The 'hook_fn' is executed in the python environment. In order to prevent running failed when switching to graph mode, it is not recommended to write it in the *construct* function of Cell object. In the pynative mode, if the *register_backward_hook* function is called in the *construct* function of the Cell object, a hook function will be added at each run time of Cell object.

Parameters

hook_fn (*function*) −Python function. Backward hook function.

Returns

A handle corresponding to the *hook_fn* . The handle can be used to remove the added *hook_fn* by calling *handle.remove()* .

Raises

TypeError −If the *hook_fn* is not a function of python.

Supported Platforms: `Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor, nn, ops
>>> ms.set_context(mode=ms.PYNATIVE_MODE)
>>> def backward_hook_fn(cell, grad_input, grad_output):
...     print("backward input: ", grad_output)
...     print("backward output: ", grad_input)
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.relu = nn.ReLU()
...         self.handle = self.relu.register_backward_hook(backward_hook_fn)
...
...     def construct(self, x):
...         x = x + x
...         x = self.relu(x)
...         return x
>>> grad = ops.GradOperation(get_all=True)
>>> net = Net()
>>> output = grad(net)(Tensor(np.ones([1]).astype(np.float32)))
backward input: (Tensor(shape=[1], dtype=Float32, value= [ 1.00000000e+00]),)
backward output: (Tensor(shape=[1], dtype=Float32, value= [ 1.00000000e+00]),)
>>> print(output)
(Tensor(shape=[1], dtype=Float32, value= [ 2.00000000e+00]),)
```

register_backward_pre_hook(*hook_fn*)

Register the backward pre hook function.

Note:

- The *register_backward_pre_hook(hook_fn)* does not work in graph mode or functions decorated with 'jit'.
- The 'hook_fn' must be defined as the following code. *cell* is the Cell object. *grad_output* is the gradient passed to the Cell.
- The 'hook_fn' should have the following signature: hook_fn(cell, grad_output) -> New grad_output gradient or None.
- The 'hook_fn' is executed in the python environment. In order to prevent running failed when switching to graph mode, it is not recommended to write it in the *construct* function of Cell object.
- In the pynative mode, if the *register_backward_pre_hook* function is called in the *construct* function of the Cell object, a hook function will be added at each run time of Cell object.

Parameters

hook_fn (*function*) –Python function. Backward pre hook function.

Returns

A handle corresponding to the *hook_fn* . The handle can be used to remove the added *hook_fn* by calling *handle.remove()* .

Raises

TypeError –If the *hook_fn* is not a function of python.

Supported Platforms: `Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor, nn, ops
>>> ms.set_context(mode=ms.PYNATIVE_MODE)
>>> def backward_pre_hook_fn(cell, grad_output):
...     print("backward input: ", grad_output)
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.relu = nn.ReLU()
...         self.handle = self.relu.register_backward_pre_hook(backward_pre_hook_fn)
...
...     def construct(self, x):
...         x = x + x
...         x = self.relu(x)
...         return x
>>> grad = ops.GradOperation(get_all=True)
>>> net = Net()
>>> output = grad(net)(Tensor(np.ones([1]).astype(np.float32)))
backward input: (Tensor(shape=[1], dtype=Float32, value= [ 1.00000000e+00]),)
>>> print(output)
(Tensor(shape=[1], dtype=Float32, value= [ 2.00000000e+00]),)
```

register_buffer(*name: str*, *tensor: Optional[*Tensor*]*, *persistent: bool = True*)

Add a buffer to the cell.

This is typically used to register a buffer that should not to be considered a model parameter. For example, BatchNorm's *running_mean* is not a parameter, but is part of the cell's state. Buffers, by default, are persistent and will be saved alongside parameters. This behavior can be changed by setting *persistent* to `False` . The only difference between a persistent buffer and a non-persistent buffer is that the latter will not be a part of this cell's *state_dict* .

Buffers can be accessed as attributes using given names.

Parameters

- **name** (*str*) –name of the buffer. The buffer can be accessed from this cell using the given name.
- **tensor** (`Tensor`) –Buffer to be registered. If `None` , the buffer is not included in the cell's *state_dict* .
- **persistent** (*bool, optional*) –Whether the buffer is part of this cell's *state_dict*. Default `True`.

Examples

```
>>> import mindspore
...
>>> class Net(mindspore.nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.register_buffer("buffer0", mindspore.tensor([1, 2, 3]))
...
...     def construct(self, x):
...         return x + self.net_buffer
...
>>> net = Net()
>>> net.register_buffer("buffer0", mindspore.tensor([4, 5, 6]))
>>> print(net.buffer0)
[4 5 6]
```

register_forward_hook(*hook_fn*)

Set the Cell forward hook function.

Note:

- The *register_forward_hook(hook_fn)* does not work in graph mode or functions decorated with 'jit'.
- 'hook_fn' must be defined as the following code. *cell* is the object of registered Cell. *inputs* is the forward input objects passed to the Cell. *output* is the forward output object of the Cell. The 'hook_fn' can modify the forward output object by returning new forward output object.
- It should have the following signature: hook_fn(cell, inputs, output) -> new output object or none.
- In order to prevent running failed when switching to graph mode, it is not recommended to write it in the *construct* function of Cell object. In the pynative mode, if the *register_forward_hook* function is called in the *construct* function of the Cell object, a hook function will be added at each run time of Cell object.

Parameters

hook_fn (*function*) – Python function. Forward hook function.

Returns

A handle corresponding to the *hook_fn* . The handle can be used to remove the added *hook_fn* by calling *handle.remove()* .

Raises

TypeError – If the *hook_fn* is not a function of python.

Supported Platforms: `Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor, nn, ops
>>> ms.set_context(mode=ms.PYNATIVE_MODE)
>>> def forward_hook_fn(cell, inputs, output):
...     print("forward inputs: ", inputs)
...     print("forward output: ", output)
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.mul = nn.MatMul()
...         self.handle = self.mul.register_forward_hook(forward_hook_fn)
...
...     def construct(self, x, y):
...         x = x + x
...         x = self.mul(x, y)
...         return x
>>> grad = ops.GradOperation(get_all=True)
>>> net = Net()
>>> output = grad(net)(Tensor(np.ones([1]).astype(np.float32)), Tensor(np.ones([1]).
↪astype(np.float32)))
forward inputs: (Tensor(shape=[1], dtype=Float32, value= [ 2.00000000e+00]),␣
↪Tensor(shape=[1],
                dtype=Float32, value= [ 1.00000000e+00]))
forward output: 2.0
>>> print(output)
(Tensor(shape=[1], dtype=Float32, value= [ 2.00000000e+00]), Tensor(shape=[1],␣
↪dtype=Float32,
value= [ 2.00000000e+00]))
```

register_forward_pre_hook(*hook_fn*)

Register forward pre hook function for Cell object.

Note:

- The *register_forward_pre_hook(hook_fn)* does not work in graph mode or functions decorated with 'jit'.
- 'hook_fn' must be defined as the following code. *cell* is the object of registered Cell. *inputs* is the forward input objects passed to the Cell. The 'hook_fn' can modify the forward input objects by returning new forward input objects.
- It should have the following signature: hook_fn(cell, inputs) -> new input objects or none.
- In order to prevent running failed when switching to graph mode, it is not recommended to write it in the *construct* function of Cell object. In the pynative mode, if the *register_forward_pre_hook* function is called in the *construct* function of the Cell object, a hook function will be added at each run time of Cell object.

Parameters

hook_fn (*function*) –Python function. Forward pre hook function.

Returns

A handle corresponding to the *hook_fn* . The handle can be used to remove the added *hook_fn* by calling *handle.remove()* .

Raises

TypeError – If the *hook_fn* is not a function of python.

Supported Platforms: `Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor, nn, ops
>>> ms.set_context(mode=ms.PYNATIVE_MODE)
>>> def forward_pre_hook_fn(cell, inputs):
...     print("forward inputs: ", inputs)
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.mul = nn.MatMul()
...         self.handle = self.mul.register_forward_pre_hook(forward_pre_hook_fn)
...
...     def construct(self, x, y):
...         x = x + x
...         x = self.mul(x, y)
...         return x
>>> grad = ops.GradOperation(get_all=True)
>>> net = Net()
>>> output = grad(net)(Tensor(np.ones([1]).astype(np.float32)), Tensor(np.ones([1]).
↪astype(np.float32)))
forward inputs: (Tensor(shape=[1], dtype=Float32, value= [ 2.00000000e+00]),␣
↪Tensor(shape=[1],
               dtype=Float32, value= [ 1.00000000e+00]))
>>> print(output)
(Tensor(shape=[1], dtype=Float32, value= [ 2.00000000e+00]), Tensor(shape=[1],␣
↪dtype=Float32,
value= [ 2.00000000e+00]))
```

register_load_state_dict_post_hook(*hook*)

Register a post-hook to be run after cell's *mindspore.nn.Cell.load_state_dict()* is called.

It should have the following signature:

hook(cell, incompatible_keys) -> None

The `cell` argument is the current cell that this hook is registered on, and the `incompatible_keys` argument is a `NamedTuple` consisting of attributes `missing_keys` and `unexpected_keys`. `missing_keys` is a `list` of `str` containing the missing keys and `unexpected_keys` is a `list` of `str` containing the unexpected keys.

The given incompatible_keys can be modified inplace if needed.

Note that the checks performed when calling *load_state_dict()* with `strict=True` are affected by modifications the hook makes to `missing_keys` or `unexpected_keys`, as expected. Additions to either set of keys will result in an error being thrown when `strict=True`, and clearing out both missing and unexpected keys will avoid an error.

Parameters

hook (*Callable*) – The hook function after *load_state_dict* is called.

Returns

A handle that can be used to remove the added hook by calling *handle.remove()*.

register_load_state_dict_pre_hook(*hook*)
Register a pre-hook to be run before cell's *mindspore.nn.Cell.load_state_dict()* is called.

It should have the following signature:

hook(cell, state_dict, prefix, local_metadata, strict, missing_keys, unexpected_keys, error_msgs) -> None # noqa: B950

Parameters

hook (*Callable*) –The hook function before *load_state_dict* is called.

Returns

A handle that can be used to remove the added hook by calling *handle.remove()*.

register_state_dict_post_hook(*hook*)
Register a post-hook for the *mindspore.nn.Cell.state_dict()* method.

It should have the following signature:

hook(cell, state_dict, prefix, local_metadata) -> None

The registered hooks can modify the `state_dict` inplace.

Parameters

hook (*Callable*) –The hook function after *state_dict* is called.

Returns

A handle that can be used to remove the added hook by calling *handle.remove()*.

register_state_dict_pre_hook(*hook*)
Register a pre-hook for the *mindspore.nn.Cell.state_dict()* method.

It should have the following signature:

hook(cell, prefix, keep_vars) -> None

The registered hooks can be used to perform pre-processing before the *state_dict* call is made.

Parameters

hook (*Callable*) –The hook function before *state_dict* is called.

Returns

A handle that can be used to remove the added hook by calling *handle.remove()*.

Examples

```
>>> import mindspore
...
...
>>> class NetA(mindspore.nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.register_buffer("buffer_a", mindspore.tensor([1, 2, 3]))
...         self.param_a = mindspore.Parameter(mindspore.tensor([1, 2, 3]))
...
...     def construct(self, x):
...         return x + self.buffer_a + self.param_a
...
...
```

(continues on next page)

(continued from previous page)

```
>>> def _add_extra_param(cell, prefix, keep_vars):
...     cell._params["extra_param"] = mindspore.Parameter(mindspore.tensor([4, 5, 6]))
...
...
>>> net = NetA()
>>> handle = net.register_state_dict_pre_hook(_add_extra_param)
>>> net_state_dict = net.state_dict()
>>> handle.remove()
>>> print("extra_param" in net_state_dict)
True
```

remove_redundant_parameters()
Remove the redundant parameters.

This interface usually needs not to be used explicitly.

run_construct(*cast_inputs*, *kwargs*)
Run the construct function.

Note: This function will be removed in a future version. It is not recommended to call this function.

Parameters

- **cast_inputs** (*tuple*) –The input objects of Cell.
- **kwargs** (*dict*) –Provide keyword arguments.

Returns

output, the output object of Cell.

set_boost(*boost_type*)
In order to improve the network performance, configure the network auto enable to accelerate the algorithm in the algorithm library.

If *boost_type* is not in the algorithm library, please view the algorithm in the algorithm library through algorithm library.

Note: Some acceleration algorithms may affect the accuracy of the network, please choose carefully.

Parameters

boost_type (*str*) –accelerate algorithm.

Returns

Cell, the cell itself.

Raises

ValueError –If boost_type is not in the algorithm library.

set_broadcast_flag(*mode=True*)
Set parameter broadcast mode for this cell.

Parameters

mode (*bool*) –Specifies whether the mode is parameter broadcast. Default: `True` .

set_comm_fusion(*fusion_type*, *recurse=True*)

Set *comm_fusion* for all the parameters in this cell. Please refer to the description of *mindspore.Parameter.comm_fusion*.

Note: The value of attribute will be overwritten when the function is called multiply.

Parameters

- **fusion_type** (*int*) −The value of *comm_fusion*.
- **recurse** (*bool*) −Whether sets the trainable parameters of subcells. Default: `True` .

set_data_parallel()

For all primitive ops in this cell(including ops of cells that wrapped by this cell), if parallel strategy is not specified, then instead of auto-searching, data parallel strategy will be generated for those primitive ops.

Note: Only effective while using auto_parallel_context = ParallelMode.AUTO_PARALLEL under graph mode.

Examples

```
>>> import mindspore.nn as nn
>>> net = nn.Dense(3, 4)
>>> net.set_data_parallel()
```

set_extra_state(*state: Any*)

Set extra state contained in the loaded *state_dict*.

This function is called from *load_state_dict* to handle any extra state found within the *state_dict*. Implement this function and a corresponding *get_extra_state* for your cell if you need to store extra state within its *state_dict*.

Parameters

state (*dict*) −Extra state from the *state_dict*.

set_grad(*requires_grad=True*)

Sets the cell flag for gradient.

Parameters

requires_grad (*bool*) −Specifies if the net need to grad, if it is `true` , the cell will construct backward network in pynative mode. Default: `True` .

Returns

Cell, the cell itself.

set_inputs(**inputs*, ***kwargs*)

Save set inputs for computation graph. The number of inputs should be the same with that of the datasets. When using Model for dynamic shape, please make sure that all networks and loss functions passed to the Model are configured with set_inputs. The shape of input Tensor can be either dynamic or static.

Note: There are two mode:

- Full mode: arguments will be used as all compile inputs for graph-compiling.

- Incremental mode: arguments will set to some of the Cell inputs, which will be substituted into the input at the corresponding position for graph-compiling.

Only one of inputs or kwargs can be set. Inputs for full mode and kwargs for incremental mode.

Parameters

- **inputs** (*tuple*) –Full mode arguments.
- **kwargs** (*dict*) –Incremental mode arguments. The acceptable key is the name of parameter defined in *self.construct*.

Warning: This is an experimental API that is subject to change or deletion.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import nn, Tensor
>>>
>>> class ReluNet(nn.Cell):
...     def __init__(self):
...         super(ReluNet, self).__init__()
...         self.relu = nn.ReLU()
...     def construct(self, x):
...         return self.relu(x)
>>>
>>> net = ReluNet()
>>> input_dyn = Tensor(shape=[3, None], dtype=ms.float32)
>>> net.set_inputs(input_dyn)
>>> input = Tensor(np.random.random([3, 10]), dtype=ms.float32)
>>> output = net(input)
>>>
>>> net2 = ReluNet()
>>> net2.set_inputs(x=input_dyn)
>>> output = net2(input)
```

set_jit_config(*jit_config*)

Set jit config for cell.

Parameters

jit_config (JitConfig) –Jit config for compile. For details, please refer to *mindspore.JitConfig*.

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn
...
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.relu = nn.ReLU()
...
...     def construct(self, x):
...         x = self.relu(x)
...         return x
>>> net = Net()
>>> jitconfig = ms.JitConfig()
>>> net.set_jit_config(jitconfig)
```

set_param_ps(*recurse=True*, *init_in_server=False*)

Set whether the trainable parameters are updated by parameter server and whether the trainable parameters are initialized on server.

Note: It only works when a running task is in the parameter server mode. It is only supported in graph mode.

Parameters

- **recurse** (*bool*) –Whether sets the trainable parameters of subcells. Default: `True` .
- **init_in_server** (*bool*) –Whether trainable parameters updated by parameter server are initialized on server. Default: `False` .

set_train(*mode=True*)

Sets the cell to training mode.

The cell itself and all children cells will be set to training mode. Layers that have different constructions for training and predicting, such as *BatchNorm*, will distinguish between the branches by this attribute. If set to true, the training branch will be executed, otherwise another branch.

Note: When execute function Model.train(), framework will call Cell.set_train(True). When execute function Model.eval(), framework will call Cell.set_train(False).

Parameters

mode (*bool*) –Specifies whether the model is training. Default: `True` .

Returns

Cell, the cell itself.

Tutorial Examples:

- Model Training - Implementing Training and Evaluation

shard(*in_strategy*, *out_strategy=None*, *parameter_plan=None*, *device='Ascend'*, *level=0*)

Defining the input and output layouts of this cell and the parallel strategies of remaining ops will be generated by sharding propagation. In PyNative mode, use this method to specify a Cell for distributed execution in graph mode. In Graph mode,

use this method to specify distribution strategy for a Cell, strategy for others will be set by sharding propagation. in_strategy and out_strategy define the input and output layout respectively. in_strategy/out_strategy should be a tuple, each element of which corresponds to the desired layout of this input/output, which can refer to the description of *mindspore.ops.Primitive.shard()*. The parallel strategies of remaining operators are derived from the strategy specified by the input and output.

Note:

- It is valid only in semi auto parallel or auto parallel mode. In other parallel modes, strategies set here will be ignored.
- If the input contain Parameter, its strategy should be set in *in_strategy*.

Parameters

- **in_strategy** (*tuple*) –Define the layout of inputs, each element of the tuple should be a tuple. Tuple defines the layout of the corresponding input.
- **out_strategy** (*Union[None, tuple]*) –Define the layout of outputs similar with in_strategy. It is not in use right now. Default: `None` .
- **parameter_plan** (*Union[dict, None]*) –Define the layout for the specified parameters. Each element in dict defines the layout of the parameter like "param_name: layout". The key is a parameter name of type 'str'. The value is a 1-D integer tuple, indicating the corresponding layout. If the parameter name is incorrect or the corresponding parameter has been set, the parameter setting will be ignored. Default: `None` .
- **device** (*str*) –Select a certain device target. It is not in use right now. Support [`"CPU"` , `"GPU"` , `"Ascend"`]. Default: `"Ascend"` .
- **level** (*int*) –Option for parallel strategy infer algorithm, namely the object function, maximize computation over communication ratio, maximize speed performance, minimize memory usage etc. It is not in use right now. Support [`"0"` , `"1"` , `"2"`]. Default: `0` .

Returns

Function, return the cell construct function that will be executed under auto parallel process.

Examples

```
>>> import mindspore.nn as nn
>>>
>>> class Block(nn.Cell):
...   def __init__(self):
...     self.dense1 = nn.Dense(10, 10)
...     self.relu = nn.ReLU()
...     self.dense2 = nn.Dense2(10, 10)
...   def construct(self, x):
...     x = self.relu(self.dense2(self.relu(self.dense1(x))))
...     return x
>>>
>>> class example(nn.Cell):
...   def __init__(self):
...     self.block1 = Block()
...     self.block2 = Block()
...     self.block2_shard = self.block2.shard(in_strategy=((2, 1),),
...                                           parameter_plan={'self.block2.shard.dense1.
↪weight': (4, 1)})
...   def construct(self, x):
```

(continues on next page)

(continued from previous page)

```
...     x = self.block1(x)
...     x = self.block2_shard(x)
...     return x
```

state_dict (**args*, *destination=None*, *prefix=''*, *keep_vars=False*)

Return a dictionary containing references to the whole state of the cell.

Both parameters and persistent buffers (e.g. running averages) are included. Keys are corresponding parameter and buffer names. Parameters and buffers set to `None` are not included.

Note: The returned object is a shallow copy. It contains references to the cell's parameters and buffers.

Warning:

- Currently `state_dict()` also accepts positional arguments for `destination`, `prefix` and `keep_vars` in order. However, this is being deprecated and keyword arguments will be enforced in future releases.
- Please avoid the use of argument `destination` as it is not designed for end-users.

Parameters

- **destination** (*dict, optional*) – If provided, the state of cell will be updated into the dict and the same object is returned. Otherwise, an `OrderedDict` will be created and returned. Default: `None`.
- **prefix** (*str, optional*) – A prefix added to parameter and buffer names to compose the keys in state_dict. Default: `''`.
- **keep_vars** (*bool, optional*) – Whether the state_dict returns a copy. Default: `False` , returns a reference.

Returns

Dict, a dictionary containing a whole state of the cell.

Examples

```
>>> import mindspore
>>> class Model(mindspore.nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.register_buffer("buffer_a", mindspore.tensor([4, 5, 6]))
...         self.param_a = mindspore.Parameter(mindspore.tensor([1, 2, 3]))
...
...     def construct(self, x):
...         return x + self.buffer_a + self.param_a
...
...
>>> model = Model()
>>> print(model.state_dict())
OrderedDict([('param_a', Parameter (name=param_a, shape=(3,), dtype=Int64, requires_
↪grad=True)), \
('buffer_a', Tensor(shape=[3], dtype=Int64, value= [4, 5, 6]))])
```

to_float (*dst_type*)

Add cast on all inputs of cell and child cells to run with certain float type.

If *dst_type* is *mindspore.dtype.float16*, all the inputs of Cell, including input, Parameter and Tensor, will be cast to float16. Please refer to the usage in source code of `mindspore.amp.build_train_network()`.

Note: Multiple calls will overwrite.

Parameters

dst_type (*mindspore.dtype*) −Transfer cell to run with dst_type. dst_type can be *mstype.float16* , *mstype.float32* or *mstype.bfloat16*.

Returns

Cell, the cell itself.

Raises

ValueError −If dst_type is not *mstype.float32* , *mstype.float16* or *mstype.bfloat16*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.nn as nn
>>> from mindspore import dtype as mstype
>>>
>>> net = nn.Conv2d(120, 240, 4, has_bias=False, weight_init='normal')
>>> net.to_float(mstype.float16)
Conv2d(input_channels=120, output_channels=240, kernel_size=(4, 4), stride=(1, 1), pad_
↪mode=same,
padding=0, dilation=(1, 1), group=1, has_bias=False, weight_init=normal, bias_init=None,␣
↪format=NCHW)
```

trainable_params(*recurse=True*)

Returns all trainable parameters.

Returns a list of all trainable parameters.

Parameters

recurse (*bool*) −Whether contains the trainable parameters of subcells. Default: `True` .

Returns

List, the list of trainable parameters.

Tutorial Examples:

- Model Training - Optimizer

untrainable_params(*recurse=True*)

Returns all untrainable parameters.

Returns a list of all untrainable parameters.

Parameters

recurse (*bool*) −Whether contains the untrainable parameters of subcells. Default: `True` .

Returns

List, the list of untrainable parameters.

update_cell_prefix()
Update the *param_prefix* of all child cells.

After being invoked, it can get all the cell's children's name prefix by '_param_prefix'.

update_cell_type(*cell_type*)
The current cell type is updated when a quantization aware training network is encountered.

After being invoked, it can set the cell type to 'cell_type'.

Parameters

cell_type (*str*) –The type of cell to be updated, cell_type can be "quant" or "second-order".

update_parameters_name(*prefix=''*, *recurse=True*)
Adds the *prefix* string to the names of parameters.

Parameters

- **prefix** (*str*) –The prefix string. Default: `''` .
- **recurse** (*bool*) –Whether contains the parameters of subcells. Default: `True` .

3.1.2 mindspore.nn.GraphCell

class mindspore.nn.**GraphCell**(*graph*, *params_init=None*, *obf_random_seed=None*)
Base class for running the graph loaded from a MindIR.

This feature is still under development. Currently *GraphCell* do not support modifying the structure of the diagram, and can only use data that shape and type are the same as the input when exporting the MindIR.

Parameters

- **graph** (*FuncGraph*) –A compiled graph loaded from MindIR.
- **params_init** (*dict*) –Parameters need to be inited in the graph. The key is the parameter name whose type is str, and the value is a Tensor or Parameter. If the parameter exists in the graph according to the name, update it's value. If the parameter does not exist, ignore it. Default: `None` .
- **obf_random_seed** (*Union[int, None]*) –The random seed used for dynamic obfuscation, which is not supported now.

Raises

- **NotImplementedError** –Dynamic structure obfuscation is not supported now.
- **TypeError** –If the *graph* is not a FuncGraph.
- **TypeError** –If the *params_init* is not a dict.
- **TypeError** –If the key of the *params_init* is not a str.
- **TypeError** –If the value of the *params_init* is neither a Tensor nor a Parameter.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> from mindspore import Tensor
>>> from mindspore import context
>>> context.set_context(mode=context.GRAPH_MODE)
>>> net = nn.Conv2d(1, 1, kernel_size=3, weight_init="ones")
>>> input = Tensor(np.ones([1, 1, 3, 3]).astype(np.float32))
>>> ms.export(net, input, file_name="net", file_format="MINDIR")
>>> graph = ms.load("net.mindir")
>>> net = nn.GraphCell(graph)
>>> output = net(input)
>>> print(output)
[[[[4. 6. 4.]
   [6. 9. 6.]
   [4. 6. 4.]]]]
```

3.1.3 mindspore.nn.LossBase

class mindspore.nn.**LossBase**(*reduction='mean'*)

Base class for other losses.

Other losses derived from this should implement their own *construct* and use method *self.get_loss* to apply reduction to loss values.

Parameters

reduction (*str, optional*) – Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'mean'`.

- `'none'`: no reduction will be applied.
- `'mean'`: compute and return the (weighted) mean of elements in the output.
- `'sum'`: the output elements will be summed.

Raises

ValueError – If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import ops, Tensor, nn
>>> import numpy as np
>>>
>>> class Net(nn.LossBase):
...     def __init__(self, reduction='mean'):
...         super(Net, self).__init__(reduction)
...         self.abs = ops.Abs()
...
...     def construct(self, logits, labels):
```

(continues on next page)

(continued from previous page)

```
...         x = self.abs(logits - labels)
...         output = self.get_loss(x)
...         axis = self.get_axis(x)
...         return output, axis
>>> net = Net()
>>> # Case 1: logits.shape = labels.shape = (3,)
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([1, 2, 2]), mindspore.float32)
>>> output, axis = net(logits, labels)
>>> print(output)
0.33333334
>>> print(axis)
(0,)
>>> # Case 2: logits.shape = labels.shape = (3, 3)
>>> logits = Tensor(np.array([[1, 2, 3],[1, 2, 3],[1, 2, 3]]), mindspore.float32)
>>> labels = Tensor(np.array([[1, 2, 2],[1, 2, 3],[1, 2, 3]]), mindspore.float32)
>>> output, axis = net(logits, labels)
>>> print(output)
0.11111111
>>> print(axis)
(0, 1)
```

get_axis(*x*)

Get a range of axis for input.

Parameters

x (Tensor) – Tensor of any shape.

get_loss(*x*, *weights=1.0*)

Computes the weighted loss.

Parameters

- **x** (Tensor) – Tensor of shape $(N, *)$ where $*$ means, any number of additional dimensions.
- **weights** (*Union[float, Tensor], optional*) – Weights. When *weights* is a Tensor, the rank is either 0, or the same rank as inputs, and must be broadcastable to inputs (i.e., all dimensions must be either *1*, or the same as the corresponding inputs dimension). Default: `1.0`.

Returns

Return the weighted loss.

3.1.4 mindspore.nn.Optimizer

class mindspore.nn.**Optimizer**(*learning_rate*, *parameters*, *weight_decay=0.0*, *loss_scale=1.0*)

Base class for updating parameters. Never use this class directly, but instantiate one of its subclasses instead.

Grouping parameters is supported. If parameters are grouped, different strategy of *learning_rate*, *weight_decay* and *grad_centralization* can be applied to each group.

Note: If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Parameters

- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule]*) –
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.
  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of current step.
- **parameters** (*Union[list[Parameter], list[dict]]*) –Must be list of *Parameter* or list of *dict*. When the *parameters* is a list of *dict*, the string "params", "lr", "weight_decay", "grad_centralization" and "order_params" are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used.
  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.
- **weight_decay** (*Union[float, int], optional*) –An int or a floating point value for the weight decay. It must be equal to or greater than 0. If the type of *weight_decay* input is int, it will be converted to float. Default: `0.0` .
- **loss_scale** (*float, optional*) –A floating point value for the loss scale. It must be greater than 0. If the type of *loss_scale* input is int, it will be converted to float. In general, use the default value. Only when *FixedLossScaleManager* is used for training and the *drop_overflow_update* in *FixedLossScaleManager* is set to `False` , this value needs to be the same as the *loss_scale* in *FixedLossScaleManager*. Refer to class *mindspore.amp.FixedLossScaleManager* for more details. Default: `1.0` .

Raises

- **TypeError** –If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** –If element of *parameters* is neither Parameter nor dict.
- **TypeError** –If *loss_scale* is not a float.
- **TypeError** –If *weight_decay* is neither float nor int.
- **ValueError** –If *loss_scale* is less than or equal to 0.
- **ValueError** –If *weight_decay* is less than 0.
- **ValueError** –If *learning_rate* is a Tensor, but the dimension of tensor is greater than 1.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>> import numpy as np
>>> import mindspore
>>> from mindspore import nn, ops, Tensor
>>>
>>> class MyMomentum(nn.Optimizer):
...     def __init__(self, params, learning_rate, momentum=0.9):
...         super(MyMomentum, self).__init__(learning_rate, params)
...         self.moments = self.parameters.clone(prefix="moments", init="zeros")
...         self.momentum = momentum
...         self.opt = ops.ApplyMomentum()
...
...     def construct(self, gradients):
...         params = self.parameters
...         lr = self.get_lr()
...         gradients = self.flatten_gradients(gradients)
...         gradients = self.decay_weight(gradients)
...         gradients = self.gradients_centralization(gradients)
...         gradients = self.scale_grad(gradients)
...
...         success = None
...         for param, mom, grad in zip(params, self.moments, gradients):
...             success = self.opt(param, mom, lr, grad, self.momentum)
...         return success
>>>
>>> net = nn.Dense(2, 3)
>>> loss_fn = nn.MAELoss()
>>> opt = MyMomentum(net.trainable_params(), 0.01)
>>>
>>> device_target = opt.target
>>> opt_unique = opt.unique
>>> weight_decay_value = opt.get_weight_decay()
>>>
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>>
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, opt.parameters, has_aux=True)
>>>
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     opt(grads)
...     return loss
>>>
>>> data = Tensor(np.random.rand(4, 10, 2), mindspore.dtype.float32)
>>> label = Tensor(np.random.rand(4, 10, 3), mindspore.dtype.float32)
>>> train_step(data, label)
```

broadcast_params(*optim_result*)

Apply Broadcast operations in the sequential order of parameter groups.

Parameters

optim_result (*bool*) – The results of updating parameters. This input is used to ensure that the parameters are updated before they are broadcast.

Returns

The broadcast parameters.

decay_weight(*gradients*)

Weight decay.

An approach to reduce the overfitting of a deep learning neural network model. User-defined optimizers based on *mindspore.nn.Optimizer* can also call this interface to apply weight decay.

Parameters

gradients (*tuple[Tensor]*) – The gradients of network parameters, and have the same shape as the parameters.

Returns

tuple[Tensor], The gradients after weight decay.

flatten_gradients(*gradients*)

Flatten gradients into several chunk tensors grouped by data type if network parameters are flattened.

A method to enable performance improvement by using contiguous memory for parameters and gradients. User-defined optimizers based on *mindspore.nn.Optimizer* should call this interface to support contiguous memory for network parameters.

Parameters

gradients (*tuple[Tensor]*) – The gradients of network parameters.

Returns

tuple[Tensor], The gradients after flattened, or the original gradients if parameters are not flattened.

get_lr()

The optimizer calls this interface to get the learning rate for the current step. User-defined optimizers based on *mindspore.nn.Optimizer* can also call this interface before updating the parameters.

Returns

float, the learning rate of current step.

get_lr_parameter(*param*)

When parameters is grouped and learning rate is different for each group, get the learning rate of the specified *param*.

Parameters

param (*Union[Parameter, list[Parameter]]*) – The *Parameter* or list of *Parameter*.

Returns

A single *Parameter* or *list[Parameter]* according to the input type. If learning rate is dynamic, *LearningRateSchedule* or *list[LearningRateSchedule]* that used to calculate the learning rate will be returned.

Examples

```
>>> from mindspore import nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> conv_params = list(filter(lambda x: 'conv' in x.name, net.trainable_params()))
>>> no_conv_params = list(filter(lambda x: 'conv' not in x.name, net.trainable_params()))
>>> group_params = [{'params': conv_params, 'lr': 0.05},
...                 {'params': no_conv_params, 'lr': 0.01}]
```

(continues on next page)

(continued from previous page)

```
>>> optim = nn.Momentum(group_params, learning_rate=0.1, momentum=0.9, weight_decay=0.0)
>>> conv_lr = optim.get_lr_parameter(conv_params)
>>> print(conv_lr[0].asnumpy())
0.05
```

get_weight_decay()

The optimizer calls this interface to get the weight decay value for the current step. User-defined optimizers based on *mindspore.nn.Optimizer* can also call this interface before updating the parameters.

Returns

float, the weight decay value of current step.

gradients_centralization(*gradients*)

Gradients centralization.

A method for optimizing convolutional layer parameters to improve the training speed of a deep learning neural network model. User-defined optimizers based on *mindspore.nn.Optimizer* can also call this interface to centralize gradients.

Parameters

gradients (*tuple[Tensor]*) – The gradients of network parameters, and have the same shape as the parameters.

Returns

tuple[Tensor], The gradients after gradients centralization.

scale_grad(*gradients*)

Restore gradients for mixed precision.

User-defined optimizers based on *mindspore.nn.Optimizer* can also call this interface to restore gradients.

Parameters

gradients (*tuple[Tensor]*) – The gradients of network parameters, and have the same shape as the parameters.

Returns

tuple[Tensor], The gradients after loss scale.

property target

The property is used to determine whether the parameter is updated on host or device. The input type is str and can only be 'CPU', 'Ascend' or 'GPU'.

property unique

Whether to make the gradients unique in optimizer. Generally, it is used in sparse networks. Set to True if the gradients of the optimizer are sparse, while set to False if the forward network has made the parameters unique, that is, the gradients of the optimizer is no longer sparse. The default value is True when it is not set.

3.2 Container

API Name	Description	Supported Platforms
mindspore.nn.CellDict	Holds Cells in a dictionary.	Ascend GPU CPU
mindspore.nn.CellList	Holds Cells in a list.	Ascend GPU CPU
mindspore.nn.SequentialCell	Sequential Cell container.	Ascend GPU CPU

3.2.1 mindspore.nn.CellDict

class mindspore.nn.**CellDict**(**args*, ***kwargs*)

Holds Cells in a dictionary. For more details about *Cell* , please refer to *mindspore.nn.Cell* .

CellDict can be used like a regular Python dictionary.

Parameters

- **args** (*iterable, optional*) – An iterable of key-value pairs of (key, Cell), the type of key-value pairs is (string, Cell); Or a mapping(dictionary) from string to Cell. The type of Cell can not be CellDict, CellList or SequentialCell. The key can not be same with the attributes of class Cell, can not contain '.', can not be an empty string. The key of type string is used to search corresponding Cell in the CellDict.
- **kwargs** (*dict*) – Reserved for keyword argument to be expanded.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import collections
>>> from collections import OrderedDict
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, nn
>>>
>>> cell_dict = nn.CellDict({'conv': nn.Conv2d(10, 6, 5),
...                          'relu': nn.ReLU(),
...                          'max_pool2d': nn.MaxPool2d(kernel_size=4, stride=4)})
>>> print(len(cell_dict))
3
>>> cell_dict.clear()
>>> print(len(cell_dict))
0
>>> ordered_cells = OrderedDict([('conv', nn.Conv2d(10, 6, 5, pad_mode='valid')),
...                              ('relu', nn.ReLU()),
...                              ('max_pool2d', nn.MaxPool2d(kernel_size=2, stride=2))])
>>> cell_dict.update(ordered_cells)
>>> x = Tensor(np.ones([1, 10, 6, 10]), ms.float32)
>>> for cell in cell_dict.values():
...     x = cell(x)
>>> print(x.shape)
(1, 6, 1, 3)
>>> x = Tensor(np.ones([1, 10, 6, 10]), ms.float32)
>>> for item in cell_dict.items():
...     x = item[1](x)
>>> print(x.shape)
(1, 6, 1, 3)
>>> print(cell_dict.keys())
odict_keys(['conv', 'relu', 'max_pool2d'])
>>> pop_cell = cell_dict.pop('conv')
>>> x = Tensor(np.ones([1, 10, 6, 5]), ms.float32)
>>> x = pop_cell(x)
>>> print(x.shape)
(1, 6, 2, 1)
```

(continues on next page)

(continued from previous page)

```
>>> print(len(cell_dict))
2
```

clear()
Remove all Cells from the CellDict.

items()
Return an iterable of the CellDict key-value pairs.

Returns

An iterable object.

keys()
Return an iterable of the CellDict keys.

Returns

An iterable object.

pop(*key*)
Remove key from the CellDict and return its cell.

Parameters

key (*str*) – key to pop from the CellDict.

Raises

KeyError – If *key* not exist in CellDict when attempt to access cell.

update(*cells*)
Update the CellDict by overwriting the existing keys with the key-value pairs from a mapping or an iterable.

Parameters

cells (*iterable*) – An iterable of key-value pairs of (key, Cell), the type of key-value pairs is (string, Cell); Or a mapping(dictionary) from string to Cell. The type of Cell can not be CellDict, CellList or SequentialCell. The key can not be same with the attributes of class Cell, can not contain '.', can not be an empty string.

Note: If the *cells* is a CellDict, an OrderedDict or an iterable containing key-value pairs, the order of newly added elements is maintained.

Raises

- **TypeError** – If *cells* is not an iterable object.
- **TypeError** – If key-value pairs in *cells* are not iterable objects.
- **ValueError** – If the length of key-value pairs in *cells* is not 2.
- **TypeError** – If the cell in *cells* is None.
- **TypeError** – If the type of cell in *cells* is not Cell.
- **TypeError** – If the type of cell in *cells* is CellDict, CellList or SequentialCell.
- **TypeError** – If the type of key in *cells* is not string.
- **KeyError** – If the key in *cells* is same with the attributes of class Cell.
- **KeyError** – If the key in *cells* contain ".".

- **KeyError** –If the key in *cells* is an empty string.

values()
Return an iterable of the CellDict values.

Returns

An iterable object.

3.2.2 mindspore.nn.CellList

class mindspore.nn.**CellList**(**args*, ***kwargs*)
Holds Cells in a list. For more details about Cell, please refer to Cell.

CellList can be used like a regular Python list, the Cells it contains have been initialized and the types of Cells it contains can not be CellDict. Unlike the SequentialCell, the cells in CellList are not connected.

Parameters

args (*list, optional*) –List of subclass of Cell.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>>
>>> conv = ms.nn.Conv2d(100, 20, 3)
>>> bn = ms.nn.BatchNorm2d(20)
>>> relu = ms.nn.ReLU()
>>> cell_ls = ms.nn.CellList([bn])
>>> cell_ls.insert(0, conv)
>>> cell_ls.append(relu)
>>> cell_ls.extend([relu, relu])
>>> cell_ls_3 = cell_ls[3]
>>> input1 = ms.Tensor(np.ones([2, 3]), ms.float32)
>>> output = cell_ls_3(input1)
>>> print(output)
[[1. 1. 1.]
[1. 1. 1.]]
```

append(*cell*)
Appends a given Cell to the end of the list.

Parameters

cell (Cell) –The subcell to be appended.

extend(*cells*)
Appends Cells from a Python iterable to the end of the list.

Parameters

cells (*list*) –The Cells to be extended, the types of Cells can not be CellDict.

Raises

TypeError –If the argument cells are not a list of Cells.

insert (*index*, *cell*)
Inserts a given Cell before a given index in the list.

Parameters

- **index** (*int*) –The Insert index in the CellList.
- **cell** (Cell) –The Cell to be inserted.

3.2.3 mindspore.nn.SequentialCell

class mindspore.nn.**SequentialCell**(**args*)
Sequential Cell container. For more details about Cell, please refer to Cell.

A list of Cells will be added to it in the order they are passed in the constructor. Alternatively, an ordered dict of cells can also be passed in.

Parameters

args (*list, OrderedDict*) –List or OrderedDict of subclass of Cell.

Inputs:

- **x** (Tensor) - Tensor with shape according to the first Cell in the sequence.

Outputs:

Tensor, the output Tensor with shape depending on the input *x* and defined sequence of Cells.

Raises

TypeError –If the type of the *args* is not list or OrderedDict.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>>
>>> conv = nn.Conv2d(3, 2, 3, pad_mode='valid', weight_init="ones")
>>> relu = nn.ReLU()
>>> seq = nn.SequentialCell([conv, relu])
>>> x = Tensor(np.ones([1, 3, 4, 4]), dtype = mindspore.float32)
>>> output = seq(x)
>>> print(output)
[[[[27. 27.]
   [27. 27.]]
  [[27. 27.]
   [27. 27.]]]]
>>> from collections import OrderedDict
>>> d = OrderedDict()
>>> d["conv"] = conv
```

(continues on next page)

(continued from previous page)

```
>>> d["relu"] = relu
>>> seq = nn.SequentialCell(d)
>>> x = Tensor(np.ones([1, 3, 4, 4]), dtype=mindspore.float32)
>>> output = seq(x)
>>> print(output)
[[[[27. 27.]
   [27. 27.]]
  [[27. 27.]
   [27. 27.]]]]
```

append(*cell*)

Appends a given Cell to the end of the list.

Parameters

cell (Cell) –The Cell to be appended.

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>>
>>> conv = nn.Conv2d(3, 2, 3, pad_mode='valid', weight_init="ones")
>>> bn = nn.BatchNorm2d(2)
>>> relu = nn.ReLU()
>>> seq = nn.SequentialCell([conv, bn])
>>> seq.append(relu)
>>> x = Tensor(np.ones([1, 3, 4, 4]), dtype=mindspore.float32)
>>> output = seq(x)
>>> print(output)
[[[[26.999863 26.999863]
   [26.999863 26.999863]]
  [[26.999863 26.999863]
   [26.999863 26.999863]]]]
```

3.3 Wrapper Layer

API Name	Description	Supported Platforms
mindspore.nn.DistributedGradReducer	A distributed optimizer.	Ascend GPU
mindspore.nn.DynamicLossScaleUpdateCell	Dynamic Loss scale update cell.	Ascend GPU
mindspore.nn.FixedLossScaleUpdateCell	Update cell with fixed loss scaling value.	Ascend GPU
mindspore.nn.ForwardValueAndGrad	Encapsulate training network.	Ascend GPU CPU
mindspore.nn.GetNextSingleOp	Cell to run for getting the next operation.	Ascend GPU
mindspore.nn.GradAccumulationCell	Wrap the network with Micro Batch to enable the grad accumulation in semi_auto_parallel/auto_parallel mode.	Ascend GPU
mindspore.nn.ParameterUpdate	Cell that updates parameter.	Ascend GPU CPU

continues on next page

Table 3 – continued from previous page

mindspore.nn.PipelineCell	Slice MiniBatch into finer-grained MicroBatch for use in pipeline-parallel training.	Ascend GPU
mindspore.nn.TimeDistributed	The time distributed layer.	Ascend GPU CPU
mindspore.nn.TrainOneStepCell	Network training package class.	Ascend GPU CPU
mindspore.nn.TrainOneStepWithLossScaleCell	Network training with loss scaling.	Ascend GPU
mindspore.nn.WithEvalCell	Wraps the forward network with the loss function.	Ascend GPU CPU
mindspore.nn.WithLossCell	Cell with loss function.	Ascend GPU CPU

3.3.1 mindspore.nn.DistributedGradReducer

class mindspore.nn.**DistributedGradReducer**(*parameters*, *mean=None*, *degree=None*, *fusion_type=1*, *group=GlobalComm.WORLD_COMM_GROUP*)

A distributed optimizer.

Aggregate the gradients for all cards by using AllReduce in data parallel.

Parameters

- **parameters** (*list*) –the parameters to be updated.
- **mean** (*bool*) –When mean is true, the mean coefficient (degree) would apply on gradients. When it is not specified, using the configuration *gradients_mean* in auto_parallel_context. Default: `None` .
- **degree** (*int*) –The mean coefficient. Usually it equals to device number. Default: `None` .
- **fusion_type** (*int*) –The type of all reduce fusion. Default: `1` .
- **group** (*str*) –The communication group to work on. Normally, the group should be created by create_group, otherwise, using the default group. Default: `GlobalComm.WORLD_COMM_GROUP` .

Raises

ValueError –If degree is not an int or less than 0.

Supported Platforms:

`Ascend` `GPU`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For the Ascend devices, users need to prepare the rank table, set rank_id and device_id. Please see the rank table Startup for more details.

For the GPU devices, users need to prepare the host file and mpi, please see the mpirun Startup .

For the CPU device, users need to write a dynamic cluster startup script, please see the Dynamic Cluster Startup .

This example should be run with multiple devices.

256.0
```

3.3.2 mindspore.nn.DynamicLossScaleUpdateCell

class mindspore.nn.**DynamicLossScaleUpdateCell**(*loss_scale_value*, *scale_factor*, *scale_window*)

Dynamic Loss scale update cell.

For loss scaling training, the initial loss scaling value will be set to be *loss_scale_value*. In each training step, the loss scaling value will be decreased by $loss\_scale/scale\_factor$ when there is an overflow. And it will be increased by $loss\_scale*scale\_factor$ if there is no overflow for a continuous *scale_window* steps.

get_update_cell method of *mindspore.amp.DynamicLossScaleManager* will return this class. It will be called by *mindspore.nn.TrainOneStepWithLossScaleCell* during training to update loss scale.

Parameters

- **loss_scale_value** (*float*) –Initializes loss scale.
- **scale_factor** (*int*) –Coefficient of increase and decrease.
- **scale_window** (*int*) –Maximum continuous training steps that do not have overflow to increase the loss scale.

Inputs:

- **loss_scale** (Tensor) - The loss scale value during training with shape ().
- **overflow** (bool) - Whether the overflow occurs or not.

Outputs:

bool, the input *overflow*.

Supported Platforms:

Ascend GPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, Parameter, nn, ops
>>>
>>> class Net(nn.Cell):
...     def __init__(self, in_features, out_features):
...         super(Net, self).__init__()
...         self.weight = Parameter(Tensor(np.ones([in_features, out_features]).astype(np.
↪float32)),
...                                 name='weight')
...         self.matmul = ops.MatMul()
...
...     def construct(self, x):
...         output = self.matmul(x, self.weight)
```

(continues on next page)

(continued from previous page)

```
...         return output
...
>>> in_features, out_features = 16, 10
>>> net = Net(in_features, out_features)
>>> loss = nn.MSELoss()
>>> optimizer = nn.Momentum(net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> net_with_loss = nn.WithLossCell(net, loss)
>>> manager = nn.DynamicLossScaleUpdateCell(loss_scale_value=2**12, scale_factor=2, scale_
↪window=1000)
>>> train_network = nn.TrainOneStepWithLossScaleCell(net_with_loss, optimizer, scale_
↪sense=manager)
>>> input = Tensor(np.ones([out_features, in_features]), mindspore.float32)
>>> labels = Tensor(np.ones([out_features,]), mindspore.float32)
>>> output = train_network(input, labels)
```

get_loss_scale()

Get Loss Scale value.

Returns

float, the loss scale value.

Examples

```
>>> from mindspore import nn
>>> manager = nn.DynamicLossScaleUpdateCell(loss_scale_value=212, scale_factor=2, scale_
↪window=1000)
>>> output = manager.get_loss_scale()
>>> print(output)
212
```

3.3.3 mindspore.nn.FixedLossScaleUpdateCell

class mindspore.nn.**FixedLossScaleUpdateCell**(*loss_scale_value*)

Update cell with fixed loss scaling value.

get_update_cell method of *mindspore.amp.FixedLossScaleManager* will return this class. It will be called by *mindspore.nn.TrainOneStepWithLossScaleCell* during trainning.

Parameters

loss_scale_value (*float*) –Initializes loss scale.

Inputs:

- **loss_scale** (Tensor) - The loss scale value during training with shape (), it is ignored in this class.
- **overflow** (bool) - Whether the overflow occurs or not.

Outputs:

bool, the input *overflow*.

Supported Platforms:

Ascend GPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, Parameter, nn, ops
>>>
>>> class Net(nn.Cell):
...     def __init__(self, in_features, out_features):
...         super(Net, self).__init__()
...         self.weight = Parameter(Tensor(np.ones([in_features, out_features]).astype(np.
↪float32)),
...                                 name='weight')
...         self.matmul = ops.MatMul()
...
...     def construct(self, x):
...         output = self.matmul(x, self.weight)
...         return output
...
>>> in_features, out_features = 16, 10
>>> net = Net(in_features, out_features)
>>> loss = nn.MSELoss()
>>> optimizer = nn.Momentum(net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> net_with_loss = nn.WithLossCell(net, loss)
>>> manager = nn.FixedLossScaleUpdateCell(loss_scale_value=2**12)
>>> train_network = nn.TrainOneStepWithLossScaleCell(net_with_loss, optimizer, scale_
↪sense=manager)
>>> input = Tensor(np.ones([out_features, in_features]), mindspore.float32)
>>> labels = Tensor(np.ones([out_features,]), mindspore.float32)
>>> output = train_network(input, labels)
```

get_loss_scale()

Get Loss Scale value.

Returns

float, the loss scale value.

Examples

```
>>> from mindspore import nn
>>> manager = nn.FixedLossScaleUpdateCell(loss_scale_value=212)
>>> output = manager.get_loss_scale()
>>> print(output)
212
```

3.3.4 mindspore.nn.ForwardValueAndGrad

class mindspore.nn.**ForwardValueAndGrad**(*network*, *weights=None*, *get_all=False*, *get_by_list=False*, *sens_param=False*)

Encapsulate training network.

Including the network and a gradient function. The resulting Cell is trained with input '*inputs'. The backward graph will be created in the gradient function to calculating gradient.

Parameters

- **network** (*Union[Cell, Function, MethodType]*) –The training network.
- **weights** (ParameterTuple) –The parameters of the training network that need to calculate the gradient. Default: None .
- **get_all** (*bool*) –If True , get all the gradients with respect to inputs. Default: False .
- **get_by_list** (*bool*) –If True s, get all the gradients with respect to Parameter variables. If get_all and get_by_list are both False , get the gradient with respect to first input. If get_all and get_by_list are both True , get the gradients with respect to inputs and Parameter variables at the same time in the form of ((gradients with respect to inputs), (gradients with respect to parameters)). Default: False .
- **sens_param** (*bool*) –Whether to append sensitivity (gradient with respect to output) as input. If sens_param is False , a 'ones_like(outputs)' sensitivity will be attached automatically. Default: False . If the sens_param is True , a sensitivity (gradient with respect to output) needs to be transferred through the input parameter.

Inputs:

- ***inputs** (Tuple(Tensor···)) - Tuple of inputs with shape $(N, \ldots)$.
- **sens** - A sensitivity (gradient with respect to output) as the input of backpropagation. If network has single output, the sens is a tensor. If network has multiple outputs, the sens is the tuple(tensor).

Outputs:

- **forward value** - The result of network forward running.
- **gradients** (tuple(tensor)) - The gradients of network parameters and inputs.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, nn, ops, ParameterTuple, Parameter
>>>
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.weight = Parameter(Tensor(np.ones([2, 2]).astype(np.float32)), name="weight")
...         self.matmul = ops.MatMul()
...
...     def construct(self, x):
...         out = self.matmul(x, self.weight)
...         return out
...
>>> net = Net()
>>> criterion = nn.SoftmaxCrossEntropyWithLogits()
>>> net_with_criterion = nn.WithLossCell(net, criterion)
>>> weight = ParameterTuple(net.trainable_params())
>>> train_network = nn.ForwardValueAndGrad(net_with_criterion, weights=weight, get_all=True,␣
↪get_by_list=True)
>>> inputs = Tensor(np.ones([1, 2]).astype(np.float32))
>>> labels = Tensor(np.ones([1, 2]).astype(np.float32))
>>> result = train_network(inputs, labels)
>>> print(result)
 (Tensor(shape=[1], dtype=Float32, value= [ 1.38629436e+00]), ((Tensor(shape=[1, 2],␣
↪dtype=Float32, value=
```

(continues on next page)

(continued from previous page)

```
[[ -1.00000000e+00,  -1.00000000e+00]]), Tensor(shape=[1, 2], dtype=Float32, value=
[[ 0.00000000e+00,  0.00000000e+00]])), (Tensor(shape=[2, 2], dtype=Float32, value=
[[ -5.00000000e-01,  -5.00000000e-01],
 [ -5.00000000e-01,  -5.00000000e-01]]),)))
```

3.3.5 mindspore.nn.GetNextSingleOp

class mindspore.nn.**GetNextSingleOp**(*dataset_types*, *dataset_shapes*, *queue_name*)

Cell to run for getting the next operation.

For detailed information, refer to *mindspore.ops.GetNext*.

Parameters

- **dataset_types** (list[*mindspore.dtype*]) –The types of dataset.
- **dataset_shapes** (*list[tuple[int]]*) –The shapes of dataset.
- **queue_name** (*str*) –Queue name to fetch the data.

Outputs:

tuple[Tensor], the data gets from Dataset.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> from mindspore import ops, nn
>>> from mindspore import dataset as ds
>>> from mindspore import dtype as mstype
>>>
>>> data_path =  "/path/to/MNIST_Data/train/"
>>> train_dataset = ds.MnistDataset(data_path, num_samples=10)
>>> dataset_helper = mindspore.DatasetHelper(train_dataset, dataset_sink_mode=True)
>>> dataset = dataset_helper.iter.dataset
>>> dataset_types, dataset_shapes = dataset_helper.types_shapes()
>>> queue_name = dataset.__transfer_dataset__.queue_name
>>> get_next_single_op_net = nn.GetNextSingleOp(dataset_types, dataset_shapes, queue_name)
>>> data, label = get_next_single_op_net()
>>> relu = ops.ReLU()
>>> result = relu(data.astype(mstype.float32))
>>> print(result.shape)
(28, 28, 1)
```

3.3.6 mindspore.nn.GradAccumulationCell

class mindspore.nn.**GradAccumulationCell**(*network*, *micro_size*)

Wrap the network with Micro Batch to enable the grad accumulation in semi_auto_parallel/auto_parallel mode.

Note: The api will be deprecated, please use the api *mindspore.parallel.nn.GradAccumulation* instead.

Parameters

- **network** (Cell) –The target network to wrap.
- **micro_size** (*int*) –MicroBatch size.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore.nn as nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> net = nn.GradAccumulationCell(net, 4)
```

3.3.7 mindspore.nn.ParameterUpdate

class mindspore.nn.**ParameterUpdate**(*param*)

Cell that updates parameter.

With this Cell, one can manually update *param* with the input *Tensor*.

Parameters

param (Parameter) –The parameter to be updated manually.

Inputs:

- **x** (Tensor) - A tensor whose shape and type are the same with *param*.

Outputs:

Tensor, the updated value.

Raises

KeyError –If parameter with the specified name does not exist.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import nn, Tensor
>>> network = nn.Dense(3, 4)
>>> param = network.parameters_dict()['weight']
>>> update = nn.ParameterUpdate(param)
>>> update.phase = "update_param"
>>> weight = Tensor(np.arange(12).reshape((4, 3)), mindspore.float32)
>>> output = update(weight)
>>> print(output)
[[ 0.  1.  2.]
 [ 3.  4.  5.]
 [ 6.  7.  8.]
 [ 9. 10. 11.]]
```

3.3.8 mindspore.nn.PipelineCell

class mindspore.nn.**PipelineCell**(*network*, *micro_size*, *stage_config=None*)

Slice MiniBatch into finer-grained MicroBatch for use in pipeline-parallel training.

Note:

- micro_size must be greater or equal to pipeline stages.
- The api will be deprecated, please use the api *mindspore.parallel.nn.Pipeline* instead.

Parameters

- **network** (Cell) – The target network to wrap.
- **micro_size** (*int*) – MicroBatch size.
- **stage_config** (*dict, optional*) – The stage configuration for each cell's execution in pipeline parallel. Default None.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore.nn as nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> net = nn.PipelineCell(net, 4)
```

3.3.9 mindspore.nn.TimeDistributed

class mindspore.nn.**TimeDistributed**(*layer*, *time_axis*, *reshape_with_axis=None*)

The time distributed layer.

Time distributed is a wrapper which allows to apply a layer to every temporal slice of an input. And the *x* should be at least 3D. There are two cases in the implementation. When reshape_with_axis provided, the reshape method will be chosen, which is more efficient; otherwise, the method of dividing the inputs along time axis will be used, which is more general. For example, reshape_with_axis could not be provided when deal with Batch Normalization.

Parameters

- **layer** (*Union[Cell, Primitive]*) –The Cell or Primitive which will be wrapped.
- **time_axis** (*int*) –The axis of time_step.
- **reshape_with_axis** (*int*) –The axis which will be reshaped with time_axis. Default: None .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, T, *)$, where $*$ means any number of additional dimensions.

Outputs:

Tensor of shape $(N, T, *)$.

Raises

TypeError –If layer is not a Cell or Primitive.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> x = ms.Tensor(np.random.random([32, 10, 3]), ms.float32)
>>> dense = ms.nn.Dense(3, 6)
>>> net = ms.nn.TimeDistributed(dense, time_axis=1, reshape_with_axis=0)
>>> output = net(x)
>>> print(output.shape)
(32, 10, 6)
```

3.3.10 mindspore.nn.TrainOneStepCell

class mindspore.nn.**TrainOneStepCell**(*network*, *optimizer*, *sens=None*, *return_grad=False*)

Network training package class.

Wraps the *network* with the *optimizer*. The resulting Cell is trained with input '*inputs'. The backward graph will be created in the construct function to update the parameter. Different parallel modes are available for training.

Parameters

- **network** (Cell) –The training network. The network only supports single output.
- **optimizer** (*Union[Cell]*) –Optimizer for updating the network parameters.

- **sens** (*numbers.Number, optional*) – The scaling number to be filled as the input of backpropagation. Default value is `None` , which is `1.0` .
- **return_grad** (*bool, optional*) – Whether to return gradient. If `True`, it will return the gradient in the form of a dict while returning loss. The key of the dict is the parameter name corresponding to the gradient, and value is the gradient value. Default value is `False` .

Inputs:

- ***inputs** (Tuple(Tensor)) - Tuple of input tensors with shape $(N, \ldots)$.

Outputs:

Tensor, a tensor means the loss value, the shape of which is usually ().

Raises

TypeError – If *sens* is not a numbers.Number.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.nn as nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits()
>>> optim = nn.Momentum(net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> #1) Using the WithLossCell provided by MindSpore
>>> loss_net = nn.WithLossCell(net, loss_fn)
>>> train_net = nn.TrainOneStepCell(loss_net, optim)
>>>
>>> #2) Using user-defined WithLossCell
>>> class MyWithLossCell(nn.Cell):
...     def __init__(self, backbone, loss_fn):
...         super(MyWithLossCell, self).__init__(auto_prefix=False)
...         self._backbone = backbone
...         self._loss_fn = loss_fn
...
...     def construct(self, x, y, label):
...         out = self._backbone(x, y)
...         return self._loss_fn(out, label)
...
...     @property
...     def backbone_network(self):
...         return self._backbone
...
>>> loss_net = MyWithLossCell(net, loss_fn)
>>> train_net = nn.TrainOneStepCell(loss_net, optim)
```

3.3.11 mindspore.nn.TrainOneStepWithLossScaleCell

class mindspore.nn.**TrainOneStepWithLossScaleCell**(*network*, *optimizer*, *scale_sense*)

Network training with loss scaling.

This is a training step with loss scaling. It takes a network, an optimizer and a scale update Cell(or a Tensor) as args. The loss scale value can be updated in both host side or device side. If you want to update it on host side, using a value of Tensor type as *scale_sense*, otherwise, using a Cell instance for updating loss scale as *scale_sense*.

Parameters

- **network** (Cell) –The training network. The network only supports single output.
- **optimizer** (Cell) –Optimizer for updating the network parameters.
- **scale_sense** (*Union[Tensor, Cell]*) –If this value is a Cell, it will be called by *TrainOneStepWithLossScaleCell* to update loss scale. If this value is a Tensor, the loss scale can be modified by *set_sense_scale*, the shape should be () or (1,).

Inputs:

- ***inputs** (Tuple(Tensor)) - Tuple of input tensors with shape $(N, \ldots)$.

Outputs:

Tuple of 3 Tensor, the loss, overflow flag and current loss scale value.

- **loss** (Tensor) - A scalar, the loss value.
- **overflow** (Tensor) - A scalar, whether overflow occur or not, the type is bool.
- **loss scale** (Tensor) - The loss scale value, the shape is () or (1,).

Raises

- **TypeError** –If *scale_sense* is neither Cell nor Tensor.
- **ValueError** –If shape of *scale_sense* is neither (1,) nor ().

Supported Platforms:

Ascend GPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, Parameter, nn, ops
>>>
>>> class Net(nn.Cell):
...     def __init__(self, in_features, out_features):
...         super(Net, self).__init__()
...         self.weight = Parameter(Tensor(np.ones([in_features, out_features]).astype(np.
↪float32)),
...                                 name='weight')
...         self.matmul = ops.MatMul()
...
...     def construct(self, x):
...         output = self.matmul(x, self.weight)
...         return output
```

(continues on next page)

(continued from previous page)

```
...
>>> size, in_features, out_features = 16, 16, 10
>>> #1) when the type of scale_sense is Cell:
>>> net = Net(in_features, out_features)
>>> loss_fn = nn.MSELoss()
>>> optimizer = nn.Momentum(net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> net_with_loss = nn.WithLossCell(net, loss_fn)
>>> input = Tensor(np.ones([out_features, in_features]), mindspore.float32)
>>> labels = Tensor(np.ones([out_features,]), mindspore.float32)

>>> scaling_sens = Tensor([1024], dtype=mindspore.float32)
>>> train_network = nn.TrainOneStepWithLossScaleCell(net_with_loss, optimizer, scale_
↪sense=scaling_sens)
>>> scaling_sens = Tensor([1], dtype=mstype.float32)
>>> train_network.set_sense_scale(scaling_sens)
>>> output = train_network(inputs, label)
>>>
>>> # update scaling sens and train the network
>>> scaling_sens = Tensor([1], dtype=mindspore.float32)
>>> train_network.set_sense_scale(scaling_sens)
>>> output = train_network(inputs, label)
```

get_overflow_status(*status*, *compute_output*)

Get floating-point overflow status.

Get overflow results after executing the target process for overflow detection. User-defined training network based on this class can also call this interface to process the overflow.

Parameters

- **status** (*object*) –To control the execution sequence with start_overflow_check, it should be set as the first output of start_overflow_check.
- **compute_output** –Overflow detection should be performed in a certain computation process. Set *compute_output* as the output of the computation process.

Returns

bool, whether the overflow occurs or not.

process_loss_scale(*overflow*)
Calculate loss scale according to the overflow.

User-defined training network based on this class can also call this interface to process the overflow.

Parameters

overflow (*bool*) −Whether the overflow occurs or not.

Returns

bool, the input overflow value.

set_sense_scale(*sens*)
If the user has set the *scale_sense* of Tensor type, he can call this function to reassign the value.

Parameters

sens (Tensor) −The new sense whose shape and type are the same with original *scale_sense*.

start_overflow_check(*pre_cond*, *compute_input*)
Start floating-point overflow detection. Create and clear the overflow detection state.

Specify the argument 'pre_cond' and 'compute_input' to make sure overflow status is cleared at the right time. Taking this situation as an example, we need to execute state clearing after loss calculation and then detect overflow in the process of gradient calculation. In this case, pre_cond should be the output of the loss function, and compute_input should be the input of gradients-computing function. User-defined training network based on this class can also call this interface to process the overflow.

Parameters

- **pre_cond** (Tensor) −A precondition for starting overflow detection. It determines the executing order of overflow state clearing and prior processions. It makes sure that the function 'start_overflow' clears status after finishing the process of precondition.
- **compute_input** (*object*) −The input of subsequent process. Overflow detection should be performed on a certain computation. Set *compute_input* as the input of the computation, to ensure overflow status is cleared before executing the computation.

Returns

Tuple[object, object], the first output is used to control the execution sequence. To ensure that the *start_overflow_check* is executed before get_overflow_status after compilation optimization is performed. This value should be used as the first input of get_overflow_status. The second output is the same as the input of compute_input, used to control the execution sequence, and make ensure that the overflow flag is cleaned up when the function returns.

3.3.12 mindspore.nn.WithEvalCell

class mindspore.nn.**WithEvalCell**(*network*, *loss_fn*, *add_cast_fp32=False*)
Wraps the forward network with the loss function.

It returns loss, forward output and label to calculate the metrics.

Parameters

- **network** (Cell) −The forward network.
- **loss_fn** (Cell) −The loss function.
- **add_cast_fp32** (*bool*) −Whether to adjust the data type to float32. Default: False .

Inputs:

- **data** (Tensor) - Tensor of shape $(N, \ldots)$.
- **label** (Tensor) - Tensor of shape $(N, \ldots)$.

Outputs:

Tuple(Tensor), containing a scalar loss Tensor, a network output Tensor of shape $(N, \ldots)$ and a label Tensor of shape $(N, \ldots)$.

Raises

TypeError – If *add_cast_fp32* is not a bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.nn as nn
>>> # Define a forward network without loss function, taking LeNet5 as an example.
>>> # Refer to https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits()
>>> eval_net = nn.WithEvalCell(net, loss_fn)
```

3.3.13 mindspore.nn.WithLossCell

class mindspore.nn.**WithLossCell**(*backbone*, *loss_fn*)

Cell with loss function.

Wraps the network with loss function. This Cell accepts data and label as inputs and the computed loss will be returned.

Parameters

- **backbone** (`Cell`) – The backbone network to wrap.
- **loss_fn** (`Cell`) – The loss function used to compute loss.

Inputs:

- **data** (Tensor) - Tensor of shape $(N, \ldots)$. The dtype of *data* must be float16 or float32.
- **label** (Tensor) - Tensor of shape $(N, \ldots)$. The dtype of *label* must be float16 or float32.

Outputs:

Tensor, a tensor means the loss value, the shape of which is usually ().

Raises

TypeError – If dtype of *data* or *label* is neither float16 nor float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=False)
>>> net_with_criterion = nn.WithLossCell(net, loss_fn)
>>>
>>> batch_size = 2
>>> data = Tensor(np.ones([batch_size, 1, 32, 32]).astype(np.float32) * 0.01)
>>> label = Tensor(np.ones([batch_size, 10]).astype(np.float32))
>>>
>>> output_data = net_with_criterion(data, label)
```

property backbone_network

Get the backbone network.

Returns

Cell, the backbone network.

Examples

```
>>> from mindspore import nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=False)
>>> net_with_criterion = nn.WithLossCell(net, loss_fn)
>>> backbone = net_with_criterion.backbone_network
```

3.4 Convolutional Layer

API Name	Description	Supported Platforms
mindspore.nn.Conv1d	1D convolution layer.	Ascend GPU CPU
mindspore.nn.Conv1dTranspose	Calculates a 1D transposed convolution, which can be regarded as Conv1d for the gradient of the input, also called deconvolution (although it is not an actual deconvolution).	Ascend GPU CPU
mindspore.nn.Conv2d	2D convolution layer.	Ascend GPU CPU

3.4.1 mindspore.nn.Conv1d

class mindspore.nn.**Conv1d**(*in_channels*, *out_channels*, *kernel_size*, *stride=1*, *pad_mode='same'*, *padding=0*, *dilation=1*, *group=1*, *has_bias=False*, *weight_init=None*, *bias_init=None*, *dtype=mstype.float32*)

1D convolution layer.

Applies a 1D convolution over an input tensor which is typically of shape (N, C_{in}, L_{in}), where N is batch size, C is channel number, L is input sequence width.

The output is calculated based on formula:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{in}-1} \text{ccor}(\text{weight}(C_{\text{out}_j}, k), \text{X}(N_i, k))$$

where $bias$ is the output channel bias, $ccor$ is the cross-correlation, $weight$ is the convolution kernel value and X represents the input feature map.

Here are the indices' meanings:

- i corresponds to the batch number, the range is $[0, N-1]$, where N is the batch size of the input.
- j corresponds to the output channel, the range is $[0, C_{out}-1]$, where C_{out} is the number of output channels, which is also equal to the number of kernels.
- k corresponds to the input channel, the range is $[0, C_{in}-1]$, where C_{in} is the number of input channels, which is also equal to the number of channels in the convolutional kernels.

Therefore, in the above formula, $bias(C_{\text{out}_j})$ represents the bias of the j-th output channel, $weight(C_{\text{out}_j}, k)$ represents the slice of the j-th convolutional kernel in the k-th channel, and $X(N_i, k)$ represents the slice of the k-th input channel in the i-th batch of the input feature map.

The shape of the convolutional kernel is given by (kernel_size), where kernel_size is the width of the kernel. If we consider the input and output channels as well as the *group* parameter, the complete kernel shape will be $(C_{out}, C_{in}/\text{group}, \text{kernel\_size})$, where *group* is the number of groups dividing *x*'s input channel when applying group convolution.

For more details about convolution layer, please refer to Gradient Based Learning Applied to Document Recognition and ConvNets .

Note: On Ascend platform, only group convolution in depthwise convolution scenarios is supported. That is, when *group>1*, condition *in_channels* = *out_channels* = *group* must be satisfied.

Parameters

- **in_channels** (*int*) –The channel number of the input tensor of the Conv1d layer.
- **out_channels** (*int*) –The channel number of the output tensor of the Conv1d layer.
- **kernel_size** (*int*) –Specifies the width of the 1D convolution kernel.
- **stride** (*int, optional*) –The movement stride of the 1D convolution kernel. Default: `1` .
- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"same"` .
  - `"same"`: Pad the input at the begin and end so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally. If the amount is even, it is uniformly distributed around the input, if it is odd, the excess padding is goes to the right side. If this mode is set, *padding* must be 0.

  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible length. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *padding* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding at the begin and end is determined by the *padding* parameter. If this mode is set, *padding* must be greater than or equal to 0.

- **padding** (*Union(int, tuple[int], list[int]), optional*) – Specifies the amount of padding to apply on both side of *input* when *pad_mode* is set to `"pad"`. The paddings of left and right are the same, equal to padding or padding[0] when padding is a tuple of 1 integer. Default: `0` .
- **dilation** (*Union(int, tuple[int]), optional*) – Specifies the dilation rate to use for dilated convolution. It can be a single int or a tuple of 1 integer. Assuming $dilation = (d0,)$, the convolutional kernel samples the input with a spacing of $d0 - 1$ elements in the width direction. The value should be in the ranges [1, L]. Default: `1` .
- **group** (*int, optional*) – Splits filter into groups, *in_channels* and *out_channels* must be divisible by *group*. Default: `1` .
- **has_bias** (*bool, optional*) – Whether the Conv1d layer has a bias parameter. Default: `False` .
- **weight_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) – Initialization method of weight parameter. It can be a Tensor, a string, an Initializer or a numbers.Number. When a string is specified, values from `'TruncatedNormal'` , `'Normal'` , `'Uniform'` , `'HeUniform'` and `'XavierUniform'` distributions as well as constant 'One' and 'Zero' distributions are possible. Alias `'xavier_uniform'` , `'he_uniform'` , `'ones'` and `'zeros'` are acceptable. Uppercase and lowercase are both acceptable. Refer to the values of Initializer, for more details. Default: `None` , weight will be initialized using `'HeUniform'`.
- **bias_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) – Initialization method of bias parameter. Available initialization methods are the same as 'weight_init'. Refer to the values of Initializer, for more details. Default: `None` , bias will be initialized using `'Uniform'`.
- **dtype** (*mindspore.dtype*) – Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape (N, C_{in}, L_{in}) .

Outputs:

Tensor of shape (N, C_{out}, L_{out}).

pad_mode is `'same'`:

$$L_{out} = \left\lceil \frac{L_{in}}{\text{stride}} \right\rceil$$

pad_mode is `'valid'`:

$$L_{out} = \left\lfloor \frac{L_{in} - \text{dilation} \times (\text{kernel\_size} - 1) - 1}{\text{stride}} \right\rfloor + 1$$

pad_mode is `'pad'`:

$$L_{out} = \left\lfloor \frac{L_{in} + 2 \times padding - \text{dilation} \times (\text{kernel\_size} - 1) - 1}{\text{stride}} \right\rfloor + 1$$

Raises

- **TypeError** – If *in_channels*, *out_channels*, *kernel_size*, *stride*, *padding* or *dilation* is not an int.
- **ValueError** – If *in_channels*, *out_channels*, *kernel_size*, *stride* or *dilation* is less than 1.

- **ValueError** –If *padding* is less than 0.
- **ValueError** –If *pad_mode* is not one of 'same', 'valid', 'pad'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> net = nn.Conv1d(120, 240, 4, has_bias=False, weight_init='normal')
>>> x = Tensor(np.ones([1, 120, 640]), mindspore.float32)
>>> output = net(x).shape
>>> print(output)
(1, 240, 640)
```

3.4.2 mindspore.nn.Conv1dTranspose

class mindspore.nn.**Conv1dTranspose**(*in_channels*, *out_channels*, *kernel_size*, *stride=1*, *pad_mode='same'*, *padding=0*, *dilation=1*, *group=1*, *has_bias=False*, *weight_init=None*, *bias_init=None*, *dtype=mstype.float32*)

Calculates a 1D transposed convolution, which can be regarded as Conv1d for the gradient of the input, also called deconvolution (although it is not an actual deconvolution).

The input is typically of shape (N, C_{in}, L_{in}), where N is batch size, C_{in} is a number of channels and L_{in} is a length of sequence.

When Conv1d and ConvTranspose1d are initialized with the same parameters, and *pad_mode* is set to 'pad', $dilation * (kernel\_size - 1) - padding$ amount of zero will be paded to both sizes of input, they are inverses of each other in regard to the input and output shapes in this case. However, when *stride* > 1, Conv1d maps multiple input shapes to the same output shape. Deconvolutional network can refer to Deconvolutional Networks.

Parameters

- **in_channels** (*int*) –The channel number of the input tensor of the Conv1dTranspose layer.
- **out_channels** (*int*) –The channel number of the output tensor of the Conv1dTranspose layer.
- **kernel_size** (*int*) –Specifies the width of the 1D convolution kernel.
- **stride** (*int*) –The movement stride of the 1D convolution kernel. Default: `1` .
- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"same"` .
  - `"same"`: Pad the input at the begin and end so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally. If the amount is even, it is uniformly distributed around the input, if it is odd, the excess padding is goes to the right side. If this mode is set, *padding* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible length. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *padding* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding at the begin and end is determined by the *padding* parameter. If this mode is set, *padding* must be greater than or equal to 0.

- **padding** (*int*) −The number of padding on both sides of input. The value should be greater than or equal to 0. Default: `0` .
- **dilation** (*int*) −Dilation size of 1D convolution kernel. If $k > 1$, the kernel is sampled every k elements. The value of k is in range of [1, L]. Default: `1` .
- **group** (*int*) −Splits filter into groups, *in_channels* and *out_channels* must be divisible by *group*. When *group* > 1, the Ascend platform is not supported yet. Default: `1` .
- **has_bias** (*bool*) −Whether the Conv1dTranspose layer has a bias parameter. Default: `False`.
- **weight_init** (*Union[Tensor, str, Initializer, numbers.Number]*) −Initialization method of weight parameter. It can be a Tensor, a string, an Initializer or a numbers.Number. When a string is specified, values from `'TruncatedNormal'` , `'Normal'` , `'Uniform'` , `'HeUniform'` and `'XavierUniform'` distributions as well as constant `'One'` and `'Zero'` distributions are possible. Alias `'xavier_uniform'` , `'he_uniform'`, `'ones'` and `'zeros'` are acceptable. Uppercase and lowercase are both acceptable. Refer to the values of Initializer for more details. Default: `None` , weight will be initialized using HeUniform.
- **bias_init** (*Union[Tensor, str, Initializer, numbers.Number]*) −Initialization method of bias parameter. Available initialization methods are the same as 'weight_init'. Refer to the values of Initializer for more details. Default: `None` , bias will be initialized using Uniform.
- **dtype** (*mindspore.dtype*) −Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape (N, C_{in}, L_{in}).

Outputs:

Tensor of shape (N, C_{out}, L_{out}).

pad_mode is `'same'`: $L_{out} = \frac{L_{in}+\text{stride}-1}{\text{stride}}$

pad_mode is `'valid'`: $L_{out} = (L_{in} - 1) \times \text{stride} + \text{dilation} \times (\text{kernel\_size} - 1) + 1$

pad_mode is `'pad'`: $L_{out} = (L_{in} - 1) \times \text{stride} - 2 \times \text{padding} + \text{dilation} \times (\text{kernel\_size} - 1) + 1$

Raises

- **TypeError** −If *in_channels*, *out_channels*, *kernel_size*, *stride*, *padding* or *dilation* is not an int.
- **ValueError** −If *in_channels*, *out_channels*, *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** −If *padding* is less than 0.
- **ValueError** −If *pad_mode* is not one of 'same', 'valid', 'pad'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> net = nn.Conv1dTranspose(3, 64, 4, has_bias=False, weight_init='normal', pad_mode='pad')
>>> x = Tensor(np.ones([1, 3, 50]), mindspore.float32)
>>> output = net(x).shape
>>> print(output)
(1, 64, 53)
```

3.4.3 mindspore.nn.Conv2d

class mindspore.nn.**Conv2d**(*in_channels*, *out_channels*, *kernel_size*, *stride=1*, *pad_mode='same'*, *padding=0*, *dilation=1*, *group=1*, *has_bias=False*, *weight_init=None*, *bias_init=None*, *data_format='NCHW'*, *dtype=mstype.float32*)

2D convolution layer.

Applies a 2D convolution over an input tensor which is typically of shape $(N, C_{in}, H_{in}, W_{in})$, where N is batch size, C is channel number, H is feature height, W is feature width.

The output is calculated based on formula:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{in}-1} \text{ccor}(\text{weight}(C_{\text{out}_j}, k), \text{X}(N_i, k))$$

where $bias$ is the output channel bias, $ccor$ is the cross-correlation, $weight$ is the convolution kernel value and X represents the input feature map.

Here are the indices' meanings:

- i corresponds to the batch number, the range is $[0, N-1]$, where N is the batch size of the input.
- j corresponds to the output channel, the range is $[0, C_{out}-1]$, where C_{out} is the number of output channels, which is also equal to the number of kernels.
- k corresponds to the input channel, the range is $[0, C_{in}-1]$, where C_{in} is the number of input channels, which is also equal to the number of channels in the convolutional kernels.

Therefore, in the above formula, $bias(C_{\text{out}_j})$ represents the bias of the j-th output channel, $weight(C_{\text{out}_j}, k)$ represents the slice of the j-th convolutional kernel in the k-th channel, and $X(N_i, k)$ represents the slice of the k-th input channel in the i-th batch of the input feature map.

The shape of the convolutional kernel is given by (kernel_size[0], kernel_size[1]), where kernel_size[0] and kernel_size[1] are the height and width of the kernel, respectively. If we consider the input and output channels as well as the *group* parameter, the complete kernel shape will be $(C_{out}, C_{in}/\text{group}, \text{kernel\_size}[0], \text{kernel\_size}[1])$, where *group* is the number of groups dividing *x*'s input channel when applying group convolution.

For more details about convolution layer, please refer to Gradient Based Learning Applied to Document Recognition.

Note: On Ascend platform, only group convolution in depthwise convolution scenarios is supported. That is, when *group>1*, condition *in_channels* = *out_channels* = *group* must be satisfied.

Parameters

- **in_channels** (*int*) −The channel number of the input tensor of the Conv2d layer.

- **out_channels** (*int*) –The channel number of the output tensor of the Conv2d layer.
- **kernel_size** (*Union[int, tuple[int]]*) –Specifies the height and width of the 2D convolution kernel. The data type is an integer or a tuple of two integers. An integer represents the height and width of the convolution kernel. A tuple of two integers represents the height and width of the convolution kernel respectively.
- **stride** (*Union[int, tuple[int]], optional*) –The movement stride of the 2D convolution kernel. The data type is an integer or a tuple of two or four integers. An integer represents the movement step size in both height and width directions. A tuple of two integers represents the movement step size in the height and width directions respectively. Default: `1` .
- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"same"` .
  - `"same"`: Pad the input around its edges so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally, If the amount is even, it is uniformly distributed around the input, if it is odd, the excess amount goes to the right/bottom side. If this mode is set, *padding* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *padding* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the height and width directions is determined by the *padding* parameter. If this mode is set, *padding* must be greater than or equal to 0.
- **padding** (*Union[int, tuple[int]], optional*) –The number of padding on the height and width directions of the input. The data type is an integer or a tuple of four integers. If *padding* is an integer, then the top, bottom, left, and right padding are all equal to *padding*. If *padding* is a tuple of 4 integers, then the top, bottom, left, and right padding is equal to *padding[0]*, *padding[1]*, *padding[2]*, and *padding[3]* respectively. The value should be greater than or equal to 0. Default: `0` .
- **dilation** (*Union(int, tuple[int]), optional*) –Specifies the dilation rate to use for dilated convolution. It can be a single int or a tuple of 2 or 4 integers. A single int means the dilation size is the same in both the height and width directions. A tuple of two ints represents the dilation size in the height and width directions, respectively. For a tuple of four ints, the two ints correspond to (N, C) dimension are treated as 1, and the two correspond to (H, W) dimensions is the dilation size in the height and width directions respectively. Assuming $dilation = (d0, d1)$, the convolutional kernel samples the input with a spacing of $d0 - 1$ elements in the height direction and $d1 - 1$ elements in the width direction. The values in the height and width dimensions are in the ranges [1, H] and [1, W], respectively. Default: `1` .
- **group** (*int, optional*) –Splits filter into groups, *in_channels* and *out_channels* must be divisible by *group*. If the group is equal to *in_channels* and *out_channels*, this 2D convolution layer also can be called 2D depthwise convolution layer. Default: `1` .
- **has_bias** (*bool, optional*) –Whether the Conv2d layer has a bias parameter. Default: `False` .
- **weight_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –Initialization method of weight parameter. It can be a Tensor, a string, an Initializer or a numbers.Number. When a string is specified, values from `'TruncatedNormal'` , `'Normal'` , `'Uniform'` , `'HeUniform'` and `'XavierUniform'` distributions as well as constant `'One'` and `'Zero'` distributions are possible. Alias `'xavier_uniform'` , `'he_uniform'` , `'ones'` and `'zeros'` are acceptable. Uppercase and lowercase are both acceptable. Refer to the values of Initializer, for more details. Default: `None` , weight will be initialized using `'HeUniform'`.
- **bias_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –Initialization method of bias parameter. Available initialization methods are the same as 'weight_init'. Refer to the values of Initializer, for more details. Default: `None` , bias will be initialized using `'Uniform'` .
- **data_format** (*str, optional*) –The optional value for data format, is `'NHWC'` or `'NCHW'` . Default: `'NCHW'` . (NHWC is only supported in GPU now.)
- **dtype** (*mindspore.dtype*) –Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, H_{in}, W_{in})$ or $(N, H_{in}, W_{in}, C_{in})$.

Outputs:

Tensor of shape $(N, C_{out}, H_{out}, W_{out})$ or $(N, H_{out}, W_{out}, C_{out})$.

pad_mode is `'same'`:

$$\begin{aligned} H_{out} &= \left\lceil \frac{H_{in}}{\text{stride}[0]} \right\rceil \\ W_{out} &= \left\lceil \frac{W_{in}}{\text{stride}[1]} \right\rceil \end{aligned}$$

pad_mode is `'valid'`:

$$\begin{aligned} H_{out} &= \left\lfloor \frac{H_{in} - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) - 1}{\text{stride}[0]} \right\rfloor + 1 \\ W_{out} &= \left\lfloor \frac{W_{in} - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) - 1}{\text{stride}[1]} \right\rfloor + 1 \end{aligned}$$

pad_mode is `'pad'`:

$$\begin{aligned} H_{out} &= \left\lfloor \frac{H_{in} + padding[0] + padding[1] - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) - 1}{\text{stride}[0]} \right\rfloor + 1 \\ W_{out} &= \left\lfloor \frac{W_{in} + padding[2] + padding[3] - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) - 1}{\text{stride}[1]} \right\rfloor + 1 \end{aligned}$$

Raises

- **TypeError** – If *in_channels*, *out_channels* or *group* is not an int.
- **TypeError** – If *kernel_size*, *stride*, *padding* or *dilation* is neither an int not a tuple.
- **ValueError** – If *in_channels*, *out_channels*, *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** – If *padding* is less than 0.
- **ValueError** – If *pad_mode* is not one of 'same', 'valid', 'pad'.
- **ValueError** – If *padding* is a tuple whose length is not equal to 4.
- **ValueError** – If *pad_mode* is not equal to 'pad' and *padding* is not equal to (0, 0, 0, 0).
- **ValueError** – If *data_format* is neither 'NCHW' nor 'NHWC'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> net = nn.Conv2d(120, 240, 4, has_bias=False, weight_init='normal')
>>> x = Tensor(np.ones([1, 120, 1024, 640]), mindspore.float32)
>>> output = net(x).shape
>>> print(output)
(1, 240, 1024, 640)
```

3.4.4 mindspore.nn.Conv2dTranspose

class mindspore.nn.**Conv2dTranspose**(*in_channels*, *out_channels*, *kernel_size*, *stride=1*, *pad_mode='same'*, *padding=0*, *output_padding=0*, *dilation=1*, *group=1*, *has_bias=False*, *weight_init=None*, *bias_init=None*, *dtype=mstype.float32*)

Calculates a 2D transposed convolution, which can be regarded as Conv2d for the gradient of the input, also called deconvolution (although it is not an actual deconvolution).

The input is typically of shape $(N, C_{in}, H_{in}, W_{in})$, where N is batch size, C_{in} is space dimension, H_{in}, W_{in} are the height and width of the feature layer respectively.

When Conv2d and Conv2dTranspose are initialized with the same parameters, and *pad_mode* is set to 'pad', $dilation * (kernel\_size - 1) - padding$ amount of zero will be paded to the height and width directions of the input, they are inverses of each other in regard to the input and output shapes in this case. However, when *stride* > 1, Conv2d maps multiple input shapes to the same output shape. Deconvolutional network can refer to Deconvolutional Networks.

Parameters

- **in_channels** (*int*) –The channel number of the input tensor of the Conv2dTranspose layer.
- **out_channels** (*int*) –The channel number of the output tensor of the Conv2dTranspose layer.
- **kernel_size** (*Union[int, tuple[int]]*) –Specifies the height and width of the 2D convolution kernel. The data type is an integer or a tuple of two integers. An integer represents the height and width of the convolution kernel. A tuple of two integers represents the height and width of the convolution kernel respectively.
- **stride** (*Union[int, tuple[int]]*) –The movement stride of the 2D convolution kernel. The data type is an integer or a tuple of two integers. An integer represents the movement step size in both height and width directions. A tuple of two integers represents the movement step size in the height and width directions respectively. Default: `1` .
- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"same"` .
  - `"same"`: Pad the input around its edges so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally, If the amount is even, it is uniformly distributed around the input, if it is odd, the excess amount goes to the right/bottom side. If this mode is set, *padding* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *padding* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the height and width directions is determined by the *padding* parameter. If this mode is set, *padding* must be greater than or equal to 0.
- **padding** (*Union[int, tuple[int]]*) –The number of padding on the height and width directions of the input. The data type is an integer or a tuple of four integers. If *padding* is an integer, then the top, bottom, left, and right padding are all equal to *padding*. If *padding* is a tuple of 4 integers, then the top, bottom, left, and right padding is equal to *padding[0]*, *padding[1]*, *padding[2]*, and *padding[3]* respectively. The value should be greater than or equal to 0. Default: `0` .
- **output_padding** (*Union[int, tuple[int]]*) –The number of padding on the height and width directions of the output. The data type is an integer or a tuple of two integers. If *output_padding* is an integer, then the bottom and right padding are all equal to *output_padding*. If *output_padding* is a tuple of 2 integers, then the bottom and right padding is equal to *output_padding[0]*, *output_padding[1]* respectively. If *output_padding* is not equal to 0, *pad_mode* must be *pad*. The value should be in range of *[0, max(stride, dilation))* . Default: `0` .
- **dilation** (*Union[int, tuple[int]]*) –Dilation size of 2D convolution kernel. It can be a single int or a tuple of 2 integers. A single int means the dilation size is the same in both the height and width directions. A tuple of two ints represents the dilation size in the height and width directions, respectively. Assuming $dilation = (d0, d1)$, the convolutional kernel samples the input with a spacing of $d0 - 1$ elements in the height direction and $d1 - 1$ elements

in the width direction. The values in the height and width dimensions are in the ranges [1, H] and [1, W], respectively. Default: `1` .

- **group** (*int*) −Splits filter into groups, *in_channels* and *out_channels* must be divisible by *group*. Default: `1` .
- **has_bias** (*bool*) −Whether the Conv2dTranspose layer has a bias parameter. Default: `False` .
- **weight_init** (*Union[Tensor, str, Initializer, numbers.Number]*) −Initialization method of weight parameter. It can be a Tensor, a string, an Initializer or a numbers.Number. When a string is specified, values from `'TruncatedNormal'` , `'Normal'` , `'Uniform'` , `'HeUniform'` and `'XavierUniform'` distributions as well as constant `'One'` and `'Zero'` distributions are possible. Alias `'xavier_uniform'` , `'he_uniform'` , `'ones'` and `'zeros'` are acceptable. Uppercase and lowercase are both acceptable. Refer to the values of Initializer for more details. Default: `None` , weight will be initialized using HeUniform.
- **bias_init** (*Union[Tensor, str, Initializer, numbers.Number]*) −Initialization method of bias parameter. Available initialization methods are the same as 'weight_init'. Refer to the values of Initializer for more details. Default: `None` , bias will be initialized using Uniform.
- **dtype** (*mindspore.dtype*) −Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, H_{in}, W_{in})$.

Outputs:

Tensor of shape $(N, C_{out}, H_{out}, W_{out})$.

pad_mode is `'same'`:

$$H_{out} = \mathrm{H}_{in} \times \text{stride}[0]$$
$$W_{out} = \mathrm{W}_{in} \times \text{stride}[1]$$

pad_mode is `'valid'`:

$$H_{out} = \mathrm{H}_{in} \times \text{stride}[0] + \max\{(\text{dilation}[0] - 1) \times (\text{kernel\_size}[0] - 1) - \text{stride}[0], 0\}$$
$$W_{out} = \mathrm{W}_{in} \times \text{stride}[1] + \max\{(\text{dilation}[1] - 1) \times (\text{kernel\_size}[1] - 1) - \text{stride}[1], 0\}$$

pad_mode is `'pad'`:

$$H_{out} = \mathrm{H}_{in} \times \text{stride}[0] - (padding[0] + padding[1]) + \text{kernel\_size}[0] + (\text{dilation}[0] - 1) \times (\text{kernel\_size}[0] - 1) - \text{stride}[0] + \text{outp}$$
$$W_{out} = \mathrm{W}_{in} \times \text{stride}[1] - (padding[2] + padding[3]) + \text{kernel\_size}[1] + (\text{dilation}[1] - 1) \times (\text{kernel\_size}[1] - 1) - \text{stride}[1] + \text{out}$$

Raises

- **TypeError** −If *in_channels*, *out_channels* or *group* is not an int.
- **TypeError** −If *kernel_size*, *stride*, *padding* or *dilation* is neither an int nor a tuple.
- **ValueError** −If *in_channels*, *out_channels*, *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** −If *padding* is less than 0.
- **ValueError** −If *pad_mode* is not one of 'same', 'valid', 'pad'.
- **ValueError** −If *padding* is a tuple whose length is not equal to 4.
- **ValueError** −If *pad_mode* is not equal to 'pad' and *padding* is not equal to (0, 0, 0, 0).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> net = nn.Conv2dTranspose(3, 64, 4, has_bias=False, weight_init='normal', pad_mode='pad')
>>> x = Tensor(np.ones([1, 3, 16, 50]), mindspore.float32)
>>> output = net(x).shape
>>> print(output)
(1, 64, 19, 53)
```

3.4.5 mindspore.nn.Conv3d

class mindspore.nn.**Conv3d**(*in_channels*, *out_channels*, *kernel_size*, *stride=1*, *pad_mode='same'*, *padding=0*, *dilation=1*, *group=1*, *has_bias=False*, *weight_init=None*, *bias_init=None*, *data_format='NCDHW'*, *dtype=mstype.float32*)

3D convolution layer.

Applies a 3D convolution over an input tensor which is typically of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$, where N is batch size, C is channel number, D, H, W are the depth, height and width of the feature map, respectively.

The output is calculated based on formula:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{in}-1} \text{ccor}(\text{weight}(C_{\text{out}_j}, k), \text{X}(N_i, k))$$

where $bias$ is the output channel bias, $ccor$ is the cross-correlation, $weight$ is the convolution kernel value and X represents the input feature map.

Here are the indices' meanings:

- i corresponds to the batch number, the range is $[0, N-1]$, where N is the batch size of the input.
- j corresponds to the output channel, the range is $[0, C_{out}-1]$, where C_{out} is the number of output channels, which is also equal to the number of kernels.
- k corresponds to the input channel, the range is $[0, C_{in}-1]$, where C_{in} is the number of input channels, which is also equal to the number of channels in the convolutional kernels.

Therefore, in the above formula, $bias(C_{out_j})$ represents the bias of the j-th output channel, $weight(C_{out_j}, k)$ represents the slice of the j-th convolutional kernel in the k-th channel, and $X(N_i, k)$ represents the slice of the k-th input channel in the i-th batch of the input feature map.

The shape of the convolutional kernel is given by (kernel_size[0], kernel_size[1], kernel_size[2]) where kernel_size[0], kernel_size[1] and kernel_size[2] are the depth, height and width of the kernel, respectively. If we consider the input and output channels as well as the *group* parameter, the complete kernel shape will be $(C_{out}, C_{in}/\text{group}, \text{kernel\_size}[0], \text{kernel\_size}[1], \text{kernel\_size}[2])$, where *group* is the number of groups dividing *x*'s input channel when applying group convolution.

For more details about convolution layer, please refer to Gradient Based Learning Applied to Document Recognition.

Note: On Ascend platform, only group convolution in depthwise convolution scenarios is supported. That is, when *group>1*, condition *in_channels* = *out_channels* = *group* must be satisfied.

Parameters

- **in_channels** (*int*) –The channel number of the input tensor of the Conv3d layer.
- **out_channels** (*int*) –The channel number of the output tensor of the Conv3d layer.
- **kernel_size** (*Union[int, tuple[int]]*) –Specifies the depth, height and width of the 3D convolution kernel. It can be a single int or a tuple of 3 integers. A single int means the value is for depth, height and the width. A tuple of 3 ints means the first value is for depth and the rest is for the height and width.
- **stride** (*Union[int, tuple[int]], optional*) –The movement stride of the 3D convolution kernel. The data type is an integer or a tuple of three integers. An integer represents the movement step size in depth, height and width directions. A tuple of three integers represents the movement step size in the depth, height and width directions respectively. Default: `1` .
- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"same"` .
  - `"same"`: Pad the input around its depth/height/width dimension so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally. If the amount is even, it isuniformly distributed around the input, if it is odd, the excess amount goes to the front/right/bottom side. If this mode is set, *padding* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible depth, height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *padding* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the depth, height and width dimension is determined by the *padding* parameter. If this mode is set, *padding* must be greater than or equal to 0.
- **padding** (*Union(int, tuple[int]), optional*) –The number of padding on the depth, height and width directions of the input. The data type is an integer or a tuple of six integers. If *padding* is an integer, then the head, tail, top, bottom, left, and right padding are all equal to *padding*. If *padding* is a tuple of six integers, then the head, tail, top, bottom, left, and right padding is equal to *padding[0]*, *padding[1]*, *padding[2]*, *padding[3]*, *padding[4]* and *padding[5]* respectively. The value should be greater than or equal to 0. Default: `0` .
- **dilation** (*Union[int, tuple[int]], optional*) –Specifies the dilation rate to use for dilated convolution. It can be a single int or a tuple of 3 integers. A single int means the dilation size is the same in the depth, height and width directions. A tuple of 3 ints represents the dilation size in the depth, height and width directions, respectively. Assuming $dilation = (d0, d1, d2)$, the convolutional kernel samples the input with a spacing of $d0 - 1$ elements in the depth direction, $d1 - 1$ elements in the height direction, $d2 - 1$ elements in the width direction respectively. The values in the depth, height and width dimensions are in the ranges [1, D], [1, H] and [1, W], respectively. Default: `1` .
- **group** (*int, optional*) –Splits filter into groups, *in_channels* and *out_channels* must be divisible by *group*. Default: `1` .
- **has_bias** (*bool, optional*) –Whether the Conv3d layer has a bias parameter. Default: `False` .
- **weight_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –Initialization method of weight parameter. It can be a Tensor, a string, an Initializer or a numbers.Number. When a string is specified, values from `'TruncatedNormal'` , `'Normal'` , `'Uniform'` , `'HeUniform'` and `'XavierUniform'` distributions as well as constant `'One'` and `'Zero'` distributions are possible. Alias `'xavier_uniform'` , `'he_uniform'` , `'ones'` and `'zeros'` are acceptable. Uppercase and lowercase are both acceptable. Refer to the values of Initializer, for more details. Default: `None` , weight will be initialized using `'HeUniform'`.
- **bias_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –Initialization method of bias parameter. Available initialization methods are the same as 'weight_init'. Refer to the values of Initializer, for more details. Default: `None` , bias will be initialized using `'Uniform'` .
- **data_format** (*str, optional*) –The optional value for data format. Currently only support `'NCDHW'` .
- **dtype** (*mindspore.dtype*) –Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$. Currently, input data type support float16 and float32 in CPU and GPU, and only float16 in Ascend.

Outputs:

Tensor of shape is $(N, C_{out}, D_{out}, H_{out}, W_{out})$.

pad_mode is `'same'` :

$$\begin{aligned} D_{out} &= \left\lceil \frac{D_{in}}{\text{stride}[0]} \right\rceil \\ H_{out} &= \left\lceil \frac{H_{in}}{\text{stride}[1]} \right\rceil \\ W_{out} &= \left\lceil \frac{W_{in}}{\text{stride}[2]} \right\rceil \end{aligned}$$

pad_mode is `'valid'` :

$$\begin{aligned} D_{out} &= \left\lfloor \frac{D_{in} - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) - 1}{\text{stride}[0]} \right\rfloor + 1 \\ H_{out} &= \left\lfloor \frac{H_{in} - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) - 1}{\text{stride}[1]} \right\rfloor + 1 \\ W_{out} &= \left\lfloor \frac{W_{in} - \text{dilation}[2] \times (\text{kernel\_size}[2] - 1) - 1}{\text{stride}[2]} \right\rfloor + 1 \end{aligned}$$

pad_mode is `'pad'` :

$$\begin{aligned} D_{out} &= \left\lfloor \frac{D_{in} + padding[0] + padding[1] - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) - 1}{\text{stride}[0]} \right\rfloor + 1 \\ H_{out} &= \left\lfloor \frac{H_{in} + padding[2] + padding[3] - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) - 1}{\text{stride}[1]} \right\rfloor + 1 \\ W_{out} &= \left\lfloor \frac{W_{in} + padding[4] + padding[5] - \text{dilation}[2] \times (\text{kernel\_size}[2] - 1) - 1}{\text{stride}[2]} \right\rfloor + 1 \end{aligned}$$

Raises

- **TypeError** – If *in_channels*, *out_channels* or *group* is not an int.
- **TypeError** – If *kernel_size*, *stride*, *padding* or *dilation* is neither an int nor a tuple.
- **ValueError** – If *out_channels*, *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** – If *padding* is less than 0.
- **ValueError** – If *pad_mode* is not one of 'same', 'valid', 'pad'.
- **ValueError** – If *padding* is a tuple whose length is not equal to 6.
- **ValueError** – If *pad_mode* is not equal to 'pad' and *padding* is not equal to (0, 0, 0, 0, 0, 0).
- **ValueError** – If *data_format* is not 'NCDHW'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.ones([16, 3, 10, 32, 32]), mindspore.float32)
>>> conv3d = nn.Conv3d(in_channels=3, out_channels=32, kernel_size=(4, 3, 3))
>>> output = conv3d(x)
>>> print(output.shape)
(16, 32, 10, 32, 32)
```

3.4.6 mindspore.nn.Conv3dTranspose

class mindspore.nn.**Conv3dTranspose**(*in_channels*, *out_channels*, *kernel_size*, *stride=1*, *pad_mode='same'*, *padding=0*, *dilation=1*, *group=1*, *output_padding=0*, *has_bias=False*, *weight_init=None*, *bias_init=None*, *data_format='NCDHW'*, *dtype=mstype.float32*)

Calculates a 3D transposed convolution, which can be regarded as Conv3d for the gradient of the input. It also called deconvolution (although it is not an actual deconvolution).

The input is typically of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$, where N is batch size, C_{in} is a number of channels, D_{in}, H_{in}, W_{in} are the depth, height and width of the feature layer respectively.

When Conv3d and Conv3dTranspose are initialized with the same parameters, and *pad_mode* is set to `'pad'`, $dilation * (kernel\_size - 1) - padding$ amount of zero will be paded to the depth, height and width directions of the input, they are inverses of each other in regard to the input and output shapes in this case. However, when *stride* > 1, Conv2d maps multiple input shapes to the same output shape. For the detailed information of Deconvolutional network, refer to Deconvolutional Networks.

Note: For Atlas A2 training series products, *output_padding* is currently not supported.

Parameters

- **in_channels** (*int*) –The channel number of the input tensor of the Conv3dTranspose layer.
- **out_channels** (*int*) –The channel number of the output tensor of the Conv3dTranspose layer.
- **kernel_size** (*Union[int, tuple[int]]*) –Specifies the depth, height and width of the 3D convolution kernel. The data type is an integer or a tuple of three integers. An integer represents the depth, height and width of the convolution kernel. A tuple of three integers represents the depth, height and width of the convolution kernel respectively.
- **stride** (*Union[int, tuple[int]], optional*) –The movement stride of the 3D convolution kernel. The data type is an integer or a tuple of three integers. An integer represents the movement step size in depth, height and width directions. A tuple of three integers represents the movement step size in the depth, height and width directions respectively. Default: `1` .
- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"same"` .
  - `"same"`: Pad the input around its depth/height/width dimension so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally. If the amount is even, it isuniformly distributed around the input, if it is odd, the excess amount goes to the front/right/bottom side. If this mode is set, *padding* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible depth, height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *padding* must be 0.

  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the depth, height and width dimension is determined by the *padding* parameter. If this mode is set, *padding* must be greater than or equal to 0.

- **padding** (*Union(int, tuple[int]), optional*) – The number of padding on the depth, height and width directions of the input. The data type is an integer or a tuple of six integers. If *padding* is an integer, then the head, tail, top, bottom, left, and right padding are all equal to *padding*. If *padding* is a tuple of six integers, then the head, tail, top, bottom, left, and right padding is equal to *padding[0]*, *padding[1]*, *padding[2]*, *padding[3]*, *padding[4]* and *padding[5]* respectively. The value should be greater than or equal to 0. Default: `0` .
- **dilation** (*Union[int, tuple[int]], optional*) – Specifies the dilation rate to use for dilated convolution. The data type can be a single int or a tuple of 3 integers. A single int means the dilation size is the same in the depth, height and width directions. A tuple of 3 ints represents the dilation size in the depth, height and width directions, respectively. Assuming $dilation = (d0, d1, d2)$, the convolutional kernel samples the input with a spacing of $d0 - 1$ elements in the depth direction, $d1-1$ elements in the height direction, $d2-1$ elements in the width direction respectively. The values in the depth, height and width dimensions are in the ranges [1, D], [1, H] and [1, W], respectively. Default: `1` .
- **group** (*int, optional*) – Splits filter into groups, *in_channels* and *out_channels* must be divisible by *group*. Default: `1` .
- **output_padding** (*Union(int, tuple[int]), optional*) – The number of padding on the depth, height and width directions of the output. The data type is an integer or a tuple of three integers. If *output_padding* is an integer, then the depth, height, and width dimension padding are all equal to *output_padding*. If *output_padding* is a tuple of three integers, then the depth, height, and width padding is equal to *output_padding[0]*, *output_padding[1]* and *output_padding[2]* respectively. The value should be greater than or equal to 0. Default: `0` .
- **has_bias** (*bool, optional*) – Whether the Conv3dTranspose layer has a bias parameter. Default: `False` .
- **weight_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) – Initialization method of weight parameter. It can be a Tensor, a string, an Initializer or a numbers.Number. When a string is specified, values from `'TruncatedNormal'` , `'Normal'` , `'Uniform'` , `'HeUniform'` and `'XavierUniform'` distributions as well as constant `'One'` and `'Zero'` distributions are possible. Alias `'xavier_uniform'` , `'he_uniform'` , `'ones'` and `'zeros'` are acceptable. Uppercase and lowercase are both acceptable. Refer to the values of Initializer for more details. Default: `None` , weight will be initialized using HeUniform.
- **bias_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) – Initialization method of bias parameter. Available initialization methods are the same as 'weight_init'. Refer to the values of Initializer for more details. Default: `None` , bias will be initialized using Uniform.
- **data_format** (*str, optional*) – The optional value for data format. Currently only support `'NCDHW'` . Default: `'NCDHW'` .
- **dtype** (*mindspore.dtype*, optional) – Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$. Currently input data dtype only supports float16 and float32.

Outputs:

Tensor, the shape is $(N, C_{out}, D_{out}, H_{out}, W_{out})$.

pad_mode is `'same'` :

$$
\begin{aligned}
D_{out} &= \left\lfloor \frac{D_{in}}{\text{stride}[0]} + 1 \right\rfloor \\
H_{out} &= \left\lfloor \frac{H_{in}}{\text{stride}[1]} + 1 \right\rfloor \\
W_{out} &= \left\lfloor \frac{W_{in}}{\text{stride}[2]} + 1 \right\rfloor
\end{aligned}
$$

pad_mode is `'valid'` :

$$
\begin{aligned}
D_{out} &= \left\lfloor \frac{D_{in} - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1)}{\text{stride}[0]} + 1 \right\rfloor \\
H_{out} &= \left\lfloor \frac{H_{in} - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1)}{\text{stride}[1]} + 1 \right\rfloor \\
W_{out} &= \left\lfloor \frac{W_{in} - \text{dilation}[2] \times (\text{kernel\_size}[2] - 1)}{\text{stride}[2]} + 1 \right\rfloor
\end{aligned}
$$

pad_mode is `'pad'` :

$$
\begin{aligned}
D_{out} &= \left\lfloor \frac{D_{in} + padding[0] + padding[1] - (\text{dilation}[0] - 1) \times \text{kernel\_size}[0] - 1}{\text{stride}[0]} + 1 \right\rfloor \\
H_{out} &= \left\lfloor \frac{H_{in} + padding[2] + padding[3] - (\text{dilation}[1] - 1) \times \text{kernel\_size}[1] - 1}{\text{stride}[1]} + 1 \right\rfloor \\
W_{out} &= \left\lfloor \frac{W_{in} + padding[4] + padding[5] - (\text{dilation}[2] - 1) \times \text{kernel\_size}[2] - 1}{\text{stride}[2]} + 1 \right\rfloor
\end{aligned}
$$

Raises

- **TypeError** – If *in_channels*, *out_channels* or *group* is not an int.
- **TypeError** – If *kernel_size*, *stride*, *padding* , *dilation* or *output_padding* is neither an int nor a tuple of three.
- **TypeError** – If input data type is not float16 or float32.
- **ValueError** – If *in_channels*, *out_channels*, *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** – If *padding* is less than 0.
- **ValueError** – If *pad_mode* is not one of `'same'`, `'valid'`, `'pad'`.
- **ValueError** – If *padding* is a tuple whose length is not equal to 6.
- **ValueError** – If *pad_mode* is not equal to `'pad'` and *padding* is not equal to (0, 0, 0, 0, 0, 0).
- **ValueError** – If *data_format* is not `'NCDHW'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.ones([32, 16, 10, 32, 32]), mindspore.float32)
>>> conv3d_transpose = nn.Conv3dTranspose(in_channels=16, out_channels=3, kernel_size=(4, 6,␣
↪2),
...                                       pad_mode='pad')
>>> output = conv3d_transpose(x)
>>> print(output.shape)
(32, 3, 13, 37, 33)
```

3.4.7 mindspore.nn.Unfold

class mindspore.nn.**Unfold**(*ksizes*, *strides*, *rates*, *padding='valid'*)

Extracts patches from images. The input tensor must be a 4-D tensor and the data format is NCHW.

Parameters

- **ksizes** (*Union[tuple[int], list[int]]*) –The size of sliding window, must be a tuple or a list of integers, and the format is [1, ksize_row, ksize_col, 1].
- **strides** (*Union[tuple[int], list[int]]*) –Distance between the centers of the two consecutive patches, must be a tuple or list of int, and the format is [1, stride_row, stride_col, 1].
- **rates** (*Union[tuple[int], list[int]]*) –In each extracted patch, the gap between the corresponding dimension pixel positions, must be a tuple or a list of integers, and the format is [1, rate_row, rate_col, 1].
- **padding** (*str*) –The type of padding algorithm, is a string whose value is `"same"` or `"valid"` , not case sensitive. Default: `"valid"` .
  - `"same"`: Means that the patch can take the part beyond the original image, and this part is filled with 0.
  - `"valid"`: Means that the taken patch area must be completely covered in the original image.

Inputs:

- **x** (Tensor) - A 4-D tensor whose shape is $[in\_batch, in\_depth, in\_row, in\_col]$ and data type is number.

Outputs:

Tensor, a 4-D tensor whose data type is same as *x*, and the shape is $(out\_batch, out\_depth, out\_row, out\_col)$ where *out_batch* is the same as the *in_batch*.

- $out\_depth = ksize\_row * ksize\_col * in\_depth$
- $out\_row = (in\_row - (ksize\_row + (ksize\_row - 1) * (rate\_row - 1)))//stride\_row + 1$
- $out\_col = (in\_col - (ksize\_col + (ksize\_col - 1) * (rate\_col - 1)))//stride\_col + 1$

Raises

- **TypeError** –If *ksizes*, *strides* or *rates* is neither a tuple nor list.
- **ValueError** –If shape of *ksizes*, *strides* or *rates* is not $(1, x\_row, x\_col, 1)$.
- **ValueError** –If the second and third element of *ksizes*, *strides* or *rates* is less than 1.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> net = nn.Unfold(ksizes=[1, 2, 2, 1], strides=[1, 2, 2, 1], rates=[1, 2, 2, 1])
>>> # As stated in the above code:
>>> # ksize_row = 2, ksize_col = 2, rate_row = 2, rate_col = 2, stride_row = 2, stride_col =␣
↪2.
>>> image = Tensor(np.ones([2, 3, 6, 6]), dtype=mindspore.float16)
>>> # in_batch = 2, in_depth = 3, in_row = 6, in_col = 6.
```

(continues on next page)

(continued from previous page)

```
>>> # Substituting the formula to get:
>>> # out_batch = in_batch = 2
>>> # out_depth = 2 * 2 * 3 = 12
>>> # out_row = (6 - (2 + (2 - 1) * (2 - 1))) // 2 + 1 = 2
>>> # out_col = (6 - (2 + (2 - 1) * (2 - 1))) // 2 + 1 = 2
>>> output = net(image)
>>> print(output.shape)
(2, 12, 2, 2)
```

3.5 Recurrent Layer

API Name	Description	Supported Platforms
mindspore.nn.RNN	Stacked Elman RNN layers, applying RNN layer with tanh or ReLU non-linearity to the input.	Ascend GPU CPU
mindspore.nn.RNNCell	An Elman RNN cell with tanh or ReLU non-linearity.	Ascend GPU CPU
mindspore.nn.GRU	Stacked GRU (Gated Recurrent Unit) layers.	Ascend GPU CPU
mindspore.nn.GRUCell	A GRU(Gated Recurrent Unit) cell.	Ascend GPU CPU
mindspore.nn.LSTM	Stacked LSTM (Long Short-Term Memory) layers.	Ascend GPU CPU
mindspore.nn.LSTMCell	A LSTM (Long Short-Term Memory) cell.	Ascend GPU CPU

3.5.1 mindspore.nn.RNN

class mindspore.nn.**RNN**(**args*, ***kwargs*)

Stacked Elman RNN layers, applying RNN layer with tanh or ReLU non-linearity to the input.

For each element in the input sequence, each layer computes the following function:

$$h_t = activation(W_{ih}x_t + b_{ih} + W_{hh}h_{(t-1)} + b_{hh})$$

Here h_t is the hidden state at time t, x_t is the input at time t, and $h_{(t-1)}$ is the hidden state of the previous layer at time $t-1$ or the initial hidden state at time *0*. W_{ih} is the learnable input-hidden weights, and b_{ih} is the learnable input-hidden bias. W_{hh} is the learnable hidden-hidden weights, and b_{hh} is the learnable hidden-hidden bias.

Parameters

- **input_size** (*int*) –Number of features of input.
- **hidden_size** (*int*) –Number of features of hidden layer.
- **num_layers** (*int*) –Number of layers of stacked RNN. Default: `1` .
- **nonlinearity** (*str*) –The non-linearity to use. Can be either `'tanh'` or `'relu'`. Default: `'tanh'`.
- **has_bias** (*bool*) –Whether the cell has bias b_{ih} and b_{hh}. Default: `True` .
- **batch_first** (*bool*) –Specifies whether the first dimension of input *x* is batch_size. Default: `False` .
- **dropout** (*float*) –If not 0.0, append *Dropout* layer on the outputs of each RNN layer except the last layer. Default `0.0` . The range of dropout is [0.0, 1.0).
- **bidirectional** (*bool*) –Specifies whether it is a bidirectional RNN, num_directions=2 if bidirectional=True otherwise 1. Default: `False` .
- **dtype** (*mindspore.dtype*) –Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of data type mindspore.float32 or mindspore.float16 and shape $(seq\_len, batch\_size, input\_size)$ or $(batch\_size, seq\_len, input\_size)$.
- **hx** (Tensor) - Tensor of data type mindspore.float32 or mindspore.float16 and shape $(num\_directions * num\_layers, batch\_size, hidden\_size)$.
- **seq_length** (Tensor) - The length of each sequence in an input batch. Tensor of shape $(batch\_size)$. Default: `None` . This input indicates the real sequence length before padding to avoid padded elements have been used to compute hidden state and affect the final output. It is recommended to use this input when *x* has padding elements.

Outputs:

Tuple, a tuple contains (*output*, *hx_n*).

- **output** (Tensor) - Tensor of shape $(seq\_len, batch\_size, num\_directions * hidden\_size)$ or $(batch\_size, seq\_len, num\_directions * hidden\_size)$.
- **hx_n** (Tensor) - Tensor of shape $(num\_directions * num\_layers, batch\_size, hidden\_size)$.

Raises

- **TypeError** – If *input_size*, *hidden_size* or *num_layers* is not an int.
- **TypeError** – If *has_bias*, *batch_first* or *bidirectional* is not a bool.
- **TypeError** – If *dropout* is not a float.
- **ValueError** – If *dropout* is not in range [0.0, 1.0).
- **ValueError** – If *nonlinearity* is not in ['tanh', 'relu'].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> net = ms.nn.RNN(10, 16, 2, has_bias=True, batch_first=True, bidirectional=False)
>>> x = ms.Tensor(np.ones([3, 5, 10]).astype(np.float32))
>>> h0 = ms.Tensor(np.ones([1 * 2, 3, 16]).astype(np.float32))
>>> output, hn = net(x, h0)
>>> print(output.shape)
(3, 5, 16)
```

3.5.2 mindspore.nn.RNNCell

class mindspore.nn.**RNNCell**(*input_size: int*, *hidden_size: int*, *has_bias: bool = True*, *nonlinearity: str = 'tanh'*, *dtype=mstype.float32*)

An Elman RNN cell with tanh or ReLU non-linearity.

$$h_t = \tanh(W_{ih}x_t + b_{ih} + W_{hh}h_{(t-1)} + b_{hh})$$

Here h_t is the hidden state at time *t*, x_t is the input at time *t*, and $h_{(t-1)}$ is the hidden state of the previous layer at time $t-1$ or the initial hidden state at time *0*. If *nonlinearity* is *relu*, then *relu* is used instead of *tanh*.

Parameters

- **input_size** (*int*) –Number of features of input.
- **hidden_size** (*int*) –Number of features of hidden layer.
- **has_bias** (*bool*) –Whether the cell has bias b_{ih} and b_{hh}. Default: `True` .
- **nonlinearity** (*str*) –The non-linearity to use. Can be either `"tanh"` or `"relu"` . Default: `"tanh"` .
- **dtype** (*mindspore.dtype*) –Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape $(batch\_size, input\_size)$.
- **hx** (Tensor) - Tensor of data type mindspore.float32 and shape $(batch\_size, hidden\_size)$.

Outputs:

- **hx'** (Tensor) - Tensor of shape $(batch\_size, hidden\_size)$.

Raises

- **TypeError** –If *input_size* or *hidden_size* is not an int or not greater than 0.
- **TypeError** –If *has_bias* is not a bool.
- **ValueError** –If *nonlinearity* is not in ['tanh', 'relu'].

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> net = ms.nn.RNNCell(10, 16)
>>> x = ms.Tensor(np.ones([5, 3, 10]).astype(np.float32))
>>> hx = ms.Tensor(np.ones([3, 16]).astype(np.float32))
>>> output = []
>>> for i in range(5):
...     hx = net(x[i], hx)
...     output.append(hx)
>>> print(output[0].shape)
(3, 16)
```

3.5.3 mindspore.nn.GRU

class mindspore.nn.**GRU**(**args*, ***kwargs*)

Stacked GRU (Gated Recurrent Unit) layers.

Apply GRU layer to the input.

There are two gates in a GRU model. One is update gate and the other is reset gate. Denote two consecutive time nodes as $t-1$ and t. Given an input x_t at time t, a hidden state h_{t-1}, the update and reset gate at time t is computed using a gating mechanism. Update gate z_t is designed to protect the cell from perturbation by irrelevant inputs and past hidden state. Reset gate r_t determines how much information should be reset from old hidden state. New memory state n_t is calculated with the current input, on which

the reset gate will be applied. Finally, current hidden state h_t is computed with the calculated update grate and new memory state. The complete formulation is as follows:

$$
\begin{aligned}
r_t &= \sigma(W_{ir}x_t + b_{ir} + W_{hr}h_{(t-1)} + b_{hr}) \\
z_t &= \sigma(W_{iz}x_t + b_{iz} + W_{hz}h_{(t-1)} + b_{hz}) \\
n_t &= \tanh(W_{in}x_t + b_{in} + r_t * (W_{hn}h_{(t-1)} + b_{hn})) \\
h_t &= (1 - z_t) * n_t + z_t * h_{(t-1)}
\end{aligned}
$$

Here σ is the sigmoid function, and $*$ is the Hadamard product. W, b are learnable weights between the output and the input in the formula. For instance, W_{ir}, b_{ir} are the weight and bias used to transform from input x to r. Details can be found in paper Learning Phrase Representations using RNN Encoder-Decoder for Statistical Machine Translation.

Note: When using GRU on Ascend, the hidden size only supports multiples of 16.

Parameters

- **input_size** (*int*) −Number of features of input.
- **hidden_size** (*int*) −Number of features of hidden layer.
- **num_layers** (*int*) −Number of layers of stacked GRU. Default: `1` .
- **has_bias** (*bool*) −Whether the cell has bias b_{in} and b_{hn}. Default: `True` .
- **batch_first** (*bool*) −Specifies whether the first dimension of input *x* is batch_size. Default: `False` .
- **dropout** (*float*) −If not 0.0, append *Dropout* layer on the outputs of each GRU layer except the last layer. Default `0.0` . The range of dropout is [0.0, 1.0).
- **bidirectional** (*bool*) −Specifies whether it is a bidirectional GRU, num_directions=2 if bidirectional=True otherwise 1. Default: `False` .
- **dtype** (*mindspore.dtype*) −Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of data type mindspore.float32 or mindspore.float16 and shape $(seq\_len, batch\_size, input\_size)$ or $(batch\_size, seq\_len, input\_size)$.
- **hx** (Tensor) - Tensor of data type mindspore.float32 or mindspore.float16 and shape $(num\_directions * num\_layers, batch\_size, hidden\_size)$.
- **seq_length** (Tensor) - The length of each sequence in an input batch. Tensor of shape (batch_size). Default: `None` . This input indicates the real sequence length before padding to avoid padded elements have been used to compute hidden state and affect the final output. It is recommended to use this input when **x** has padding elements.

Outputs:

Tuple, a tuple contains (*output*, *h_n*).

- **output** (Tensor) - Tensor of shape $(seq\_len, batch\_size, num\_directions * hidden\_size)$ or $(batch\_size, seq\_len, num\_directions * hidden\_size)$.
- **hx_n** (Tensor) - Tensor of shape $(num\_directions * num\_layers, batch\_size, hidden\_size)$.

Raises

- **TypeError** −If *input_size*, *hidden_size* or *num_layers* is not an int.
- **TypeError** −If *has_bias*, *batch_first* or *bidirectional* is not a bool.
- **TypeError** −If *dropout* is not a float.

- **ValueError** –If *dropout* is not in range [0.0, 1.0).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> net = ms.nn.GRU(10, 16, 2, has_bias=True, batch_first=True, bidirectional=False)
>>> x = ms.Tensor(np.ones([3, 5, 10]).astype(np.float32))
>>> h0 = ms.Tensor(np.ones([1 * 2, 3, 16]).astype(np.float32))
>>> output, hn = net(x, h0)
>>> print(output.shape)
(3, 5, 16)
```

3.5.4 mindspore.nn.GRUCell

class mindspore.nn.**GRUCell**(*input_size: int*, *hidden_size: int*, *has_bias: bool = True*, *dtype=mstype.float32*)

A GRU(Gated Recurrent Unit) cell.

$$
\begin{aligned}
r &= \sigma(W_{ir}x + b_{ir} + W_{hr}h + b_{hr}) \\
z &= \sigma(W_{iz}x + b_{iz} + W_{hz}h + b_{hz}) \\
n &= \tanh(W_{in}x + b_{in} + r * (W_{hn}h + b_{hn})) \\
h' &= (1 - z) * n + z * h
\end{aligned}
$$

Here σ is the sigmoid function, and $*$ is the Hadamard product. W, b are learnable weights between the output and the input in the formula. h is hidden state. r is reset gate. z is update gate. n is n-th layer. For instance, W_{ir}, b_{ir} are the weight and bias used to transform from input x to r. Details can be found in paper Learning Phrase Representations using RNN Encoder-Decoder for Statistical Machine Translation.

Parameters

- **input_size** (*int*) –Number of features of input.
- **hidden_size** (*int*) –Number of features of hidden layer.
- **has_bias** (*bool*) –Whether the cell has bias b_{in} and b_{hn}. Default: `True` .
- **dtype** (*mindspore.dtype*) –Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape $(batch\_size, input\_size)$.
- **hx** (Tensor) - Tensor of data type mindspore.float32 and shape $(batch\_size, hidden\_size)$.

Outputs:

- **hx'** (Tensor) - Tensor of shape $(batch\_size, hidden\_size)$.

Raises

- **TypeError** –If *input_size*, *hidden_size* is not an int.
- **TypeError** –If *has_bias* is not a bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> net = ms.nn.GRUCell(10, 16)
>>> x = ms.Tensor(np.ones([5, 3, 10]).astype(np.float32))
>>> hx = ms.Tensor(np.ones([3, 16]).astype(np.float32))
>>> output = []
>>> for i in range(5):
...     hx = net(x[i], hx)
...     output.append(hx)
>>> print(output[0].shape)
(3, 16)
```

3.5.5 mindspore.nn.LSTM

class mindspore.nn.**LSTM**(**args*, ***kwargs*)

Stacked LSTM (Long Short-Term Memory) layers.

Apply LSTM layer to the input.

There are two pipelines connecting two consecutive cells in a LSTM model; one is cell state pipeline and the other is hidden state pipeline. Denote two consecutive time nodes as $t-1$ and t. Given an input x_t at time t, an hidden state h_{t-1} and an cell state c_{t-1} of the layer at time $t-1$, the cell state and hidden state at time t is computed using an gating mechanism. Input gate i_t is designed to protect the cell from perturbation by irrelevant inputs. Forget gate f_t affords protection of the cell by forgetting some information in the past, which is stored in h_{t-1}. Output gate o_t protects other units from perturbation by currently irrelevant memory contents. Candidate cell state $\tilde{c}_t$ is calculated with the current input, on which the input gate will be applied. Finally, current cell state c_t and hidden state h_t are computed with the calculated gates and cell states. The complete formulation is as follows.

$$
\begin{aligned}
i_t &= \sigma(W_{ix}x_t + b_{ix} + W_{ih}h_{(t-1)} + b_{ih}) \\
f_t &= \sigma(W_{fx}x_t + b_{fx} + W_{fh}h_{(t-1)} + b_{fh}) \\
\tilde{c}_t &= \tanh(W_{cx}x_t + b_{cx} + W_{ch}h_{(t-1)} + b_{ch}) \\
o_t &= \sigma(W_{ox}x_t + b_{ox} + W_{oh}h_{(t-1)} + b_{oh}) \\
c_t &= f_t * c_{(t-1)} + i_t * \tilde{c}_t \\
h_t &= o_t * \tanh(c_t)
\end{aligned}
$$

Here σ is the sigmoid function, and $*$ is the Hadamard product. W, b are learnable weights between the output and the input in the formula. For instance, W_{ix}, b_{ix} are the weight and bias used to transform from input x to i. Details can be found in paper LONG SHORT-TERM MEMORY and Long Short-Term Memory Recurrent Neural Network Architectures for Large Scale Acoustic Modeling.

LSTM hides the cycle of the whole cyclic neural network on the time step of the sequence, and input the sequence and initial state to obtain the matrix spliced by the hidden state of each time step and the hidden state of the last time step. We use the hidden state of the last time step as the coding feature of the input sentence and output it to the next layer.

$$h_{0:n}, (h_n, c_n) = LSTM(x_{0:n}, (h_0, c_0))$$

Parameters

- **input_size** (*int*) –Number of features of input.
- **hidden_size** (*int*) –Number of features of hidden layer.

- **num_layers** (*int*) −Number of layers of stacked LSTM . Default: `1` .
- **has_bias** (*bool*) −Whether the cell has bias b_{ih} and b_{fh}. Default: `True` .
- **batch_first** (*bool*) −Specifies whether the first dimension of input *x* is batch_size. Default: `False` .
- **dropout** (*float, int*) −If not 0, append *Dropout* layer on the outputs of each LSTM layer except the last layer. Default `0` . The range of dropout is [0.0, 1.0).
- **bidirectional** (*bool*) −Specifies whether it is a bidirectional LSTM, num_directions=2 if bidirectional=True otherwise 1. Default: `False` .
- **dtype** (*mindspore.dtype*) −Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of data type mindspore.float32 or mindspore.float16 and shape ($seq\_len, batch\_size, input\_size$) or ($batch\_size, seq\_len, input\_size$) .
- **hx** (tuple) - A tuple of two Tensors (h_0, c_0) both of data type mindspore.float32 or mindspore.float16 and shape ($num\_directions * num\_layers, batch\_size, hidden\_size$) .
- **seq_length** (Tensor) - The length of each sequence in an input batch. Tensor of shape ($batch\_size$). Default: `None` . This input indicates the real sequence length before padding to avoid padded elements have been used to compute hidden state and affect the final output. It is recommended to use this input when **x** has padding elements.

Outputs:

Tuple, a tuple contains (*output*, (*h_n*, *c_n*)).

- **output** (Tensor) - Tensor of shape ($seq\_len, batch\_size, num\_directions * hidden\_size$) .
- **hx_n** (tuple) - A tuple of two Tensor (h_n, c_n) both of shape ($num\_directions * num\_layers, batch\_size, hidden\_size$) .

Raises

- **TypeError** −If *input_size*, *hidden_size* or *num_layers* is not an int.
- **TypeError** −If *has_bias*, *batch_first* or *bidirectional* is not a bool.
- **TypeError** −If *dropout* is not a float.
- **ValueError** −If *dropout* is not in range [0.0, 1.0).

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> net = ms.nn.LSTM(10, 16, 2, has_bias=True, batch_first=True, bidirectional=False)
>>> x = ms.Tensor(np.ones([3, 5, 10]).astype(np.float32))
>>> h0 = ms.Tensor(np.ones([1 * 2, 3, 16]).astype(np.float32))
>>> c0 = ms.Tensor(np.ones([1 * 2, 3, 16]).astype(np.float32))
>>> output, (hn, cn) = net(x, (h0, c0))
>>> print(output.shape)
(3, 5, 16)
```

3.5.6 mindspore.nn.LSTMCell

class mindspore.nn.**LSTMCell**(*input_size: int*, *hidden_size: int*, *has_bias: bool = True*, *dtype=mstype.float32*)

A LSTM (Long Short-Term Memory) cell.

$$
\begin{aligned}
i_t &= \sigma(W_{ix}x_t + b_{ix} + W_{ih}h_{(t-1)} + b_{ih}) \\
f_t &= \sigma(W_{fx}x_t + b_{fx} + W_{fh}h_{(t-1)} + b_{fh}) \\
\tilde{c}_t &= \tanh(W_{cx}x_t + b_{cx} + W_{ch}h_{(t-1)} + b_{ch}) \\
o_t &= \sigma(W_{ox}x_t + b_{ox} + W_{oh}h_{(t-1)} + b_{oh}) \\
c_t &= f_t * c_{(t-1)} + i_t * \tilde{c}_t \\
h_t &= o_t * \tanh(c_t)
\end{aligned}
$$

Here σ is the sigmoid function, and $*$ is the Hadamard product. W, b are learnable weights between the output and the input in the formula. For instance, W_{ix}, b_{ix} are the weight and bias used to transform from input x to i. Details can be found in paper LONG SHORT-TERM MEMORY and Long Short-Term Memory Recurrent Neural Network Architectures for Large Scale Acoustic Modeling.

The encapsulated LSTMCell can be simplified to the following formula:

$$h^{'}, c^{'} = LSTMCell(x, (h_0, c_0))$$

Parameters

- **input_size** (*int*) −Number of features of input.
- **hidden_size** (*int*) −Number of features of hidden layer.
- **has_bias** (*bool*) −Whether the cell has bias *b_{ih}* and *b_{hh}*. Default: `True` .
- **dtype** (*mindspore.dtype*) −Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape $(batch\_size, input\_size)$.
- **hx** (tuple) - A tuple of two Tensors (h_0, c_0) both of data type mindspore.float32 and shape $(batch\_size, hidden\_size)$.

Outputs:

- **hx'** (Tensor) - A tuple of two Tensors (h', c') both of data shape $(batch\_size, hidden\_size)$.

Raises

- **TypeError** −If *input_size*, *hidden_size* is not an int.
- **TypeError** −If *has_bias* is not a bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> net = ms.nn.LSTMCell(10, 16)
>>> x = ms.Tensor(np.ones([5, 3, 10]).astype(np.float32))
>>> h = ms.Tensor(np.ones([3, 16]).astype(np.float32))
>>> c = ms.Tensor(np.ones([3, 16]).astype(np.float32))
>>> output = []
>>> for i in range(5):
...     hx = net(x[i], (h, c))
...     output.append(hx)
>>> print(output[0][0].shape)
(3, 16)
```

3.6 Transformer Layer

API Name	Description	Supported Platforms
mindspore.nn.MultiheadAttention	This is an implementation of multihead attention in the paper Attention is all you need.	Ascend GPU CPU
mindspore.nn.TransformerEncoderLayer	Transformer Encoder Layer.	Ascend GPU CPU
mindspore.nn.TransformerDecoderLayer	Transformer Decoder Layer.	Ascend GPU CPU
mindspore.nn.TransformerEncoder	Transformer Encoder module with multi-layer stacked of *mindspore.nn.TransformerEncoderLayer*, including multihead attention and feedforward layer.	Ascend GPU CPU
mindspore.nn.TransformerDecoder	Transformer Decoder module with multi-layer stacked of *mindspore.nn.TransformerDecoderLayer*, including multihead self attention, cross attention and feedforward layer.	Ascend GPU CPU
mindspore.nn.Transformer	Transformer module including encoder and decoder.	Ascend GPU CPU

3.6.1 mindspore.nn.MultiheadAttention

class mindspore.nn.**MultiheadAttention**(*embed_dim*, *num_heads*, *dropout=0.0*, *has_bias=True*, *add_bias_kv=False*, *add_zero_attn=False*, *kdim=None*, *vdim=None*, *batch_first=False*, *dtype=mstype.float32*)

This is an implementation of multihead attention in the paper Attention is all you need. Given the query vector, the key vector and value vector, the attention will be performed as the following:

$$MultiHeadAttention(query, key, value) = Concat(head_1, \ldots, head_h)W^O$$

where $head_i = Attention(QW_i^Q, KW_i^K, VW_i^V)$, and W^O , W_i^Q , W_i^K , W_i^V are weight matrices. The default input / output projection layers is with a bias.

if query, key and value tensor is same, then it will be self attention.

Parameters

- **embed_dim** (*int*) −Total dimension of MultiheadAttention.
- **num_heads** (*int*) −Number of attention heads. Note that *embed_dim* will be split across *num_heads* (i.e. each head will have dimension *embed_dim // num_heads*).
- **dropout** (*float, optional*) −Dropout probability of *attn_output_weights*. Default: `0.0`.
- **has_bias** (*bool, optional*) −Whether adds bias to input / output projection layers. Default: `True`.
- **add_bias_kv** (*bool, optional*) −Whether adds bias to the key and value sequences at axis=0. Default: `False`.
- **add_zero_attn** (*bool, optional*) −Whether adds a new batch of zeros to the key and value sequences at axis=1. Default: `False`.
- **kdim** (*int, optional*) −Total number of features for keys. Default: `None` (*kdim=embed_dim*).
- **vdim** (*int, optional*) −Total number of features for values. Default: `None` (*vdim=embed_dim*).
- **batch_first** (*bool, optional*) −If `True`, then the input and output shape are $(batch, seq, feature)$, else $(seq, batch, feature)$. Default: `False`.
- **dtype** (*mindspore.dtype*, optional) −Data type of Parameter. Default: `mstype.float32` .

Inputs:

- **query** (Tensor) - The query embeddings. If *query* is unbatched, the shape is (L, E_q), otherwise the shape is (L, N, E_q) when *batch_first=False* or (N, L, E_q) when *batch_first=True* , where L is the batch size, and E_q is the query embedding dimension *embed_dim*. Supported types: float16, float32, float64. Queries are compared against key-value pairs to produce the output.
- **key** (Tensor) - The key embeddings. If *key* is unbatched, the shape is (S, E_k), otherwise the shape is (S, N, E_k) when *batch_first=False* or (N, S, E_k) when *batch_first=True* , where S is the source sequence length, N is the batch size, and E_k is the key embedding dimension *kdim*. Supported types: float16, float32, float64.
- **value** (Tensor) - The value embeddings. If *value* is unbatched, the shape is (S, E_v), otherwise the shape is (S, N, E_v) when *batch_first=False* or (N, S, E_v) when *batch_first=True* , where S is the source sequence length, N is the batch size, and E_v is the value embedding dimension *vdim*. Supported types: float16, float32, float64.
- **key_padding_mask** (Tensor, optional) - If specified, a mask of shape (N, S) indicating which elements within *key* to ignore for the purpose of attention (i.e. treat as "padding"). For unbatched *query*, shape should be (S). Binary and float masks are supported. For a binary mask, a `True` value indicates that the corresponding *key* value will be ignored for the purpose of attention. For a float mask, it will be directly added to the corresponding *key* value. Supported float types: float16, float32, float64. Default: `None`.
- **need_weights** (bool, optional) - Whether returns *attn_output_weights* in addition to *attn_outputs*. Default: `True`.
- **attn_mask** (Tensor, optional) - If specified, a 2D or 3D mask preventing attention to certain positions. Must be of shape (L, S) or $(N \cdot \text{num\_heads}, L, S)$, where N is the batch size, L is the target sequence length, and S is the source sequence length. A 2D mask will be broadcasted across the batch while a 3D mask allows for a different mask for each entry in the batch. For a binary mask, a `True` value indicates that the corresponding position is not allowed to attend. For a float mask, the mask values will be added to the attention weight. Supported float types: float16, float32, float64. Default: `None`.
- **average_attn_weights** (bool, optional) - If true, indicates that the returned *attn_weights* should be averaged across heads. Otherwise, *attn_weights* are provided separately per head. Note that this flag only has an effect when *need_weights=True*. Default: `True` (i.e. average weights across heads)

Outputs:

Tuple, a tuple contains(*attn_output*, *attn_output_weights*)

- **attn_output** - Attention outputs. If input is unbatched, the output shape is (L, E), otherwise the output shape is (L, N, E) when *batch_first=False* or (N, L, E) when *batch_first=True* , where L is the target sequence length, N is the batch size, and E is the embedding dimension *embed_dim*.
- **attn_output_weights** - Only returned when *need_weights=True*. If *average_attn_weights=True*, returns attention weights averaged across heads with shape (L, S) when input is unbatched or (N, L, S) when input is batched, where N is the batch size, L is the target sequence length, and S is the source sequence length. If *average_attn_weights=False*, returns attention weights per head of shape (num_heads, L, S) when input is unbatched or (N, num_heads, L, S) when input is batched.

Raises

- **ValueError** –If the init argument *embed_dim* is not divisible by *num_heads*.
- **TypeError** –If the input argument *key_padding_mask* is not bool or floating types.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> embed_dim, num_heads = 128, 8
>>> seq_length, batch_size = 10, 8
>>> query = ms.Tensor(np.random.randn(seq_length, batch_size, embed_dim), ms.float32)
>>> key = ms.Tensor(np.random.randn(seq_length, batch_size, embed_dim), ms.float32)
>>> value = ms.Tensor(np.random.randn(seq_length, batch_size, embed_dim), ms.float32)
>>> multihead_attn = ms.nn.MultiheadAttention(embed_dim, num_heads)
>>> attn_output, attn_output_weights = multihead_attn(query, key, value)
>>> print(attn_output.shape)
(10, 8, 128)
```

3.6.2 mindspore.nn.TransformerEncoderLayer

class mindspore.nn.**TransformerEncoderLayer**(*d_model: int*, *nhead: int*, *dim_feedforward: int = 2048*, *dropout: float = 0.1*, *activation: Union[str, Cell, callable] = 'relu'*, *layer_norm_eps: float = 1e-5*, *batch_first: bool = False*, *norm_first: bool = False*, *dtype=mstype.float32*)

Transformer Encoder Layer. This is an implementation of the single layer of the transformer encoder layer, including multihead attention and feedward layer.

Parameters

- **d_model** (*int*) –The number of features in the input tensor.
- **nhead** (*int*) –The number of heads in the MultiheadAttention modules.
- **dim_feedforward** (*int*) –The dimension of the feedforward layer. Default: `2048`.
- **dropout** (*float*) –The dropout value. Default: `0.1`.
- **activation** (*Union[str, callable, Cell]*) –The activation function of the intermediate layer, can be a string (`"relu"` or `"gelu"`), Cell instance (*mindspore.nn.ReLU* or *mindspore.nn.GELU*) or a callable (*mindspore.ops.relu()* or *mindspore.ops.gelu()*). Default: `"relu"`.
- **layer_norm_eps** (*float*) –The epsilon value in LayerNorm modules. Default: `1e-5`.

- **batch_first** (*bool*) –If *batch_first=True* , then the shape of input and output tensors is $(batch, seq, feature)$, otherwise the shape is $(seq, batch, feature)$. Default: `False`.
- **norm_first** (*bool*) –If *norm_first = True*, layer norm is located prior to attention and feedforward operations; if *norm_first = False*, layer norm is located after the attention and feedforward operations. Default: `False`.
- **dtype** (*mindspore.dtype*) –Data type of Parameter. Default: `mstype.float32` .

Inputs:

- **src** (Tensor) - the sequence to the encoder layer. For unbatched input, the shape is (S, E) ; otherwise if *batch_first=False* , the shape is (S, N, E) and if *batch_first=True* , the shape is (N, S, E), where (S) is the source sequence length, (N) is the batch number and (E) is the feature number. Supported types: float16, float32, float64.
- **src_mask** (Tensor, optional) - the mask for the src sequence. The shape is (S, S) or $(N * nhead, S, S)$. Supported types: float16, float32, float64, bool. Default: `None`.
- **src_key_padding_mask** (Tensor, optional) - the mask for the src keys per batch. The shape is (S) for unbatched input, otherwise (N, S) . Supported types: float16, float32, float64, bool. Default: `None`.

Outputs:

Tensor. The shape and dtype of Tensor is the same with *src* .

Raises

- **ValueError** –If the init argument *activation* is not str, callable or Cell instance.
- **ValueError** –If the init argument *activation* is not *mindspore.nn.ReLU*, *mindspore.nn.GELU* instance, *mindspore.ops.relu()*, *mindspore.ops.gelu()*, "relu" or "gelu" .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> encoder_layer = ms.nn.TransformerEncoderLayer(d_model=512, nhead=8)
>>> src = ms.Tensor(np.random.rand(10, 32, 512), ms.float32)
>>> out = encoder_layer(src)
>>> print(out.shape)
(10, 32, 512)
>>> # Alternatively, when batch_first=True:
>>> encoder_layer = ms.nn.TransformerEncoderLayer(d_model=512, nhead=8, batch_first=True)
>>> src = ms.Tensor(np.random.rand(32, 10, 512), ms.float32)
>>> out = encoder_layer(src)
>>> print(out.shape)
(32, 10, 512)
```

3.6.3 mindspore.nn.TransformerDecoderLayer

class mindspore.nn.**TransformerDecoderLayer**(*d_model: int*, *nhead: int*, *dim_feedforward: int = 2048*, *dropout: float = 0.1*, *activation: Union[str, Cell, callable] = 'relu'*, *layer_norm_eps: float = 1e-5*, *batch_first: bool = False*, *norm_first: bool = False*, *dtype=mstype.float32*)

Transformer Decoder Layer. This is an implementation of the single layer of the transformer decoder layer, including self-attention, cross attention and feedward layer.

Parameters

- **d_model** (*int*) –The number of expected features in the input tensor.
- **nhead** (*int*) –The number of heads in the MultiheadAttention modules.
- **dim_feedforward** (*int*) –The dimension of the feedforward layer. Default: `2048`.
- **dropout** (*float*) –The dropout value. Default: `0.1`.
- **activation** (*Union[str, callable, Cell]*) –The activation function of the intermediate layer, can be a string (`"relu"` or `"gelu"`), Cell instance (*mindspore.nn.ReLU* or *mindspore.nn.GELU*) or a callable (*mindspore.ops.relu()* or *mindspore.ops.gelu()*). Default: `"relu"`.
- **layer_norm_eps** (*float*) –The epsilon value in LayerNorm modules. Default: `1e-5`.
- **batch_first** (*bool*) –If *batch_first=True* , then the shape of input and output tensors is $(batch, seq, feature)$, otherwise the shape is $(seq, batch, feature)$. Default: `False`.
- **norm_first** (*bool*) –If *norm_first = True*, layer norm is located prior to attention and feedforward operations; if *norm_first = False*, layer norm is located after the attention and feedforward operations. Default: `False`.
- **dtype** (*mindspore.dtype*) –Data type of Parameter. Default: `mstype.float32` .

Inputs:

- **tgt** (Tensor) - The sequence to the decoder layer. For unbatched input, the shape is (T, E) ; otherwise if *batch_first=False* , the shape is (T, N, E) and if *batch_first=True* , the shape is (N, T, E), where (T) is the target sequence length. Supported types: float16, float32, float64.
- **memory** (Tensor) - The sequence from the last layer of the encoder. Supported types: float16, float32, float64.
- **tgt_mask** (Tensor, optional) - The mask of the tgt sequence. The shape is (T, T) or $(N * nhead, T, T)$. Supported types: float16, float32, float64, bool. Default: `None`.
- **memory_mask** (Tensor, optional) - The mask of the memory sequence. The shape is (T, S) . Supported types: float16, float32, float64, bool. Default: `None`.
- **tgt_key_padding_mask** (Tensor, optional): The mask of the tgt keys per batch. The shape is (T) for unbatched input, otherwise (N, T) . Supported types: float16, float32, float64, bool. Default: `None`.
- **memory_key_padding_mask** (Tensor, optional) - The mask of the memory keys per batch. The shape is (S) for unbatched input, otherwise (N, S) . Supported types: float16, float32, float64, bool. Default: `None`.

Outputs:

Tensor. The shape and dtype of Tensor is the same with *tgt* .

Raises

- **ValueError** –If the init argument *activation* is not str, callable or Cell instance.
- **ValueError** –If the init argument *activation* is not *mindspore.nn.ReLU*, *mindspore.nn.GELU* instance, *mindspore.ops.relu()*, *mindspore.ops.gelu()* , "relu" or "gelu" .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> decoder_layer = ms.nn.TransformerDecoderLayer(d_model=512, nhead=8)
>>> memory = ms.Tensor(np.random.rand(10, 32, 512), ms.float32)
>>> tgt = ms.Tensor(np.random.rand(20, 32, 512), ms.float32)
>>> out = decoder_layer(tgt, memory)
>>> print(out.shape)
(20, 32, 512)
>>> # Alternatively, when `batch_first` is ``True``:
>>> decoder_layer = ms.nn.TransformerDecoderLayer(d_model=512, nhead=8, batch_first=True)
>>> memory = ms.Tensor(np.random.rand(32, 10, 512), ms.float32)
>>> tgt = ms.Tensor(np.random.rand(32, 20, 512), ms.float32)
>>> out = decoder_layer(tgt, memory)
>>> print(out.shape)
(32, 20, 512)
```

3.6.4 mindspore.nn.TransformerEncoder

class mindspore.nn.**TransformerEncoder**(*encoder_layer*, *num_layers*, *norm=None*)

Transformer Encoder module with multi-layer stacked of *mindspore.nn.TransformerEncoderLayer*, including multihead attention and feedforward layer. Users can build the BERT(https://arxiv.org/abs/1810.04805) model with corresponding parameters.

Parameters

- **encoder_layer** (Cell) –An instance of the *mindspore.nn.TransformerEncoderLayer* class.
- **num_layers** (*int*) –The number of encoder-layers in the encoder.
- **norm** (Cell, *optional*) –The layer normalization module. Default: None.

Inputs:

- **src** (Tensor) - The sequence to the encoder. For unbatched input, the shape is (S, E) ; otherwise if *batch_first=False* in *mindspore.nn.TransformerEncoderLayer*, the shape is (S, N, E) and if *batch_first=True* , the shape is (N, S, E), where (S) is the source sequence length, (N) is the batch number and (E) is the feature number. Supported types: float16, float32, float64.
- **src_mask** (Tensor, optional) - The mask of the src sequence. The shape is (S, S) or $(N * nhead, S, S)$, where *nhead* is the arguent in *mindspore.nn.TransformerEncoderLayer*. Supported types: float16, float32, float64, bool. Default: None.
- **src_key_padding_mask** (Tensor, optional) - the mask of the src keys per batch. The shape is (S) for unbatched input, otherwise (N, S) . Supported types: float16, float32, float64, bool. Default: None.

Outputs:

Tensor. The shape and dtype of Tensor is the same with *src* .

Raises

AssertionError –If the input argument *src_key_padding_mask* is not bool or floating types.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> encoder_layer = ms.nn.TransformerEncoderLayer(d_model=512, nhead=8)
>>> transformer_encoder = ms.nn.TransformerEncoder(encoder_layer, num_layers=6)
>>> src = ms.Tensor(np.random.rand(10, 32, 512), ms.float32)
>>> out = transformer_encoder(src)
>>> print(out.shape)
(10, 32, 512)
```

3.6.5 mindspore.nn.TransformerDecoder

class mindspore.nn.**TransformerDecoder**(*decoder_layer*, *num_layers*, *norm=None*)

Transformer Decoder module with multi-layer stacked of *mindspore.nn.TransformerDecoderLayer*, including multihead self attention, cross attention and feedforward layer.

Parameters

- **decoder_layer** (`Cell`) – An instance of the *mindspore.nn.TransformerDecoderLayer* class.
- **num_layers** (*int*) – The number of decoder-layers in the decoder.
- **norm** (`Cell, optional`) – The layer normalization module. Default: `None`.

Inputs:

- **tgt** (Tensor) - The sequence to the decoder. For unbatched input, the shape is (T, E) ; otherwise if *batch_first=False* in *mindspore.nn.TransformerDecoderLayer*, the shape is (T, N, E) and if *batch_first=True* , the shape is (N, T, E), where (T) is the target sequence length, (N) is the number of batches, and (E) is the number of features. Supported types: float16, float32, float64.
- **memory** (Tensor) - The sequence from the last layer of the encoder. Supported types: float16, float32, float64.
- **tgt_mask** (Tensor, optional) - the mask of the tgt sequence. The shape is (T, T) or $(N * nhead, T, T)$, where *nhead* is the arguent in *mindspore.nn.TransformerDecoderLayer*. Supported types: float16, float32, float64, bool. Default: `None`.
- **memory_mask** (Tensor, optional) - the mask of the memory sequence. The shape is (T, S) . Supported types: float16, float32, float64, bool. Default: `None`.
- **tgt_key_padding_mask** (Tensor, optional) - the mask of the tgt keys per batch. Shape is (T). Supported types: float16, float32, float64, bool. Default: `None`.
- **memory_key_padding_mask** (Tensor, optional) - the mask of the memory keys per batch. The shape is (S) for unbatched input, otherwise (N, S) . Supported types: float16, float32, float64, bool. Default: `None`.

Outputs:

Tensor. The shape and dtype of Tensor is the same with *tgt* .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> decoder_layer = ms.nn.TransformerDecoderLayer(d_model=512, nhead=8)
>>> transformer_decoder = ms.nn.TransformerDecoder(decoder_layer, num_layers=6)
>>> memory = ms.Tensor(np.random.rand(10, 32, 512), ms.float32)
>>> tgt = ms.Tensor(np.random.rand(20, 32, 512), ms.float32)
>>> out = transformer_decoder(tgt, memory)
>>> print(out.shape)
(20, 32, 512)
```

3.6.6 mindspore.nn.Transformer

class mindspore.nn.**Transformer**(*d_model: int = 512*, *nhead: int = 8*, *num_encoder_layers: int = 6*, *num_decoder_layers: int = 6*, *dim_feedforward: int = 2048*, *dropout: float = 0.1*, *activation: Union[str, Cell, callable] = 'relu'*, *custom_encoder: Optional[Cell] = None*, *custom_decoder: Optional[Cell] = None*, *layer_norm_eps: float = 1e-5*, *batch_first: bool = False*, *norm_first: bool = False*, *dtype=mstype.float32*)

Transformer module including encoder and decoder. The difference with the original implements is the module use the residual addition before the layer normalization. And the default hidden activation is *gelu*. The details can be found in Attention is all you need.

Parameters

- **d_model** (*int*) –The number of expected features in the inputs tensor for Encoder and Decoder. Default: `512`.
- **nhead** (*int*) –The number of heads in the MultiheadAttention modules. Default: `8`.
- **num_encoder_layers** (*int*) –The number of encoder-layers in the encoder. Default: `6`.
- **num_decoder_layers** (*int*) –The number of decoder-layers in the decoder. Default: `6`.
- **dim_feedforward** (*int*) –The dimension of the feedforward layer. Default: `2048`.
- **dropout** (*float*) –The dropout value. Default: `0.1`.
- **activation** (*Union[str, callable, Cell]*) –The activation function of the intermediate layer, can be a string (`"relu"` or `"gelu"`), Cell instance (*mindspore.nn.ReLU* or *mindspore.nn.GELU*) or a callable (*mindspore.ops.relu()* or *mindspore.ops.gelu()*). Default: `"relu"`.
- **custom_encoder** (*Cell*) –Custom encoder. Default: `None`.
- **custom_decoder** (*Cell*) –Custom decoder. Default: `None`.
- **layer_norm_eps** (*float*) –the epsilion value in layer normalization module. Default: `1e-5`.
- **batch_first** (*bool*) –If *batch_first=True*, then the shape of input and output tensors is $(batch, seq, feature)$, otherwise the shape is $(seq, batch, feature)$. Default: `False`.
- **norm_first** (*bool*) –If *norm_first = True*, layer norm is located prior to attention and feedforward operations; if *norm_first = False*, layer norm is located after the attention and feedforward operations. Default: `False`.
- **dtype** (*mindspore.dtype*) –Data type of Parameter. Default: `mstype.float32` .

Inputs:

- **src** (Tensor) - The source sequence to the encoder. For unbatched input, the shape is (S, E) ; otherwise if *batch_first=False* , the shape is (S, N, E) and if *batch_first=True* , the shape is (N, S, E), where (S) is the source sequence length, (N) is the batch number and (E) is the feature number. Supported types: float16, float32, float64.

- **tgt** (Tensor) - The target sequence to the decoder. For unbatched input, the shape is (T, E) ; otherwise if *batch_first=False* , the shape is (T, N, E) and if *batch_first=True* , the shape is (N, T, E), where (T) is the target sequence length. Supported types: float16, float32, float64.
- **src_mask** (Tensor, optional) - The mask of the src sequence. The shape is (S, S) or $(N * nhead, S, S)$. Supported types: float16, float32, float64, bool. Default: `None`.
- **tgt_mask** (Tensor, optional) - The mask of the tgt sequence. The shape is (T, T) or $(N * nhead, T, T)$. Supported types: float16, float32, float64, bool. Default: `None`.
- **memory_mask** (Tensor, optional) - The additive mask of the encoder output. The shape is (T, S) . Supported types: float16, float32, float64, bool. Default: `None`.
- **src_key_padding_mask** (Tensor, optional) - The mask of src keys per batch. The shape is (S) for unbatched input, otherwise (N, S) . Supported types: float16, float32, float64, bool. Default: `None`.
- **tgt_key_padding_mask** (Tensor, optional) - The mask of tgt keys per batch. The shape is (T) for unbatched input, otherwise (N, S) . Supported types: float16, float32, float64, bool. Default: `None`.
- **memory_key_padding_mask** (Tensor, optional) - The mask of memory keys per batch. The shape is (S) for unbatched input, otherwise (N, S) . Supported types: float16, float32, float64, bool. Default: `None`.

Outputs:

Tensor. The shape is (T, E) for unbatched input, otherwise if *batch_first=False* , the shape is (T, N, E) and if *batch_first=True* , the shape is (N, T, E).

Raises

- **ValueError** –If the batch sizes of the init argument *src* and *tgt* are not equal.
- **ValueError** –If the number of features of the init argument *src* and *tgt* is not equal to that of *d_model*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> transformer_model = ms.nn.Transformer(nhead=16, num_encoder_layers=12)
>>> src = ms.Tensor(np.random.rand(10, 32, 512), ms.float32)
>>> tgt = ms.Tensor(np.random.rand(20, 32, 512), ms.float32)
>>> out = transformer_model(src, tgt)
>>> print(out.shape)
(20, 32, 512)
```

3.7 Embedding Layer

API Name	Description	Supported Platforms
mindspore.nn.Embedding	A simple lookup table that stores embeddings of a fixed dictionary and size.	`Ascend` `GPU` `CPU`
mindspore.nn.EmbeddingLookup	EmbeddingLookup layer.	`Ascend` `GPU` `CPU`

continues on next page

Table 7 – continued from previous page

mindspore.nn.MultiFieldEmbeddingLookup	Returns a slice of input tensor based on the specified indices and the field ids.	Ascend GPU

3.7.1 mindspore.nn.Embedding

class mindspore.nn.**Embedding**(*vocab_size*, *embedding_size*, *use_one_hot=False*, *embedding_table='normal'*, *dtype=mstype.float32*, *padding_idx=None*)

A simple lookup table that stores embeddings of a fixed dictionary and size.

This module is often used to store word embeddings and retrieve them using indices. The input to the module is a list of indices, and the output is the corresponding word embeddings.

Note: When 'use_one_hot' is set to True, the type of the *x* must be mindspore.int32.

Parameters

- **vocab_size** (*int*) –Size of the dictionary of embeddings.
- **embedding_size** (*int*) –The size of each embedding vector.
- **use_one_hot** (*bool*) –Specifies whether to apply one_hot encoding form. Default: `False` .
- **embedding_table** (*Union[Tensor, str, Initializer, numbers.Number]*) –Initializer for the embedding_table. Refer to class mindspore.common.initializer for the values of string when a string is specified. Default: `'normal'` .
- **dtype** (*mindspore.dtype*) –Data type of *x*. Default: `mstype.float32` .
- **padding_idx** (*int, None*) –When the padding_idx encounters index, the output embedding vector of this index will be initialized to zero. Default: `None` . The feature is inactivated.

Inputs:

- **x** (Tensor) - Tensor of shape (batch_size, x_length). The elements of the Tensor must be integer and not larger than vocab_size. Otherwise the corresponding embedding vector will be zero. The data type is int32 or int64.

Outputs:

Tensor of shape (batch_size, x_length, embedding_size).

Raises

- **TypeError** –If *vocab_size* or *embedding_size* is not an int.
- **TypeError** –If *use_one_hot* is not a bool.
- **ValueError** –If *padding_idx* is an int which not in range [0, *vocab_size*).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> net = nn.Embedding(20000, 768,  True)
>>> x = Tensor(np.ones([8, 128]), mindspore.int32)
>>> # Maps the input word IDs to word embedding.
>>> output = net(x)
>>> result = output.shape
>>> print(result)
(8, 128, 768)
```

3.7.2 mindspore.nn.EmbeddingLookup

class mindspore.nn.**EmbeddingLookup**(*vocab_size*, *embedding_size*, *param_init='normal'*, *target='CPU'*, *slice_mode='batch_slice'*, *manual_shapes=None*, *max_norm=None*, *sparse=True*, *vocab_cache_size=0*, *dtype=mstype.float32*)

EmbeddingLookup layer. Same function as the embedding layer, mainly used for heterogeneous parallel scenarios where large-scale embedding layers exist when automatic parallelism or semi-automatic parallelism is present.

Note: When 'target' is set to 'CPU', this module will use P.EmbeddingLookup().set_device('CPU') which specified 'offset = 0' to lookup table. When 'target' is set to 'DEVICE', this module will use P.Gather() which specified 'axis = 0' to lookup table. In field slice mode, the manual_shapes must be given. It is a tuple ,where the element is vocab[i], vocab[i] is the row numbers for i-th part. This module does not support the PyNative mode.

Parameters

- **vocab_size** (*int*) –Size of the dictionary of embeddings.
- **embedding_size** (*int*) –The size of each embedding vector.
- **param_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –Initializer for the embedding_table. Refer to class *initializer* for the values of string when a string is specified. Default: `'normal'` .
- **target** (*str*) –Specifies the target where the op is executed. The value must in [`'DEVICE'` , `'CPU'`]. Default: `'CPU'` .
- **slice_mode** (*str*) –The slicing way in semi_auto_parallel/auto_parallel. Default: `'batch_slice'` .
  - batch_slice (str): Divides the input index tensor into batches and retrieves the corresponding embedding vectors. This is applicable when each sample has the same number of indices.
  - field_slice (str): Divides the input index tensor into fields and retrieves the corresponding embedding vectors. This is applicable when each sample may have a different number of indices, but have the same feature dimensions.
  - table_row_slice (str): Treats the input index tensor as a 2D table, divides it by rows, and retrieves the corresponding embedding vectors.
  - table_column_slice (str): Treats the input index tensor as a 2D table, divides it by columns, and retrieves the corresponding embedding vectors.
- **manual_shapes** (*tuple*) –The accompaniment array in field slice mode. Default: `None` .
- **max_norm** (*Union[float, None]*) –A maximum clipping value. The data type must be float16, float32 or None. Default: `None` .

- **sparse** (*bool*) –Using sparse mode. When 'target' is set to 'CPU', 'sparse' has to be true. Default: `True` .
- **vocab_cache_size** (*int*) –Cache size of the dictionary of embeddings. Default: `0` . It is valid only in parameter server trainning mode and 'DEVICE' target. And the moment parameter of corresponding optimizer will also be set to the cache size. In addition, it should be noted that it will cost the 'DEVICE' memory, so suggests setting a reasonable value to avoid insufficient memory.
- **dtype** (*mindspore.dtype*) –Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **input_indices** (Tensor) - The shape of tensor is $(y_1, y_2, ..., y_S)$. Specifies the indices of elements of the original Tensor. Values can be out of range of embedding_table, and the exceeding part will be filled with 0 in the output. Values does not support negative and the result is undefined if values are negative. Input_indices must only be a 2d tensor in this interface when run in semi auto parallel/auto parallel mode.

Outputs:

Tensor, the shape of tensor is $(z_1, z_2, ..., z_N)$.

Raises

- **TypeError** –If *vocab_size* or *embedding_size* or *vocab_cache_size* is not an int.
- **TypeError** –If *sparse* is not a bool or *manual_shapes* is not a tuple.
- **ValueError** –If *vocab_size* or *embedding_size* is less than 1.
- **ValueError** –If *vocab_cache_size* is less than 0.
- **ValueError** –If *target* is neither 'CPU' nor 'DEVICE'.
- **ValueError** –If *slice_mode* is not one of 'batch_slice' or 'field_slice' or 'table_row_slice' or 'table_column_slice'.
- **ValueError** –If *sparse* is False and *target* is 'CPU'.
- **ValueError** –If *slice_mode* is 'field_slice' and *manual_shapes* is None.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> input_indices = Tensor(np.array([[1, 0], [3, 2]]), mindspore.int32)
>>> result = nn.EmbeddingLookup(4,2)(input_indices)
>>> print(result.shape)
(2, 2, 2)
```

3.7.3 mindspore.nn.MultiFieldEmbeddingLookup

class mindspore.nn.**MultiFieldEmbeddingLookup**(*vocab_size*, *embedding_size*, *field_size*, *param_init='normal'*, *target='CPU'*, *slice_mode='batch_slice'*, *feature_num_list=None*, *max_norm=None*, *sparse=True*, *operator='SUM'*, *dtype=mstype.float32*)

Returns a slice of input tensor based on the specified indices and the field ids. This operation supports looking up embeddings using multi hot and one hot fields simultaneously.

Note: When 'target' is set to 'CPU', this module will use P.EmbeddingLookup().set_device('CPU') which specified 'offset = 0' to lookup table. When 'target' is set to 'DEVICE', this module will use P.Gather() which specified 'axis = 0' to lookup table. The vectors with the same field_ids will be combined by the *operator*, such as 'SUM', 'MAX' and 'MEAN'. Ensure the input_values of the padded id is zero, so that they can be ignored. The final output will be zeros if the sum of absolute weight of the field is zero. This class only supports ['table_row_slice', 'batch_slice' and 'table_column_slice']. For the operation 'MAX' on device Ascend, there is a constraint where $batch\_size * (seq\_length + field\_size) < 3500$.

Parameters

- **vocab_size** (*int*) −The size of the dictionary of embeddings.
- **embedding_size** (*int*) −The size of each embedding vector.
- **field_size** (*int*) −The field size of the final outputs.
- **param_init** (*Union[Tensor, str, Initializer, numbers.Number]*) −Initializer for the embedding_table. Refer to class *initializer* for the values of string when a string is specified. Default: `'normal'` .
- **target** (*str*) −Specifies the target where the op is executed. The value must in [`'DEVICE'` , `'CPU'`]. Default: `'CPU'` .
- **slice_mode** (*str*) −The slicing way in semi_auto_parallel/auto_parallel. Default: `'batch_slice'`.
  - batch_slice (str): Divides the input index tensor into batches and retrieves the corresponding embedding vectors. This is applicable when each sample has the same number of indices.
  - field_slice (str): Divides the input index tensor into fields and retrieves the corresponding embedding vectors. This is applicable when each sample may have a different number of indices, but have the same feature dimensions.
  - table_row_slice (str): Treats the input index tensor as a 2D table, divides it by rows, and retrieves the corresponding embedding vectors.
  - table_column_slice (str): Treats the input index tensor as a 2D table, divides it by columns, and retrieves the corresponding embedding vectors.
- **feature_num_list** (*tuple*) −The accompaniment array in field slice mode. This is unused currently. Default: `None` .
- **max_norm** (*Union[float, None]*) −A maximum clipping value. The data type must be float16, float32. Default: `None` .
- **sparse** (*bool*) −Using sparse mode. When 'target' is set to `'CPU'` , 'sparse' has to be true. Default: `True` .
- **operator** (*str*) −The pooling method for the features in one field. Support `'SUM'` , `'MEAN'` and `'MAX'` . Default: `'SUM'` .
- **dtype** (*mindspore.dtype*) −Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **input_indices** (Tensor) - The shape of tensor is $(batch\_size, seq\_length)$. Specifies the indices of elements of the original Tensor. Input_indices must be a 2d tensor in this interface. Type is Int32, Int64.
- **input_values** (Tensor) - The shape of tensor is $(batch\_size, seq\_length)$. Specifies the weights of elements of the input_indices. The lookout vector will multiply with the input_values. Type is float32.
- **field_ids** (Tensor) - The shape of tensor is $(batch\_size, seq\_length)$. Specifies the field id of elements of the input_indices. Type is Int32.

Outputs:

Tensor, the shape of tensor is $(batch\_size, field\_size, embedding\_size)$. Type is float32.

Raises

- **TypeError** – If *vocab_size* or *embedding_size* or *field_size* is not an int.
- **TypeError** – If *sparse* is not a bool or *feature_num_list* is not a tuple.
- **ValueError** – If *vocab_size* or *embedding_size* or *field_size* is less than 1.
- **ValueError** – If *target* is neither `'CPU'` nor `'DEVICE'`.
- **ValueError** – If *slice_mode* is not one of `'batch_slice'`, `'field_slice'`, `'table_row_slice'`, `'table_column_slice'`.
- **ValueError** – If *sparse* is False and *target* is `'CPU'`.
- **ValueError** – If *slice_mode* is `'field_slice'` and *feature_num_list* is None.
- **ValueError** – If *operator* is not one of `'SUM'`, `'MAX'`, `'MEAN'`.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> input_indices = Tensor([[2, 4, 6, 0, 0], [1, 3, 5, 0, 0]], mindspore.int32)
>>> input_values = Tensor([[1, 1, 1, 0, 0], [1, 1, 1, 0, 0]], mindspore.float32)
>>> field_ids = Tensor([[0, 1, 1, 0, 0], [0, 0, 1, 0, 0]], mindspore.int32)
>>> net = nn.MultiFieldEmbeddingLookup(10, 2, field_size=2, operator='SUM', target='DEVICE')
>>> out = net(input_indices, input_values, field_ids)
>>> print(out.shape)
(2, 2, 2)
```

3.8 Nonlinear Activation Layer

API Name	Description	Supported Platforms
mindspore.nn.CELU	CELU Activation Operator.	`Ascend` `GPU` `CPU`
mindspore.nn.ELU	Applies the exponential linear unit function element-wise.	`Ascend` `GPU` `CPU`
mindspore.nn.FastGelu	Applies FastGelu function to each element of the input.	`Ascend` `GPU` `CPU`

continues on next page

Table 8 – continued from previous page

mindspore.nn.GELU	Applies GELU function to each element of the input.	Ascend GPU CPU
mindspore.nn.GLU	The gated linear unit function.	Ascend GPU CPU
mindspore.nn.get_activation	Gets the activation function.	Ascend GPU CPU
mindspore.nn.Hardtanh	Applies the Hardtanh function element-wise.	Ascend GPU CPU
mindspore.nn.HShrink	Applies Hard Shrink activation function element-wise.	Ascend GPU CPU
mindspore.nn.HSigmoid	Applies Hard Sigmoid activation function element-wise.	Ascend GPU CPU
mindspore.nn.HSwish	Applies Hard Swish activation function element-wise.	Ascend GPU CPU
mindspore.nn.LeakyReLU	Leaky ReLU activation function.	Ascend GPU CPU
mindspore.nn.LogSigmoid	Applies logsigmoid activation element-wise.	Ascend GPU CPU
mindspore.nn.LogSoftmax	Applies the LogSoftmax function to n-dimensional input tensor element-wise.	Ascend GPU CPU
mindspore.nn.LRN	Local Response Normalization.	GPU CPU
mindspore.nn.Mish	Computes MISH (A Self Regularized Non-Monotonic Neural Activation Function) of input tensors element-wise.	Ascend GPU CPU
mindspore.nn.Softsign	Applies softsign activation function element-wise.	Ascend GPU CPU
mindspore.nn.PReLU	Applies PReLU activation function element-wise.	Ascend GPU CPU
mindspore.nn.ReLU	Applies ReLU (Rectified Linear Unit activation function) element-wise.	Ascend GPU CPU
mindspore.nn.ReLU6	Compute ReLU6 activation function element-wise.	Ascend GPU CPU
mindspore.nn.RReLU	Applies RReLU (Randomized Leaky ReLU activation function) element-wise.	Ascend GPU CPU
mindspore.nn.SeLU	Applies activation function SeLU (Scaled exponential Linear Unit) element-wise.	Ascend GPU CPU
mindspore.nn.SiLU	Applies the silu linear unit function element-wise.	Ascend GPU CPU
mindspore.nn.Sigmoid	Applies sigmoid activation function element-wise.	Ascend GPU CPU
mindspore.nn.Softmin	Softmin activation function, which is a two-category function mindspore.nn.Sigmoid in the promotion of multi-classification, and the purpose is to show the results of multi-classification in the form of probability.	Ascend GPU CPU
mindspore.nn.Softmax	Softmax activation function, which is a two-category function mindspore.nn.Sigmoid in the promotion of multi-classification, the purpose is to show the results of multi-classification in the form of probability.	Ascend GPU CPU
mindspore.nn.Softmax2d	Softmax function applied to 2D features data.	Ascend GPU CPU
mindspore.nn.SoftShrink	Applies the SoftShrink function element-wise.	Ascend GPU CPU
mindspore.nn.Tanh	Applies the Tanh function element-wise, returns a new tensor with the hyperbolic tangent of the elements of input, The input is a Tensor with any valid shape.	Ascend GPU CPU
mindspore.nn.Tanhshrink	Applies Tanhshrink activation function element-wise and returns a new tensor.	Ascend GPU CPU
mindspore.nn.Threshold	Thresholds each element of the input Tensor.	Ascend GPU CPU

3.8.1 mindspore.nn.CELU

class mindspore.nn.**CELU**(*alpha=1.0*)

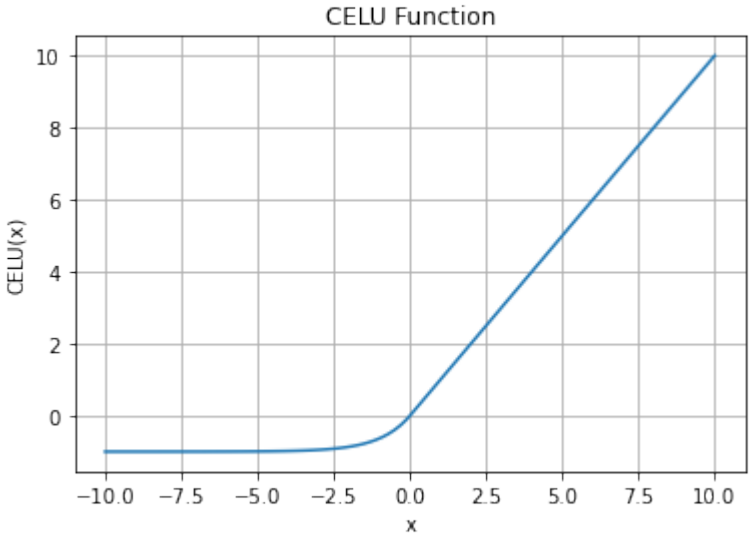
CELU Activation Operator.

Applies the continuously differentiable exponential linear units function element-wise.

$$\text{CELU}(x) = \max(0, x) + \min(0, \alpha * (\exp(x/\alpha) - 1))$$

For more details, refer to CELU .

CELU Activation Function Graph:



Parameters

alpha (*float, optional*) – The α value for the Celu formulation. Default: 1.0 .

Inputs:

- **x** (Tensor) - The input of CELU. The required dtype is float16 or float32. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.

Outputs:

Tensor, with the same type and shape as the *x*.

Raises

- **TypeError** – If *alpha* is not a float.
- **ValueError** – If *alpha* has the value of 0.
- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If the dtype of *x* is neither float16 nor float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([-2.0, -1.0, 1.0, 2.0]), mindspore.float32)
>>> celu = nn.CELU()
>>> output = celu(x)
>>> print(output)
[-0.86466473 -0.63212055  1.          2.        ]
```

3.8.2 mindspore.nn.ELU

class mindspore.nn.**ELU**(*alpha=1.0*)

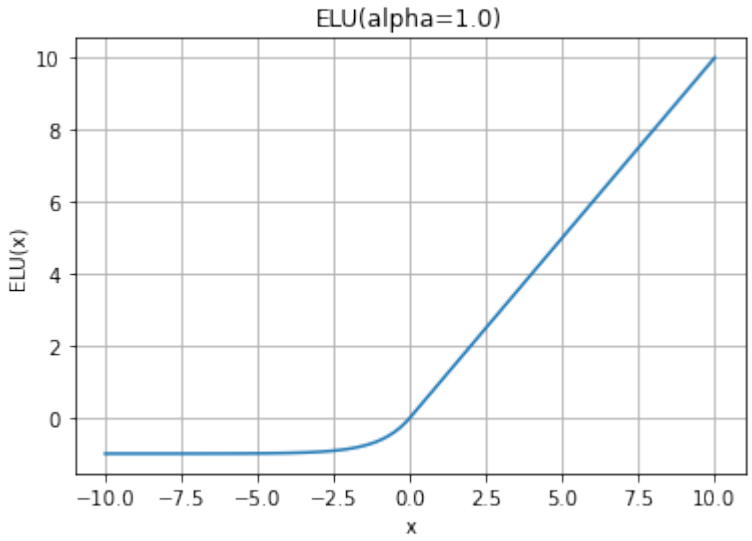
Applies the exponential linear unit function element-wise.

The activation function is defined as:

$$E_i = \begin{cases} x_i, & \text{if } x_i \geq 0; \\ \alpha * (\exp(x_i) - 1), & \text{otherwise.} \end{cases}$$

where x_i represents the element of the input and α represents the *alpha* parameter.

ELU Activation Function Graph:



Parameters

alpha (*float*) – The alpha value of ELU, the data type is float. Default: `1.0`. Only alpha equal to `1.0` is supported currently.

Inputs:

- **input_x** (Tensor) - The input of ELU is a Tensor of any dimension with data type of float16 or float32.

Outputs:

Tensor, with the same type and shape as the *input_x*.

Raises

- **TypeError** – If *alpha* is not a float.
- **TypeError** – If dtype of *input_x* is neither float16 nor float32.
- **ValueError** – If *alpha* is not equal to 1.0.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float32)
>>> elu = nn.ELU()
>>> result = elu(x)
>>> print(result)
[-0.63212055  -0.86466473  0.  2.  1.]
```

3.8.3 mindspore.nn.FastGelu

class mindspore.nn.**FastGelu**

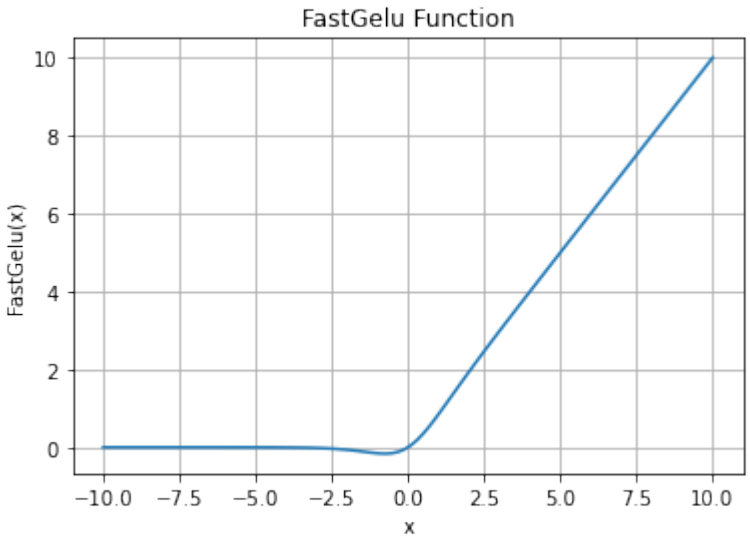
Applies FastGelu function to each element of the input. The input is a Tensor with any valid shape.

FastGelu is defined as:

$$FastGelu(x_i) = \frac{x_i}{1 + \exp(-1.702 * |x_i|)} * \exp(0.851 * (x_i - |x_i|))$$

where x_i is the element of the input.

FastGelu Activation Function Graph:



Inputs:

- **x** (Tensor) - The input of FastGelu with data type of float16 or float32. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.

Outputs:

Tensor, with the same type and shape as the *x*.

Raises

TypeError – If dtype of *x* is neither float16 nor float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> fast_gelu = nn.FastGelu()
>>> output = fast_gelu(x)
>>> print(output)
[[-1.5418735e-01  3.9921875e+00 -9.7473649e-06]
 [ 1.9375000e+00 -1.0052517e-03  8.9824219e+00]]
```

3.8.4 mindspore.nn.GELU

class mindspore.nn.**GELU**(*approximate=True*)

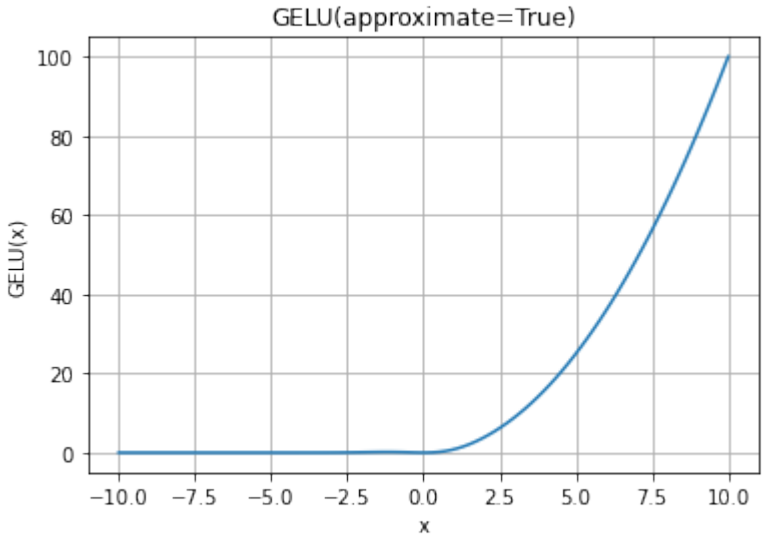
Applies GELU function to each element of the input. The input is a Tensor with any valid shape.

GELU is defined as:

$$GELU(x_i) = x_i * P(X < x_i),$$

where P is the cumulative distribution function of standard Gaussian distribution and x_i is the element of the input.

GELU Activation Function Graph:



Parameters

approximate (*bool, optional*) – Whether to enable approximation. Default: `True` .

If *approximate* is `True`, The gaussian error linear activation is:

$0.5 * x * (1 + tanh(\sqrt{(2/\pi)} * (x + 0.044715 * x^3)))$

else, it is:

$x * P(X <= x) = 0.5 * x * (1 + erf(x/\sqrt{(2)}))$, where $P(X)$ $N(0, 1)$.

Note:

- when calculating the input gradient of GELU with an input value of infinity, there are differences in the output of the backward between `Ascend` and `GPU`.
- when x is -inf, the computation result of `Ascend` is 0, and the computation result of `GPU` is Nan.
- when x is inf, the computation result of `Ascend` is dy, and the computation result of `GPU` is Nan.
- In mathematical terms, the result of Ascend has higher precision.

Inputs:

- **x** (Tensor) - The input of GELU with data type of float16, float32, or float64. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.

Outputs:

Tensor, with the same type and shape as the *x*.

Raises

TypeError – If dtype of *x* is not one of float16, float32, or float64.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> gelu = nn.GELU()
>>> output = gelu(x)
>>> print(output)
[[-1.5880802e-01  3.9999299e+00 -3.1077917e-21]
 [ 1.9545976e+00 -2.2918017e-07  9.0000000e+00]]
>>> gelu = nn.GELU(approximate=False)
>>> # CPU not support "approximate=False", using "approximate=True" instead
>>> output = gelu(x)
>>> print(output)
[[-1.5865526e-01  3.9998732e+00 -0.0000000e+00]
 [ 1.9544997e+00 -1.4901161e-06  9.0000000e+00]]
```

3.8.5 mindspore.nn.GLU

class mindspore.nn.**GLU**(*axis=-1*)

The gated linear unit function.

$$GLU(a, b) = a \otimes \sigma(b)$$

where a is the first half of the input matrices and b is the second half.

Here σ is the sigmoid function, and $\otimes$ is the Hadamard product.

Parameters

axis (*int, optional*) – the axis to split the input. Default: `-1` , the last axis in x.

Inputs:

- **x** (Tensor) - $(*_1, N, *_2)$ where * means, any number of additional dimensions.

Outputs:

Tensor, the same dtype as the x, with the shape $(*_1, M, *_2)$ where $M = N/2$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> m = ms.nn.GLU()
>>> input = ms.Tensor([[0.1,0.2,0.3,0.4],[0.5,0.6,0.7,0.8]])
>>> output = m(input)
>>> print(output)
[[0.05744425 0.11973753]
 [0.33409387 0.41398472]]
```

3.8.6 mindspore.nn.get_activation

mindspore.nn.**get_activation**(*name*, *prim_name=None*)

Gets the activation function.

Parameters

- **name** (*str*) – The name of the activation function.
- **prim_name** (*Union[str, None]*) – The name of primitive. Default: `None` .

Returns

Function, the activation function.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.nn as nn
>>> sigmoid = nn.get_activation('sigmoid')
>>> print(sigmoid)
Sigmoid()
```

3.8.7 mindspore.nn.Hardtanh

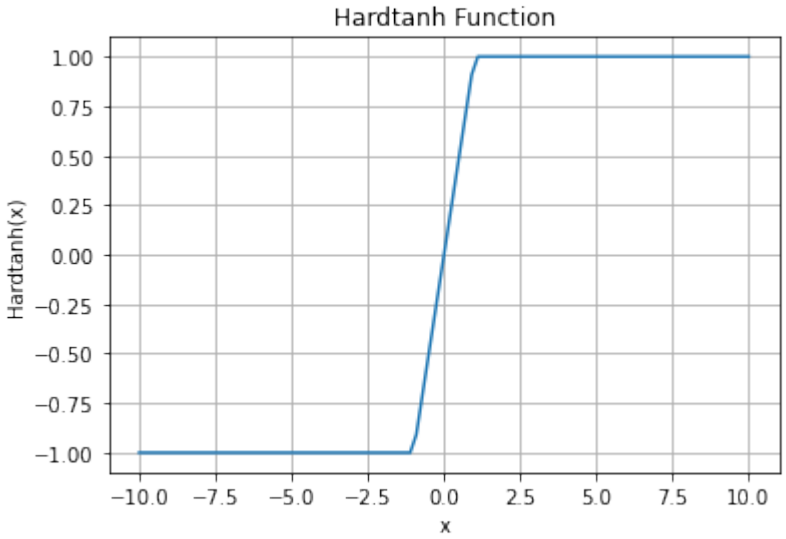
class mindspore.nn.**Hardtanh**(*min_val=- 1.0*, *max_val=1.0*)

Applies the Hardtanh function element-wise. The activation function is defined as:

$$\text{Hardtanh}(x) = \begin{cases} 1, & \text{if } x > 1; \\ -1, & \text{if } x < -1; \\ x, & \text{otherwise.} \end{cases}$$

Linear region range $[-1, 1]$ can be adjusted using *min_val* and *max_val*.

Hardtanh Activation Function Graph:



Note: On Ascend, data type of float16 might lead to accidental accuracy problem.

Parameters

- **min_val** (*Union[int, float]*) – Minimum value of the linear region range. Default: `-1.0`.
- **max_val** (*Union[int, float]*) – Maximum value of the linear region range. Default: `1.0`.

Inputs:

- **x** (Tensor) - Input Tensor with data type of float16 or float32. On CPU and Ascend support dimension 0-7D. On GPU support dimension 0-4D.

Outputs:

Tensor, with the same dtype and shape as *x*.

Raises

- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If dtype of *x* is neither float16 nor float32.
- **TypeError** – If dtype of *min_val* is neither float nor int.
- **TypeError** – If dtype of *max_val* is neither float nor int.
- **ValueError** – If *min_val* is not less than *max_val*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> hardtanh = nn.Hardtanh(min_val=-1.0, max_val=1.0)
>>> output = hardtanh(x)
>>> print(output)
[-1. -1.  0.  1.  1.]
```

3.8.8 mindspore.nn.HShrink

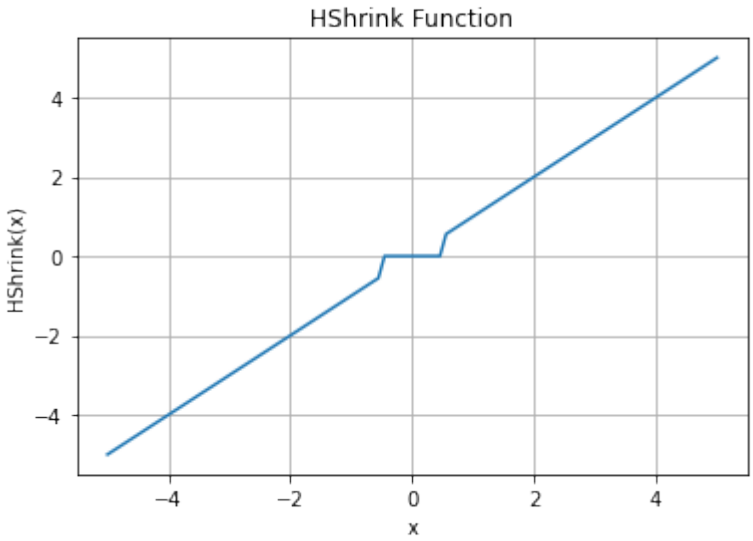
class mindspore.nn.**HShrink**(*lambd=0.5*)

Applies Hard Shrink activation function element-wise.

The formula is defined as follows:

$$\text{HShrink}(x) = \begin{cases} x, & \text{if } x > \lambda \\ x, & \text{if } x < -\lambda \\ 0, & \text{otherwise} \end{cases}$$

HShrink Activation Function Graph:



Parameters

lambd (*number, optional*) – The threshold λ defined by the Hard Shrink formula. Default: `0.5`.

Inputs:

- **input** (Tensor) - The input of Hard Shrink. Supported dtypes:
  - Ascend: float16, float32, bfloat16.
  - CPU/GPU: float16, float32.

Outputs:

Tensor, the same shape and data type as the input.

Raises

- **TypeError** – If *lambd* is not a float, int or bool.
- **TypeError** – If *input* is not a tensor.
- **TypeError** – If dtype of *input* is not float16, float32 or bfloat16.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> input = Tensor(np.array([[0.5, 1, 2.0], [0.0533, 0.0776, -2.1233]]), mindspore.float32)
>>> hshrink = nn.HShrink()
>>> output = hshrink(input)
>>> print(output)
[[ 0.      1.      2.    ]
 [ 0.      0.     -2.1233]]
```

3.8.9 mindspore.nn.HSigmoid

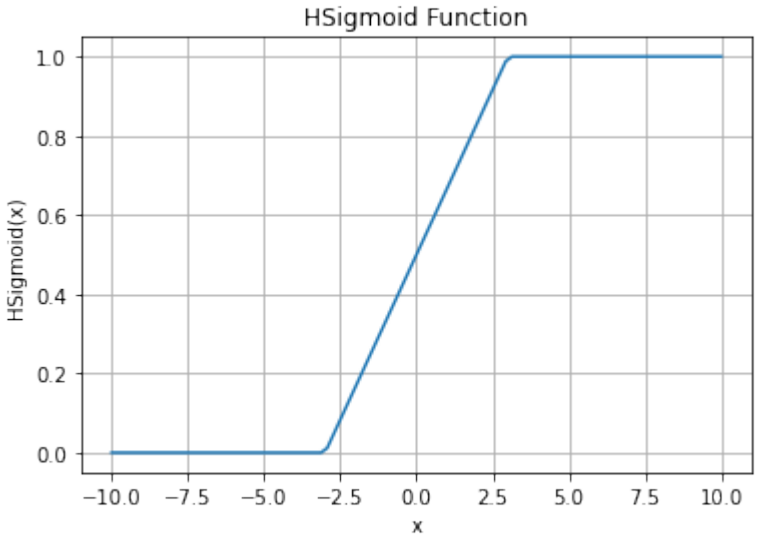
class mindspore.nn.**HSigmoid**

Applies Hard Sigmoid activation function element-wise.

Hard Sigmoid is defined as:

$$\text{HSigmoid}(input) = \begin{cases} 0, & \text{if } input \leq -3, \\ 1, & \text{if } input \geq +3, \\ input/6 + 1/2, & \text{otherwise} \end{cases}$$

HSigmoid Activation Function Graph:



Inputs:

- **input** (Tensor) - The input of HSigmoid.

Outputs:

Tensor, with the same type and shape as the *input*.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If *input* is neither int nor float.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> hsigmoid = nn.HSigmoid()
>>> result = hsigmoid(input)
>>> print(result)
[0.3333 0.1666 0.5    0.8335 0.6665]
```

3.8.10 mindspore.nn.HSwish

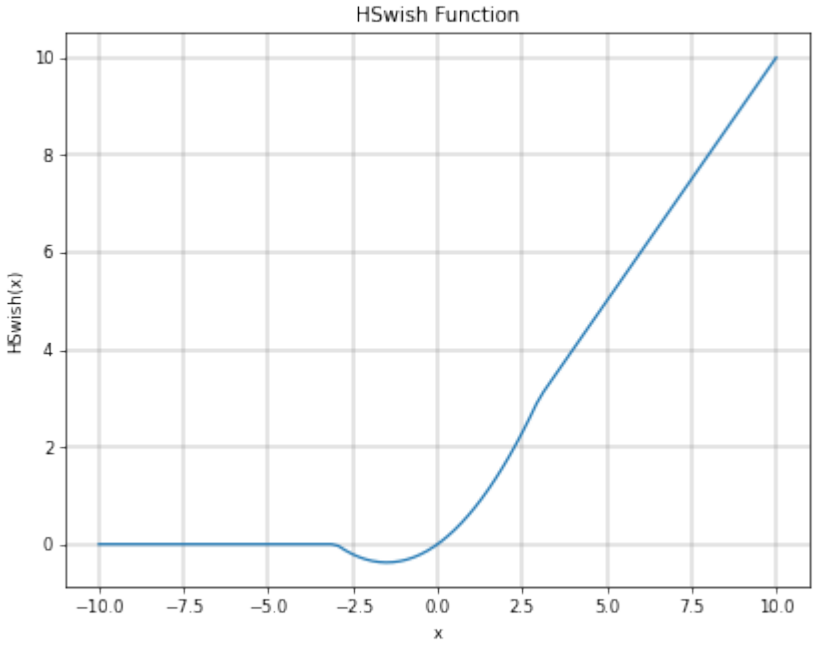
class mindspore.nn.**HSwish**

Applies Hard Swish activation function element-wise.

Hard swish is defined as:

$$\text{HSwish}(input) = \begin{cases} 0, & \text{if } input \leq -3, \\ input, & \text{if } input \geq +3, \\ input * (input + 3)/6, & \text{otherwise} \end{cases}$$

HSwish Activation Function Graph:



Inputs:

- **input** (Tensor) - The input of HSwish.

Outputs:

Tensor, with the same type and shape as the *input*.

Raises

- **TypeError** – If *input* is not a tensor.
- **TypeError** – If *input* is neither int nor float.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> hswish = nn.HSwish()
>>> result = hswish(input)
>>> print(result)
[-0.3333 -0.3333  0.      1.667   0.6665]
```

3.8.11 mindspore.nn.LeakyReLU

class mindspore.nn.**LeakyReLU**(*alpha=0.2*)

Leaky ReLU activation function.

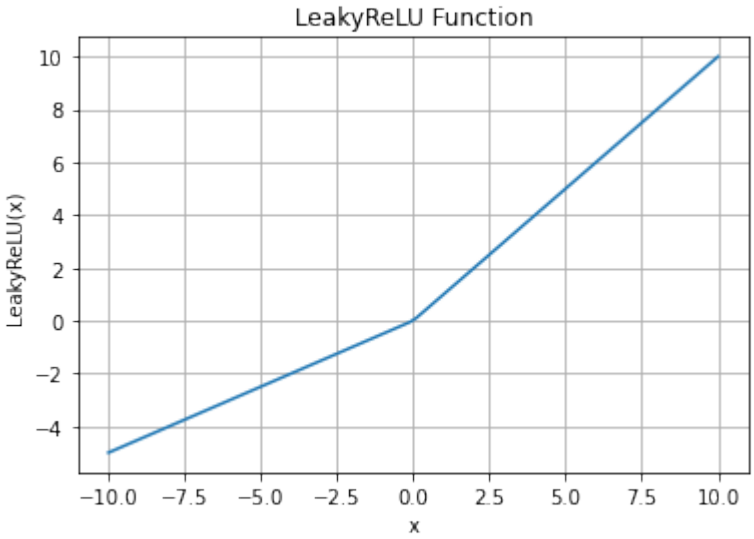
The activation function is defined as:

$$\text{leaky\_relu}(x) = \begin{cases} x, & \text{if } x \geq 0; \\ \alpha * x, & \text{otherwise.} \end{cases}$$

where α represents the *alpha* parameter.

For more details, see Rectifier Nonlinearities Improve Neural Network Acoustic Models.

LeakyReLU Activation Function Graph:



Parameters

alpha (*Union[int, float]*) – Slope of the activation function at x < 0. Default: `0.2` .

Inputs:

- **x** (Tensor) - The input of LeakyReLU is a Tensor of any dimension.

Outputs:

Tensor, has the same type and shape as the *x*.

Raises

TypeError – If *alpha* is not a float or an int.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> leaky_relu = nn.LeakyReLU()
>>> output = leaky_relu(x)
>>> print(output)
[[-0.2  4.  -1.6]
 [ 2.  -1.   9. ]]
```

3.8.12 mindspore.nn.LogSigmoid

class mindspore.nn.**LogSigmoid**

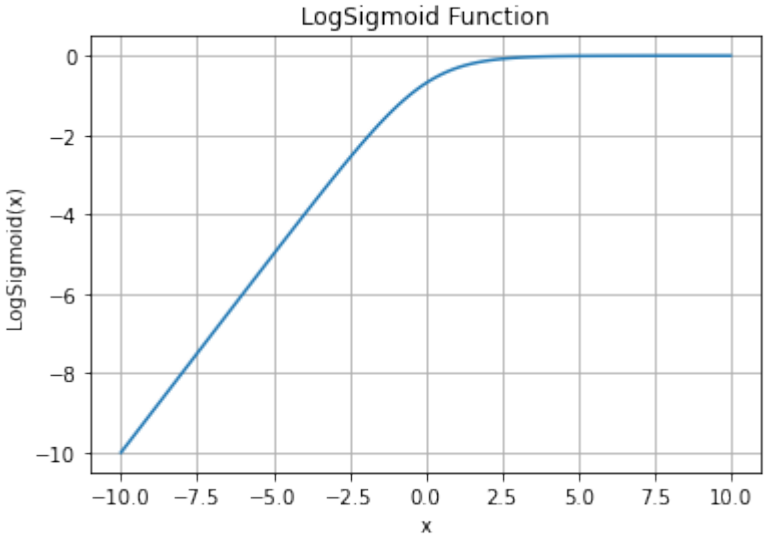
Applies logsigmoid activation element-wise. The input is a Tensor with any valid shape.

Logsigmoid is defined as:

$$\text{logsigmoid}(x_i) = \log(\frac{1}{1 + \exp(-x_i)}),$$

where x_i is the element of the input.

LogSigmoid Activation Function Graph:



Inputs:

- **x** (Tensor) - The input of LogSigmoid with data type of float16 or float32. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.

Outputs:

Tensor, with the same type and shape as the *x*.

Raises

TypeError – If dtype of *x* is neither float16 nor float32.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> net = nn.LogSigmoid()
>>> x = Tensor(np.array([1.0, 2.0, 3.0]), mindspore.float32)
>>> output = net(x)
>>> print(output)
[-0.31326166 -0.12692806 -0.04858734]
```

3.8.13 mindspore.nn.LogSoftmax

class mindspore.nn.**LogSoftmax**(*axis=-1*)

Applies the LogSoftmax function to n-dimensional input tensor element-wise.

The input is transformed by the Softmax function and then by the log function to lie in range[-inf,0).

Logsoftmax is defined as:

$$\text{logsoftmax}(x_i) = \log\left(\frac{\exp(x_i)}{\sum_{j=0}^{n-1}\exp(x_j)}\right)$$

Parameters

axis (*int*) – The axis to apply LogSoftmax operation, -1 means the last dimension. Default: `-1` .

Inputs:

- **x** (Tensor) - The input of LogSoftmax, with float16 or float32 data type.

Outputs:

Tensor, which has the same type and shape as *x* with output values in the range[-inf,0).

Raises

- **TypeError** – If *axis* is not an int.
- **TypeError** – If dtype of *x* is neither float16 nor float32.
- **ValueError** – If *axis* is not in range [-len(x), len(x)).

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> log_softmax = nn.LogSoftmax()
>>> output = log_softmax(x)
>>> print(output)
[[-5.00672150e+00 -6.72150636e-03 -1.20067215e+01]
 [-7.00091219e+00 -1.40009127e+01 -9.12250078e-04]]
```

3.8.14 mindspore.nn.LRN

class mindspore.nn.**LRN**(*depth_radius=5*, *bias=1.0*, *alpha=1.0*, *beta=0.5*, *norm_region='ACROSS_CHANNELS'*)

Local Response Normalization.

> **Warning:** LRN is deprecated on Ascend due to potential accuracy problem. It's recommended to use other normalization methods, e.g. *mindspore.nn.BatchNorm1d* , *mindspore.nn.BatchNorm2d* , *mindspore.nn.BatchNorm3d*.

Refer to *mindspore.ops.lrn()* for more details.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> input_x = Tensor(np.array([[[[0.1], [0.2]],
...                            [[0.3], [0.4]]]]), mindspore.float32)
>>> output = nn.LRN()(input_x)
>>> print(output)
[[[[0.09534626]
   [0.1825742 ]]
  [[0.2860388 ]
   [0.3651484 ]]]]
```

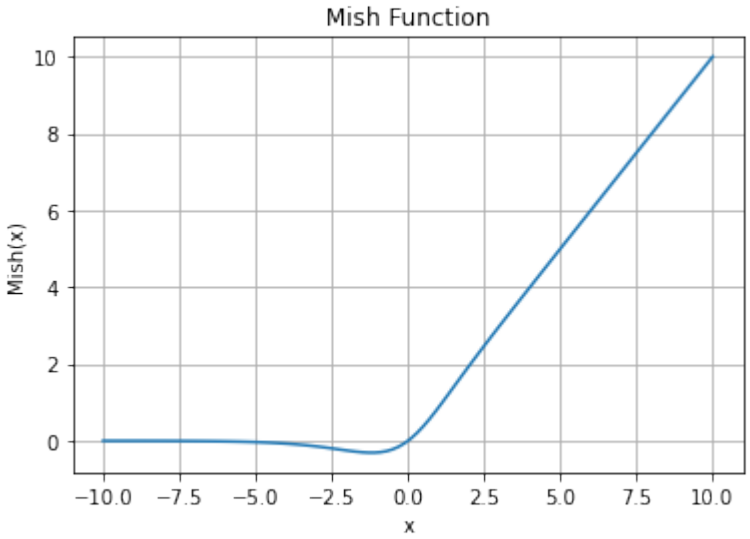
3.8.15 mindspore.nn.Mish

class mindspore.nn.**Mish**

Computes MISH (A Self Regularized Non-Monotonic Neural Activation Function) of input tensors element-wise.

Refer to *mindspore.ops.mish()* for more details.

Mish Activation Function Graph:



Supported Platforms:

Ascend GPU CPU

Examples

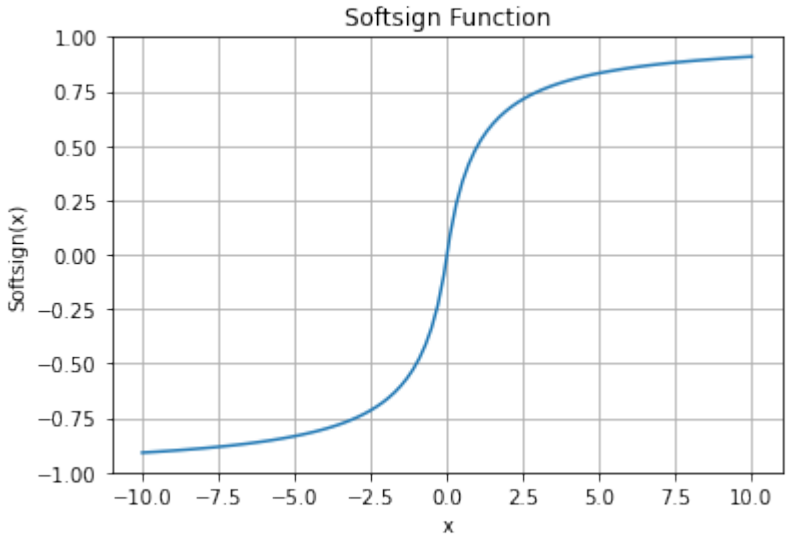
```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> mish = nn.Mish()
>>> output = mish(x)
>>> print(output)
[[-3.03401530e-01 3.99741292e+00 -2.68321624e-03]
 [ 1.94395900e+00 -3.35762873e-02 9.00000000e+00]]
```

3.8.16 mindspore.nn.Softsign

class mindspore.nn.**Softsign**

Applies softsign activation function element-wise.

Softsign Activation Function Graph:



Refer to *mindspore.ops.softsign()* for more details.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([0, -1, 2, 30, -30]), mindspore.float32)
>>> softsign = nn.Softsign()
>>> output = softsign(x)
>>> print(output)
[ 0.        -0.5         0.6666667  0.9677419 -0.9677419]
```

3.8.17 mindspore.nn.PReLU

class mindspore.nn.**PReLU**(*channel=1*, *w=0.25*)

Applies PReLU activation function element-wise.

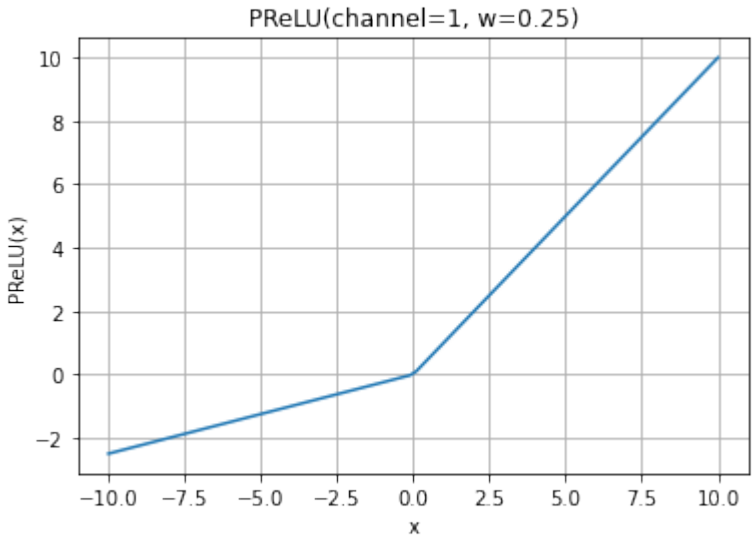
PReLU is defined as:

$$PReLU(x_i) = \max(0, x_i) + w * \min(0, x_i),$$

where x_i is an element of an channel of the input.

Here w is a learnable parameter with a default initial value `0.25`. Parameter w has dimensionality of the argument channel. If called without argument channel, a single parameter w will be shared across all channels.

PReLU Activation Function Graph:



Parameters

- **channel** (*int, optional*) – The elements number of parameter w. It could be an int, and the value is `1` or the channels number of input tensor x. Default: `1` .
- **w** (*Union[float, list, Tensor], optional*) – The initial value of parameter. It could be a float, a float list or a tensor has the same dtype as the input tensor x. Default: `0.25` .

Inputs:

- **x** (Tensor) - The input of PReLU with data type of float16 or float32. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.

Outputs:

Tensor, with the same dtype and shape as the x.

Raises

- **TypeError** – If *channel* is not an int.
- **TypeError** – If w is not one of a float, a list[float], a Tensor[float].
- **TypeError** – If dtype of x is neither float16 nor float32.
- **ValueError** – If the x is a 0-D or 1-D Tensor on Ascend.

- **ValueError** – If *channel* is less than 1.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([[[[0.1, 0.6], [0.9, 0.9]]]]), mindspore.float32)
>>> prelu = nn.PReLU()
>>> output = prelu(x)
>>> print(output)
[[[[0.1 0.6]
   [0.9 0.9]]]]
```

3.8.18 mindspore.nn.ReLU

class mindspore.nn.**ReLU**

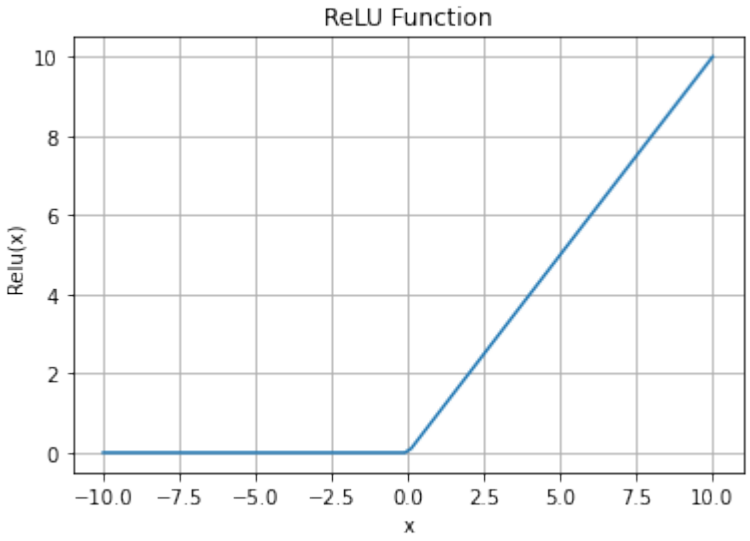
Applies ReLU (Rectified Linear Unit activation function) element-wise.

$$\text{ReLU}(input) = (input)^+ = \max(0, input),$$

It returns element-wise $\max(0, input)$.

Note: The neurons with the negative output will be suppressed and the active neurons will stay the same.

ReLU Activation Function Graph:



Inputs:

- **input** (Tensor) - The input of ReLU is a Tensor of any dimension.

Outputs:

Tensor, with the same type and shape as the *input*.

Raises

TypeError – If dtype of *input* is not supported.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> input = Tensor(np.array([-1, 2, -3, 2, -1]), mindspore.float16)
>>> relu = nn.ReLU()
>>> output = relu(input)
>>> print(output)
[0. 2. 0. 2. 0.]
```

3.8.19 mindspore.nn.ReLU6

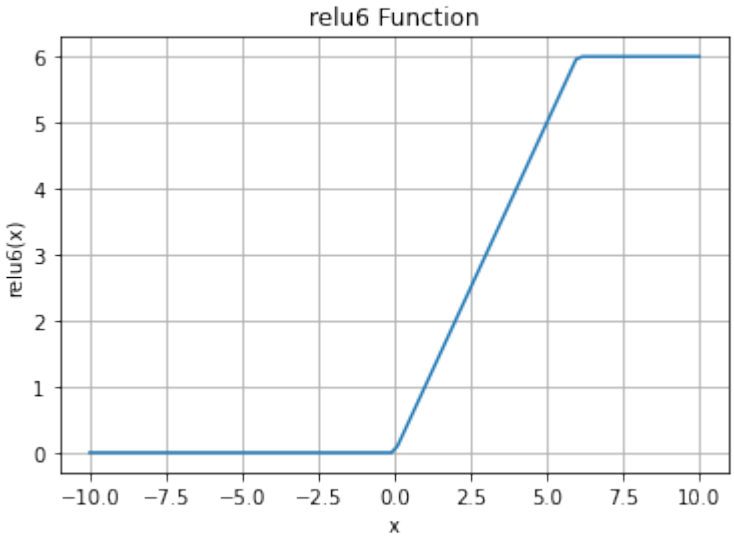
class mindspore.nn.**ReLU6**

Compute ReLU6 activation function element-wise.

ReLU6 is similar to ReLU with a upper limit of 6, which if the inputs are greater than 6, the outputs will be suppressed to 6. It computes element-wise as

$$Y = \min(\max(0, x), 6)$$

ReLU6 Activation Function Graph:



Inputs:

- **x** (Tensor) - The input of ReLU6 with data type of float16 or float32 and that is a Tensor of any valid shape.

Outputs:

Tensor, which has the same type as *x*.

Raises

TypeError –If dtype of *x* is neither float16 nor float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> relu6 = nn.ReLU6()
>>> output = relu6(x)
>>> print(output)
[0. 0. 0. 2. 1.]
```

3.8.20 mindspore.nn.RReLU

class mindspore.nn.**RReLU**(*lower=1 / 8*, *upper=1 / 3*)

Applies RReLU (Randomized Leaky ReLU activation function) element-wise.

The activation function is defined as:

$$\text{RReLU}(x_{ji}) = \begin{cases} x_{ji}, & \text{if } x_{ji} \geq 0; \\ \alpha_{ji} * x_{ji}, & \text{otherwise.} \end{cases}$$

where $\alpha_{ji} \sim U(l, u), l \leq u$.

Applies the RReLU function elementally, as described in the paper: Empirical Evaluation of Rectified Activations in Convolution Network .

Parameters

- **lower** (*Union[int, float]*) –Slope of the activation function at x < 0. Default: `1 / 8` .
- **upper** (*Union[int, float]*) –Slope of the activation function at x < 0. Default: `1 / 3` .

Inputs:

- **x** (Tensor) - The input of RReLU is a Tensor of any dimension.

Outputs:

Tensor, after RReLU, has the same type and shape as the *x*.

Raises

- **TypeError** –If *lower* is not a float or an int.
- **TypeError** –If *upper* is not a float or an int.

- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If *x* is not a Tensor of mindspore.float16 or mindspore.float32.
- **ValueError** – If *lower* is greater than upper.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

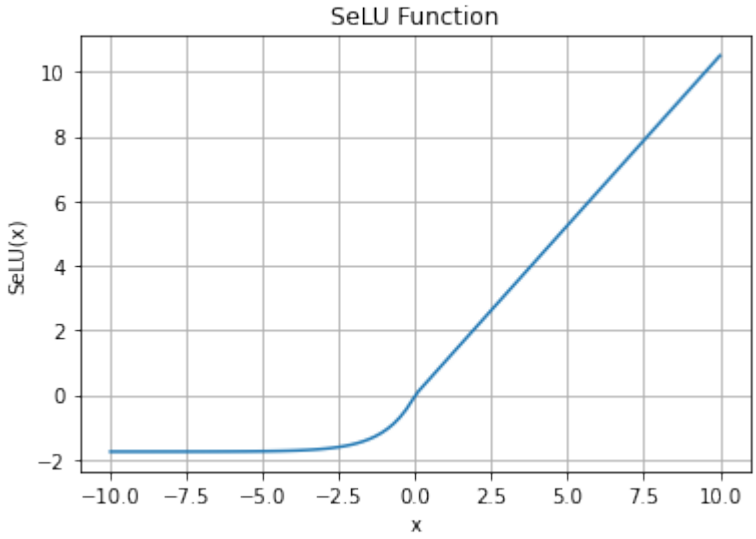
```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([[-1.0, 4.0], [2.0, 0]]), mindspore.float32)
>>> r_relu = nn.RReLU()
>>> output = r_relu(x)
>>> print(output)
[[-0.31465699  4.        ]
 [ 2.          0.        ]]
```

3.8.21 mindspore.nn.SeLU

class mindspore.nn.**SeLU**

Applies activation function SeLU (Scaled exponential Linear Unit) element-wise.

SeLU Activation Function Graph:



Refer to *mindspore.ops.selu()* for more details.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> input_x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> selu = nn.SeLU()
>>> output = selu(input_x)
>>> print(output)
[[-1.1113307 4.202804 -1.7575096]
 [ 2.101402 -1.7462534 9.456309 ]]
```

3.8.22 mindspore.nn.SiLU

class mindspore.nn.**SiLU**

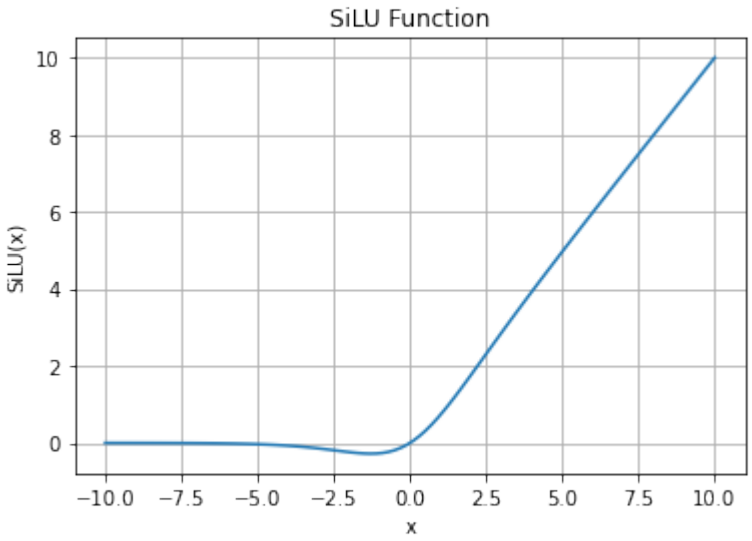
Applies the silu linear unit function element-wise.

$$\text{SiLU}(x) = x * \sigma(x),$$

where x_i is an element of the input, $\sigma(x)$ is Sigmoid function.

$$\text{sigmoid}(x_i) = \frac{1}{1 + \exp(-x_i)},$$

SiLU Activation Function Graph:



Inputs:

- **input** (Tensor) - *input* is x in the preceding formula. Input with the data type float16 or float32. Tensor of any dimension.

Outputs:

Tensor, with the same type and shape as the *input*.

Raises

TypeError – If dtype of *input* is neither float16 nor float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> input = Tensor(np.array([-1, 2, -3, 2, -1]), mindspore.float16)
>>> silu = nn.SiLU()
>>> output = silu(input)
>>> print(output)
[-0.269  1.762  -0.1423  1.762  -0.269]
```

3.8.23 mindspore.nn.Sigmoid

class mindspore.nn.**Sigmoid**

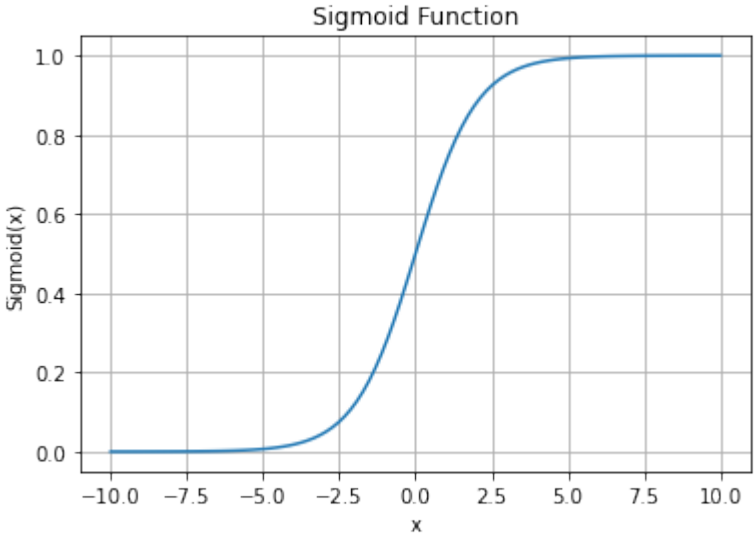
Applies sigmoid activation function element-wise.

Sigmoid function is defined as:

$$\text{sigmoid}(x_i) = \frac{1}{1 + \exp(-x_i)},$$

where x_i is the element of x.

Sigmoid Activation Function Graph:



Inputs:

- **input** (Tensor) - *input* is x in the preceding formula. Tensor of any dimension, the data type is float16, float32, float64, complex64 or complex128.

Outputs:

Tensor, with the same type and shape as the *input*.

Raises

- **TypeError** –If dtype of *input* is not float16, float32, float64, complex64 or complex128.
- **TypeError** –If *input* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> sigmoid = nn.Sigmoid()
>>> output = sigmoid(input)
>>> print(output)
[0.2688  0.11914 0.5     0.881   0.7305 ]
```

3.8.24 mindspore.nn.Softmin

class mindspore.nn.**Softmin**(*axis=-1*)

Softmin activation function, which is a two-category function *mindspore.nn.Sigmoid* in the promotion of multi-classification, and the purpose is to show the results of multi-classification in the form of probability.

Calculate the value of the exponential function for the elements of the input Tensor on the *axis*, and then normalized to lie in range [0, 1] and sum up to 1.

Softmin is defined as:

$$\text{softmin}(x_i) = \frac{\exp(-x_i)}{\sum_{j=0}^{n-1}\exp(-x_j)},$$

where x_i is the i-th slice in the given dimension of the input Tensor.

Parameters

axis (*Union[int, tuple[int]], optional*) –The axis to apply Softmin operation, if the dimension of input x is x.ndim, the range of axis is $[-x.ndim, x.ndim)$. -1 means the last dimension. Default: `-1` . In CPU environment, *axis* only supports int type.

Inputs:

- **x** (Tensor) - Tensor for computing Softmin functions with data type of float16 or float32.

Outputs:

Tensor, which has the same type and shape as x with values in the range $[0, 1]$.

Raises

- **TypeError** –If *axis* is neither an int nor a tuple.
- **TypeError** –If dtype of x is neither float16 nor float32.
- **ValueError** –If *axis* is a tuple whose length is less than 1.
- **ValueError** –If *axis* is a tuple whose elements are not all in the range $[-x.ndim, x.ndim)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> # axis = -1(default), and the sum of return value is 1.0.
>>> x = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> softmin = nn.Softmin()
>>> output = softmin(x)
>>> print(output)
[0.2341  0.636  0.0862  0.01165  0.03168 ]
```

3.8.25 mindspore.nn.Softmax

class mindspore.nn.**Softmax**(*axis=-1*)

Softmax activation function, which is a two-category function *mindspore.nn.Sigmoid* in the promotion of multi-classification, the purpose is to show the results of multi-classification in the form of probability.

Calculate the value of the exponential function for the elements of the input Tensor on the *axis*, and then normalized to lie in range [0, 1] and sum up to 1.

Softmax is defined as:

$$\text{softmax}(input_i) = \frac{\exp(input_i)}{\sum_{j=0}^{n-1}\exp(input_j)},$$

where $input_i$ is the i-th slice in the given dimension of the input Tensor.

Parameters

axis (*int, optional*) – The axis to apply Softmax operation, if the dimension of *input* is input.ndim, the range of axis is *[-input.ndim, input.ndim)*, -1 means the last dimension. Default: `-1` .

Inputs:

- **input** (Tensor) - The input of Softmax.

Outputs:

Tensor, which has the same type and shape as *input* with values in the range[0, 1].

Raises

- **TypeError** – If *axis* is neither an int nor a tuple.
- **ValueError** – If *axis* is a tuple whose length is less than 1.
- **ValueError** – If *axis* is a tuple whose elements are not all in range *[-input.ndim, input.ndim)*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> # axis = -1(default), and the sum of return value is 1.0.
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> softmax = nn.Softmax()
>>> output = softmax(input)
>>> print(output)
[0.03168 0.01166 0.0861  0.636   0.2341 ]
```

3.8.26 mindspore.nn.Softmax2d

class mindspore.nn.**Softmax2d**

Softmax function applied to 2D features data.

Applies *Softmax* to each location with an input Tensor of shape (C, H, W) .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, H_{in}, W_{in})$ or (C_{in}, H_{in}, W_{in}). The input of Softmax with data type of float16 or float32.

Outputs:

Tensor, which has the same type and shape as x with values in the range[0,1].

Raises

- **TypeError** – If dtype of x is neither float16 nor float32.
- **ValueError** – If *data_format* is neither 'NCHW' nor 'CHW'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([[[[0.1, 0.2]], [[0.3, 0.4]], [[0.6, 0.5]]]]), mindspore.float32)
>>> softmax2d = nn.Softmax2d()
>>> output = softmax2d(x)
>>> print(output)
[[[[0.25838965 0.28001308]]
[[0.31559783 0.34200877]]
[[0.42601252 0.37797815]]]]
```

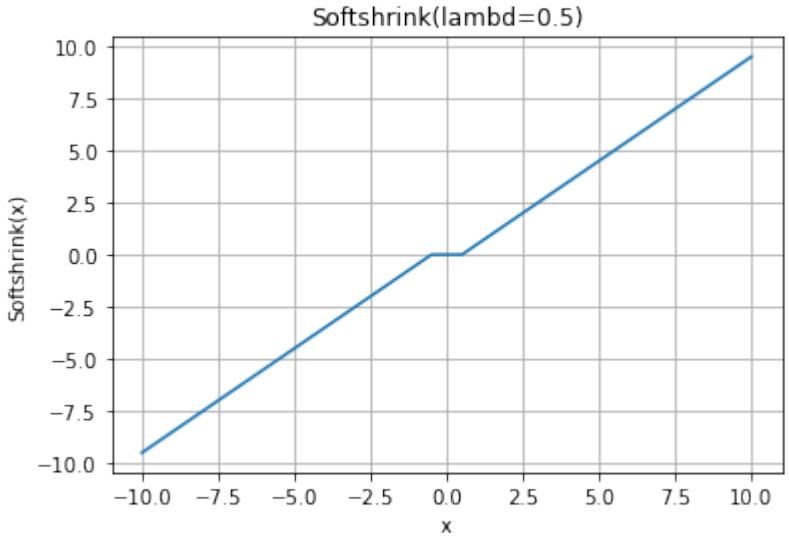
3.8.27 mindspore.nn.SoftShrink

class mindspore.nn.**SoftShrink**(*lambd=0.5*)

Applies the SoftShrink function element-wise.

$$\text{SoftShrink}(x) = \begin{cases} x - \lambda, & \text{if } x > \lambda \\ x + \lambda, & \text{if } x < -\lambda \\ 0, & \text{otherwise} \end{cases}$$

SoftShrink Activation Function Graph:



Parameters

lambd (*number, optional*) – The threshold λ defined by the Soft Shrink formula. It should be greater than or equal to 0, default: 0.5.

Inputs:

- **input** (Tensor) - The input of Soft Shrink. Supported dtypes:
  - Ascend: float16, float32, bfloat16.
  - CPU/GPU: float16, float32.

Outputs:

Tensor, the same shape and data type as the input.

Raises

- **TypeError** – If *lambd* is not a float, int or bool.
- **TypeError** – If *input* is not a tensor.
- **TypeError** – If dtype of *input* is not float16, float32 or bfloat16.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> input = Tensor(np.array([[ 0.5297,  0.7871,  1.1754], [ 0.7836,  0.6218, -1.1542]]),␣
↪mindspore.float16)
>>> softshrink = nn.SoftShrink()
>>> output = softshrink(input)
>>> print(output)
[[ 0.02979  0.287    0.676  ]
 [ 0.2837   0.1216  -0.6543 ]]
```

3.8.28 mindspore.nn.Tanh

class mindspore.nn.**Tanh**

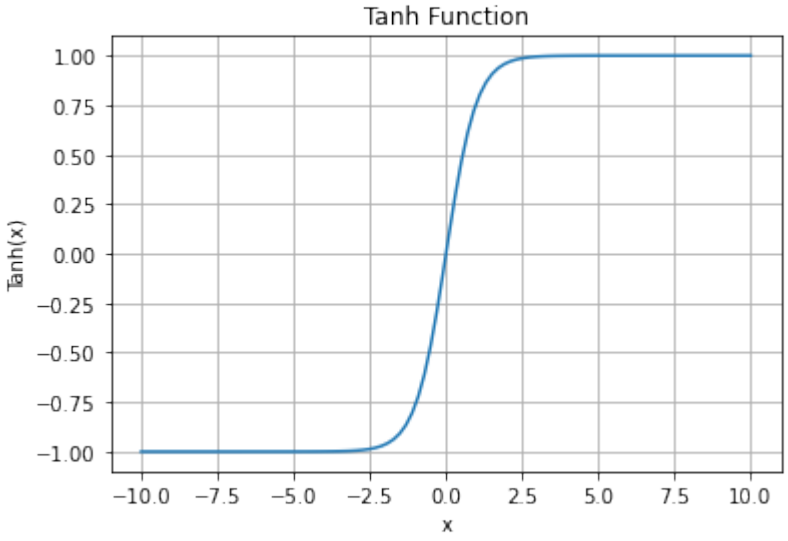
Applies the Tanh function element-wise, returns a new tensor with the hyperbolic tangent of the elements of input, The input is a Tensor with any valid shape.

Tanh function is defined as:

$$tanh(x_i) = \frac{\exp(x_i) - \exp(-x_i)}{\exp(x_i) + \exp(-x_i)} = \frac{\exp(2x_i) - 1}{\exp(2x_i) + 1},$$

where x_i is an element of the input Tensor.

Tanh Activation Function Graph:



Inputs:

- **x** (Tensor) - Tensor of any dimension, input with data type of float16 or float32.

Outputs:

Tensor, with the same type and shape as the *x*.

Raises

TypeError – If dtype of *x* is neither float16 nor float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([1, 2, 3, 2, 1]), mindspore.float16)
>>> tanh = nn.Tanh()
>>> output = tanh(x)
>>> print(output)
[0.7617 0.964  0.995  0.964  0.7617]
```

3.8.29 mindspore.nn.Tanhshrink

class mindspore.nn.**Tanhshrink**

Applies Tanhshrink activation function element-wise and returns a new tensor.

Tanh function is defined as:

$$tanhshrink(x_i) = x_i - \frac{\exp(x_i) - \exp(-x_i)}{\exp(x_i) + \exp(-x_i)} = x_i - \frac{\exp(2x_i) - 1}{\exp(2x_i) + 1},$$

where x_i is an element of the input Tensor.

Inputs:

- **x** (Tensor) - Tensor of any dimension.

Outputs:

Tensor, with the same shape as the x.

Raises

TypeError – If x is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([1, 2, 3, 2, 1]), ms.float16)
>>> tanhshrink = nn.Tanhshrink()
>>> output = tanhshrink(x)
>>> print(output)
[0.2383 1.036  2.004  1.036  0.2383]
```

3.8.30 mindspore.nn.Threshold

class mindspore.nn.**Threshold**(*threshold*, *value*)

Thresholds each element of the input Tensor.

The formula is defined as follows:

$$y = \begin{cases} x, & \text{if } x > \text{threshold} \\ \text{value}, & \text{otherwise} \end{cases}$$

Parameters

- **threshold** (*Union[int, float]*) – The value to threshold at.
- **value** (*Union[int, float]*) – The value to replace with when element is less than threshold.

Inputs:

- **input_x** (Tensor) - The input of Threshold with data type of float16 or float32.

Outputs:

Tensor, the same shape and data type as the *input_x*.

Raises

- **TypeError** – If *threshold* is not a float or an int.
- **TypeError** – If *value* is not a float or an int.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> m = nn.Threshold(0.1, 20)
>>> inputs = Tensor([0.1, 0.2, 0.3], mindspore.float32)
>>> outputs = m(inputs)
>>> print(outputs)
[ 20.0     0.2      0.3]
```

3.9 Linear Layer

API Name	Description	Supported Platforms
mindspore.nn.Dense	The dense connected layer.	`Ascend GPU CPU`
mindspore.nn.BiDense	The bilinear dense connected layer.	`Ascend GPU CPU`

3.9.1 mindspore.nn.Dense

class mindspore.nn.**Dense**(*in_channels*, *out_channels*, *weight_init=None*, *bias_init=None*, *has_bias=True*, *activation=None*, *dtype=mstype.float32*)

The dense connected layer.

Applies dense connected layer for the input. This layer implements the operation as:

$$\text{outputs} = \text{activation}(X * \text{kernel} + \text{bias}),$$

where X is the input tensors, activation is the activation function passed as the activation argument (if passed in), kernel is a weight matrix with the same data type as the X created by the layer, and bias is a bias vector with the same data type as the X created by the layer (only if *has_bias* is `True`).

Warning: On the Ascend platform, if *bias* is `False` , the *x* cannot be greater than 6D in PYNATIVE or KBK mode.

Parameters

- **in_channels** (*int*) –The number of channels in the input space.
- **out_channels** (*int*) –The number of channels in the output space.
- **weight_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –The trainable weight_init parameter. The dtype is same as *x*. The values of str refer to the function *initializer*. Default: `None` , weight will be initialized using HeUniform.
- **bias_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –The trainable bias_init parameter. The dtype is same as *x*. The values of str refer to the function *initializer*. Default: `None` , bias will be initialized using Uniform.
- **has_bias** (*bool, optional*) –Specifies whether the layer uses a bias vector bias. Default: `True`.
- **activation** (*Union[str, Cell, Primitive, None], optional*) –activate function applied to the output of the fully connected layer. Both activation name, e.g. 'relu', and mindspore activation function, e.g. mindspore.ops.ReLU(), are supported. Default: `None` .
- **dtype** (*mindspore.dtype*, optional) –Data type of Parameter. Default: `mstype.float32` . When *weight_init* is Tensor, Parameter has the same data type as *weight_init* , in other cases, Parameter has the same data type as *dtype*, the same goes for *bias_init*.

Inputs:

- **x** (Tensor) - Tensor of shape $(*, in\_channels)$. The *in_channels* in *Args* should be equal to $in\_channels$ in *Inputs*.

Outputs:

Tensor of shape $(*, out\_channels)$.

Raises

- **TypeError** –If *in_channels* or *out_channels* is not an int.
- **TypeError** –If *has_bias* is not a bool.
- **TypeError** –If *activation* is not one of str, Cell, Primitive, None.
- **ValueError** –If length of shape of *weight_init* is not equal to 2 or shape[0] of *weight_init* is not equal to *out_channels* or shape[1] of *weight_init* is not equal to *in_channels*.
- **ValueError** –If length of shape of *bias_init* is not equal to 1 or shape[0] of *bias_init* is not equal to *out_channels*.

- **RuntimeError** –On the Ascend platform, if *bias* is `False` and *x* is greater than 6D in PYNATIVE or KBK mode.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([[180, 234, 154], [244, 48, 247]]), mindspore.float32)
>>> net = nn.Dense(3, 4)
>>> output = net(x)
>>> print(output.shape)
(2, 4)
```

3.9.2 mindspore.nn.BiDense

class mindspore.nn.**BiDense**(*in1_channels*, *in2_channels*, *out_channels*, *weight_init=None*, *bias_init=None*, *has_bias=True*, *dtype=mstype.float32*)

The bilinear dense connected layer.

Applies dense connected layer for two inputs. This layer implements the operation as:

$$y = x_1^T A x_2 + b,$$

where x_1 is the first input tensor, x_2 is the second input tensor , A is a weight matrix with the same data type as the x_* created by the layer , and b is a bias vector with the same data type as the x_* created by the layer (only if has_bias is `True`).

Parameters

- **in1_channels** (*int*) –The number of channels in the input1 space.
- **in2_channels** (*int*) –The number of channels in the input2 space.
- **out_channels** (*int*) –The number of channels in the output space.
- **weight_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –The trainable weight_init parameter. The values of str refer to the function *initializer*. Default: `None` .
- **bias_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –The trainable bias_init parameter. The values of str refer to the function *initializer*. Default: `None` .
- **has_bias** (*bool*) –Specifies whether the layer uses bias vector. Default: `True` .
- **dtype** (*mindspore.dtype*) –Dtype of Parameters. Default: `mstype.float32` .

Shape:

- **input1** - $(*, H_{in1})$ where H_{in1} = in1_channels and $*$ means any number of additional dimensions including none. All but the last dimension of the inputs should be the same.
- **input2** - $(*, H_{in2})$ where H_{in2} = in2_channels and $*$ means any number of additional dimensions including none. All but the last dimension of the inputs should be the same.
- **output** - $(*, H_{out})$ where H_{out} = out_channels and $*$ means any number of additional dimensions including none. All but the last dimension are the same shape as the inputs.

Dtype:

- **input1** (Tensor) - The dtype must be float16 or float32 and be same as **input2** .
- **input2** (Tensor) - The dtype must be float16 or float32 and be same as **input1** .
- **output** (Tensor) - With the same dtype as the inputs.

Weights:

- **weight** (Parameter) - The learnable weights with shape (out_channels, in1_channels, in2_channels). When *weight_init* is `None` , the values are initialized from $\mathcal{U}(-\sqrt{k}, \sqrt{k})$, where $k = \frac{1}{\text{in1\_channels}}$.
- **bias** (Parameter) - The learnable bias of shape (out_channels). If *has_bias* is `True` and *bias_init* is `None` , the values are initialized from $\mathcal{U}(-\sqrt{k}, \sqrt{k})$, where $k = \frac{1}{\text{in1\_channels}}$.

Raises

- **`TypeError`** –If *in1_channels*, *in2_channels* or *out_channels* is not an int.
- **`TypeError`** –If *has_bias* is not a bool.
- **`ValueError`** –If length of shape of *weight_init* is not equal to 3 or shape[0] of *weight_init* is not equal to *out_channels* or shape[1] of *weight_init* is not equal to *in1_channels* or shape[2] of *weight_init* is not equal to *in2_channels*.
- **`ValueError`** –If length of shape of *bias_init* is not equal to 1 or shape[0] of *bias_init* is not equal to *out_channels*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x1 = Tensor(np.random.randn(128, 20), mindspore.float32)
>>> x2 = Tensor(np.random.randn(128, 30), mindspore.float32)
>>> net = nn.BiDense(20, 30, 40)
>>> output = net(x1, x2)
>>> print(output.shape)
(128, 40)
```

3.10 Dropout Layer

API Name	Description	Supported Platforms
mindspore.nn.Dropout	Dropout layer for the input.	`Ascend` `GPU` `CPU`
mindspore.nn.Dropout1d	During training, randomly zeroes entire channels of the input tensor with probability p from a Bernoulli distribution (For a 3-dimensional tensor with a shape of (N, C, L), the channel feature map refers to a 1-dimensional feature map with the shape of L).	`Ascend` `GPU` `CPU`

continues on next page

Table 10 – continued from previous page

mindspore.nn.Dropout2d	During training, randomly zeroes some channels of the input tensor with probability *p* from a Bernoulli distribution (For a 4-dimensional tensor with a shape of $NCHW$, the channel feature map refers to a 2-dimensional feature map with the shape of HW).	Ascend GPU CPU
mindspore.nn.Dropout3d	During training, randomly zeroes some channels of the input tensor with probability *p* from a Bernoulli distribution (For a 5-dimensional tensor with a shape of $NCDHW$, the channel feature map refers to a 3-dimensional feature map with a shape of DHW).	Ascend GPU CPU

3.10.1 mindspore.nn.Dropout

class mindspore.nn.**Dropout**(*keep_prob=0.5*, *p=None*, *dtype=mstype.float32*)

Dropout layer for the input.

Dropout is a means of regularization that reduces overfitting by preventing correlations between neuronal nodes. The operator randomly sets some neurons output to 0 according to *p*, which means the probability of discarding during training. And the return will be multiplied by $\frac{1}{1-p}$ during training. During the reasoning, this layer returns the same Tensor as the *x*.

This technique is proposed in paper Dropout: A Simple Way to Prevent Neural Networks from Overfitting and proved to be effective to reduce over-fitting and prevents neurons from co-adaptation. See more details in Improving neural networks by preventing co-adaptation of feature detectors.

Note:

- Each channel will be zeroed out independently on every construct call.
- Parameter *keep_prob* will be removed in a future version, please use parameter *p* instead. Parameter *p* means the probability of the element of the input tensor to be zeroed.
- Parameter *dtype* will be removed in a future version. It is not recommended to define this parameter.

Parameters

- **keep_prob** (*float*) –Deprecated. The keep rate, greater than 0 and less equal than 1. E.g. rate=0.9, dropping out 10% of input neurons. Default: `0.5`.
- **p** (*Union[float, int, None]*) –The dropout rate, greater than or equal to 0 and less than 1. E.g. rate=0.9, dropping out 90% of input neurons. Default: `None`.
- **dtype** (*mindspore.dtype*) –Data type of *input*. Default: `mstype.float32`.

Inputs:

- **x** (Tensor) - The input of Dropout with data type of float16 or float32. The shape of *x* cannot be less than 1.

Outputs:

Tensor, output tensor with the same shape as the *x*.

Raises

- **TypeError** –If *keep_prob* is not a float.

- **TypeError** – If the dtype of *p* is not float or int.
- **TypeError** – If dtype of *x* is not neither float16 nor float32.
- **ValueError** – If *keep_prob* is not in range (0, 1].
- **ValueError** – If *p* is not in range [0, 1).
- **ValueError** – If length of shape of *x* is less than 1.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.ones([2, 2, 3]), mindspore.float32)
>>> net = nn.Dropout(p=0.2)
>>> net.set_train()
>>> output = net(x)
>>> print(output.shape)
(2, 2, 3)
```

3.10.2 mindspore.nn.Dropout1d

class mindspore.nn.**Dropout1d**(*p=0.5*)

During training, randomly zeroes entire channels of the input tensor with probability *p* from a Bernoulli distribution (For a 3-dimensional tensor with a shape of (N, C, L), the channel feature map refers to a 1-dimensional feature map with the shape of L).

For example, the *j_th* channel of the *i_th* sample in the batched input is a to-be-processed *1D* tensor input[i,j]. Each channel will be zeroed out independently on every forward call with probability *p* using samples from a Bernoulli distribution.

The paper Dropout: A Simple Way to Prevent Neural Networks from Overfitting mentioned this technology, And it is proved that it can effectively reduce over fitting and prevent neuronal coadaptation. For more details, refer to Improving neural networks by preventing co-adaptation of feature detectors .

Dropout1d can improve the independence between channel feature maps.

Parameters

p (*float, optional*) – The dropping probability of a channel, between 0 and 1, e.g. $p = 0.8$, which means an 80% chance of being set to 0. Default: `0.5` .

Inputs:

- **x** (Tensor) - A tensor with shape (N, C, L) or (C, L), where N is the batch size, C is the number of channels, L is the feature length. The data type must be int8, int16, int32, int64, float16, float32 or float64.

Outputs:

Tensor, has the same shape and data type as *x*.

Raises

- **TypeError** – If *x* is not a Tensor.

- **TypeError** – If the data type of *p* is not float.
- **ValueError** – If *p* is out of the range *[0.0, 1.0]*.
- **ValueError** – If the shape of *x* is not *2D* or *3D*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> op = ms.nn.Dropout1d(p=0.6)
>>> op.training = True
>>> a = ms.Tensor(np.ones((3, 3)), ms.float32)
>>> output = op(a)
```

3.10.3 mindspore.nn.Dropout2d

class mindspore.nn.**Dropout2d**(*p=0.5*)

During training, randomly zeroes some channels of the input tensor with probability *p* from a Bernoulli distribution (For a 4-dimensional tensor with a shape of *NCHW*, the channel feature map refers to a 2-dimensional feature map with the shape of *HW*).

For example, the *j_th* channel of the *i_th* sample in the batched input is a to-be-processed *2D* tensor input[i,j]. At each forward propagation, each channel will be independently determined to be set to zero with probability *p*.

Dropout2d can improve the independence between channel feature maps.

Refer to *mindspore.ops.dropout2d()* for more details.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> dropout = nn.Dropout2d(p=0.5)
>>> x = Tensor(np.ones([2, 1, 2, 3]), mindspore.float32)
>>> output = dropout(x)
>>> print(output.shape)
(2, 1, 2, 3)
```

3.10.4 mindspore.nn.Dropout3d

class mindspore.nn.**Dropout3d**(*p=0.5*)

During training, randomly zeroes some channels of the input tensor with probability *p* from a Bernoulli distribution (For a 5-dimensional tensor with a shape of $NCDHW$, the channel feature map refers to a 3-dimensional feature map with a shape of DHW).

For example, the j_th channel of the i_th sample in the batched input is a to-be-processed *3D* tensor input[i,j]. Each channel will be zeroed out independently on every forward call which based on Bernoulli distribution probability *p*.

Dropout3d can improve the independence between channel feature maps.

Refer to *mindspore.ops.dropout3d()* for more details.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> dropout = nn.Dropout3d(p=0.5)
>>> x = Tensor(np.ones([2, 1, 2, 1, 2]), mindspore.float32)
>>> output = dropout(x)
>>> print(output.shape)
(2, 1, 2, 1, 2)
```

3.11 Normalization Layer

API Name	Description	Supported Platforms
mindspore.nn.BatchNorm1d	This layer applies Batch Normalization over a 2D or 3D input (a mini-batch of 1D or 2D inputs) to reduce internal covariate shift.	`Ascend` `GPU` `CPU`
mindspore.nn.BatchNorm2d	Batch Normalization is widely used in convolutional networks.	`Ascend` `GPU` `CPU`
mindspore.nn.BatchNorm3d	Batch Normalization is widely used in convolutional networks.	`Ascend` `GPU` `CPU`
mindspore.nn.GroupNorm	Group Normalization over a mini-batch of inputs.	`Ascend` `GPU` `CPU`
mindspore.nn.InstanceNorm1d	This layer applies Instance Normalization over a 3D input (a mini-batch of 1D inputs with additional channel dimension).	`GPU`
mindspore.nn.InstanceNorm2d	This layer applies Instance Normalization over a 4D input (a mini-batch of 2D inputs with additional channel dimension).	`GPU`
mindspore.nn.InstanceNorm3d	This layer applies Instance Normalization over a 5D input (a mini-batch of 3D inputs with additional channel dimension).	`GPU`
mindspore.nn.LayerNorm	Applies Layer Normalization over a mini-batch of inputs.	`Ascend` `GPU` `CPU`

Table 11 – continued from previous page

mindspore.nn.SyncBatchNorm	Sync Batch Normalization layer over a N-dimension input. Ascend

3.11.1 mindspore.nn.BatchNorm1d

class mindspore.nn.**BatchNorm1d**(*num_features*, *eps=1e-5*, *momentum=0.9*, *affine=True*, *gamma_init='ones'*, *beta_init='zeros'*, *moving_mean_init='zeros'*, *moving_var_init='ones'*, *use_batch_statistics=None*, *data_format='NCHW'*, *dtype=mstype.float32*)

This layer applies Batch Normalization over a 2D or 3D input (a mini-batch of 1D or 2D inputs) to reduce internal covariate shift. Batch Normalization is widely used in convolutional networks. For the setailed contents, refer to Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift. It rescales and recenters the feature using a mini-batch of data and the learned parameters which can be described in the following formula.

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

Note: The implementation of BatchNorm is different in graph mode and pynative mode, therefore the mode is not recommended to be changed after net was initialized.

Parameters

- **num_features** (*int*) –number of features or channels C of the input x .
- **eps** (*float*) –ϵ added to the denominator for numerical stability. Default: `1e-5` .
- **momentum** (*float*) –A floating hyperparameter of the momentum for the running_mean and running_var computation. Default: `0.9` .
- **affine** (*bool*) –A bool value. When set to `True` , γ and β can be learned. Default: `True` .
- **gamma_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –Initializer for the γ weight. The values of str refer to the function mindspore.common.initializer including `'zeros'` , `'ones'` , etc. Default: `'ones'` .
- **beta_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –Initializer for the β weight. The values of str refer to the function mindspore.common.initializer including `'zeros'` , `'ones'`, etc. Default: `'zeros'` .
- **moving_mean_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –Initializer for the moving mean. The values of str refer to the function mindspore.common.initializer including `'zeros'` , `'ones'` , etc. Default: `'zeros'` .
- **moving_var_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –Initializer for the moving variance. The values of str refer to the function mindspore.common.initializer including `'zeros'` , `'ones'` , etc. Default: `'ones'` .
- **use_batch_statistics** (*bool*) –If `true` , use the mean value and variance value of current batch data. If `false` , use the mean value and variance value of specified value. If `None` , the training process will use the mean and variance of current batch data and track the running mean and variance, the evaluation process will use the running mean and variance. Default: `None` .
- **data_format** (*str*) –The optional value for data format, is `'NHWC'` or `'NCHW'` . Default: `'NCHW'` .
- **dtype** (*mindspore.dtype*) –Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape (N, C) or (N, C, L) , where N is the batch size, C is the number of features or channels, and L is the sequence length. Supported types: float16, float32.

Outputs:

Tensor, the normalized, scaled, offset tensor, of shape (N, C) or (N, C, L) .

Raises

- **TypeError** – If *num_features* is not an int.
- **TypeError** – If *eps* is not a float.
- **ValueError** – If *num_features* is less than 1.
- **ValueError** – If *momentum* is not in range [0, 1].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> net = ms.nn.BatchNorm1d(num_features=4)
>>> x = ms.Tensor(np.array([[0.7, 0.5, 0.5, 0.6],
...                         [0.5, 0.4, 0.6, 0.9]]).astype(np.float32))
>>> output = net(x)
>>> print(output)
[[ 0.6999965   0.4999975  0.4999975  0.59999704 ]
 [ 0.4999975   0.399998   0.59999704 0.89999545 ]]
```

3.11.2 mindspore.nn.BatchNorm2d

class mindspore.nn.**BatchNorm2d**(*num_features*, *eps=1e-5*, *momentum=0.9*, *affine=True*, *gamma_init='ones'*, *beta_init='zeros'*, *moving_mean_init='zeros'*, *moving_var_init='ones'*, *use_batch_statistics=None*, *data_format='NCHW'*, *dtype=mstype.float32*)

Batch Normalization is widely used in convolutional networks. This layer applies Batch Normalization over a 4D input (a mini-batch of 2D inputs with additional channel dimension) to avoid internal covariate shift as described in the paper Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift. It rescales and recenters the feature using a mini-batch of data and the learned parameters which can be described in the following formula.

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

Note: The implementation of BatchNorm is different in graph mode and pynative mode, therefore that mode can not be changed after net was initialized. Note that the formula for updating the *moving_mean* and *moving_var* is

$$\text{moving\_mean} = \text{moving\_mean} * \text{momentum} + * (1 - \text{momentum})$$

$$\text{moving\_var} = \text{moving\_var} * \text{momentum} + {}^{2} * (1 - \text{momentum})$$

where *moving_mean* is the updated mean, *moving_var* is the updated variance, , ^{2} are the observed value (mean and variance respectively) of each batch of data.

Parameters

- **num_features** (*int*) –The number of channels of the input tensor. Expected input size is (N, C, H, W), C represents the number of channels.
- **eps** (*float, optional*) –ϵ added to the denominator for numerical stability. Default: `1e-5` .
- **momentum** (*float, optional*) –A floating hyperparameter of the momentum for the running_mean and running_var computation. Default: `0.9` .
- **affine** (*bool, optional*) –A bool value. When set to `True` , γ and β can be learned. Default: `True` .
- **gamma_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –Initializer for the γ weight. The values of str refer to the function mindspore.common.initializer including `'zeros'` , `'ones'` , etc. Default: `'ones'` .
- **beta_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –Initializer for the β weight. The values of str refer to the function mindspore.common.initializer including `'zeros'` , `'ones'` , etc. Default: `'zeros'` .
- **moving_mean_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –Initializer for the moving mean. The values of str refer to the function mindspore.common.initializer including `'zeros'` , `'ones'` , etc. Default: `'zeros'` .
- **moving_var_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –Initializer for the moving variance. The values of str refer to the function mindspore.common.initializer including `'zeros'` , `'ones'` , etc. Default: `'ones'` .
- **use_batch_statistics** (*bool, optional*) –Default: `None` .
  - If `true` , use the mean value and variance value of current batch data and track running mean and running variance.
  - If `false` , use the mean value and variance value of specified value, and not track statistical value.
  - If `None` , the use_batch_statistics is automatically set to `true` or `false` according to the training and evaluation mode. During training, the parameter is set to true, and during evaluation, the parameter is set to false.
- **data_format** (*str, optional*) –The optional value for data format, is `'NHWC'` or `'NCHW'` . Default: `'NCHW'` .
- **dtype** (*mindspore.dtype*, optional) –Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape (N, C, H, W). Supported types: float16, float32.

Outputs:

Tensor, the normalized, scaled, offset tensor, of shape (N, C, H, W).

Raises

- **TypeError** –If *num_features* is not an int.
- **TypeError** –If *eps* is not a float.
- **ValueError** –If *num_features* is less than 1.
- **ValueError** –If *momentum* is not in range [0, 1].
- **ValueError** –If *data_format* is neither `'NHWC'` not `'NCHW'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> net = ms.nn.BatchNorm2d(num_features=3)
>>> x = ms.Tensor(np.ones([1, 3, 2, 2]).astype(np.float32))
>>> output = net(x)
>>> print(output)
[[[[ 0.999995 0.999995 ]
   [ 0.999995 0.999995 ]]
  [[ 0.999995 0.999995 ]
   [ 0.999995 0.999995 ]]
  [[ 0.999995 0.999995 ]
   [ 0.999995 0.999995 ]]]]
```

3.11.3 mindspore.nn.BatchNorm3d

class mindspore.nn.**BatchNorm3d**(*num_features*, *eps=1e-5*, *momentum=0.9*, *affine=True*, *gamma_init='ones'*, *beta_init='zeros'*, *moving_mean_init='zeros'*, *moving_var_init='ones'*, *use_batch_statistics=None*, *dtype=mstype.float32*)

Batch Normalization is widely used in convolutional networks. This layer applies Batch Normalization over a 5D input (a mini-batch of 3D inputs with additional channel dimension) to avoid internal covariate shift.

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

Note: The implementation of BatchNorm is different in graph mode and pynative mode, therefore that mode can not be changed after net was initialized. Note that the formula for updating the running_mean and running_var is $\hat{x}_{\text{new}} = (1 - \text{momentum}) \times x_t + \text{momentum} \times \hat{x}$, where $\hat{x}$ is the estimated statistic and x_t is the new observed value.

Parameters

- **num_features** (*int*) – C from an expected input of size (N, C, D, H, W) .
- **eps** (*float*) – A value added to the denominator for numerical stability. Default: `1e-5` .
- **momentum** (*float*) – A floating hyperparameter of the momentum for the running_mean and running_var computation. Default: `0.9` .
- **affine** (*bool*) – A bool value. When set to `True` , gamma and beta can be learned. Default: `True` .
- **gamma_init** (*Union[Tensor, str, Initializer, numbers.Number]*) – Initializer for the gamma weight. The values of str refer to the function mindspore.common.initializer including `'zeros'` , `'ones'` , etc. Default: `'ones'` .
- **beta_init** (*Union[Tensor, str, Initializer, numbers.Number]*) – Initializer for the beta weight. The values of str refer to the function mindspore.common.initializer including `'zeros'` , `'ones'` , etc. Default: `'zeros'` .
- **moving_mean_init** (*Union[Tensor, str, Initializer, numbers.Number]*) – Initializer for the moving mean. The values of str refer to the function mindspore.common.initializer including `'zeros'` , `'ones'` , etc. Default: `'zeros'` .
- **moving_var_init** (*Union[Tensor, str, Initializer, numbers.Number]*) – Initializer for the moving variance. The values of str refer to the function mindspore.common.initializer including `'zeros'` , `'ones'` , etc. Default: `'ones'` .

- **use_batch_statistics** (*bool*) –If true, use the mean value and variance value of current batch data. If `false`, use the mean value and variance value of specified value. If `None` , the training process will use the mean and variance of current batch data and track the running mean and variance, the evaluation process will use the running mean and variance. Default: `None` .
- **dtype** (*mindspore.dtype*) –Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$. Supported types: float16, float32.

Outputs:

Tensor, the normalized, scaled, offset tensor, of shape $(N, C_{out}, D_{out}, H_{out}, W_{out})$.

Raises

- **TypeError** –If *num_features* is not an int.
- **TypeError** –If *eps* is not a float.
- **ValueError** –If *num_features* is less than 1.
- **ValueError** –If *momentum* is not in range [0, 1].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> net = ms.nn.BatchNorm3d(num_features=3)
>>> x = ms.Tensor(np.ones([16, 3, 10, 32, 32]).astype(np.float32))
>>> output = net(x)
>>> print(output.shape)
(16, 3, 10, 32, 32)
```

3.11.4 mindspore.nn.GroupNorm

class mindspore.nn.**GroupNorm**(*num_groups*, *num_channels*, *eps=1e-05*, *affine=True*, *gamma_init='ones'*, *beta_init='zeros'*, *dtype=mstype.float32*)

Group Normalization over a mini-batch of inputs.

Group Normalization is widely used in recurrent neural networks. It applies normalization on a mini-batch of inputs for each single training case as described in the paper Group Normalization. Group Normalization divides the channels into groups and computes within each group the mean and variance for normalization. γ and β are scale and shift values obtained by training learning. It can be described using the following formula:

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

Parameters

- **num_groups** (*int*) –The number of groups to be divided along the channel dimension.
- **num_channels** (*int*) –The number of input channels.

- **eps** (*float*) –A value added to the denominator for numerical stability. Default: `1e-05` .
- **affine** (*bool*) –A bool value, this layer will have learnable affine parameters when set to `true` . Default: `True` .
- **gamma_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –Initializer for the gamma weight. The values of str refer to the function *initializer* including `'zeros'` , `'ones'` , `'xavier_uniform'` , `'he_uniform'` , etc. Default: `'ones'` . If gamma_init is a Tensor, the shape must be (*num_channels*).
- **beta_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –Initializer for the beta weight. The values of str refer to the function *initializer* including `'zeros'` , `'ones'` , `'xavier_uniform'` , `'he_uniform'` , etc. Default: `'zeros'` . If beta_init is a Tensor, the shape must be (*num_channels*).
- **dtype** (*mindspore.dtype*) –Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - The input feature with shape $(N, C, *)$, where $*$ means, any number of additional dimensions.

Outputs:

Tensor, the normalized and scaled offset tensor, has the same shape and data type as the *x*.

Raises

- **TypeError** –If *num_groups* or *num_channels* is not an int.
- **TypeError** –If *eps* is not a float.
- **TypeError** –If *affine* is not a bool.
- **ValueError** –If *num_groups* or *num_channels* is less than 1.
- **ValueError** –If *num_channels* is not divided by *num_groups*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> group_norm_op = ms.nn.GroupNorm(2, 2)
>>> x = ms.Tensor(np.ones([1, 2, 4, 4], np.float32))
>>> output = group_norm_op(x)
>>> print(output)
[[[[0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]]
  [[0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]]]]
```

3.11.5 mindspore.nn.InstanceNorm1d

class mindspore.nn.**InstanceNorm1d**(*num_features*, *eps=1e-5*, *momentum=0.1*, *affine=True*, *gamma_init='ones'*, *beta_init='zeros'*, *dtype=mstype.float32*)

This layer applies Instance Normalization over a 3D input (a mini-batch of 1D inputs with additional channel dimension). Refer to the paper Instance Normalization: The Missing Ingredient for Fast Stylization. It rescales and recenters the feature using a mini-batch of data and the learned parameters which can be described in the following formula.

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

The size of γ and β, learnable parameters vectors, is num_features if affine is True. The standard-deviation is calculated via the biased estimator.

This layer uses instance statistics computed from input data in both training and evaluation modes.

InstanceNorm1d and BatchNorm1d are very similar, but have some differences. InstanceNorm1d is applied on each channel of channeled data like RGB images, but BatchNorm1d is usually applied on each batch of batched data.

Note: Note that the formula for updating the running_mean and running_var is $\hat{x}_{\text{new}} = (1 - \text{momentum}) \times x_t + \text{momentum} \times \hat{x}$, where $\hat{x}$ is the estimated statistic and x_t is the new observed value.

Parameters

- **num_features** (*int*) – C from an expected input of size (N, C, L).
- **eps** (*float*) – A value added to the denominator for numerical stability. Default: `1e-5`.
- **momentum** (*float*) – A floating hyperparameter of the momentum for the running_mean and running_var computation. Default: `0.1`.
- **affine** (*bool*) – A bool value. When set to True, gamma and beta can be learned. Default: `True`.
- **gamma_init** (*Union[Tensor, str, Initializer, numbers.Number]*) – Initializer for the gamma weight. The values of str refer to the function *initializer* including `'zeros'`, `'ones'`, etc. When initialized with Tensor, the shape should be (C). Default: `'ones'`.
- **beta_init** (*Union[Tensor, str, Initializer, numbers.Number]*) – Initializer for the beta weight. The values of str refer to the function *initializer* including `'zeros'`, `'ones'`, etc. When initialized with Tensor, the shape should be (C). Default: `'zeros'`.
- **dtype** (*mindspore.dtype*) – Dtype of Parameters. Default: `mstype.float32`.

Inputs:

- **x** (Tensor) - Tensor of shape (N, C, L). Data type: float16 or float32.

Outputs:

Tensor, the normalized, scaled, offset tensor, of shape (N, C, L). Same type and shape as the x.

Raises

- **TypeError** – If the type of *num_features* is not int.
- **TypeError** – If the type of *eps* is not float.
- **TypeError** – If the type of *momentum* is not float.
- **TypeError** – If the type of *affine* is not bool.

- **TypeError** –If the type of *gamma_init*/*beta_init* is not same, or if the initialized element type is not float32.
- **ValueError** –If *num_features* is less than 1.
- **ValueError** –If *momentum* is not in range [0, 1].
- **ValueError** –If the shape of *gamma_init* / *beta_init* is not (C).
- **KeyError** –If any of *gamma_init*/*beta_init* is str and there is no homonymous class inheriting from *Initializer*.

Supported Platforms:

`GPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> net = ms.nn.InstanceNorm1d(3)
>>> x = ms.Tensor(np.ones([2, 3, 5]), ms.float32)
>>> output = net(x)
>>> print(output.shape)
(2, 3, 5)
```

3.11.6 mindspore.nn.InstanceNorm2d

class mindspore.nn.**InstanceNorm2d**(*num_features*, *eps=1e-5*, *momentum=0.1*, *affine=True*, *gamma_init='ones'*, *beta_init='zeros'*, *dtype=mstype.float32*)

This layer applies Instance Normalization over a 4D input (a mini-batch of 2D inputs with additional channel dimension). Refer to the paper Instance Normalization: The Missing Ingredient for Fast Stylization. It rescales and recenters the feature using a mini-batch of data and the learned parameters which can be described in the following formula.

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

γ and β are learnable parameter vectors of size num_features if affine is True. The standard-deviation is calculated via the biased estimator.

This layer uses instance statistics computed from input data in both training and evaluation modes.

InstanceNorm2d and BatchNorm2d are very similar, but have some differences. InstanceNorm2d is applied on each channel of channeled data like RGB images, but BatchNorm2d is usually applied on each batch of batched data.

Note: Note that the formula for updating the running_mean and running_var is $\hat{x}_{\text{new}} = (1 - \text{momentum}) \times x_t + \text{momentum} \times \hat{x}$, where $\hat{x}$ is the estimated statistic and x_t is the new observed value.

Parameters

- **num_features** (*int*) –C from an expected input of size (N, C, H, W).
- **eps** (*float*) –A value added to the denominator for numerical stability. Default: `1e-5` .
- **momentum** (*float*) –A floating hyperparameter of the momentum for the running_mean and running_var computation. Default: `0.1` .
- **affine** (*bool*) –A bool value. When set to `True` , gamma and beta can be learned. Default: `True` .

- **gamma_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –Initializer for the gamma weight. The values of str refer to the function *initializer* including `'zeros'` , `'ones'` , etc. When initialized with Tensor, the shape should be (C). Default: `'ones'` .
- **beta_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –Initializer for the beta weight. The values of str refer to the function *initializer* including `'zeros'` , `'ones'` , etc. When initialized with Tensor, the shape should be (C). Default: `'zeros'` .
- **dtype** (*mindspore.dtype*) –Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape (N, C, H, W). Data type: float16 or float32.

Outputs:

Tensor, the normalized, scaled, offset tensor, of shape (N, C, H, W). Same type and shape as the *x*.

Raises

- **TypeError** –If the type of *num_features* is not int.
- **TypeError** –If the type of *eps* is not float.
- **TypeError** –If the type of *momentum* is not float.
- **TypeError** –If the type of *affine* is not bool.
- **TypeError** –If the type of *gamma_init*/*beta_init* is not same, or if the initialized element type is not float32.
- **ValueError** –If *num_features* is less than 1.
- **ValueError** –If *momentum* is not in range [0, 1].
- **ValueError** –If the shape of *gamma_init* / *beta_init* is not (C).
- **KeyError** –If any of *gamma_init*/*beta_init* is str and there is no homonymous class inheriting from *Initializer*.

Supported Platforms:

`GPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> net = ms.nn.InstanceNorm2d(3)
>>> x = ms.Tensor(np.ones([2, 3, 2, 2]), ms.float32)
>>> output = net(x)
>>> print(output.shape)
(2, 3, 2, 2)
```

3.11.7 mindspore.nn.InstanceNorm3d

class mindspore.nn.**InstanceNorm3d**(*num_features*, *eps=1e-5*, *momentum=0.1*, *affine=True*, *gamma_init='ones'*, *beta_init='zeros'*, *dtype=mstype.float32*)

This layer applies Instance Normalization over a 5D input (a mini-batch of 3D inputs with additional channel dimension). Refer to the paper Instance Normalization: The Missing Ingredient for Fast Stylization. It rescales and recenters the feature using a mini-batch of data and the learned parameters which can be described in the following formula.

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

γ and β are learnable parameter vectors of size num_features if affine is True. The standard-deviation is calculated via the biased estimator.

This layer uses instance statistics computed from input data in both training and evaluation modes.

InstanceNorm3d and BatchNorm3d are very similar, but have some differences. InstanceNorm3d is applied on each channel of channeled data like RGB images, but BatchNorm3d is usually applied on each batch of batched data.

Note: Note that the formula for updating the running_mean and running_var is $\hat{x}_{\text{new}} = (1 - \text{momentum}) \times x_t + \text{momentum} \times \hat{x}$, where $\hat{x}$ is the estimated statistic and x_t is the new observed value.

Parameters

- **num_features** (*int*) – C from an expected input of size (N, C, D, H, W).
- **eps** (*float*) – A value added to the denominator for numerical stability. Default: `1e-5` .
- **momentum** (*float*) – A floating hyperparameter of the momentum for the running_mean and running_var computation. Default: `0.1` .
- **affine** (*bool*) – A bool value. When set to `True` , gamma and beta can be learned. Default: `True` .
- **gamma_init** (*Union[Tensor, str, Initializer, numbers.Number]*) – Initializer for the gamma weight. The values of str refer to the function *initializer* including `'zeros'` , `'ones'` , etc. When initialized with Tensor, the shape should be (C). Default: `'ones'` .
- **beta_init** (*Union[Tensor, str, Initializer, numbers.Number]*) – Initializer for the beta weight. The values of str refer to the function *initializer* including `'zeros'` , `'ones'` , etc. When initialized with Tensor, the shape should be (C). Default: `'zeros'` .
- **dtype** (*mindspore.dtype*) – Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - Tensor of shape (N, C, D, H, W). Data type: float16 or float32.

Outputs:

Tensor, the normalized, scaled, offset tensor, of shape (N, C, D, H, W). Same type and shape as the x.

Raises

- **TypeError** – If the type of *num_features* is not int.
- **TypeError** – If the type of *eps* is not float.
- **TypeError** – If the type of *momentum* is not float.
- **TypeError** – If the type of *affine* is not bool.

- **TypeError** –If the type of *gamma_init*/*beta_init* is not same, or if the initialized element type is not float32.
- **ValueError** –If *num_features* is less than 1.
- **ValueError** –If *momentum* is not in range [0, 1].
- **ValueError** –If the shape of *gamma_init* / *beta_init* is not (C).
- **KeyError** –If any of *gamma_init*/*beta_init* is str and the homonymous class inheriting from *Initializer* not exists.

Supported Platforms:

`GPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> net = ms.nn.InstanceNorm3d(3)
>>> x = ms.Tensor(np.ones([2, 3, 5, 2, 2]), ms.float32)
>>> output = net(x)
>>> print(output.shape)
(2, 3, 5, 2, 2)
```

3.11.8 mindspore.nn.LayerNorm

class mindspore.nn.**LayerNorm**(*normalized_shape*, *begin_norm_axis=- 1*, *begin_params_axis=- 1*, *gamma_init='ones'*, *beta_init='zeros'*, *epsilon=1e-7*, *dtype=mstype.float32*)

Applies Layer Normalization over a mini-batch of inputs.

Layer Normalization is widely used in recurrent neural networks. It applies normalization on a mini-batch of inputs for each single training case as described in the paper Layer Normalization. Unlike Batch Normalization, Layer Normalization performs exactly the same computation at training and testing time. It is applied across all channels and pixel but only one batch size. γ and β are trainable scale and shift. It can be described using the following formula:

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

Parameters

- **normalized_shape** (*Union(tuple[int], list[int])*) –The normalization is performed over axis *begin_norm_axis* $\cdots$ *R - 1*. R is the dimension size of input *x*.
- **begin_norm_axis** (*int*) –The first normalization dimension: normalization will be performed along dimensions *begin_norm_axis: R*, the value should be in [-1, R). Default: `-1` .
- **begin_params_axis** (*int*) –The begin axis of the parameter input (γ, β) to apply LayerNorm, the value should be in [-1, R). Default: `-1` .
- **gamma_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –Initializer for the γ weight. The values of str refer to the function *initializer* including `'zeros'` , `'ones'` , `'xavier_uniform'` , `'he_uniform'` , etc. Default: `'ones'` .
- **beta_init** (*Union[Tensor, str, Initializer, numbers.Number]*) –Initializer for the β weight. The values of str refer to the function *initializer* including `'zeros'` , `'ones'` , `'xavier_uniform'` , `'he_uniform'` , etc. Default: `'zeros'` .
- **epsilon** (*float*) –A value added to the denominator for numerical stability(ϵ). Default: `1e-7` .

- **dtype** (*mindspore.dtype*) –Dtype of Parameters. Default: `mstype.float32` .

Inputs:

- **x** (Tensor) - The shape of x is $(x_1, x_2, ..., x_R)$, and *input_shape[begin_norm_axis:]* is equal to *normalized_shape*.

Outputs:

Tensor, the normalized and scaled offset tensor, has the same shape and data type as the x.

Raises

- **TypeError** –If *normalized_shape* is neither a list nor tuple.
- **TypeError** –If *begin_norm_axis* or *begin_params_axis* is not an int.
- **TypeError** –If *epsilon* is not a float.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> x = ms.Tensor(np.ones([20, 5, 10, 10]), ms.float32)
>>> shape1 = x.shape[1:]
>>> m = ms.nn.LayerNorm(shape1,  begin_norm_axis=1, begin_params_axis=1)
>>> output = m(x).shape
>>> print(output)
(20, 5, 10, 10)
```

3.11.9 mindspore.nn.SyncBatchNorm

class mindspore.nn.**SyncBatchNorm**(*num_features*, *eps=1e-5*, *momentum=0.9*, *affine=True*, *gamma_init='ones'*, *beta_init='zeros'*, *moving_mean_init='zeros'*, *moving_var_init='ones'*, *use_batch_statistics=None*, *process_groups=None*, *dtype=mstype.float32*)

Sync Batch Normalization layer over a N-dimension input.

Sync Batch Normalization is cross device synchronized Batch Normalization. The implementation of Batch Normalization only normalizes the data within each device. Sync Batch Normalization will normalize the input within the group. It has been described in the paper Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift. It rescales and recenters the feature using a mini-batch of data and the learned parameters which can be described in the following formula.

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

Note: Currently, SyncBatchNorm only supports 2D and 4D inputs. γ and β are trainable scale and shift.

Parameters

- **num_features** (*int*) –C from an expected input of size (N, C, H, W).
- **eps** (*float, optional*) –ϵ, a value added to the denominator for numerical stability. Default: `1e-5` .

- **momentum** (*float, optional*) –A floating hyperparameter of the momentum for the running_mean and running_var computation. Default: `0.9`.
- **affine** (*bool, optional*) –A bool value. When set to `True`, γ and β are learnable parameters. When set to `False`, γ and β are unlearnable parameters. Default: `True`.
- **gamma_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –Initializer for the γ weight. The values of str refer to the function *initializer* including `'zeros'`, `'ones'`, `'xavier_uniform'`, `'he_uniform'`, etc. Default: `'ones'`.
- **beta_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –Initializer for the β weight. The values of str refer to the function *initializer* including `'zeros'`, `'ones'`, `'xavier_uniform'`, `'he_uniform'`, etc. Default: `'zeros'`.
- **moving_mean_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) – Initializer for the moving mean. The values of str refer to the function *initializer* including `'zeros'`, `'ones'`, `'xavier_uniform'`, `'he_uniform'`, etc. Default: `'zeros'`.
- **moving_var_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) – Initializer for the moving variance. The values of str refer to the function *initializer* including `'zeros'`, `'ones'`, `'xavier_uniform'`, `'he_uniform'`, etc. Default: `'ones'`.
- **use_batch_statistics** (*bool, optional*) –If `true`, use the mean value and variance value of current batch data. If `false`, use the mean value and variance value of specified value. If `None`, training process will use the mean and variance of current batch data and track the running mean and variance, eval process will use the running mean and variance. Default: `None`.
- **process_groups** (*list, optional*) –A list to divide devices into different sync groups, containing N subtraction lists. Each subtraction list contains int numbers identifying rank ids which need to be synchronized in the same group. All int values must be in [0, rank_size) and different from each other. Default: `None`, indicating synchronization across all devices.
- **dtype** (*mindspore.dtype*, optional) –Dtype of Parameters. Default: `mstype.float32`.

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, H_{in}, W_{in})$.

Outputs:

Tensor, the normalized, scaled, offset tensor, of shape $(N, C_{out}, H_{out}, W_{out})$.

Raises

- **TypeError** –If *num_features* is not an int.
- **TypeError** –If *eps* is not a float.
- **TypeError** –If *process_groups* is not a list.
- **ValueError** –If *num_features* is less than 1.
- **ValueError** –If *momentum* is not in range [0, 1].
- **ValueError** –If rank_id in *process_groups* is not in range [0, rank_size).

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For the Ascend devices, users need to prepare the rank table, set rank_id and device_id. Please see the Ascend tutorial for more details.

For the GPU devices, users need to prepare the host file and mpi, please see the mpirun Startup .

For the CPU device, users need to write a dynamic cluster startup script, please see the Dynamic Cluster Startup .

This example should be run with multiple devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore.communication import init
>>>
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> init()
>>> ms.reset_auto_parallel_context()
>>> ms.set_auto_parallel_context(parallel_mode=ms.ParallelMode.DATA_PARALLEL)
>>> sync_bn_op = ms.nn.SyncBatchNorm(num_features=3, process_groups=[[0, 1], [2, 3]])
>>> x = ms.Tensor(np.ones([1, 3, 2, 2]), ms.float32)
>>> output = sync_bn_op(x)
>>> print(output)
[[[[ 0.999995 0.999995 ]
   [ 0.999995 0.999995 ]]
  [[ 0.999995 0.999995 ]
   [ 0.999995 0.999995 ]]
  [[ 0.999995 0.999995 ]
   [ 0.999995 0.999995 ]]]]
```

3.12 Pooling Layer

API Name	Description	Supported Platforms
mindspore.nn.AdaptiveAvgPool1d	Applies a 1D adaptive average pooling over an input Tensor which can be regarded as a composition of 1D input planes.	Ascend GPU CPU
mindspore.nn.AdaptiveAvgPool2d	This operator applies a 2D adaptive average pooling to an input signal composed of multiple input planes.	Ascend GPU CPU
mindspore.nn.AdaptiveAvgPool3d	This operator applies a 3D adaptive average pooling to an input signal composed of multiple input planes.	Ascend GPU CPU
mindspore.nn.AdaptiveMaxPool1d	Applies a 1D adaptive maximum pooling over an input Tensor which can be regarded as a composition of 1D input planes.	Ascend GPU CPU
mindspore.nn.AdaptiveMaxPool2d	This operator applies a 2D adaptive max pooling to an input signal composed of multiple input planes.	Ascend GPU CPU
mindspore.nn.AdaptiveMaxPool3d	Calculates the 3D adaptive max pooling for an input Tensor.	GPU CPU

3.12.1 mindspore.nn.AdaptiveAvgPool1d

class mindspore.nn.**AdaptiveAvgPool1d**(*output_size*)

Applies a 1D adaptive average pooling over an input Tensor which can be regarded as a composition of 1D input planes.

Typically, the input is of shape (N_{in}, C_{in}, L_{in}), AdaptiveAvgPool1d outputs regional average in the L_{in}-dimension. The output is of shape $(N_{in}, C_{in}, L_{out})$, where L_{out} is defined by *output_size*.

Note: L_{in} must be divisible by *output_size*.

Parameters

output_size (*int*) –the target output size L_{out}.

Inputs:

- **input** (Tensor) - Tensor of shape (N, C_{in}, L_{in}), with float16 or float32 data type.

Outputs:

Tensor of shape (N, C_{in}, L_{out}), has the same type as *input*.

Raises

- **TypeError** –If *output_size* is not an int.
- **TypeError** –If *input* is neither float16 nor float32.
- **ValueError** –If *output_size* is less than 1.
- **ValueError** –If length of shape of *input* is not equal to 3.
- **ValueError** –If the last dimension of *input* is smaller than *output_size*.
- **ValueError** –If the last dimension of *input* is not divisible by *output_size*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> pool = ms.nn.AdaptiveAvgPool1d(output_size=2)
>>> input = ms.Tensor(np.random.randint(0, 10, [1, 3, 6]), ms.float32)
>>> output = pool(input)
>>> result = output.shape
>>> print(result)
(1, 3, 2)
```

3.12.2 mindspore.nn.AdaptiveAvgPool2d

class mindspore.nn.**AdaptiveAvgPool2d**(*output_size*)

This operator applies a 2D adaptive average pooling to an input signal composed of multiple input planes. That is, for any input size, the size of the specified output is H x W. The number of output features is equal to the number of input features.

The input and output data format can be "NCHW" and "CHW". N is the batch size, C is the number of channels, H is the feature height, and W is the feature width.

$$
\begin{aligned}
h_{start} &= floor(i * H_{in}/H_{out}) \\
h_{end} &= ceil((i+1) * H_{in}/H_{out}) \\
w_{start} &= floor(j * W_{in}/W_{out}) \\
w_{end} &= ceil((j+1) * W_{in}/W_{out}) \\
Output(i,j) &= \frac{\sum Input[h_{start}:h_{end}, w_{start}:w_{end}]}{(h_{end}-h_{start})*(w_{end}-w_{start})}
\end{aligned}
$$

Parameters

output_size (*Union[int, tuple]*) –The target output size is H x W. *output_size* can be a tuple consisted of int type H and W, or a single H for H x H, or None. If it is None, it means the output size is the same as the input size.

Inputs:

- **input** (Tensor) - The input of AdaptiveAvgPool2d, which is a 3D or 4D tensor, with float16, float32 or float64 data type.

Outputs:

Tensor of shape $(N, C_{out}, H_{out}, W_{out})$.

Raises

- **ValueError** –If *output_size* is a tuple and the length of *output_size* is not 2.
- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If dtype of *input* is not float16, float32 or float64.
- **ValueError** –If the dimension of *input* is less than or equal to the dimension of *output_size*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> pool = ms.nn.AdaptiveAvgPool2d(2)
>>> input_x = ms.Tensor(np.array([[[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]],
...                               [[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]],
...                               [[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]]]), ms.
↪float32)
>>> output = pool(input_x)
>>> result = output.shape
>>> print(result)
(3, 2, 2)
```

3.12.3 mindspore.nn.AdaptiveAvgPool3d

class mindspore.nn.**AdaptiveAvgPool3d**(*output_size*)

This operator applies a 3D adaptive average pooling to an input signal composed of multiple input planes. That is, for any input size, the size of the specified output is (D, H, W). The number of output features is equal to the number of input planes.

Suppose the last 3 dimension size of input is (inD, inH, inW), then the last 3 dimension size of output is $(outD, outH, outW)$.

$$
\begin{aligned}
&\forall \quad od \in [0, outD-1], oh \in [0, outH-1], ow \in [0, outW-1] \\
&output[od, oh, ow] = \\
&\qquad mean(input[istartD : iendD+1, istartH : iendH+1, istartW : iendW+1]) \\
&where, \\
&\qquad istartD = \left\lceil \frac{od * inD}{outD} \right\rceil \\
&\qquad iendD = \left\lfloor \frac{(od+1) * inD}{outD} \right\rfloor \\
&\qquad istartH = \left\lceil \frac{oh * inH}{outH} \right\rceil \\
&\qquad iendH = \left\lfloor \frac{(oh+1) * inH}{outH} \right\rfloor \\
&\qquad istartW = \left\lceil \frac{ow * inW}{outW} \right\rceil \\
&\qquad iendW = \left\lfloor \frac{(ow+1) * inW}{outW} \right\rfloor
\end{aligned}
$$

Parameters

output_size (*Union[int, tuple]*) –The target output size. *output_size* can be a tuple (D, H, W), or an int D for (D, D, D). D, H and W can be int or None which means the output size is the same as that of the input.

Inputs:

- **input** (Tensor) - The input of AdaptiveAvgPool3d, which is a 5D or 4D Tensor, with float16, float32 or float64 data type.

Outputs:

Tensor, with the same type as the *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If dtype of *input* is not float16, float32 or float64.
- **ValueError** –If the dimension of *input* is not 4D or 5D.
- **ValueError** –If *output_size* value is not positive.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> # case 1: output_size=(3, 3, 4)
>>> output_size=(3, 3, 4)
>>> input_x_val = np.random.randn(4, 3, 5, 6, 7)
>>> input_x = ms.Tensor(input_x_val, ms.float32)
>>> net = ms.nn.AdaptiveAvgPool3d(output_size)
>>> output = net(input_x)
>>> print(output.shape)
(4, 3, 3, 3, 4)
>>> # case 2: output_size=4
>>> output_size=5
>>> input_x_val = np.random.randn(2, 3, 8, 6, 12)
>>> input_x = ms.Tensor(input_x_val, ms.float32)
>>> net = ms.nn.AdaptiveAvgPool3d(output_size)
>>> output = net(input_x)
>>> print(output.shape)
(2, 3, 5, 5, 5)
>>> # case 3: output_size=(None, 4, 5)
>>> output_size=(None, 4, 5)
>>> input_x_val = np.random.randn(4, 1, 9, 10, 8)
>>> input_x = ms.Tensor(input_x_val, ms.float32)
>>> net = ms.nn.AdaptiveAvgPool3d(output_size)
>>> output = net(input_x)
>>> print(output.shape)
(4, 1, 9, 4, 5)
```

3.12.4 mindspore.nn.AdaptiveMaxPool1d

class mindspore.nn.**AdaptiveMaxPool1d**(*output_size*)

Applies a 1D adaptive maximum pooling over an input Tensor which can be regarded as a composition of 1D input planes.

Typically, the input is of shape (N_{in}, C_{in}, L_{in}), AdaptiveMaxPool1d outputs regional maximum in the L_{in}-dimension. The output is of shape $(N_{in}, C_{in}, L_{out})$, where L_{out} is defined by *output_size*.

Note: L_{in} must be divisible by *output_size*.

Parameters

output_size (*int*) –the target output size L_{out}.

Inputs:

- **x** (Tensor) - Tensor of shape (N, C_{in}, L_{in}), with float16 or float32 data type.

Outputs:

Tensor of shape (N, C_{in}, L_{out}), has the same type as x.

Raises

- **TypeError** –If x is neither float16 nor float32.
- **TypeError** –If *output_size* is not an int.
- **ValueError** –If *output_size* is less than 1.
- **ValueError** –If the last dimension of x is smaller than *output_size*.
- **ValueError** –If the last dimension of x is not divisible by *output_size*.
- **ValueError** –If length of shape of x is not equal to 3.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> pool = ms.nn.AdaptiveMaxPool1d(output_size=3)
>>> x = ms.Tensor(np.random.randint(0, 10, [1, 3, 6]), ms.float32)
>>> output = pool(x)
>>> result = output.shape
>>> print(result)
(1, 3, 3)
```

3.12.5 mindspore.nn.AdaptiveMaxPool2d

class mindspore.nn.**AdaptiveMaxPool2d**(*output_size*, *return_indices=False*)

This operator applies a 2D adaptive max pooling to an input signal composed of multiple input planes. That is, for any input size, the size of the specified output is H x W. The number of output features is equal to the number of input planes.

The input and output data format can be "NCHW" and "CHW". N is the batch size, C is the number of channels, H is the feature height, and W is the feature width.

For max adaptive pool2d:

$$
\begin{aligned}
h_{start} &= floor(i * H_{in}/H_{out}) \\
h_{end} &= ceil((i+1) * H_{in}/H_{out}) \\
w_{start} &= floor(j * W_{in}/W_{out}) \\
w_{end} &= ceil((j+1) * W_{in}/W_{out}) \\
Output(i,j) &= \max Input[h_{start}:h_{end}, w_{start}:w_{end}]
\end{aligned}
$$

Note: In KBK mode, *output_size* does not support mutable.

Parameters

- **output_size** (*Union[int, tuple]*) –The target output size. *output_size* can be a tuple (H, W), or an int H for (H, H). H and W can be int or None. If it is None, it means the output size is the same as the input size.
- **return_indices** (*bool, optional*) –Whether to output the index of the maximum value. If *return_indices* is `True` , the indices of max value would be output. Default: `False` .

Inputs:

- **input** (Tensor) - The input of AdaptiveMaxPool2d, which is a 3D or 4D tensor, with float16, float32 or float64 data type.

Outputs:

Tensor, with the same type as the *input*. Shape of the output is $input\_shape[: len(input\_shape) - len(out\_shape)] + out\_shape$.

Raises

- **TypeError** –If *output_size* is not int or tuple.
- **TypeError** –If *input* is not a tensor.
- **TypeError** –If *return_indices* is not a bool.
- **TypeError** –If dtype of *input* is not float16, float32 or float64.
- **ValueError** –If *output_size* is a tuple and the length of *output_size* is not 2.
- **ValueError** –If the dimension of *input* is not NCHW or CHW.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> # case 1: output_size=(None, 2)
>>> input = ms.Tensor(np.array([[[[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]],
...                              [[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]],
...                              [[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]]]]), ms.
↪float32)
>>> adaptive_max_pool_2d = ms.nn.AdaptiveMaxPool2d((None, 2))
>>> output = adaptive_max_pool_2d(input)
>>> print(output)
[[[[2. 3.]
   [5. 6.]
   [8. 9.]]
  [[2. 3.]
   [5. 6.]
   [8. 9.]]
  [[2. 3.]
```

[[[[8. 9.]]
  [[8. 9.]]
  [[8. 9.]]]]
```

3.12.6 mindspore.nn.AdaptiveMaxPool3d

class mindspore.nn.**AdaptiveMaxPool3d**(*output_size*, *return_indices=False*)

Calculates the 3D adaptive max pooling for an input Tensor. That is, for any input size, the size of the specified output is (D, H, W).

Parameters

- **output_size** (*Union[int, tuple]*) –The specified output size, which is a positive integer that represents depth, height and width, or a tuple of three positive integers that represent depth, height and width respectively. If it is None, the output size and input size of the corresponding dimension are the same.
- **return_indices** (*bool, optional*) –If *return_indices* is `True` , the indices of max value would be output. Otherwise, the indices will not be returned. Default: `False` .

Inputs:

- **input** (Tensor) - Tensor, has shape of (C, D, H, W) or (N, C, D, H, W).

Outputs:

- **y** (Tensor) - Tensor, has the same number of dims and data type as the *input* .
- **argmax** (Tensor) - Tensor, the indices of the maximum values along with the outputs, has the same shape as *y* and a dtype of int32. Return this only when *return_indices* is `True` .

Raises

- **TypeError** –If *input* is not a Tensor.
- **ValueError** –If the dimensions number of *input* is not 4 or 5.
- **TypeError** –If dtype of *input* is not int, uint or float.
- **ValueError** –If *output_size* is neither an int nor a tuple with shape $(3,)$.

Supported Platforms:

`GPU CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> input = ms.Tensor(np.arange(0,36).reshape((1, 3, 3, 4)).astype(np.float32))
>>> output_size = (1, 1, 2)
>>> net = ms.nn.AdaptiveMaxPool3d(output_size, True)
>>> output = net(input)
>>> print(output[0].asnumpy())
[[[[33. 35.]]]]
>>> print(output[1].asnumpy())
[[[[33 35]]]]
```

3.12.7 mindspore.nn.AvgPool1d

class mindspore.nn.**AvgPool1d**(*kernel_size=1*, *stride=1*, *pad_mode='valid'*, *padding=0*, *ceil_mode=False*, *count_include_pad=True*)

Applies a 1D average pooling over an input Tensor which can be regarded as a composition of 1D input planes.

Typically the input is of shape (N_{in}, C_{in}, L_{in}), AvgPool1d outputs regional average in the (L_{in})-dimension. Given *kernel_size* l_{ker} and *stride* s_0, the operation is as follows:

$$\text{output}(N_i, C_j, l) = \frac{1}{l_{ker}} \sum_{n=0}^{l_{ker}-1} \text{input}(N_i, C_j, s_0 \times l + n)$$

Note: This interface currently does not support Atlas A2 training series products.

Parameters

- **kernel_size** (*int, optional*) – The size of kernel window used to take the average value, Default: `1` .
- **stride** (*int, optional*) – The distance of kernel moving, an int number that represents the width of movement is strides, Default: `1` .
- **pad_mode** (*str, optional*) – Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"valid"` .
  - `"same"`: Pad the input at the begin and end so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally. If the amount is even, it is uniformly distributed around the input, if it is odd, the excess padding is goes to the right side. If this mode is set, *padding* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible length. If a full stride cannot be formed, the extra pixels will be discarded. If this mode is set, *padding* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding at the begin and end is determined by the *padding* parameter. If this mode is set, *padding* must be greater than or equal to 0.
- **padding** (*Union(int, tuple[int], list[int]), optional*) – Pooling padding value, only `"pad"` mode can be set to non-zero. Default: `0` . padding can only be an integer or a tuple/list containing a single integer, in which case padding times or padding[0] times are padded on both sides of the input.
- **ceil_mode** (*bool, optional*) – If `True` , use ceil to compute the output shape instead of floor. Default: `False` .

- **count_include_pad** (*bool, optional*) – If `True` , averaging calculation will include the zero-padding. Default: `True` .

Inputs:

- **x** (Tensor) - Tensor of shape (N, C_{in}, L_{in}) or (C_{in}, L_{in}).

Outputs:

Tensor of shape (N, C_{out}, L_{out}) or (C_{out}, L_{out}).

If *pad_mode* is in *pad* mode, the output shape calculation formula is as follows:

$$L_{out} = \left\lfloor \frac{L_{in} + 2 \times \text{padding} - \text{kernel\_size}}{\text{stride}} + 1 \right\rfloor$$

Raises

- **TypeError** – If *kernel_size* or *stride* is not an int.
- **ValueError** – If *pad_mode* is not `"valid"` , `"same"` or `"pad"` with not case sensitive.
- **ValueError** – If *kernel_size* or *strides* is less than 1.
- **ValueError** – If length of *padding* tuple/list is not 1.
- **ValueError** – If length of shape of *x* is not equal to 2 or 3.
- **ValueError** – If *padding* is non-zero when *pad_mode* is not `"pad"`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> pool = ms.nn.AvgPool1d(kernel_size=6, stride=1)
>>> x = ms.Tensor(np.random.randint(0, 10, [1, 3, 6]), ms.float32)
>>> output = pool(x)
>>> result = output.shape
>>> print(result)
(1, 3, 1)
>>> pool2 = ms.nn.AvgPool1d(4, stride=1, ceil_mode=True, pad_mode="pad", padding=2)
>>> x1 = ms.ops.randn(6, 6, 8)
>>> output = pool2(x1)
>>> print(output.shape)
(6, 6, 9)
```

3.12.8 mindspore.nn.AvgPool2d

class mindspore.nn.**AvgPool2d**(*kernel_size=1*, *stride=1*, *pad_mode='valid'*, *padding=0*, *ceil_mode=False*, *count_include_pad=True*, *divisor_override=None*, *data_format='NCHW'*)

Applies a 2D average pooling over an input Tensor which can be regarded as a composition of 2D input planes.

Typically the input is of shape $(N_{in}, C_{in}, H_{in}, W_{in})$, AvgPool2d outputs regional average in the (H_{in}, W_{in})-dimension. Given kernel size $ks = (h_{ker}, w_{ker})$ and stride $s = (s_0, s_1)$, the operation is as follows:

$$\text{output}(N_i, C_j, h, w) = \frac{1}{h_{ker} * w_{ker}} \sum_{m=0}^{h_{ker}-1} \sum_{n=0}^{w_{ker}-1} \text{input}(N_i, C_j, s_0 \times h + m, s_1 \times w + n)$$

Note: This interface currently does not support Atlas A2 training series products.

Parameters

- **kernel_size** (*Union[int, tuple[int]]*) –The size of kernel used to take the average value. The data type of kernel_size must be int or a single element tuple and the value represents the height and width, or a tuple of two int numbers that represent height and width respectively. Default: `1` .
- **stride** (*Union[int, tuple[int]]*) –The distance of kernel moving, an int number or a single element tuple that represents the height and width of movement are both strides, or a tuple of two int numbers that represent height and width of movement respectively. Default: `1` .
- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"valid"` .
  - `"same"`: Pad the input around its edges so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally, If the amount is even, it is uniformly distributed around the input, if it is odd, the excess amount goes to the right/bottom side. If this mode is set, *padding* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *padding* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the height and width directions is determined by the *padding* parameter. If this mode is set, *padding* must be greater than or equal to 0.
- **padding** (*Union(int, tuple[int], list[int])*) –Pooling padding value, only `"pad"` mode can be set to non-zero. Default: `0` . *padding* can only be an integer or a tuple/list containing one or two integers. If *padding* is an integer or a tuple/list containing one integer, it will be padded *padding* times in the four directions of the input. If *padding* is a tuple/list containing two integers, it will be padded *padding[0]* times in the up-down direction of the input and *padding[1]* times in the left-right direction of the input.
- **ceil_mode** (*bool*) –If `True` , use ceil to compute the output shape instead of floor. Default: `False` .
- **count_include_pad** (*bool*) –If `True` , averaging calculation will include the zero-padding. Default: `True` .
- **divisor_override** (*int*) –If it is specified as a non-zero parameter, this parameter will be used as the divisor in the average calculation. Otherwise, *kernel_size* will be used as the divisor. Default: `None` .
- **data_format** (*str*) –The optional value for data format, is `'NHWC'` or `'NCHW'` . Default: `'NCHW'` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, H_{in}, W_{in})$ or (C_{in}, H_{in}, W_{in}).

Outputs:

Tensor of shape $(N, C_{out}, H_{out}, W_{out})$ or $(C_{out}, H_{out}, W_{out})$.

If *pad_mode* is in *pad* mode, the output shape calculation formula is as follows:

$$H_{out} = \left\lfloor \frac{H_{in} + 2 \times \text{padding}[0] - \text{kernel\_size}[0]}{\text{stride}[0]} + 1 \right\rfloor$$

$$W_{out} = \left\lfloor \frac{W_{in} + 2 \times \text{padding}[1] - \text{kernel\_size}[1]}{\text{stride}[1]} + 1 \right\rfloor$$

Raises

- **TypeError** – If *kernel_size* or *strides* is neither int nor tuple.
- **ValueError** – If *pad_mode* is not `"valid"` , `"same"` or `"pad"` with not case sensitive.
- **ValueError** – If *data_format* is neither `'NCHW'` nor `'NHWC'`.
- **ValueError** – If *padding*, *ceil_mode*, *count_include_pad*, or *divisor_override* is used, or *pad_mode* is `"pad"` when *data_format* is 'NHWC'.
- **ValueError** – If *kernel_size* or *strides* is less than 1.
- **ValueError** – If length of *padding* tuple/list is not 1 or 2.
- **ValueError** – If length of shape of *x* is not equal to 3 or 4.
- **ValueError** – If *divisor_override* is less than or equal to 0.
- **ValueError** – If *padding* is non-zero when *pad_mode* is not `"pad"`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> pool = ms.nn.AvgPool2d(kernel_size=3, stride=1)
>>> x = ms.Tensor(np.random.randint(0, 10, [1, 2, 4, 4]), ms.float32)
>>> output = pool(x)
>>> print(output.shape)
(1, 2, 2, 2)
>>> x = ms.ops.randn(6, 6, 8, 8)
>>> pool2 = ms.nn.AvgPool2d(4, stride=1, pad_mode="pad", padding=2, divisor_override=5)
>>> output2 = pool2(x)
>>> print(output2.shape)
(6, 6, 9, 9)
```

3.12.9 mindspore.nn.AvgPool3d

class mindspore.nn.**AvgPool3d**(*kernel_size=1*, *stride=1*, *pad_mode='valid'*, *padding=0*, *ceil_mode=False*, *count_include_pad=True*, *divisor_override=None*)

Applies a 3D average pooling over an input Tensor which can be regarded as a composition of 3D input planes. Typically, the input is of shape $(N_{in}, C_{in}, D_{in}, H_{in}, W_{in})$, and AvgPool3D outputs regional average in the (D_{in}, H_{in}, W_{in})-dimension. Given kernel size is $ks = (d_{ker}, h_{ker}, w_{ker})$ and stride $s = (s_0, s_1, s_2)$, the operation is as follows.

Warning: *kernel_size* is in the range [1, 255]. *stride* is in the range [1, 63].

$$\text{output}(N_i, C_j, d, h, w) = \frac{1}{d_{ker} * h_{ker} * w_{ker}} \sum_{l=0}^{d_{ker}-1} \sum_{m=0}^{h_{ker}-1} \sum_{n=0}^{w_{ker}-1} \text{input}(N_i, C_j, s_0 \times d + l, s_1 \times h + m, s_2 \times w + n)$$

Note: This interface currently does not support Atlas A2 training series products.

Parameters

- **kernel_size** (*Union[int, tuple[int]], optional*) – The size of kernel used to take the average value, can be an int number or a single element tuple that represents depth, height and width, or a tuple of three positive integers that represent depth, height and width respectively. Default: `1` .
- **stride** (*Union[int, tuple[int]], optional*) – The distance of kernel moving, can be a positive int or a single element tuple that represents the depth, height and width of movement, or a tuple of three positive integers that represents depth, height and width of movement respectively. If the value is None, the default value *kernel_size* is used. Default: `1` .
- **pad_mode** (*str, optional*) – Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"valid"` .
  - `"same"`: Pad the input around its depth/height/width dimension so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally. If the amount is even, it isuniformly distributed around the input, if it is odd, the excess amount goes to the front/right/bottom side. If this mode is set, *padding* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible depth, height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *padding* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the depth, height and width dimension is determined by the *padding* parameter. If this mode is set, *padding* must be greater than or equal to 0.
- **padding** (*Union(int, tuple[int], list[int]), optional*) – Pooling padding value, only `"pad"` mode can be set to non-zero. Default: `0` . Only the following paddings are supported:
  - *padding* is an integer or a tuple/list containing one integer, it will be padded in six directions of front, back, top, bottom, left and right of the input.
  - *padding* is a tuple/list containing three integers, it will be padded in front and back of the input *padding[0]* times, up and down *padding[1]* times, and left and right of the input *padding[2]* times.
- **ceil_mode** (*bool, optional*) – If `True` , use ceil to compute the output shape instead of floor. Default: `False` .
- **count_include_pad** (*bool, optional*) – If `True` , averaging calculation will include the zero-padding. Default: `True` .

- **divisor_override** (*int, optional*) – If it is specified as a non-zero parameter, this parameter will be used as the divisor in the average calculation. Otherwise, *kernel_size* will be used as the divisor. Default: `None` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C, D_{in}, H_{in}, W_{in})$ or $(C, D_{in}, H_{in}, W_{in})$. Currently support float16, float32 and float64 data type.

Outputs:

Tensor, with shape $(N, C, D_{out}, H_{out}, W_{out})$ or $(C, D_{out}, H_{out}, W_{out})$, with the same data type as x.

If *pad_mode* is in *pad* mode, the output shape calculation formula is as follows:

$$D_{out} = \left\lfloor \frac{D_{in} + 2 \times \text{padding}[0] - \text{kernel\_size}[0]}{\text{stride}[0]} + 1 \right\rfloor$$

$$H_{out} = \left\lfloor \frac{H_{in} + 2 \times \text{padding}[1] - \text{kernel\_size}[1]}{\text{stride}[1]} + 1 \right\rfloor$$

$$W_{out} = \left\lfloor \frac{W_{in} + 2 \times \text{padding}[2] - \text{kernel\_size}[2]}{\text{stride}[2]} + 1 \right\rfloor$$

Raises

- **TypeError** – If *kernel_size* is neither an int nor a tuple.
- **TypeError** – If *stride* is neither an int nor a tuple.
- **TypeError** – If *padding* is neither an int nor a tuple/list.
- **TypeError** – If *ceil_mode* or *count_include_pad* is not a bool.
- **TypeError** – If *divisor_override* is not an int.
- **ValueError** – If numbers in *kernel_size* or *stride* are not positive.
- **ValueError** – If *kernel_size* or *stride* is a tuple whose length is not equal to 3.
- **ValueError** – If *padding* is a tuple/list whose length is neither 1 nor 3.
- **ValueError** – If element of *padding* is less than 0.
- **ValueError** – If length of shape of *x* is neither 4 nor 5.
- **ValueError** – If *divisor_override* is less than or equal to 0.
- **ValueError** – If *padding* is non-zero when *pad_mode* is not `"pad"`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> pool = ms.nn.AvgPool3d(kernel_size=3, stride=1)
>>> x = ms.ops.randn(1, 2, 4, 4, 5).astype(ms.float32)
>>> output = pool(x)
>>> print(output.shape)
(1, 2, 2, 2, 3)
>>> x1 = ms.ops.randn(6, 5, 7, 7, 5).astype(ms.float32)
```

(continues on next page)

(continued from previous page)

```
>>> pool2 = ms.nn.AvgPool3d(4, stride=2, pad_mode="pad", padding=(2, 2, 1), divisor_
↪override=10)
>>> output2 = pool2(x1)
>>> print(output2.shape)
(6, 5, 4, 4, 2)
```

3.12.10 mindspore.nn.FractionalMaxPool3d

class mindspore.nn.**FractionalMaxPool3d**(*kernel_size*, *output_size=None*, *output_ratio=None*, *return_indices=False*, *_random_samples=None*)

Applies the 3D FractionalMaxPool operation over *input*. The output Tensor shape can be determined by either *output_size* or *output_ratio*, and the step size is determined by *_random_samples*. *output_size* will take effect when *output_size* and *output_ratio* are set at the same time. And *output_size* and *output_ratio* can not be `None` at the same time.

Refer to the paper Fractional MaxPooling by Ben Graham for more details.

The input and output data format can be "NCDHW". N is the batch size, C is the number of channels, D the feature depth, H is the feature height, and W is the feature width.

Parameters

- **kernel_size** (*Union[int, tuple[int]]*) – The size of kernel used to take the maximum value, is a positive int that represents depth, height and width of the kernel, or a tuple of three positive integers that represent depth, height and width respectively.
- **output_size** (*Union[int, tuple[int]], optional*) – The shape of the target *output_size*, is an int number that represents depth, height and width, or a tuple of three positive integers that represents depth, height and width respectively. If `None` , the shape of the target will be determined by *output_ratio*. Default: `None` .
- **output_ratio** (*Union[float, tuple[float]], optional*) – The ratio of target output shape to input shape. Specifying the size of the output tensor by using a ratio of the input size. Data type : float16, float32, float64, and value is between (0, 1). If `None` , the shape of the target will be determined by *output_size*.Default: `None` .
- **return_indices** (*bool, optional*) – Whether to return the indices of max value. Default: `False` .
- **_random_samples** (*Tensor, optional*) – The random step of FractionalMaxPool3d, which is a 3D tensor. Tensor of data type: float16, float32, double, and value is between [0, 1). Supported shape $(N, C, 3)$ or $(1, C, 3)$. Default: `None`, the values of *_random_samples* will be randomly distributed using uniform distribution over an interval [0,1).

Inputs:

- **input** (Tensor) - The input of FractionalMaxPool3d, which is a 4D or 5D tensor. Tensor of data type : float16, float32, float64. Supported shape $(N, C, D_{in}, H_{in}, W_{in})$ or $(C, D_{in}, H_{in}, W_{in})$.

Outputs:

- **y** (Tensor) - A tensor, the output of FractionalMaxPool3d. Has the same data type with *input*. Has the shape $(N, C, D_{out}, H_{out}, W_{out})$ or $(C, D_{out}, H_{out}, W_{out})$, where $(D_{out}, H_{out}, W_{out})$ = *output_size* or $(D_{out}, H_{out}, W_{out})$ = *output_ratio* * (D_{in}, H_{in}, W_{in}) .
- **argmax** (Tensor) - The indices along with the outputs, which is a Tensor, with the same shape as the *y* and int32 data type. It will output only when *return_indices* is True.

Raises

- **TypeError** – If *input* is not a 4D or 5D tensor.

- **TypeError** – If *_random_samples* is not a 3D tensor.
- **TypeError** – If data type of *imput_x* is not float16, float32, float64.
- **TypeError** – If dtype of *_random_samples* is not float16, float32, float64.
- **TypeError** – If dtype of *argmax* is not int32, int64.
- **TypeError** – if _random_samples to have the different dtypes as input.
- **ValueError** – If *output_size* is a tuple and if *output_size* length is not 3.
- **ValueError** – If *kernel_size* is a tuple and if *kernel_size* length is not 3.
- **ValueError** – If numbers in *output_size* or *kernel_size* is not positive.
- **ValueError** – if *output_size* and *output_ratio* are None at the same time.
- **ValueError** – If the first dimension size of *input* and *_random_samples* is not equal.
- **ValueError** – If the second dimension size of *input* and *_random_samples* is not equal.
- **ValueError** – If the third dimension size of *_random_samples* is not 3.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = ms.Tensor(np.array([1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16])
...               .reshape([1, 1, 2, 2, 4]), ms.float32)
>>> _random_samples = ms.Tensor(np.array([0.7, 0.7, 0.7]).reshape([1, 1, 3]), ms.float32)
>>> net = ms.nn.FractionalMaxPool3d(kernel_size=(1, 1, 1), output_size=(1, 1, 3),
...                                 _random_samples=_random_samples, return_indices=True)
>>> output, argmax = net(x)
>>> print(output)
[[[[[13. 14. 16.]]]]]
>>> print(argmax)
[[[[[12 13 15]]]]]
>>> net = ms.nn.FractionalMaxPool3d(kernel_size=(1, 1, 1), output_ratio=(0.5, 0.5, 0.5),
...                                 _random_samples=_random_samples, return_indices=True)
>>> output, argmax = net(x)
>>> print(output)
[[[[[13. 16.]]]]]
>>> print(argmax)
[[[[[12 15]]]]]
```

3.12.11 mindspore.nn.LPPool1d

class mindspore.nn.**LPPool1d**(*norm_type*, *kernel_size*, *stride=None*, *ceil_mode=False*)

Applying 1D LPPooling operation on an input Tensor can be regarded as forming a 1D input plane.

Typically the input is of shape (N_{in}, C_{in}, L_{in}) or (C_{in}, L_{in}), the output is of shape $(N_{out}, C_{out}, L_{out})$ or (C_{out}, L_{out}), with the same shape as input, the operation is as follows.

$$f(X) = \sqrt[p]{\sum_{x \in X} x^p}$$

Note: This interface currently does not support Atlas A2 training series products.

Parameters

- **norm_type** (*Union[int, float]*) –Type of normalization, represents p in the formula, can not be 0.
  - if p = 1, the result is the sum of the elements within the pooling kernel(proportional to average pooling).
  - if p = ∞, the result is the result of maximum pooling.
- **kernel_size** (*int*) –The size of kernel window.
- **stride** (*int*) –The distance of kernel moving, an int number that represents the width of movement is stride, if the value is None, the default value *kernel_size* is used. Default: `None` .
- **ceil_mode** (*bool*) –If `True`, use ceil to calculate output shape. If `False`, use ceil to calculate output shape. Default: `False` .

Inputs:

- **x** (Tensor) - Tensor of shape (N_{in}, C_{in}, L_{in}) or (C_{in}, L_{in}).

Outputs:

- **output** (Tensor) - LPPool1d result, with shape $(N_{out}, C_{out}, L_{out})$ or (C_{out}, L_{out}), it has the same data type as x, where

$$L_{out} = \left\lfloor \frac{L_{in} - \text{kernel\_size}}{\text{stride}} + 1 \right\rfloor$$

Raises

- **TypeError** –If x is not a Tensor.
- **TypeError** –If *kernel_size* or *stride* is not an int.
- **TypeError** –If *ceil_mode* is not a bool.
- **TypeError** –If *norm_type* is neither float nor int.
- **ValueError** –If *norm_type* is equal to 0.
- **ValueError** –If *kernel_size* or *stride* is less than 1.
- **ValueError** –If length of shape of x is not equal to 2 or 3.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> a = ms.Tensor(np.arange(2 * 3 * 4).reshape((2, 3, 4)), dtype=ms.float32)
>>> net = ms.nn.LPPool1d(norm_type=1, kernel_size=3, stride=1)
>>> out = net(a)
>>> print(out)
[[[ 3.  6.]
  [15. 18.]
  [27. 30.]]
 [[39. 42.]
  [51. 54.]
  [63. 66.]]]
```

3.12.12 mindspore.nn.LPPool2d

class mindspore.nn.**LPPool2d**(*norm_type*, *kernel_size*, *stride=None*, *ceil_mode=False*)

Applying 2D LPPooling operation on an input Tensor can be regarded as forming a 1D input plane.

Typically the input is of shape (N, C, H_{in}, W_{in}), the output is of shape (N, C, H_{in}, W_{in}), with the same shape as input, the operation is as follows.

$$f(X) = \sqrt[p]{\sum_{x \in X} x^p}$$

Note: This interface currently does not support Atlas A2 training series products.

Parameters

- **norm_type** (*Union[int, float]*) –Type of normalization, represents p in the formula, can not be 0.
  - if p = 1, the result is the sum of the elements within the pooling kernel(proportional to average pooling).
  - if p = ∞, the result is the result of maximum pooling.
- **kernel_size** (*Union[int, tuple[int]]*) –The size of kernel window. The data type of kernel_size must be int and the value represents the height and width, or a tuple of two int numbers that represent height and width respectively.
- **stride** (*Union[int, tuple[int]]*) –The distance of kernel moving, an int number that represents the height and width of movement are both stride, or a tuple of two int numbers that represent height and width of movement respectively, if the value is `None`, the default value *kernel_size* is used. Default: `None` .
- **ceil_mode** (*bool*) –Whether to use ceil or floor to calculate output shape. Default: `False` .

Inputs:

- **x** (Tensor) - Tensor of shape (N, C, H_{in}, W_{in}).

Outputs:

- **output** (Tensor) - LPPool2d result, with shape (N, C, H_{in}, W_{in}), It has the same data type as x, where

$$H_{out} = \left\lfloor \frac{H_{in} - \text{kernel\_size}[0]}{\text{stride}[0]} + 1 \right\rfloor$$

$$W_{out} = \left\lfloor \frac{W_{in} - \text{kernel\_size}[1]}{\text{stride}[1]} + 1 \right\rfloor$$

Raises

- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If *kernel_size* or *stride* is neither int nor tuple.
- **TypeError** – If *ceil_mode* is not a bool.
- **TypeError** – If *norm_type* is neither float nor int.
- **ValueError** – If *norm_type* is equal to 0.
- **ValueError** – If *kernel_size* or *stride* is less than 1.
- **ValueError** – If *kernel_size* or *stride* is a tuple whose length is not equal to *2*.
- **ValueError** – If length of shape of *x* is not equal to 4.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> a = ms.Tensor(np.arange(2 * 3 * 4 * 5).reshape((2, 3, 4, 5)), dtype=ms.float32)
>>> net = ms.nn.LPPool2d(norm_type=1, kernel_size=3, stride=1)
>>> out = net(a)
>>> print(out)

3.12.13 mindspore.nn.MaxPool1d

class mindspore.nn.**MaxPool1d**(*kernel_size=1*, *stride=1*, *pad_mode='valid'*, *padding=0*, *dilation=1*, *return_indices=False*, *ceil_mode=False*)

Applies a 1D max pooling over an input Tensor which can be regarded as a composition of 1D planes.

Typically the input is of shape (N_{in}, C_{in}, L_{in}), MaxPool1d outputs regional maximum in the (L_{in})-dimension. Given *kernel size* $ks = (l_{ker})$ and *stride* $s = (s_0)$, the operation is as follows:

$$\text{output}(N_i, C_j, l) = \max_{n=0,\ldots,l_{ker}-1} \text{input}(N_i, C_j, s_0 \times l + n)$$

Parameters

- **kernel_size** (*int, optional*) – The size of kernel used to take the max value. Default: `1` .
- **stride** (*int, optional*) – The distance of kernel moving, an int number that represents the width of movement is stride. Default: `1` .
- **pad_mode** (*str, optional*) – Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"valid"` .
  - `"same"`: Pad the input at the begin and end so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally. If the amount is even, it is uniformly distributed around the input, if it is odd, the excess padding is goes to the right side. If this mode is set, *padding* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible length. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *padding* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding at the begin and end is determined by the *padding* parameter. If this mode is set, *padding* must be greater than or equal to 0.
- **padding** (*Union(int, tuple[int], list[int]), optional*) – Padding value for the pooling. Default value is `0`. padding can only be an integer or a tuple/list containing a single integer, in which case padding times or padding[0] times are padded on both sides of the input.
- **dilation** (*Union(int, tuple[int]), optional*) – The spacing between the elements of the kernel in convolution, used to increase the receptive field of the pooling operation. If it is a tuple, its length can only be 1. Default: `1` .
- **return_indices** (*bool, optional*) – If `True` , the function will return both the result of max pooling and the indices of the max elements. Default: `False` .
- **ceil_mode** (*bool, optional*) – If True, use ceil to compute the output shape instead of floor. Default: `False` .

Inputs:

- **x** (Tensor) - Tensor of shape (N, C_{in}, L_{in}) or (C_{in}, L_{in}).

Outputs:

If *return_indices* is `False`, output is a Tensor, with shape (N, C_{out}, L_{out}) or (C_{out}, L_{out}). It has the same data type as *x*.

If *return_indices* is `True`, output is a Tuple of 2 Tensors, representing the maxpool result and where the max values are generated.

- **output** (Tensor) - Maxpooling result, with shape (N, C_{out}, L_{out}) or (C_{out}, L_{out}). It has the same data type as *x*.
- **argmax** (Tensor) - Index corresponding to the maximum value. Data type is int64.

If *pad_mode* is in *pad* mode, the output shape calculation formula is as follows:

$$L_{out} = \left\lfloor \frac{L_{in} + 2 \times \text{padding} - \text{dilation} \times (\text{kernel\_size} - 1) - 1}{\text{stride}} + 1 \right\rfloor$$

Raises

- **TypeError** – If *kernel_size* or *strides* is not an int.
- **ValueError** – If *pad_mode* is not `"valid"`, `"same"` or `"pad"`, case-insensitive.
- **ValueError** – If *data_format* is neither `'NCHW'` nor `'NHWC'`.
- **ValueError** – If *kernel_size* or *strides* is less than 1.
- **ValueError** – If length of shape of *x* is not equal to 2 or 3.

- **ValueError** –If *pad_mode* is not "pad", *padding*, *dilation*, *return_indices*, *ceil_mode* parameters are not set to their default values.
- **ValueError** –If the length of the tuple/list *padding* parameter is not 1.
- **ValueError** –If The length of the tuple dilation parameter is not 1.
- **ValueError** –If dilation parameter is neither an integer nor a tuple.
- **ValueError** –If *padding* is non-zero when *pad_mode* is not "pad".

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> mpool1 = nn.MaxPool1d(kernel_size=3, stride=1)
>>> x = ms.Tensor(np.random.randint(0, 10, [1, 2, 4]), ms.float32)
>>> output = mpool1(x)
>>> result = output.shape
>>> print(result)
(1, 2, 2)
>>> np_x = np.random.randint(0, 10, [5, 3, 4])
>>> x = ms.Tensor(np_x, ms.float32)
>>> mpool2 = nn.MaxPool1d(kernel_size=2, stride=1, pad_mode="pad", padding=1, dilation=1,␣
↪return_indices=True)
>>> output = mpool2(x)
>>> print(output[0].shape)
(5, 3, 5)
>>> print(output[1].shape)
(5, 3, 5)
```

3.12.14 mindspore.nn.MaxPool2d

class mindspore.nn.**MaxPool2d**(*kernel_size=1*, *stride=1*, *pad_mode='valid'*, *padding=0*, *dilation=1*, *return_indices=False*, *ceil_mode=False*, *data_format='NCHW'*)

Applies a 2D max pooling over an input Tensor which can be regarded as a composition of 2D planes.

Typically the input is of shape $(N_{in}, C_{in}, H_{in}, W_{in})$, MaxPool2d outputs regional maximum in the (H_{in}, W_{in})-dimension. Given kernel size (h_{ker}, w_{ker}) and stride (s_0, s_1), the operation is as follows.

$$\text{output}(N_i, C_j, h, w) = \max_{m=0,\ldots,h_{ker}-1} \max_{n=0,\ldots,w_{ker}-1} \text{input}(N_i, C_j, s_0 \times h + m, s_1 \times w + n)$$

Parameters

- **kernel_size** (*Union[int, tuple[int]]*) –The size of kernel used to take the max value, is an int number or a single element tuple that represents height and width are both kernel_size, or a tuple of two int numbers that represent height and width respectively. Default: 1 .
- **stride** (*Union[int, tuple[int]]*) –The distance of kernel moving, an int number or a single element tuple that represents the height and width of movement are both stride, or a tuple of two int numbers that represent height and width of movement respectively. Default: 1 .

- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"valid"` .
  - `"same"`: Pad the input around its edges so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally, If the amount is even, it is uniformly distributed around the input, if it is odd, the excess amount goes to the right/bottom side. If this mode is set, *padding* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *padding* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the height and width directions is determined by the *padding* parameter. If this mode is set, *padding* must be greater than or equal to 0.
- **padding** (*Union(int, tuple[int], list[int])*) –Specifies the padding value of the pooling operation. Default: `0` . *padding* can only be an integer or a tuple/list containing one or two integers. If *padding* is an integer or a tuple/list containing one integer, it will be padded *padding* times in the four directions of the input. If *padding* is a tuple/list containing two integers, it will be padded *padding[0]* times in the up-down direction of the input and *padding[1]* times in the left-right direction of the input.
- **dilation** (*Union(int, tuple[int])*) –The spacing between the elements of the kernel in convolution, used to increase the receptive field of the pooling operation. If it is a tuple, it must contain one or two integers. Default: `1` .
- **return_indices** (*bool*) –If `True` , the function will return both the result of max pooling and the indices of the max elements. Default: `False` .
- **ceil_mode** (*bool*) –If `True` , use ceil to compute the output shape instead of floor. Default: `False` .
- **data_format** (*str*) –The optional value for data format, is `'NHWC'` or `'NCHW'` . Default: `'NCHW'` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, H_{in}, W_{in})$ or (C_{in}, H_{in}, W_{in}).

Outputs:

If *return_indices* is False, output is a Tensor, with shape (N, C, H_{out}, W_{out}) or $(C_{out}, H_{out}, W_{out})$. It has the same data type as *x*.

If *return_indices* is True, output is a Tuple of 2 Tensors, representing the maxpool result and where the max values are generated.

- **output** (Tensor) - Maxpooling result, with shape $(N_{out}, C_{out}, H_{out}, W_{out})$ or $(C_{out}, H_{out}, W_{out})$. It has the same data type as *x*.
- **argmax** (Tensor) - Index corresponding to the maximum value. Data type is int64.

If *pad_mode* is in *pad* mode, the output shape calculation formula is as follows:

$$H_{out} = \left\lfloor \frac{H_{in} + 2 * \text{padding}[0] - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) - 1}{\text{stride}[0]} + 1 \right\rfloor$$

$$W_{out} = \left\lfloor \frac{W_{in} + 2 * \text{padding}[1] - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) - 1}{\text{stride}[1]} + 1 \right\rfloor$$

Raises

- **TypeError** –If *kernel_size* or *stride* is neither int nor tuple.
- **ValueError** –If *pad_mode* is neither `"valid"` nor `"same"` with not case sensitive.
- **ValueError** –If *data_format* is neither `'NCHW'` nor `'NHWC'` .
- **ValueError** –If *kernel_size* or *stride* is less than 1.

- **ValueError** – If length of shape of *x* is not equal to 3 or 4.
- **ValueError** – If *pad_mode* is not "pad", *padding*, *dilation*, *return_indices*, *ceil_mode* parameters are not set to their default values.
- **ValueError** – If the length of the tuple/list *padding* parameter is not 2.
- **ValueError** – If The length of the tuple dilation parameter is not 2.
- **ValueError** – If dilation parameter is neither an integer nor a tuple.
- **ValueError** – If *pad_mode* is "pad" and *data_format* is 'NHWC'.
- **ValueError** – If *padding* is non-zero when *pad_mode* is not "pad".

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> pool = ms.nn.MaxPool2d(kernel_size=3, stride=1)
>>> x = ms.Tensor(np.random.randint(0, 10, [1, 2, 4, 4]), ms.float32)
>>> output = pool(x)
>>> print(output.shape)
(1, 2, 2, 2)
>>> np_x = np.random.randint(0, 10, [5, 3, 4, 5])
>>> x = ms.Tensor(np_x, ms.float32)
>>> pool2 = ms.nn.MaxPool2d(kernel_size=2, stride=1, pad_mode="pad", padding=1, dilation=1,␣
↪return_indices=True)
>>> output = pool2(x)
>>> print(output[0].shape)
(5, 3, 5, 6)
>>> print(output[1].shape)
(5, 3, 5, 6)
```

3.12.15 mindspore.nn.MaxPool3d

class mindspore.nn.**MaxPool3d**(*kernel_size=1*, *stride=1*, *pad_mode='valid'*, *padding=0*, *dilation=1*, *return_indices=False*, *ceil_mode=False*)

3D max pooling operation.

Applies a 3D max pooling over an input Tensor which can be regarded as a composition of 3D planes.

Typically the input is of shape $(N_{in}, C_{in}, D_{in}, H_{in}, W_{in})$, MaxPool outputs regional maximum in the (D_{in}, H_{in}, W_{in})-dimension. Given kernel size is $ks = (d_{ker}, h_{ker}, w_{ker})$ and stride is $s = (s_0, s_1, s_2)$, the operation is as follows.

$$\text{output}(N_i, C_j, d, h, w) = \max_{l=0,\ldots,d_{ker}-1} \max_{m=0,\ldots,h_{ker}-1} \max_{n=0,\ldots,w_{ker}-1} \text{input}(N_i, C_j, s_0 \times d + l, s_1 \times h + m, s_2 \times w + n)$$

Note: For Atlas training series products, this interface is not supported.

Parameters

- **kernel_size** (*Union[int, tuple[int]], optional*) –The size of kernel used to take the maximum value, is an int number or a single element tuple that represents depth, height and width of the kernel, or a tuple of three int numbers that represent depth, height and width respectively. The value must be a positive integer. Default: `1` .
- **stride** (*Union[int, tuple[int]], optional*) –The moving stride of pooling operation, an int number or a single element tuple that represents the moving stride of pooling kernel in the directions of depth, height and the width, or a tuple of three int numbers that represent depth, height and width of movement respectively. The value must be a positive integer. If the value is None, the default value *kernel_size* is used. Default: `1` .
- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"valid"` .
  - `"same"`: Pad the input around its depth/height/width dimension so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally. If the amount is even, it isuniformly distributed around the input, if it is odd, the excess amount goes to the front/right/bottom side. If this mode is set, *padding* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible depth, height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *padding* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the depth, height and width dimension is determined by the *padding* parameter. If this mode is set, *padding* must be greater than or equal to 0.
- **padding** (*Union(int, tuple[int], list[int]), optional*) –Pooling padding value. Default: `0` . *padding* can only be an integer or a tuple/list containing one or three integers. If *padding* is an integer or a tuple/list containing one integer, it will be padded in six directions of front, back, top, bottom, left and right of the input. If *padding* is a tuple/list containing three integers, it will be padded in front and back of the input *padding[0]* times, up and down *padding[1]* times, and left and right of the input *padding[2]* times.
- **dilation** (*Union(int, tuple[int]), optional*) –The spacing between the elements of the kernel in convolution, used to increase the receptive field of the pooling operation. If it is a tuple, it must contain one or three integers. Default: `1` .
- **return_indices** (*bool, optional*) –If `True` , output is a Tuple of 2 Tensors, representing the maxpool result and where the max values are generated. Otherwise, only the maxpool result is returned. Default: `False` .
- **ceil_mode** (*bool, optional*) –If `True`, use ceil to calculate output shape. If `False`, use ceil to calculate output shape. Default: `False` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N_{in}, C_{in}, D_{in}, H_{in}, W_{in})$ or $(C_{in}, D_{in}, H_{in}, W_{in})$.

Outputs:

If *return_indices* is False, output is a Tensor, with shape $(N_{out}, C_{out}, D_{out}, H_{out}, W_{out})$ or $(C_{out}, D_{out}, H_{out}, W_{out})$. It has the same data type as *x*.

If *return_indices* is True, output is a Tuple of 2 Tensors, representing the maxpool result and where the max values are generated.

- **output** (Tensor) - Maxpooling result, with shape $(N_{out}, C_{out}, D_{out}, H_{out}, W_{out})$ or $(C_{out}, D_{out}, H_{out}, W_{out})$. It has the same data type as *x*.
- **argmax** (Tensor) - Index corresponding to the maximum value. Data type is int64.

If *pad_mode* is in `"pad"` mode, the output shape calculation formula is as follows:

$$D_{out} = \left\lfloor \frac{D_{in} + 2 \times \text{padding}[0] - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) - 1}{\text{stride}[0]} + 1 \right\rfloor$$

$$H_{out} = \left\lfloor \frac{H_{in} + 2 \times \text{padding}[1] - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) - 1}{\text{stride}[1]} + 1 \right\rfloor$$

$$W_{out} = \left\lfloor \frac{W_{in} + 2 \times \text{padding}[2] - \text{dilation}[2] \times (\text{kernel\_size}[2] - 1) - 1}{\text{stride}[2]} + 1 \right\rfloor$$

Raises

- **ValueError** – If length of shape of *x* is not equal to 4 or 5.
- **TypeError** – If *kernel_size* , *stride* , *padding* or *dilation* is neither an int nor a tuple.
- **ValueError** – If *kernel_size* or *stride* is less than 1.
- **ValueError** – If the *padding* parameter is neither an integer nor a tuple of length 3.
- **ValueError** – If *pad_mode* is not set to `"pad"`, setting return_indices to True or dilation to a value other than 1.
- **ValueError** – If *padding* is non-zero when *pad_mode* is not `"pad"`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> from mindspore import Tensor
>>> import numpy as np
>>> np_x = np.random.randint(0, 10, [5, 3, 4, 6, 7])
>>> x = Tensor(np_x, ms.float32)
>>> pool1 = nn.MaxPool3d(kernel_size=2, stride=1, pad_mode="pad", padding=1, dilation=3,␣
↪return_indices=True)
>>> output = pool1(x)
>>> print(output[0].shape)
(5, 3, 3, 5, 6)
>>> print(output[1].shape)
(5, 3, 3, 5, 6)
>>> pool2 = nn.MaxPool3d(kernel_size=2, stride=1, pad_mode="pad", padding=1, dilation=3,␣
↪return_indices=False)
>>> output2 = pool2(x)
>>> print(output2.shape)
(5, 3, 3, 5, 6)
```

3.12.16 mindspore.nn.MaxUnpool1d

class mindspore.nn.**MaxUnpool1d**(*kernel_size*, *stride=None*, *padding=0*)

Computes the inverse of *mindspore.nn.MaxPool1d*.

MaxUnpool1d keeps the maximal value and set all position of non-maximal values to zero. Typically the input is of shape (N, C, H_{in}) or (C, H_{in}), and the output is of shape (N, C, H_{out}) or (C, H_{out}). The operation is as follows.

$$H_{out} = (H_{in} - 1) \times stride[0] - 2 \times padding[0] + kernel\_size[0]$$

Parameters

- **kernel_size** (*Union[int, tuple[int]]*) – The size of kernel used to take the maximum value.
- **stride** (*Union[int, tuple[int]]*) – The distance of kernel moving, If stride is None, then stride equal to kernel_size. Default: `None` .

- **padding** (*Union[int, tuple[int]]*) –The pad value to be filled. Default: `0` .

Inputs:

- **x** (Tensor) - The input Tensor to invert. Tensor of shape (N, C, H_{in}) or (C, H_{in}).
- **indices** (Tensor) - Max values' index represented by the indices. Tensor of shape must be same with input 'x'. Values of indices must belong to $[0, H_{in} - 1]$. Data type must be in int32 or int64.
- **output_size** (tuple[int], optional) - The output size. Default: `None` . If output_size is `None`, then the shape of output computed by kernel_size, stride and padding. If output_size is not `None`, then output_size must be (N, C, H) , (C, H) or (H) and output_size must belong to $[(N, C, H_{out} - stride[0]), (N, C, H_{out} + stride[0])]$.

Outputs:

Tensor, with shape (N, C, H_{out}) or (C, H_{out}), with the same data type with *x*.

Raises

- **TypeError** –If data type of *x* or *indices* is not supported.
- **TypeError** –If *kernel_size*, *stride* or *padding* is neither an int nor a tuple.
- **ValueError** –If numbers in *stride*, *padding* (also support 0 and (0)) or *kernel_size* is not positive.
- **ValueError** –If the shapes of *x* and *indices* are not equal.
- **ValueError** –If *x* whose length is not 2 or 3.
- **ValueError** –If type of *output_size* is not tuple.
- **ValueError** –If *output_size* whose length is not 0, 2 or 3.
- **ValueError** –If *output_size* is not close to output size computed by attr *kernel_size*, *stride*, *padding*.

Supported Platforms:

`GPU CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> x = ms.Tensor(np.array([[2, 4, 6, 8]]).astype(np.float32))
>>> indices = ms.Tensor(np.array([[1, 3, 5, 7]]).astype(np.int64))
>>> maxunpool1d = ms.nn.MaxUnpool1d(kernel_size =2, stride=2, padding=0)
>>> output = maxunpool1d(x, indices)
>>> print(output.asnumpy())
[[0. 2. 0. 4. 0. 6. 0. 8.]]
```

3.12.17 mindspore.nn.MaxUnpool2d

class mindspore.nn.**MaxUnpool2d**(*kernel_size*, *stride=None*, *padding=0*)

Computes the inverse of *mindspore.nn.MaxPool2d*.

MaxUnpool2d keeps the maximal value and set all position of non-maximal values to zero. Typically the input is of shape (N, C, H_{in}, W_{in}) or (C, H_{in}, W_{in}), and the output is of shape (N, C, H_{out}, W_{out}) or (C, H_{out}, W_{out}). The operation is as follows.

$$H_{out} = (H_{in} - 1) \times stride[0] - 2 \times padding[0] + kernel\_size[0]$$
$$W_{out} = (W_{in} - 1) \times stride[1] - 2 \times padding[1] + kernel\_size[1]$$

Parameters

- **kernel_size** (*Union[int, tuple[int]]*) – The size of kernel used to take the maximum value, an int number that represents height and width of the kernel, or a tuple of two int numbers that represent height and width respectively.
- **stride** (*Union[int, tuple[int]]*) – The distance of kernel moving, an int number that represents the height and width of movement are both stride, or a tuple of two int numbers that represent height and width of movement respectively. If stride is `None`, then stride equal to kernel_size. Default: `None` .
- **padding** (*Union[int, tuple[int]]*) – The pad value to be filled. Default: `0` . If *padding* is an integer, the paddings of height and width are the same, equal to padding. If *padding* is a tuple of two integers, the padding of height and width equal to padding[0] and padding[1] correspondingly.

Inputs:

- **x** (Tensor) - The input Tensor to invert. Tensor of shape (N, C, H_{in}, W_{in}) or (C, H_{in}, W_{in}).
- **indices** (Tensor) - Max values' index represented by the indices. Tensor of shape must be same with input 'x'. Values of indices must belong to $[0, H_{in} \times W_{in} - 1]$. Data type must be in int32 or int64.
- **output_size** (tuple[int], optional) - The output size. Default: `None` . If output_size is `None`, then the shape of output computed by kernel_size, stride and padding. If output_size is not `None`, then output_size must be (N, C, H, W), (C, H, W) or (H, W) and output_size must belong to $[(N, C, H_{out} - stride[0], W_{out} - stride[1]), (N, C, H_{out} + stride[0], W_{out} + stride[1])]$.

Outputs:

Tensor, with shape (N, C, H_{out}, W_{out}) or (C, H_{out}, W_{out}), with the same data type with *x*.

Raises

- **TypeError** – If data type of *x* or *indices* is not supported.
- **TypeError** – If *kernel_size*, *stride* or *padding* is neither an int nor a tuple.
- **ValueError** – If numbers in *stride*, *padding* (also support 0 and (0, 0)) or *kernel_size* is not positive.
- **ValueError** – If the shape of *x* and *indices* are not equal.
- **ValueError** – If *kernel_size*, *stride* or *padding* is a tuple whose length is not equal to 2.
- **ValueError** – If *x* whose length is not 3 or 4.
- **ValueError** – If *output_size* whose type is not tuple.
- **ValueError** – If *output_size* whose length is not 0, 3 or 4.
- **ValueError** – If *output_size* is not close to output size computed by attr *kernel_size*, *stride*, *padding*.

Supported Platforms:

`GPU CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> x = ms.Tensor(np.array([[[[0, 1], [8, 9]]]]).astype(np.float32))
>>> indices = ms.Tensor(np.array([[[[0, 1], [2, 3]]]]).astype(np.int64))
>>> maxunpool2d = ms.nn.MaxUnpool2d(kernel_size=1, stride=1, padding=0)
>>> output = maxunpool2d(x, indices)
>>> print(output.asnumpy())
[[[[0. 1.]
   [8. 9.]]]]
```

3.12.18 mindspore.nn.MaxUnpool3d

class mindspore.nn.**MaxUnpool3d**(*kernel_size*, *stride=None*, *padding=0*)

Computes the inverse of *mindspore.nn.MaxPool3d*.

MaxUnpool3d keeps the maximal value and set all position of non-maximal values to zero. Typically the input is of shape $(N, C, D_{in}, H_{in}, W_{in})$ or $(C, D_{in}, H_{in}, W_{in})$, and the output is of shape $(N, C, D_{out}, H_{out}, W_{out})$ or $(C, D_{out}, H_{out}, W_{out})$. The operation is as follows.

$$
\begin{aligned}
D_{out} &= (D_{in} - 1) \times stride[0] - 2 \times padding[0] + kernel\_size[0] \\
H_{out} &= (H_{in} - 1) \times stride[1] - 2 \times padding[1] + kernel\_size[1] \\
W_{out} &= (W_{in} - 1) \times stride[2] - 2 \times padding[2] + kernel\_size[2]
\end{aligned}
$$

Parameters

- **kernel_size** (*Union[int, tuple[int]]*) – The size of kernel used to take the maximum value, an int number that represents depth, height and width of the kernel, or a tuple of three int numbers that represent depth, height and width respectively.
- **stride** (*Union[int, tuple[int]]*) – The distance of kernel moving, an int number that represents the depth, height and width of movement are both stride, or a tuple of three int numbers that represent depth, height and width of movement respectively. If stride is `None`, then stride equal to kernel_size. Default: `None` .
- **padding** (*Union[int, tuple[int]]*) – The pad value to be filled. Default: `0` . If *padding* is an integer, the paddings of depth, height and width are the same, equal to padding. If *padding* is a tuple of three integers, the padding of depth, height and width equal to padding[0], padding[1] and padding[2] correspondingly.

Inputs:

- **x** (Tensor) - The input Tensor to invert. Tensor of shape $(N, C, D_{in}, H_{in}, W_{in})$ or $(C, D_{in}, H_{in}, W_{in})$.
- **indices** (Tensor) - Max values' index represented by the indices. Tensor of shape must be same with input 'x'. Values of indices must belong to $[0, D_{in} \times H_{in} \times W_{in} - 1]$. Data type must be in int32 or int64.
- **output_size** (tuple[int], optional) - The output size. Default: `None` . If output_size is `None`, then the shape of output computed by kernel_size, stride and padding. If output_size is not `None`, then output_size must be (N, C, D, H, W) , (C, D, H, W) or (D, H, W) and output_size must belong to $[(N, C, D_{out} - stride[0], H_{out} - stride[1], W_{out} - stride[2]), (N, C, D_{out} + stride[0], H_{out} + stride[1], W_{out} + stride[2])]$.

Outputs:

Tensor, with shape $(N, C, D_{out}, H_{out}, W_{out})$ or $(C, D_{out}, H_{out}, W_{out})$, with the same data type with x.

Raises

- **TypeError** – If data type of *x* or *indices* is not supported.
- **TypeError** – If *kernel_size*, *stride* or *padding* is neither an int nor a tuple.
- **ValueError** – If numbers in *stride* or *padding* (also support 0 and (0, 0, 0)) or *kernel_size* is not positive.
- **ValueError** – If the shape of *x* and *indices* are not equal.
- **ValueError** – If *kernel_size*, *stride* or *padding* is a tuple whose length is not equal to 3.
- **ValueError** – If *x* whose length is not 4 or 5.
- **ValueError** – If *output_size* whose length is not 0, 4 or 5.
- **ValueError** – If *output_size* whose type is not tuple.
- **ValueError** – If *output_size* is not close to output size computed by attr *kernel_size*, *stride*, *padding*.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> x = ms.Tensor(np.array([[[[[0, 1], [8, 9]]]]]).astype(np.float32))
>>> indices= ms.Tensor(np.array([[[[[0, 1], [2, 3]]]]]).astype(np.int64))
>>> maxunpool3d = ms.nn.MaxUnpool3d(kernel_size=1, stride=1, padding=0)
>>> output = maxunpool3d(x, indices)
>>> print(output.asnumpy())
[[[[[0. 1.]
    [8. 9.]]]]]
```

3.13 Padding Layer

API Name	Description	Supported Platforms
mindspore.nn.Pad	Pads the input tensor according to the paddings and mode.	Ascend GPU CPU
mindspore.nn.ConstantPad1d	Using a given constant value to pads the last dimensions of input tensor.	Ascend GPU CPU
mindspore.nn.ConstantPad2d	Using a given constant value to pads the last two dimensions of input tensor.	Ascend GPU CPU
mindspore.nn.ConstantPad3d	Using a given constant value to pads the last three dimensions of input tensor.	Ascend GPU CPU
mindspore.nn.ReflectionPad1d	Using a given padding to do reflection pad on the given tensor.	Ascend GPU CPU
mindspore.nn.ReflectionPad2d	Using a given padding to do reflection pad the given tensor.	Ascend GPU CPU
mindspore.nn.ReflectionPad3d	Pad the given tensor in a reflecting way using the input boundaries as the axis of symmetry.	Ascend GPU CPU
mindspore.nn.ReplicationPad1d	Pad on W dimension of input *x* according to *padding*.	GPU

continues on next page

Table 13 – continued from previous page

mindspore.nn.ReplicationPad2d	Pad on HW dimension of input *x* according to *padding*.	GPU
mindspore.nn.ReplicationPad3d	Pad on DHW dimension of input *x* according to *padding*.	GPU
mindspore.nn.ZeroPad2d	Pads the last two dimensions of input tensor with zero.	Ascend GPU CPU

3.13.1 mindspore.nn.Pad

class mindspore.nn.**Pad**(*paddings*, *mode='CONSTANT'*)

Pads the input tensor according to the paddings and mode.

Parameters

- **paddings** (*tuple*) –The shape of parameter *paddings* is $(N, 2)$. N is the rank of input data. All elements of paddings are int type. For D th dimension of the x, paddings[D, 0] indicates how many sizes to be extended ahead of the D th dimension of the input tensor, and paddings[D, 1] indicates how many sizes to be extended behind of the D th dimension of the input tensor. The padded size of each dimension D of the output is: $paddings[D, 0] + input\_x.dim\_size(D) + paddings[D, 1]$, e.g.:

```
mode = "CONSTANT".
paddings = [[1,1], [2,2]].
x = [[1,2,3], [4,5,6], [7,8,9]].
# The above can be seen: 1st dimension of `x` is 3, 2nd dimension of `x` is 3.
# Substitute into the formula to get:
# 1st dimension of output is paddings[0][0] + 3 + paddings[0][1] = 1 + 3 + 1 = 5.
# 2nd dimension of output is paddings[1][0] + 3 + paddings[1][1] = 2 + 3 + 2 = 7.
# So the shape of output is (5, 7).
```

- **mode** (*str*) –Specifies padding mode. The optional values are "CONSTANT" , "REFLECT" , "SYMMETRIC" . Default: "CONSTANT" .

Inputs:

- **x** (Tensor) - The input tensor.

Outputs:

Tensor, the tensor after padding.

- If *mode* is "CONSTANT", it fills the edge with 0, regardless of the values of the *x*. If the *x* is [[1,2,3], [4,5,6], [7,8,9]] and *paddings* is [[1,1], [2,2]], then the Outputs is [[0,0,0,0,0,0,0], [0,0,1,2,3,0,0], [0,0,4,5,6,0,0], [0,0,7,8,9,0,0], [0,0,0,0,0,0,0]].
- If *mode* is "REFLECT", it uses a way of symmetrical copying through the axis of symmetry to fill in. If the *x* is [[1,2,3], [4,5,6], [7,8,9]] and *paddings* is [[1,1], [2,2]], then the Outputs is [[6,5,4,5,6,5,4], [3,2,1,2,3,2,1], [6,5,4,5,6,5,4], [9,8,7,8,9,8,7], [6,5,4,5,6,5,4]].
- If *mode* is "SYMMETRIC", the filling method is similar to the "REFLECT". It is also copied according to the symmetry axis, except that it includes the symmetry axis. If the *x* is [[1,2,3], [4,5,6], [7,8,9]] and *paddings* is [[1,1], [2,2]], then the Outputs is [[2,1,1,2,3,3,2], [2,1,1,2,3,3,2], [5,4,4,5,6,6,5], [8,7,7,8,9,9,8], [8,7,7,8,9,9,8]].

Raises

- **TypeError** –If *paddings* is not a tuple.
- **ValueError** –If length of *paddings* is more than 4 or its shape is not $(N, 2)$.

- **ValueError** – If *mode* is not one of "CONSTANT", "REFLECT", "SYMMETRIC".

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn, ops
>>> import numpy as np
>>> # If `mode` is "CONSTANT"
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.pad = nn.Pad(paddings=((1, 1), (2, 2)), mode="CONSTANT")
...     def construct(self, x):
...         return self.pad(x)
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6]]), mindspore.float32)
>>> pad = Net()
>>> output = pad(x)
>>> print(output)
[[0. 0. 0. 0. 0. 0. 0.]
 [0. 0. 1. 2. 3. 0. 0.]
 [0. 0. 4. 5. 6. 0. 0.]
 [0. 0. 0. 0. 0. 0. 0.]]
>>> # Another way to call
>>> pad = ops.Pad(paddings=((1, 1), (2, 2)))
>>> # From the above code, we can see following:
>>> # "paddings=((1, 1), (2, 2))",
>>> # paddings[0][0] = 1, indicates a row of values is filled top of the input data in the␣
↪1st dimension.
>>> # Shown as follows:
>>> # [[0. 0. 0.]
>>> #  [1. 2. 3.]
>>> #  [4. 5. 6.]]
>>> # paddings[0][1] = 1 indicates a row of values is filled below input data in the 1st␣
↪dimension.
>>> # Shown as follows:
>>> # [[0. 0. 0.]
>>> #  [1. 2. 3.]
>>> #  [4. 5. 6.]
>>> #  [0. 0. 0.]]
>>> # paddings[1][0] = 2, indicates 2 rows of values is filled in front of input data in the␣
↪2nd dimension.
>>> # Shown as follows:
>>> # [[0. 0. 0. 0. 0.]
>>> #  [0. 0. 1. 2. 3.]
>>> #  [0. 0. 4. 5. 6.]
>>> #  [0. 0. 0. 0. 0.]]
>>> # paddings[1][1] = 2, indicates 2 rows of values is filled in front of input data in the␣
↪2nd dimension.

 [5. 4. 4. 5. 6. 6. 5.]]
```

3.13.2 mindspore.nn.ConstantPad1d

class mindspore.nn.**ConstantPad1d**(*padding*, *value*)

Using a given constant value to pads the last dimensions of input tensor.

Parameters

- **padding** (*Union[int, tuple]*) –The padding size to pad the last dimension of input tensor. If is int, uses the same padding in both boundaries of input's last dimension. If a 2-tuple, uses (padding_0, padding_1) to pad. If the input is x, the size of last dimension of output is $padding\_0 + x.shape[-1] + padding\_1$. The remaining dimensions of the output are consistent with those of the input. Only support non-negative value while running in Ascend.
- **value** (*Union[int, float]*) –Padding value.

Inputs:

- **x** (Tensor) - shape is $(N, *)$, where $*$ means, any number of additional dimensions. It is not supported that the size of dimensions is greater than 5 while running on Ascend.

Returns

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not a tuple or int.
- **TypeError** – If *value* is not int or float.
- **ValueError** – If the length of *padding* with tuple type is not equal to 2.
- **ValueError** – If the output shape after padding is not positive.
- **ValueError** – If the rank of 'x' is more than 5 while running in Ascend.
- **ValueError** – If *padding* contains negative value while running in Ascend.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = np.ones(shape=(1, 2, 3, 4)).astype(np.float32)
>>> x = ms.Tensor(x)
>>> # padding is tuple
>>> padding = (0, 1)
>>> value = 0.5
>>> pad1d = ms.nn.ConstantPad1d(padding, value)
>>> out = pad1d(x)
>>> print(out)
[[[[1.  1.  1.  1.  0.5]
   [1.  1.  1.  1.  0.5]
   [1.  1.  1.  1.  0.5]]
  [[1.  1.  1.  1.  0.5]

```

3.13.3 mindspore.nn.ConstantPad2d

class mindspore.nn.**ConstantPad2d**(*padding*, *value*)

Using a given constant value to pads the last two dimensions of input tensor.

Parameters

- **padding** (*Union[int, tuple]*) – The padding size to pad the last two dimensions of input tensor. If is int, uses the same padding in boundaries of input's last two dimensions. If is tuple and length of padding is 4 uses (padding_0, padding_1, padding_2, padding_3) to pad. If the input is x, the size of last dimension of output is $padding\_0 + x.shape[-1] + padding\_1$. The size of penultimate dimension of output is $padding\_2 + x.shape[-2] + padding\_3$. The remaining dimensions of the output are consistent with those of the input. Only support non-negative value while running in Ascend.
- **value** (*Union[int, float]*) – Padding value.

Inputs:

- **x** (Tensor) - shape is $(N, *)$, where $*$ means, any number of additional dimensions. It is not supported that the size of dimensions is greater than 5 while running on Ascend.

Returns

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not a tuple or int.
- **TypeError** – If *value* is not int or float.
- **ValueError** – If the length of *padding* is more than 4 or not a multiple of 2.
- **ValueError** – If the output shape after padding is not positive.
- **ValueError** – If the rank of 'x' is more than 5 while running in Ascend.
- **ValueError** – If *padding* contains negative value while running in Ascend.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = np.ones(shape=(1, 2, 3, 4)).astype(np.float32)
>>> x = ms.Tensor(x)
>>> padding = (1, 1, 0, 1)
>>> value = 0.5
>>> pad2d = ms.nn.ConstantPad2d(padding, value)
>>> out = pad2d(x)
>>> print(out)
[[[[0.5  1.  1.  1.  1.  0.5]
   [0.5  1.  1.  1.  1.  0.5]
   [0.5  1.  1.  1.  1.  0.5]
   [0.5  0.5 0.5 0.5 0.5 0.5]]
  [[0.5  1.  1.  1.  1.  0.5]
   [0.5  1.  1.  1.  1.  0.5]
```

(continues on next page)

(continued from previous page)

```
   [0.5  1.  1.  1.  1.  0.5]
   [0.5  0.5 0.5 0.5 0.5 0.5]]]]
>>> print(out.shape)
(1, 2, 4, 6)
```

3.13.4 mindspore.nn.ConstantPad3d

class mindspore.nn.**ConstantPad3d**(*padding*, *value*)

Using a given constant value to pads the last three dimensions of input tensor.

Parameters

- **padding** (*Union[int, tuple]*) – The padding size to pad the last three dimensions of input tensor. If is int, uses the same padding in boundaries of input's last three dimensions. If is tuple and length of padding is 6 uses (padding_0, padding_1, padding_2, padding_3, padding_4, padding_5) to pad. If the input is x, the size of last dimension of output is $padding\_0 + x.shape[-1] + padding\_1$. The size of penultimate dimension of output is $padding\_2 + x.shape[-2] + padding\_3$. The size of 3rd to last dimension of output is $padding\_4 + x.shape[-3] + padding\_5$. The remaining dimensions of the output are consistent with those of the input. Only support non-negative value while running in Ascend.
- **value** (*Union[int, float]*) – Padding value.

Inputs:

- **x** (Tensor) - shape is $(N, *)$, where $*$ means, any number of additional dimensions. It is not supported that the size of dimensions is greater than 5 while running on Ascend.

Returns

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not a tuple or int.
- **TypeError** – If *value* is not int or float.
- **ValueError** – If the length of *padding* is more than 6 or not a multiple of 2.
- **ValueError** – If the output shape after padding is not positive.
- **ValueError** – If the rank of 'x' is more than 5 while running in Ascend.
- **ValueError** – If *padding* contains negative value while running in Ascend.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = np.ones(shape=(1, 2, 3, 4)).astype(np.float32)
>>> x = ms.Tensor(x)
>>> padding = (1, 1, 0, 1, 1, 0)
>>> value = 0.5
>>> pad3d = ms.nn.ConstantPad3d(padding, value)
>>> out = pad3d(x)
>>> print(out)
[[[[0.5 0.5 0.5 0.5 0.5 0.5]
   [0.5 0.5 0.5 0.5 0.5 0.5]
   [0.5 0.5 0.5 0.5 0.5 0.5]
   [0.5 0.5 0.5 0.5 0.5 0.5]]
  [[0.5 1.  1.  1.  1.  0.5]
   [0.5 1.  1.  1.  1.  0.5]
   [0.5 1.  1.  1.  1.  0.5]
   [0.5 0.5 0.5 0.5 0.5 0.5]]
  [[0.5 1.  1.  1.  1.  0.5]
   [0.5 1.  1.  1.  1.  0.5]
   [0.5 1.  1.  1.  1.  0.5]
   [0.5 0.5 0.5 0.5 0.5 0.5]]]]
>>> print(out.shape)
(1, 3, 4, 6)
```

3.13.5 mindspore.nn.ReflectionPad1d

class mindspore.nn.**ReflectionPad1d**(*padding*)

Using a given padding to do reflection pad on the given tensor. 1d means the dimension of padding is 1-dimension.

Parameters

padding (*union[int, tuple]*) – The padding size to pad the last dimension of input tensor. If padding is an integer: all directions will be padded with the same size. If padding is a tuple: uses (pad_left, pad_right) to pad.

Inputs:

- **x** (Tensor) - 2D or 3D, shape: (C, W_{in}) or (N, C, W_{in}).

Outputs:

Tensor, after padding. Shape: (C, W_{out}) or (N, C, W_{out}), where $W_{out} = W_{in} + pad\_left + pad\_right$.

Raises

- **TypeError** – If 'padding' is not a tuple or int.
- **TypeError** – If there is an element in 'padding' that is not int.
- **ValueError** – If the length of 'padding' is not divisible by 2.
- **ValueError** – If there is an element in 'padding' that is negative.
- **ValueError** – If the there is a dimension mismatch between the padding and the tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = ms.Tensor(np.array([[[0, 1, 2, 3], [4, 5, 6, 7]]]).astype(np.float32))
>>> # x has shape (1, 2, 4)
>>> padding = (3, 1)
>>> # The first and the second dimension of x remain the same.
>>> # The third dimension of x: W_out = W_in + pad_left + pad_right = 4 + 3 + 1 = 8
>>> pad1d = ms.nn.ReflectionPad1d(padding)
>>> out = pad1d(x)
>>> # The shape of out is (1, 2, 8)
>>> print(out)
[[[3. 2. 1. 0. 1. 2. 3. 2.]
  [7. 6. 5. 4. 5. 6. 7. 6.]]]
```

3.13.6 mindspore.nn.ReflectionPad2d

class mindspore.nn.**ReflectionPad2d**(*padding*)

Using a given padding to do reflection pad the given tensor. 2d means the dimension of padding is 2-dimension.

Parameters

padding (*union[int, tuple]*) –The padding size to pad the input tensor. If padding is an integer: all directions will be padded with the same size. If padding is a tuple: uses $(pad\_left, pad\_right, pad\_up, pad\_down)$ to pad.

Inputs:

- **x** (Tensor) - 3D or 4D, shape: (C, H_{in}, W_{in}) or (N, C, H_{in}, W_{in}).

Outputs:

Tensor, after padding. Shape: (C, H_{out}, W_{out}) or (N, C, H_{out}, W_{out}), where $H_{out} = H_{in} + pad\_up + pad\_down$, $W_{out} = W_{in} + pad\_left + pad\_right$.

Raises

- **TypeError** –If 'padding' is not a tuple or int.
- **TypeError** –If there is an element in 'padding' that is not int.
- **ValueError** –If the length of 'padding' is not divisible by 2.
- **ValueError** –If there is an element in 'padding' that is negative.
- **ValueError** –If the there is a dimension mismatch between the padding and the tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = ms.Tensor(np.array([[[0, 1, 2], [3, 4, 5], [6, 7, 8]]]).astype(np.float32))
>>> # x has shape (1, 3, 3)
>>> padding = (1, 1, 2, 0)
>>> pad2d = ms.nn.ReflectionPad2d(padding)
>>> # The first dimension of x remains the same.
>>> # The second dimension of x: H_out = H_in + pad_up + pad_down = 3 + 1 + 1 = 5
>>> # The third dimension of x: W_out = W_in + pad_left + pad_right = 3 + 2 + 0 = 5
>>> out = pad2d(x)
>>> # The shape of out is (1, 5, 5)
>>> print(out)
[[[7. 6. 7. 8. 7.]
  [4. 3. 4. 5. 4.]
  [1. 0. 1. 2. 1.]
  [4. 3. 4. 5. 4.]
  [7. 6. 7. 8. 7.]]]
```

3.13.7 mindspore.nn.ReflectionPad3d

class mindspore.nn.**ReflectionPad3d**(*padding*)

Pad the given tensor in a reflecting way using the input boundaries as the axis of symmetry. 3d means the dimension of padding is 3-dimension.

Note: ReflectionPad3d has not supported 5D tensor yet.

Parameters

padding (*union[int, tuple]*) – The padding size to pad the input tensor. If padding is an integer: all directions will be padded with the same size. If padding is a tuple: uses $(pad\_left, pad\_right, pad\_up, pad\_down, pad\_front, pad\_back)$ to pad.

Inputs:

- **x** (Tensor) - 4D Tensor, shape: $(N, D_{in}, H_{in}, W_{in})$.

Outputs:

Tensor, after padding. Shape: $(N, D_{out}, H_{out}, W_{out})$, where $D_{out} = D_{in} + pad\_front + pad\_back$, $H_{out} = H_{in} + pad\_up + pad\_down$ $W_{out} = W_{in} + pad\_left + pad\_right$.

Raises

- **TypeError** – If 'padding' is not a tuple or int.
- **TypeError** – If there is an element in 'padding' that is not int.
- **ValueError** – If the length of 'padding' is not divisible by 2.
- **ValueError** – If there is an element in 'padding' that is negative.
- **ValueError** – If the there is a dimension mismatch between the padding and the tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> arr = np.arange(8).astype(np.float32).reshape((1, 2, 2, 2))
>>> x = ms.Tensor(arr)
>>> # x has shape (1, 2, 2, 2)
>>> padding = (1, 1, 1, 0, 0, 1)
>>> pad3d = ms.nn.ReflectionPad3d(padding)
>>> out = pad3d(x)
>>> # The first dimension of x remains the same.
>>> # The second dimension of x: D_out = D_in + pad_front + pad_back = 2 + 0 + 1 = 3
>>> # The third dimension of x: H_out = H_in + pad_up + pad_down = 2 + 1 + 0 = 3
>>> # The last dimension of x: W_out = W_in + pad_left + pad_right = 2 + 1 + 1 = 4
>>> # The shape of out is (1, 3, 3, 4)
>>> print(out)
[[[[3. 2. 3. 2.]
   [1. 0. 1. 0.]
   [3. 2. 3. 2.]]
  [[7. 6. 7. 6.]
   [5. 4. 5. 4.]
   [7. 6. 7. 6.]]
  [[3. 2. 3. 2.]
   [1. 0. 1. 0.]
   [3. 2. 3. 2.]]]]
```

3.13.8 mindspore.nn.ReplicationPad1d

class mindspore.nn.**ReplicationPad1d**(*padding*)

Pad on W dimension of input *x* according to *padding*.

Parameters

padding (*union[int, tuple]*) –The padding size to pad the last dimension of *x* .

- If *padding* is an integer, all directions will be padded with the same size.
- If *padding* is a tuple, uses $(pad_{left}, pad_{right})$ to pad.

Inputs:

- **x** (Tensor) - 2D or 3D, shape: (C, W_{in}) or (N, C, W_{in}).

Outputs:

Tensor, after padding. Shape: (C, W_{out}) or (N, C, W_{out}), where $W_{out} = W_{in} + pad_{left} + pad_{right}$

Raises

- **TypeError** –If *padding* is neither a tuple nor an int.
- **TypeError** –If there is an element in *padding* that is not int.
- **ValueError** –If *padding* is tuple and the length of *padding* is not divisible by 2.
- **ValueError** –If *padding* is tuple and there is a dimension mismatch between the padding and the tensor.

Supported Platforms:

GPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> pad1d = ms.nn.ReplicationPad1d(2)
>>> input = ms.Tensor(np.arange(0, 8).reshape(1, 2, 4), ms.float32)
>>> print(input)
[[[0. 1. 2. 3.]
  [4. 5. 6. 7.]]]
>>> out = pad1d(input)
>>> print(out)
[[[0. 0. 0. 1. 2. 3. 3. 3.]
  [4. 4. 4. 5. 6. 7. 7. 7.]]]
>>> pad1d = ms.nn.ReplicationPad1d((3, 1))
>>> out = pad1d(input)
>>> print(out)
[[[0. 0. 0. 0. 1. 2. 3. 3.]
  [4. 4. 4. 4. 5. 6. 7. 7.]]]
```

3.13.9 mindspore.nn.ReplicationPad2d

class mindspore.nn.**ReplicationPad2d**(*padding*)

Pad on HW dimension of input *x* according to *padding*.

Parameters

padding (*union[int, tuple]*) – The padding size to pad the last two dimension of x .

- If *padding* is an integer, all directions will be padded with the same size.
- If *padding* is a tuple, uses $(pad_{left}, pad_{right}, pad_{up}, pad_{down})$ to pad.

Inputs:

- **x** (Tensor) - 3D or 4D, shape: (C, H_{in}, W_{in}) or (N, C, H_{in}, W_{in}).

Outputs:

Tensor, after padding. Shape: (C, H_{out}, W_{out}) or (N, C, H_{out}, W_{out}), where $H_{out} = H_{in} + pad_{up} + pad_{down}$, $W_{out} = W_{in} + pad_{left} + pad_{right}$.

Raises

- **TypeError** – If *padding* is neither a tuple nor an int.
- **TypeError** – If there is an element in *padding* that is not int.
- **ValueError** – If *padding* is tuple and the length of *padding* is not divisible by 2.
- **ValueError** – If *padding* is tuple and there is a dimension mismatch between the padding and the tensor.

Supported Platforms:

GPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> pad2d = ms.nn.ReplicationPad2d(2)
>>> input = ms.Tensor(np.arange(0, 9).reshape(1, 1, 3, 3), ms.float32)
>>> print(input)
[[[[0. 1. 2.]
   [3. 4. 5.]
   [6. 7. 8.]]]]
>>> out = pad2d(input)
>>> print(out)
[[[[0. 0. 0. 1. 2. 2. 2.]
   [0. 0. 0. 1. 2. 2. 2.]
   [0. 0. 0. 1. 2. 2. 2.]
   [3. 3. 3. 4. 5. 5. 5.]
   [6. 6. 6. 7. 8. 8. 8.]
   [6. 6. 6. 7. 8. 8. 8.]
   [6. 6. 6. 7. 8. 8. 8.]]]]
>>> pad2d = ms.nn.ReplicationPad2d((1, 1, 2, 0))
>>> out = pad2d(input)
>>> print(out)
[[[[0. 0. 1. 2. 2.]
   [0. 0. 1. 2. 2.]
   [0. 0. 1. 2. 2.]
   [3. 3. 4. 5. 5.]
   [6. 6. 7. 8. 8.]]]]
```

3.13.10 mindspore.nn.ReplicationPad3d

class mindspore.nn.**ReplicationPad3d**(*padding*)

Pad on DHW dimension of input *x* according to *padding*.

Parameters

padding (*union[int, tuple]*) –The padding size to pad the last three dimension of *x* .

- If *padding* is an integer, all directions will be padded with the same size.
- If *padding* is a tuple, uses $(pad_{left}, pad_{right}, pad_{up}, pad_{down}, pad_{front}, pad_{back})$ to pad.

Inputs:

- **x** (Tensor) - 4D or 5D, shape: $(C, D_{in}, H_{in}, W_{in})$ or $(N, C, D_{in}, H_{in}, W_{in})$.

Outputs:

Tensor, after padding, shape: $(C, D_{out}, H_{out}, W_{out})$ or $(N, C, D_{out}, H_{out}, W_{out})$, where $D_{out} = D_{in} + pad_{front} + pad_{back}$, $H_{out} = H_{in} + pad_{up} + pad_{down}$, $W_{out} = W_{in} + pad_{left} + pad_{right}$.

Raises

- **TypeError** –If *padding* is neither a tuple nor an int.
- **TypeError** –If there is an element in *padding* that is not int.
- **ValueError** –If *padding* is tuple and the length of *padding* is not divisible by 2.
- **ValueError** –If *padding* is tuple and there is a dimension mismatch between the padding and the tensor.

Supported Platforms:

GPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> pad3d = ms.nn.ReplicationPad3d(1)
>>> input = ms.Tensor(np.arange(0, 9).reshape(1, 1, 1, 3, 3), ms.float32)
>>> out = pad3d(input)
>>> print(out)
[[[[[0. 0. 1. 2. 2.]
    [0. 0. 1. 2. 2.]
    [3. 3. 4. 5. 5.]
    [6. 6. 7. 8. 8.]
    [6. 6. 7. 8. 8.]]
   [[0. 0. 1. 2. 2.]
    [0. 0. 1. 2. 2.]
    [3. 3. 4. 5. 5.]
    [6. 6. 7. 8. 8.]
    [6. 6. 7. 8. 8.]]
   [[0. 0. 1. 2. 2.]
    [0. 0. 1. 2. 2.]
    [3. 3. 4. 5. 5.]
    [6. 6. 7. 8. 8.]
    [6. 6. 7. 8. 8.]]]]]
```

3.13.11 mindspore.nn.ZeroPad2d

class mindspore.nn.**ZeroPad2d**(*padding*)

Pads the last two dimensions of input tensor with zero.

Parameters

padding (*Union[int, tuple]*) – The padding size to pad the last two dimensions of input tensor. If is int, uses the same padding in boundaries of input's last two dimensions. If is tuple and length of padding is 4 uses (padding_0, padding_1, padding_2, padding_3) to pad. If the input is x, the size of last dimension of output is $padding\_0 + x.shape[-1] + padding\_1$. The size of penultimate dimension of output is $padding\_2 + x.shape[-2] + padding\_3$. The remaining dimensions of the output are consistent with those of the input. Only support non-negative value while running in Ascend.

Inputs:

- **x** (Tensor) - shape is $(N, *)$, where $*$ means, any number of additional dimensions. It is not supported that the size of dimensions is greater than 5 while running in Ascend.

Returns

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not a tuple or int.
- **ValueError** – If the length of *padding* is more than 4 or not a multiple of 2.
- **ValueError** – If the output shape after padding is not positive.

- **ValueError** – If the rank of 'x' is more than 5 while running in Ascend.
- **ValueError** – If *padding* contains negative value while running in Ascend.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = np.ones(shape=(1, 2, 3, 4)).astype(np.float32)
>>> x = ms.Tensor(x)
>>> padding = (1, 1, 0, 1)
>>> pad = ms.nn.ZeroPad2d(padding)
>>> out = pad(x)
>>> print(out)
[[[[0. 1. 1. 1. 1. 0.]
   [0. 1. 1. 1. 1. 0.]
   [0. 1. 1. 1. 1. 0.]
   [0. 0. 0. 0. 0. 0.]]
  [[0. 1. 1. 1. 1. 0.]
   [0. 1. 1. 1. 1. 0.]
   [0. 1. 1. 1. 1. 0.]
   [0. 0. 0. 0. 0. 0.]]]]
>>> print(out.shape)
(1, 2, 4, 6)
```

3.14 Loss Function

API Name	Description	Supported Platforms
mindspore.nn.BCELoss	BCELoss creates a criterion to measure the binary cross entropy between the true labels and predicted labels.	`Ascend` `GPU` `CPU`
mindspore.nn.BCEWithLogitsLoss	Adds sigmoid activation function to input *input* as logits, and uses the given logits to compute binary cross entropy between the *input* and the *target*.	`Ascend` `GPU` `CPU`
mindspore.nn.CosineEmbeddingLoss	CosineEmbeddingLoss creates a criterion to measure the similarity between two tensors using cosine distance.	`Ascend` `GPU` `CPU`
mindspore.nn.CrossEntropyLoss	The cross entropy loss between input and target.	`Ascend` `GPU` `CPU`
mindspore.nn.CTCLoss	Calculates the CTC (Connectionist Temporal Classification) loss.	`Ascend` `GPU` `CPU`
mindspore.nn.DiceLoss	The Dice coefficient is a set similarity loss, which is used to calculate the similarity between two samples.	`Ascend` `GPU` `CPU`
mindspore.nn.FocalLoss	It is a loss function to solve the imbalance of categories and the difference of classification difficulty.	`Ascend`
mindspore.nn.GaussianNLLLoss	Gaussian negative log likelihood loss.	`Ascend` `GPU` `CPU`

continues on next page

Table 14 – continued from previous page

mindspore.nn.HingeEmbeddingLoss	Calculate the Hinge Embedding Loss value based on the input 'logits' and' labels' (only including 1 or -1).	Ascend GPU CPU
mindspore.nn.HuberLoss	HuberLoss calculate the error between the predicted value and the target value.	Ascend GPU CPU
mindspore.nn.KLDivLoss	Computes the Kullback-Leibler divergence between the *logits* and the *labels*.	Ascend GPU CPU
mindspore.nn.L1Loss	L1Loss is used to calculate the mean absolute error between the predicted value and the target value.	Ascend GPU CPU
mindspore.nn.MarginRankingLoss	MarginRankingLoss creates a criterion that measures the loss.	Ascend GPU CPU
mindspore.nn.MAELoss	MAELoss creates a criterion to measure the average absolute error between x and y element-wise, where x is the input and y is the labels.	Ascend GPU CPU
mindspore.nn.MSELoss	Calculates the mean squared error between the predicted value and the label value.	Ascend GPU CPU
mindspore.nn.MultiClassDiceLoss	When there are multiple classifications, label is transformed into multiple binary classifications by one hot.	Ascend GPU CPU
mindspore.nn.MultilabelMarginLoss	Creates a loss criterion that minimizes the hinge loss for multi-class classification tasks.	Ascend GPU
mindspore.nn.MultiLabelSoftMarginLoss	Calculates the MultiLabelSoftMarginLoss.	Ascend GPU CPU
mindspore.nn.MultiMarginLoss	Creates a criterion that optimizes a multi-class classification hinge loss (margin-based loss) between input x (a 2D mini-batch *Tensor*) and output y (which is a 1D tensor of target class indices, $0 \leq y \leq$ x.size(1) $- 1$):	Ascend GPU CPU
mindspore.nn.NLLLoss	Gets the negative log likelihood loss between logits and labels.	Ascend GPU CPU
mindspore.nn.PoissonNLLLoss	Poisson negative log likelihood loss.	Ascend GPU CPU
mindspore.nn.RMSELoss	RMSELoss creates a criterion to measure the root mean square error between x and y element-wise, where x is the input and y is the labels.	Ascend GPU CPU
mindspore.nn.SampledSoftmaxLoss	Computes the sampled softmax training loss.	GPU
mindspore.nn.SmoothL1Loss	SmoothL1 loss function.	Ascend GPU CPU
mindspore.nn.SoftMarginLoss	A loss class for two-class classification problems.	Ascend GPU
mindspore.nn.SoftmaxCrossEntropyWithLogits	Computes softmax cross entropy between logits and labels.	Ascend GPU CPU
mindspore.nn.TripletMarginLoss	TripletMarginLoss operation.	GPU

3.14.1 mindspore.nn.BCELoss

class mindspore.nn.**BCELoss**(*weight=None*, *reduction='mean'*)

BCELoss creates a criterion to measure the binary cross entropy between the true labels and predicted labels.

Set the predicted labels as x, true labels as y, the output loss as $\ell(x, y)$. The formula is as follow:

$$L = \{l_1, \ldots, l_n, \ldots, l_N\}^\top, \quad l_n = -w_n \left[y_n \cdot \log x_n + (1 - y_n) \cdot \log(1 - x_n) \right]$$

where N is the batch size. Then,

$$\ell(x, y) = \begin{cases} L, & \text{if reduction = 'none';} \\ \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Note: Note that the predicted labels should always be the output of sigmoid. Because it is a two-class classification, the true labels should be numbers between 0 and 1. And if input is either 0 or 1, one of the log terms would be mathematically undefined in the above loss equation.

Parameters

- **weight** (Tensor, *optional*) –A rescaling weight applied to the loss of each batch element. And it must have the same shape and data type as *inputs*. Default: None .
- **reduction** (*str*, *optional*) –Apply specific reduction method to the output: 'none' , 'mean' , 'sum' . Default: 'mean' .
  - 'none': no reduction will be applied.
  - 'mean': compute and return the weighted mean of elements in the output.
  - 'sum': the output elements will be summed.

Inputs:

- **logits** (Tensor) - The input tensor with shape $(N, *)$ where $*$ means, any number of additional dimensions. The data type must be float16 or float32.
- **labels** (Tensor) - The label tensor with shape $(N, *)$ where $*$ means, any number of additional dimensions. The same shape and data type as *logits*.

Outputs:

Tensor, has the same dtype as *logits*. if *reduction* is 'none', then it has the same shape as *logits*. Otherwise, it is a scalar Tensor.

Raises

- **TypeError** –If dtype of *logits*, *labels* or *weight* (if given) is neither float16 not float32.
- **ValueError** –If *reduction* is not one of 'none', 'mean', 'sum'.
- **ValueError** –If shape of *logits* is not the same as *labels* or *weight* (if given).

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> weight = ms.Tensor(np.array([[1.0, 2.0, 3.0], [4.0, 3.3, 2.2]]), ms.float32)
>>> loss = nn.BCELoss(weight=weight, reduction='mean')
>>> logits = ms.Tensor(np.array([[0.1, 0.2, 0.3], [0.5, 0.7, 0.9]]), ms.float32)
>>> labels = ms.Tensor(np.array([[0, 1, 0], [0, 0, 1]]), ms.float32)
```

(continues on next page)

(continued from previous page)

```
>>> output = loss(logits, labels)
>>> print(output)
1.8952923
```

3.14.2 mindspore.nn.BCEWithLogitsLoss

class mindspore.nn.**BCEWithLogitsLoss**(*reduction='mean'*, *weight=None*, *pos_weight=None*)

Adds sigmoid activation function to input *input* as logits, and uses the given logits to compute binary cross entropy between the *input* and the *target*.

Sets input *input* as X, input *target* as Y, output as L. Then,

$$p_{ij} = sigmoid(X_{ij}) = \frac{1}{1 + e^{-X_{ij}}}$$

$$L_{ij} = -[Y_{ij} \cdot \log(p_{ij}) + (1 - Y_{ij}) \cdot \log(1 - p_{ij})]$$

Then,

$$\ell(x, y) = \begin{cases} L, & \text{if reduction = 'none';} \\ \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Parameters

- **reduction** (*str, optional*) – Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'mean'`.
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **weight** (Tensor, *optional*) – A rescaling weight applied to the loss of each batch element. If not None, it can be broadcast to a tensor with shape of *input*, data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported). Default: `None`.
- **pos_weight** (Tensor, *optional*) – A weight of positive examples. Must be a vector with length equal to the number of classes. If not None, it must be broadcast to a tensor with shape of *input*, data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported). Default: `None`.

Inputs:

- **input** (Tensor) - Input *input* with shape $(N, *)$ where $*$ means, any number of additional dimensions. The data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported).
- **target** (Tensor) - Ground truth label with shape $(N, *)$ where $*$ means, any number of additional dimensions. The same shape and data type as *input*.

Outputs:

Tensor or Scalar, if *reduction* is `'none'`, its shape is the same as *input*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** – If input *input* or *target* is not Tensor.
- **TypeError** – If data type of *input* or *target* is not float16, float32 or bfloat16.

- **TypeError** –If *weight* or *pos_weight* is a parameter.
- **TypeError** –If data type of *weight* or *pos_weight* is not float16 , float32 or bfloat16.
- **TypeError** –If data type of *reduction* is not string.
- **ValueError** –If *weight* or *pos_weight* can not be broadcast to a tensor with shape of *input*.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> input = ms.Tensor(np.array([[-0.8, 1.2, 0.7], [-0.1, -0.4, 0.7]]).astype(np.float32))
>>> target = ms.Tensor(np.array([[0.3, 0.8, 1.2], [-0.6, 0.1, 2.2]]).astype(np.float32))
>>> loss = nn.BCEWithLogitsLoss()
>>> output = loss(input, target)
>>> print(output)
0.3463612
```

3.14.3 mindspore.nn.CosineEmbeddingLoss

class mindspore.nn.**CosineEmbeddingLoss**(*margin=0.0*, *reduction='mean'*)

CosineEmbeddingLoss creates a criterion to measure the similarity between two tensors using cosine distance.

Given two tensors $x1$, $x2$, and a Tensor label y with values 1 or -1:

$$loss(x_1, x_2, y) = \begin{cases} 1 - cos(x_1, x_2), & \text{if } y = 1 \\ \max(0, cos(x_1, x_2) - margin), & \text{if } y = -1 \end{cases}$$

Parameters

- **margin** (*float*) –Should be in [-1.0, 1.0]. Default: `0.0` .
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **logits_x1** (Tensor) - Tensor of shape $(N, *)$ where $*$ means, any number of additional dimensions.
- **logits_x2** (Tensor) - Tensor of shape $(N, *)$, same shape and dtype as *logits_x1*.
- **labels** (Tensor) - Contains value 1 or -1. Suppose the shape of *logits_x1* is $(x_1, x_2, x_3, ..., x_R)$, then the shape of *labels* must be $(x_1, x_3, x_4, ..., x_R)$.

Outputs:

Tensor or Scalar, if *reduction* is `"none"`, its shape is the same as *labels*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** – If *margin* is not a float.
- **ValueError** – If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.
- **ValueError** – If *margin* is not in range [-1.0, 1.0].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> logits_x1 = ms.Tensor(np.array([[0.3, 0.8], [0.4, 0.3]]), ms.float32)
>>> logits_x2 = ms.Tensor(np.array([[0.4, 1.2], [-0.4, -0.9]]), ms.float32)
>>> labels = ms.Tensor(np.array([1, -1]), ms.int32)
>>> cosine_embedding_loss = nn.CosineEmbeddingLoss()
>>> output = cosine_embedding_loss(logits_x1, logits_x2, labels)
>>> print(output)
0.0003425479
```

3.14.4 mindspore.nn.CrossEntropyLoss

class mindspore.nn.**CrossEntropyLoss**(*weight=None*, *ignore_index=- 100*, *reduction='mean'*, *label_smoothing=0.0*)

The cross entropy loss between input and target.

The CrossEntropyLoss support two kind of targets:

- Class indices (int) in the range $[0, C)$ where C is the number of classes, when reduction is `none`, the loss can be described as:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -w_{y_n} \log \frac{\exp(x_{n,y_n})}{\sum_{c=1}^{C} \exp(x_{n,c})} \cdot \mathbb{1}\{y_n \neq \text{ignore\_index}\}$$

  where x is the inputs, t is the target, w is the weight, N is the batch size, c belonging to [0, C-1] is class index, where C is the number of classes.

  If reduction is not `'none'` (default 'mean'), then

$$\ell(x, y) = \begin{cases} \sum_{n=1}^{N} \frac{1}{\sum_{n=1}^{N} w_{y_n} \cdot \mathbb{1}\{y_n \neq \text{ignore\_index}\}} l_n, & \text{if reduction = 'mean',} \\ \sum_{n=1}^{N} l_n, & \text{if reduction = 'sum'.} \end{cases}$$

- Probabilities (float) for each class, useful when labels beyond a single class per minibatch item are required, the loss with reduction=none can be described as:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -\sum_{c=1}^{C} w_c \log \frac{\exp(x_{n,c})}{\sum_{i=1}^{C} \exp(x_{n,i})} y_{n,c}$$

  where x is the inputs, t is the target, w is the weight, N is the batch size, c belonging to [0, C-1] is class index, where C is the number of classes.

If reduction is not `'none'` (default 'mean'), then

$$\ell(x, y) = \begin{cases} \frac{\sum_{n=1}^{N} l_n}{N}, & \text{if reduction = 'mean',} \\ \sum_{n=1}^{N} l_n, & \text{if reduction = 'sum'.} \end{cases}$$

Parameters

- **weight** (Tensor) –The rescaling weight to each class. If the value is not None, the shape is $(C,)$. The data type only supports float32 or float16. Default: `None` .
- **ignore_index** (*int*) –Specifies a target value that is ignored (typically for padding value) and does not contribute to the gradient. Default: `-100` .
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **label_smoothing** (*float*) –Label smoothing values, a regularization tool used to prevent the model from overfitting when calculating Loss. The value range is [0.0, 1.0]. Default value: `0.0` .

Inputs:

- **logits** (Tensor) - Tensor of shape $(C,)$ (N, C) or $(N, C, d_1, d_2, ..., d_K)$, where *C = number of classes*. Data type must be float16 or float32.
- **labels** (Tensor) - For class indices, tensor of shape (), (N) or $(N, d_1, d_2, ..., d_K)$, data type must be int32. For probabilities, tensor of shape $(C,)$ (N, C) or $(N, C, d_1, d_2, ..., d_K)$, data type must be float16 or float32.

Returns

Tensor, the computed cross entropy loss value.

Raises

- **TypeError** –If *weight* is not a Tensor.
- **TypeError** –If *ignore_index* is not an int.
- **TypeError** –If the data type of *weight* is not float16 or float32.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.
- **TypeError** –If *label_smoothing* is not a float.
- **TypeError** –If *logits* is not a Tensor.
- **TypeError** –If *labels* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> # Case 1: Indices labels
>>> inputs = ms.Tensor(np.random.randn(3, 5), ms.float32)
>>> target = ms.Tensor(np.array([1, 0, 4]), ms.int32)
>>> loss = nn.CrossEntropyLoss()
>>> output = loss(inputs, target)
>>> # Case 2: Probability labels
>>> inputs = ms.Tensor(np.random.randn(3, 5), ms.float32)
>>> target = ms.Tensor(np.random.randn(3, 5), ms.float32)
>>> loss = nn.CrossEntropyLoss()
>>> output = loss(inputs, target)
```

3.14.5 mindspore.nn.CTCLoss

class mindspore.nn.**CTCLoss**(*blank=0*, *reduction='mean'*, *zero_infinity=False*)

Calculates the CTC (Connectionist Temporal Classification) loss. It's mainly used to calculate the loss between the continuous, unsegemented time series and the target series.

For the CTC algorithm, refer to Connectionist Temporal Classification: Labeling Unsegmented Sequence Data with Recurrent Neural Networks .

Parameters

- **blank** (*int, optional*) – The blank label. Default: `0` .
- **reduction** (*str, optional*) – Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **zero_infinity** (*bool, optional*) – If loss is infinite, this parameter determines whether to set that loss and its correlated gradient to zero. Default: `False` .

Inputs:

- **log_probs** (Tensor) - A tensor of shape (T, N, C) or (T, C), where T is length of input, N is size of the batch and C is the number of classes. T, N and C are positive integers.
- **targets** (Tensor) - A tensor of shape (N, S) or (sum(*target_lengths*)), where S is max target length, means the target sequences.
- **input_lengths** (Union[tuple, Tensor]) - A tuple or Tensor of shape (N). It means the lengths of the input.
- **target_lengths** (Union[tuple, Tensor]) - A tuple or Tensor of shape (N). It means the lengths of the target.

Outputs:

- **neg_log_likelihood** (Tensor) - A loss value which is differentiable with respect to each input node.

Raises

- **TypeError** – If *log_probs* or *targets* is not a Tensor.

- **TypeError** – If *zero_infinity* is not a bool, *reduction* is not string.
- **TypeError** – If the dtype of *log_probs* is not float or double.
- **TypeError** – If the dtype of *targets*, *input_lengths* or *target_lengths* is not int32 or int64.
- **ValueError** – If *reduction* is not `"none"`, `"mean"` or `"sum"`.
- **ValueError** – If the value of *blank* is not in range [0, C). C is number of classes of *log_probs* .
- **ValueError** – If the shape of *log_probs* is (T, C), the dimension of *targets* is not 1 or 2.
- **ValueError** – If the shape of *log_probs* is (T, C), the first dimension of 2-D *target* is not 1.
- **RuntimeError** – If any value of *input_lengths* is larger than T. T is length of *log_probs* .
- **RuntimeError** – If any target_lengths[i] is not in range [0, input_length[i]].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> T = 5      # Input sequence length
>>> C = 2      # Number of classes
>>> N = 2      # Batch size
>>> S = 3      # Target sequence length of longest target in batch (padding length)
>>> S_min = 2  # Minimum target length, for demonstration purposes
>>> arr = np.arange(T*N*C).reshape((T, N, C))
>>> ms_input = ms.Tensor(arr, dtype=ms.float32)
>>> input_lengths = np.full(shape=(N), fill_value=T)
>>> input_lengths = ms.Tensor(input_lengths, dtype=ms.int32)
>>> target_lengths = np.full(shape=(N), fill_value=S_min)
>>> target_lengths = ms.Tensor(target_lengths, dtype=ms.int32)
>>> target = np.random.randint(1, C, size=(N, S))
>>> target = ms.Tensor(target, dtype=ms.int32)
>>> ctc_loss = nn.CTCLoss(blank=0, reduction='none', zero_infinity=False)
>>> loss = ctc_loss(ms_input, target, input_lengths, target_lengths)
>>> print(loss)
[-45.79497  -55.794968]
>>> arr = np.arange(T*C).reshape((T, C))
>>> ms_input = ms.Tensor(arr, dtype=ms.float32)
>>> input_lengths = ms.Tensor([T], dtype=ms.int32)
>>> target_lengths = ms.Tensor([S_min], dtype=ms.int32)
>>> target = np.random.randint(1, C, size=(S_min,))
>>> target = ms.Tensor(target, dtype=ms.int32)
>>> ctc_loss = nn.CTCLoss(blank=0, reduction='none', zero_infinity=False)
>>> loss = ctc_loss(ms_input, target, input_lengths, target_lengths)
>>> print(loss)
-25.794968
```

3.14.6 mindspore.nn.DiceLoss

class mindspore.nn.**DiceLoss**(*smooth=1e-5*)

The Dice coefficient is a set similarity loss, which is used to calculate the similarity between two samples. The value of the Dice coefficient is 1 when the segmentation result is the best and is 0 when the segmentation result is the worst. The Dice coefficient indicates the ratio of the area between two objects to the total area. The function is shown as follows:

$$dice = 1 - \frac{2 * |pred \bigcap true|}{|pred| + |true| + smooth}$$

$pred$ represent *logits*, $true$ represent *labels* .

Parameters

smooth (*float, optional*) – A term added to the denominator to improve numerical stability. Should be greater than 0. Default: `1e-5` .

Inputs:

- **logits** (Tensor) - Input predicted value. The data type must be float16 or float32.
- **labels** (Tensor) - Input target value. Same shape as the *logits*. The data type must be float16 or float32.

Outputs:

Tensor, a tensor of shape with the per-example sampled Dice losses.

Raises

- **ValueError** – If the dimension of *logits* is different from *labels*.
- **TypeError** – If the type of *logits* or *labels* is not a tensor.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> loss = nn.DiceLoss(smooth=1e-5)
>>> logits = Tensor(np.array([[0.2, 0.5], [0.3, 0.1], [0.9, 0.6]]), mindspore.float32)
>>> labels = Tensor(np.array([[0, 1], [1, 0], [0, 1]]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
0.38596618
```

3.14.7 mindspore.nn.FocalLoss

class mindspore.nn.**FocalLoss**(*weight=None*, *gamma=2.0*, *reduction='mean'*)

It is a loss function to solve the imbalance of categories and the difference of classification difficulty. The loss function proposed by Kaiming team in their paper Focal Loss for Dense Object Detection improves the effect of image object detection. The function is shown as follows:

$$FL(p_t) = -(1 - p_t)^{\gamma} \log(p_t)$$

Parameters

- **gamma** (*float*) – Gamma is used to adjust the steepness of weight curve in focal loss. Default: `2.0`.
- **weight** (*Union[Tensor, None]*) – A rescaling weight applied to the loss of each batch element. The dimension of weight should be 1. If None, no weight is applied. Default: `None`.
- **reduction** (*str, optional*) – Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'mean'`.
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - Tensor of shape should be (N, C) or (N, C, H) or (N, C, H, W). Where C is the number of classes. Its value is greater than 1. If the shape is (N, C, H, W) or (N, C, H), the H or product of H and W should be the same as labels.
- **labels** (Tensor) - Tensor of shape should be (N, C) or (N, C, H) or (N, C, H, W). The value of C is 1 or it needs to be the same as predict's C. If C is not 1, the shape of target should be the same as that of predict, where C is the number of classes. If the shape is (N, C, H, W) or (N, C, H), the H or product of H and W should be the same as logits. The value of *labels* is should be in the range [-C, C). Where C is the number of classes in logits.

Outputs:

Tensor or Scalar, if *reduction* is `"none"`, its shape is the same as *logits*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** – If the data type of *gamma* is not a float.
- **TypeError** – If *weight* is not a Tensor.
- **ValueError** – If *labels* dim is different from *logits*.
- **ValueError** – If *labels* channel is not 1 and *labels* shape is different from *logits*.
- **ValueError** – If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> logits = ms.Tensor([[0.8, 1.4], [0.5, 0.9], [1.2, 0.9]], ms.float32)
>>> labels = ms.Tensor([[1], [1], [0]], ms.int32)
>>> focalloss = nn.FocalLoss(weight=ms.Tensor([1, 2]), gamma=2.0, reduction='mean')
>>> output = focalloss(logits, labels)
>>> print(output)
0.12516622
```

3.14.8 mindspore.nn.GaussianNLLLoss

class mindspore.nn.**GaussianNLLLoss**(*, *full=False*, *eps=1e-6*, *reduction='mean'*)

Gaussian negative log likelihood loss.

The target values are considered to be samples from a Gaussian distribution, where the expectation and variance are predicted by a neural network. For *labels* modeled on a Gaussian distribution, *logits* to record expectations, and the variance *var* (elements are all positive), the calculated loss is:

$$\text{loss} = \frac{1}{2}\left(\log\left(\max\left(\text{var},\ \text{eps}\right)\right) + \frac{\left(\text{logits} - \text{labels}\right)^2}{\max\left(\text{var},\ \text{eps}\right)}\right) + \text{const.}$$

where eps is used for stability of log. When $full = True$, a constant will be added to the loss. If the shape of var and $logits$ are not the same (due to a homoscedastic assumption), their shapes must allow correct broadcasting.

Keyword Arguments

- **full** (bool, *optional*) – Whether include the constant term in the loss calculation. When $full = True$, the constant term *const.* will be $0.5 * log(2\pi)$. Default: False .
- **eps** (float, *optional*) – Used to improve the stability of log function. Default: 1e-6 .
- **reduction** (*str*, *optional*) – Apply specific reduction method to the output: 'none' , 'mean' , 'sum' . Default: 'mean' .
  - 'none': no reduction will be applied.
  - 'mean': compute and return the mean of elements in the output.
  - 'sum': the output elements will be summed.

Inputs:

- **logits** (Tensor) - Tensor of shape $(N, *)$ or $(*)$ where $*$ means any number of additional dimensions.
- **labels** (Tensor) - Tensor of shape $(N, *)$ or $(*)$, same shape as the logits, or same shape as the logits but with one dimension equal to 1 (to allow for broadcasting).
- **var** - Tensor of shape $(N, *)$ or $(*)$, same shape as logits, or same shape as the logits but with one dimension equal to 1, or same shape as the logits but with one fewer dimension (to allow for broadcasting).

Returns

Tensor or Tensor scalar, the computed loss depending on $reduction$.

Raises

- **TypeError** – If *logits* is not a Tensor.
- **TypeError** – If *labels* is not a Tensor.

- **TypeError** – If *full* is not a bool.
- **TypeError** – If *eps* is not a float.
- **ValueError** – If *eps* is not a float within (0, inf).
- **ValueError** – If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> arr1 = np.arange(8).reshape((4, 2))
>>> arr2 = np.array([2, 3, 1, 4, 6, 4, 4, 9]).reshape((4, 2))
>>> logits = ms.Tensor(arr1, ms.float32)
>>> labels = ms.Tensor(arr2, ms.float32)
>>> loss = nn.GaussianNLLLoss(reduction='mean')
>>> var = ms.Tensor(np.ones((4, 1)), ms.float32)
>>> output = loss(logits, labels, var)
>>> print(output)
1.4374993
```

3.14.9 mindspore.nn.HingeEmbeddingLoss

class mindspore.nn.**HingeEmbeddingLoss**(*margin=1.0*, *reduction='mean'*)

Calculate the Hinge Embedding Loss value based on the input 'logits' and' labels' (only including 1 or -1). Usually used to measure the similarity between two inputs.

The loss function for n-th sample in the mini-batch is

$$l_n = \begin{cases} x_n, & \text{if } y_n = 1, \\ \max\{0, \Delta - x_n\}, & \text{if } y_n = -1, \end{cases}$$

and the total loss functions is

$$\ell(x, y) = \begin{cases} \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

where $L = \{l_1, \ldots, l_N\}^\top$.

Parameters

- **margin** (*float, int, optional*) – Threshold defined by Hinge Embedding Loss *margin*. Represented as Δ in the formula. Default: `1.0`.

- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - The predicted value, expressed as x in the equation. Tensor of shape $(*)$ where $*$ means any number of dimensions.
- **labels** (Tensor) - Label value, represented as y in the equation. Same shape as the logits, contains -1 or 1.

Returns

Tensor or Tensor scalar, the computed loss depending on $reduction$.

Raises

- **TypeError** –If *logits* is not a Tensor.
- **TypeError** –If *labels* is not a Tensor.
- **TypeError** –If *margin* is not a float or int.
- **ValueError** –If *labels* does not have the same shape as *logits* or they could not broadcast to each other.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> arr1 = np.array([0.9, -1.2, 2, 0.8, 3.9, 2, 1, 0, -1]).reshape((3, 3))
>>> arr2 = np.array([1, 1, -1, 1, -1, 1, -1, 1, 1]).reshape((3, 3))
>>> logits = ms.Tensor(arr1, ms.float32)
>>> labels = ms.Tensor(arr2, ms.float32)
>>> loss = nn.HingeEmbeddingLoss(reduction='mean')
>>> output = loss(logits, labels)
>>> print(output)
0.16666667
```

3.14.10 mindspore.nn.HuberLoss

class mindspore.nn.**HuberLoss**(*reduction='mean'*, *delta=1.0*)

HuberLoss calculate the error between the predicted value and the target value. It has the advantages of both L1Loss and MSELoss.

Assuming that the x and y are 1-D Tensor, length N, then calculate the loss of x and y without dimensionality reduction (the reduction parameter is set to "none"). The formula is as follows:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top$$

with

$$l_n = \begin{cases} 0.5 * (x_n - y_n)^2, & \text{if } |x_n - y_n| < delta; \\ delta * (|x_n - y_n| - 0.5 * delta), & \text{otherwise.} \end{cases}$$

where N is the batch size. If *reduction* is not `"none"`, then:

$$\ell(x, y) = \begin{cases} \text{mean}(L), & \text{if reduction = "mean";} \\ \text{sum}(L), & \text{if reduction = "sum".} \end{cases}$$

Parameters

- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **delta** (*Union[int, float]*) –The threshold to change between two type of loss. The value must be positive. Default: `1.0` .

Inputs:

- **logits** (Tensor) - Predicted value, Tensor of any dimension. The data type must be float16 or float32.
- **labels** (Tensor) - Target value, same dtype and shape as the *logits* in common cases. However, it supports the shape of *logits* is different from the shape of *labels* and they should be broadcasted to each other.

Outputs:

Tensor or Scalar, if *reduction* is `"none"`, return a Tensor with same shape and dtype as *logits*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** –If data type of *logits* or *labels* is neither float16 nor float32.
- **TypeError** –If data type of *logits* or *labels* are not the same.
- **TypeError** –If dtype of *delta* is neither float nor int.
- **ValueError** –If *delta* is less than or equal to 0.
- **ValueError** –If *reduction* is not one of `"none"`, `"mean"`, `"sum"`.
- **ValueError** –If *logits* and *labels* have different shapes and cannot be broadcasted to each other.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> # Case 1: logits.shape = labels.shape = (3,)
>>> loss = nn.HuberLoss()
>>> logits = ms.Tensor(np.array([1, 2, 3]), ms.float32)
>>> labels = ms.Tensor(np.array([1, 2, 2]), ms.float32)
>>> output = loss(logits, labels)
>>> print(output)
0.16666667
>>> # Case 2: logits.shape = (3,), labels.shape = (2, 3)
>>> loss = nn.HuberLoss(reduction="none")
>>> logits = ms.Tensor(np.array([1, 2, 3]), ms.float32)
>>> labels = ms.Tensor(np.array([[1, 1, 1], [1, 2, 2]]), ms.float32)
>>> output = loss(logits, labels)
>>> print(output)
[[0.  0.5 1.5]
 [0.  0.  0.5]]
```

3.14.11 mindspore.nn.KLDivLoss

class mindspore.nn.**KLDivLoss**(*reduction='mean'*)

Computes the Kullback-Leibler divergence between the *logits* and the *labels*.

For tensors of the same shape x and $target$, the updating formulas of KLDivLoss algorithm are as follows,

$$L(x, target) = target \cdot (\log target - \log x)$$

Then,

$$\ell(x, target) = \begin{cases} L(x, target), & \text{if reduction = 'none';} \\ \text{mean}(L(x, target)), & \text{if reduction = 'mean';} \\ \text{sum}(L(x, target))/x.\text{shape}[0], & \text{if reduction = 'batchmean';} \\ \text{sum}(L(x, target)), & \text{if reduction = 'sum'.} \end{cases}$$

where x represents *logits*, $target$ represents *labels*, and $\ell(x, target)$ represents *output*.

Note:

- Currently it does not support float64 input on *Ascend*.
- The output aligns with the mathematical definition of Kullback-Leibler divergence only when *reduction* is set to 'batchmean'.

Parameters

reduction (*str*) – Specifies the reduction to be applied to the output. Default: `'mean'` .

- On Ascend, the value of *reduction* must be one of `'batchmean'` , `'none'` or `'sum'` .
- On GPU, the value of *reduction* must be one of `'mean'` , `'none'` or `'sum'` .
- On CPU, the value of *reduction* must be one of `'mean'` , `'batchmean'` , `'none'` or `'sum'` .

Inputs:

- **logits** (Tensor) - The input Tensor. The data type must be float16, float32 or float64.
- **labels** (Tensor) - The label Tensor which has the same shape and data type as *logits*.

Outputs:

Tensor or Scalar, if *reduction* is `'none'`, then output is a tensor and has the same shape as *logits*. Otherwise, it is a scalar.

Raises

- **TypeError** –If *reduction* is not a str.
- **TypeError** –If neither *logits* nor *labels* is a Tensor.
- **TypeError** –If dtype of *logits* or *labels* is not currently supported.
- **ValueError** –If shape of *logits* is not the same as *labels*.
- **RuntimeError** –If *logits* or *labels* is a scalar when *reduction* is 'batchmean'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> logits = ms.Tensor(np.array([0.2, 0.7, 0.1]), ms.float32)
>>> labels = ms.Tensor(np.array([0., 1., 0.]), ms.float32)
>>> loss = nn.KLDivLoss(reduction='mean')
>>> output = loss(logits, labels)
>>> print(output)
-0.23333333
```

3.14.12 mindspore.nn.L1Loss

class mindspore.nn.**L1Loss**(*reduction='mean'*)

L1Loss is used to calculate the mean absolute error between the predicted value and the target value.

Assuming that the x and y are 1-D Tensor, length N, then calculate the loss of x and y without dimensionality reduction (the reduction parameter is set to "none"). The formula is as follows:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad \text{with } l_n = |x_n - y_n|,$$

where N is the batch size. If *reduction* is not `'none'`, then:

$$\ell(x, y) = \begin{cases} \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Parameters

reduction (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .

- `'none'`: no reduction will be applied.
- `'mean'`: compute and return the mean of elements in the output.

- `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - Predicted value, Tensor of any dimension.
- **labels** (Tensor) - Target value, same shape as the *logits* in common cases. However, it supports the shape of *logits* is different from the shape of *labels* and they should be broadcasted to each other.

Outputs:

Tensor, data type is float.

Raises

- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.
- **ValueError** –If *logits* and *labels* have different shapes and cannot be broadcasted to each other.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> # Case 1: logits.shape = labels.shape = (3,)
>>> loss = nn.L1Loss()
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([1, 2, 2]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
0.33333334
>>> # Case 2: logits.shape = (3,), labels.shape = (2, 3)
>>> loss = nn.L1Loss(reduction='none')
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([[1, 1, 1], [1, 2, 2]]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
[[0. 1. 2.]
 [0. 0. 1.]]
```

3.14.13 mindspore.nn.MarginRankingLoss

class mindspore.nn.**MarginRankingLoss**(*margin=0.0*, *reduction='mean'*)

MarginRankingLoss creates a criterion that measures the loss.

Given two tensors $input1$, $input2$ and a Tensor label $target$ with values 1 or -1, the operation is as follows:

$$\text{loss}(input1, input2, target) = \max(0, -target * (input1 - input2) + \text{margin})$$

Parameters

- **margin** (*float, optional*) –Specify the adjustment factor of the operation. Default: `0.0`.

- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **input1** (Tensor) - Tensor of shape $(N, *)$ where $*$ means, any number of additional dimensions.
- **input2** (Tensor) - Tensor of shape $(N, *)$, same shape and dtype as *input1*.
- **target** (Tensor) - Contains value 1 or -1. Suppose the shape of *input1* is $(x_1, x_2, x_3, ..., x_R)$, then the shape of *target* must be $(x_1, x_2, x_3, ..., x_R)$.

Outputs:

Tensor or Scalar. if *reduction* is `'none'`, its shape is the same as *input1*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** –If *margin* is not a float.
- **TypeError** –If *input1*, *input2* or *target* is not a Tensor.
- **TypeError** –If the types of *input1* and *input2* are inconsistent.
- **TypeError** –If the types of *input1* and *target* are inconsistent.
- **ValueError** –If the shape of *input1* and *input2* are inconsistent.
- **ValueError** –If the shape of *input1* and *target* are inconsistent.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'` , `'sum'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, nn, ops
>>> import numpy as np
>>> loss1 = nn.MarginRankingLoss(reduction='none')
>>> loss2 = nn.MarginRankingLoss(reduction='mean')
>>> loss3 = nn.MarginRankingLoss(reduction='sum')
>>> sign = ops.Sign()
>>> input1 = Tensor(np.array([0.3864, -2.4093, -1.4076]), ms.float32)
>>> input2 = Tensor(np.array([-0.6012, -1.6681, 1.2928]), ms.float32)
>>> target = sign(Tensor(np.array([-2, -2, 3]), ms.float32))
>>> output1 = loss1(input1, input2, target)
>>> print(output1)
[0.98759997 0.         2.7003999 ]
>>> output2 = loss2(input1, input2, target)
>>> print(output2)
1.2293333
>>> output3 = loss3(input1, input2, target)
```

(continues on next page)

(continued from previous page)

```
>>> print(output3)
3.6879997
```

3.14.14 mindspore.nn.MAELoss

class mindspore.nn.**MAELoss**(*reduction='mean'*)

MAELoss creates a criterion to measure the average absolute error between x and y element-wise, where x is the input and y is the labels.

For simplicity, let x and y be 1-dimensional Tensor with length N, the unreduced loss (i.e. with argument reduction set to 'none') of x and y is given as:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad \text{with } l_n = |x_n - y_n|$$

where N is the batch size. If *reduction* is not `'none'`, then:

$$\ell(x, y) = \begin{cases} \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Parameters

reduction (*str, optional*) – Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .

- `'none'`: no reduction will be applied.
- `'mean'`: compute and return the mean of elements in the output.
- `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - Tensor of shape $(M, *)$ where $*$ means, any number of additional dimensions.
- **labels** (Tensor) - Tensor of shape $(N, *)$, same shape as the *logits* in common cases. However, it supports the shape of *logits* is different from the shape of *labels* and they should be broadcasted to each other.

Outputs:

Tensor, weighted loss float tensor, the shape is zero if *reduction* is `'mean'` or `'sum'` ., while the shape of output is the broadcasted shape if *reduction* is 'none'.

Raises

ValueError – If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> # Case 1: logits.shape = labels.shape = (3,)
>>> loss = nn.MAELoss()
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([1, 2, 2]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
0.33333334
>>> # Case 2: logits.shape = (3,), labels.shape = (2, 3)
>>> loss = nn.MAELoss(reduction='none')
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([[1, 1, 1], [1, 2, 2]]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
[[0. 1. 2.]
 [0. 0. 1.]]
```

3.14.15 mindspore.nn.MSELoss

class mindspore.nn.**MSELoss**(*reduction='mean'*)

Calculates the mean squared error between the predicted value and the label value.

For simplicity, let x and y be 1-dimensional Tensor with length N, the unreduced loss (i.e. with argument reduction set to 'none') of x and y is given as:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad \text{with} \quad l_n = (x_n - y_n)^2.$$

where N is the batch size. If *reduction* is not `'none'`, then:

$$\ell(x, y) = \begin{cases} \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Parameters

reduction (*str, optional*) – Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .

- `'none'`: no reduction will be applied.
- `'mean'`: compute and return the mean of elements in the output.
- `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - The predicted value of the input. Tensor of any dimension.
- **labels** (Tensor) - The input label. Tensor of any dimension, same shape as the *logits* in common cases. However, it supports the shape of *logits* is different from the shape of *labels* and they should be broadcasted to each other.

Outputs:

Tensor, loss of type float, the shape is zero if *reduction* is `'mean'` or `'sum'` , while the shape of output is the broadcasted shape if *reduction* is 'none'.

Raises

- **ValueError** –If *reduction* is not one of `'none'`, `'mean'` or `'sum'`.
- **ValueError** –If *logits* and *labels* have different shapes and cannot be broadcasted.
- **TypeError** –if *logits* and *labels* have different data types.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> # Case 1: logits.shape = labels.shape = (3,)
>>> loss = nn.MSELoss()
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([1, 1, 1]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
1.6666667
>>> # Case 2: logits.shape = (3,), labels.shape = (2, 3)
>>> loss = nn.MSELoss(reduction='none')
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([[1, 1, 1], [1, 2, 2]]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
[[0. 1. 4.]
 [0. 0. 1.]]
```

3.14.16 mindspore.nn.MultiClassDiceLoss

class mindspore.nn.**MultiClassDiceLoss**(*weights=None*, *ignore_indiex=None*, *activation='softmax'*)

When there are multiple classifications, label is transformed into multiple binary classifications by one hot. For each channel section in the channel, it can be regarded as a binary classification problem, so it can be obtained through the binary *mindspore.nn.DiceLoss* losses of each category, and then the average value of the binary losses.

Parameters

- **weights** (*Union[Tensor, None]*) –Tensor of shape ($num\_classes, dim$). The weight shape[0] should be equal to labels shape[1]. Default: `None` .
- **ignore_indiex** (*Union[int, None]*) –Class index to ignore. Default: `None` .
- **activation** (*Union[str, Cell]*) –Activate function applied to the output of the fully connected layer, eg. 'ReLU'. Default: `'softmax'` . Choose from: [`'softmax'` , `'logsoftmax'` , `'relu'` , `'relu6'` , `'tanh'` , `'Sigmoid'`]

Inputs:

- **logits** (Tensor) - Tensor of shape $(N, C, *)$ where $*$ means, any number of additional dimensions. The logits dimension should be greater than 1. The data type must be float16 or float32.
- **labels** (Tensor) - Tensor of shape $(N, C, *)$, same shape as the *logits*. The labels dimension should be greater than 1. The data type must be float16 or float32.

Outputs:

Tensor, a tensor of shape with the per-example sampled MultiClass Dice Losses.

Raises

- **ValueError** –If the shape of *logits* is different from *labels*.
- **TypeError** –If the type of *logits* or *labels* is not a tensor.
- **ValueError** –If the dimension of *logits* or *labels* is less than 2.
- **ValueError** –If the weights.shape[0] is not equal to labels.shape[1].
- **ValueError** –If *weights* is a tensor, but its dimension is not 2.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> loss = nn.MultiClassDiceLoss(weights=None, ignore_indiex=None, activation="softmax")
>>> logits = Tensor(np.array([[0.2, 0.5, 0.7], [0.3, 0.1, 0.5], [0.9, 0.6, 0.3]]), mindspore.
↪float32)
>>> labels = Tensor(np.array([[0, 1, 0], [1, 0, 0], [0, 0, 1]]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
0.54958105
```

3.14.17 mindspore.nn.MultilabelMarginLoss

class mindspore.nn.**MultilabelMarginLoss**(*reduction='mean'*)

Creates a loss criterion that minimizes the hinge loss for multi-class classification tasks. It takes a 2D mini-batch Tensor x as input and a 2D Tensor y containing target class indices as output.

Each sample in the mini-batch, the loss is computed as follows:

$$\text{loss}(x, y) = \sum_{ij} \frac{\max(0, 1 - (x[y[j]] - x[i]))}{\text{x.size}(0)}$$

where $x \in \{0, \cdots, \text{x.size}(0) - 1\}$, $y \in \{0, \cdots, \text{y.size}(0) - 1\}$, $0 \leq y[j] \leq \text{x.size}(0) - 1$, and for all i and j, i does not equal to $y[j]$.

Furthermore, both y and x should have identical sizes.

Note: For this operator, only a contiguous sequence of non-negative targets that starts at the beginning is taken into consideration, which means that different samples can have different number of target classes.

Parameters

reduction (*str, optional*) –Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'mean'`.

- `'none'`: no reduction will be applied.
- `'mean'`: compute and return the mean of elements in the output.
- `'sum'`: the output elements will be summed.

Inputs:

- **x** (Tensor) - Predict data. Tensor of shape (C) or (N, C), where N is the batch size and C is the number of classes. Data type must be float16 or float32.
- **target** (Tensor) - Ground truth data, with the same shape as x, data type must be int32 and label targets padded by -1.

Outputs:

- **y** (Union[Tensor, Scalar]) - The loss of MultilabelMarginLoss. If *reduction* is `"none"`, its shape is (N). Otherwise, a scalar value will be returned.

Raises

- **TypeError** –If x or *target* is not a Tensor.
- **TypeError** –If dtype of x is neither float16 nor float32.
- **TypeError** –If dtype of *target* is not int32.
- **ValueError** –If length of shape of x is neither 1 nor 2.
- **ValueError** –If shape of x is not the same as *target*.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> loss = nn.MultilabelMarginLoss()
>>> x = ms.Tensor(np.array([[0.1, 0.2, 0.4, 0.8], [0.2, 0.3, 0.5, 0.7]]), ms.float32)
>>> target = ms.Tensor(np.array([[1, 2, 0, 3], [2, 3, -1, 1]]), ms.int32)
>>> output = loss(x, target)
>>> print(output)
0.325
```

3.14.18 mindspore.nn.MultiLabelSoftMarginLoss

class mindspore.nn.**MultiLabelSoftMarginLoss**(*weight=None*, *reduction='mean'*)

Calculates the MultiLabelSoftMarginLoss. The multi-label soft margin loss is a commonly used loss function in multi-label classification tasks where an input sample can belong to multiple classes. Given an input x and binary labels y of size (N, C), where N denotes the number of samples and C denotes the number of classes.

$$loss\,(x, y) = -\frac{1}{N}\frac{1}{C}\sum_{i=1}^{N}\sum_{j=1}^{C}\left(y_{ij}\log\frac{1}{1+e^{-x_{ij}}} + (1-y_{ij})\log\frac{e^{-x_{ij}}}{1+e^{-x_{ij}}}\right)$$

where x_{ij} represents the predicted score of sample i for class j. y_{ij} represents the binary label of sample i for class j, where sample i belongs to class j if $y_{ij} = 1$, and sample i does not belong to class j if $y_{ij} = 0$. For a multi-label classification task, each sample may have multiple labels with a value of 1 in the binary label y. *weight* will multiply to the loss of each class if given.

Parameters

- **weight** (*Union[Tensor, int, float]*) –The manual rescaling weight given to each class. Default: `None` .
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **x** (Tensor) - A tensor of shape (N, C), where N is batch size and C is number of classes.
- **target** (Tensor) - The label target Tensor which has the same shape as x.

Outputs:

Tensor, the data type is the same as x, if the reduction is `'none'`, its shape is (N), otherwise it is zero.

Raises

ValueError –If the rank of x or *target* is not 2.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> x = ms.Tensor([[0.3, 0.6, 0.6], [0.9, 0.4, 0.2]])
>>> target = ms.Tensor([[0.0, 0.0, 1.0], [0.0, 0.0, 1.0]])
>>> loss = nn.MultiLabelSoftMarginLoss(reduction='mean')
>>> out = loss(x, target)
>>> print(out.asnumpy())
0.84693956
```

3.14.19 mindspore.nn.MultiMarginLoss

class mindspore.nn.**MultiMarginLoss**(*p=1*, *margin=1.0*, *reduction='mean'*, *weight=None*)

Creates a criterion that optimizes a multi-class classification hinge loss (margin-based loss) between input x (a 2D mini-batch *Tensor*) and output y (which is a 1D tensor of target class indices, $0 \leq y \leq \text{x.size}(1) - 1$):

For each mini-batch sample, the loss in terms of the 1D input x and scalar output y is:

$$\text{loss}(x, y) = \frac{\sum_i \max(0, w[y] * (\text{margin} - x[y] + x[i]))^p}{\text{x.size}(0)}$$

where $x \in \{0, \cdots, \text{x.size}(0) - 1\}$ and $i \neq y$.

Parameters

- **p** (*int, optional*) −The norm degree for pairwise distance. Should be 1 or 2. Default: `1` .
- **margin** (*float, optional*) −A parameter to change pairwise distance. Default: 1.0.
- **reduction** (*str, optional*) −Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **weight** (`Tensor`, *optional*) −The rescaling weight to each class with shape $(C,)$. Data type only support float32, float16 or float64. Default: `None` , all classes are weighted equally.

Inputs:

- **x** (Tensor) - Input x, with shape (N, C). Data type only supports float32, float16 or float64. x is *x* in the above formula.
- **target** (Tensor) - Ground truth labels, with shape $(N,)$. Data type only supports int64. The value of target should be non-negative, less than C. *target* is *y* in the above formula.

Outputs:

Tensor. When *reduction* is `'none'`, the shape is $(N,)$. Otherwise, it is a scalar. Has the same data type with *x*.

Raises

- **TypeError** −If dtype of *p* or *target* is not int.
- **TypeError** −If dtype of *margin* is not float.
- **TypeError** −If dtype of *reduction* is not str.
- **TypeError** −If dtype of *x* is not float16, float or float64.
- **TypeError** −If dtype of *weight* and *x* is not the same.
- **ValueError** −If *p* is not 1 or 2.
- **ValueError** −If *reduction* is not one of { `'none'` , `'sum'` , `'mean'` }.
- **ValueError** −If shape[0] of *x* is not equal to shape[0] of *target*.
- **ValueError** −If shape[1] of *x* is not equal to shape[0] of *weight*.
- **ValueError** −IF rank of *weight* is not 1.
- **ValueError** −If rank of *x* is not 2 or rank of 'target' is not 1.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> x = ms.Tensor(np.ones(shape=[3, 3]), ms.float32)
>>> target = ms.Tensor(np.array([1, 2, 1]), ms.int64)
>>> loss = nn.MultiMarginLoss()
>>> output = loss(x, target)
>>> print(output)
0.6666667
```

3.14.20 mindspore.nn.NLLLoss

class mindspore.nn.**NLLLoss**(*weight=None*, *ignore_index=- 100*, *reduction='mean'*)

Gets the negative log likelihood loss between logits and labels.

The nll loss with $reduction = none$ can be described as:

$$\ell(x, t) = L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -w_{t_n} x_{n,t_n}, \quad w_c = \text{weight}\,[c] \cdot \mathbb{1}\{c \neq \text{ignore\_index}\}$$

where x is the logits, t is the labels, w is the weight, N is the batch size, c belonging to $[0, C-1]$ is class index, where C is the number of classes.

If $reduction \neq none$ (default `'mean'`), then

$$\ell(x, t) = \begin{cases} \sum_{n=1}^{N} \frac{1}{\sum_{n=1}^{N} w_{tn}} l_n, & \text{if reduction = 'mean',} \\ \sum_{n=1}^{N} l_n, & \text{if reduction = 'sum'} \end{cases}$$

Parameters

- **weight** (Tensor) – The rescaling weight to each class. If the value is not None, the shape is $(C,)$. The data type only supports float32 or float16. Default: `None`.
- **ignore_index** (*int*) – Specifies a target value that is ignored (typically for padding value) and does not contribute to the gradient. Default: `-100`.
- **reduction** (*str, optional*) – Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'mean'`.
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - Tensor of shape (N, C) or $(N, C, d_1, d_2, ..., d_K)$ for K-dimensional data, where $C = number\ of\ classes$. Data type must be float16 or float32. *inputs* needs to be logarithmic probability.
- **labels** (Tensor) -(N) or $(N, d_1, d_2, ..., d_K)$ for K-dimensional data. Data type must be int32.

Returns

Tensor, the computed negative log likelihood loss value.

Raises

- **TypeError** – If *weight* is not a Tensor.

- **TypeError** –If *ignore_index* is not an int.
- **TypeError** –If the data type of *weight* is not float16 or float32.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.
- **TypeError** –If *logits* is not a Tensor.
- **TypeError** –If *labels* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> logits = ms.Tensor(np.random.randn(3, 5), ms.float32)
>>> labels = ms.Tensor(np.array([1, 0, 4]), ms.int32)
>>> loss = nn.NLLLoss()
>>> output = loss(logits, labels)
```

3.14.21 mindspore.nn.PoissonNLLLoss

class mindspore.nn.**PoissonNLLLoss**(*log_input=True*, *full=False*, *eps=1e-08*, *reduction='mean'*)

Poisson negative log likelihood loss.

The loss is:

$$\mathcal{L}_D = \sum_{i=0}^{|D|} (x_i - y_i \ln x_i + \ln y_i!)$$

where $\mathcal{L}_D$ is the loss, y_i is the *target*, x_i is the *input*.

If *log_input* is True, use $e^{x_i} - y_i x_i$ instead of $x_i - y_i \ln x_i$. When calculating logarithms, the lower bound of *input* is set to *eps* to avoid numerical errors.

If *full* is False, the last term $\ln y_i!$ will be omitted, otherwise the last term will be approximated using Stirling formula:

$$n! \approx \sqrt{2\pi n} \left(\frac{n}{e}\right)^n$$

Note: Calculating the logarithm of a negative number or the exponent of a large positive number under Ascend will have a different range of return values and results different from those under GPU and CPU.

Parameters

- **log_input** (*bool, optional*) –Whether use log input. Default: `True` .
- **full** (*bool, optional*) –Whether include the Stirling approximation term in the loss calculation. Default: `False` .
- **eps** (*float, optional*) –Lower bound of *input* when calculating logarithms. Default: `1e-08` .

- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **input** (Tensor) - The input Tensor. The shape can be any number of dimensions.
- **target** (Tensor) - The label Tensor which has the same shape as *input*.

Outputs:

Tensor or Scalar, if *reduction* is `'none'`, then output is a tensor and has the same shape as *input*. Otherwise it is a scalar.

Raises

- **TypeError** –If *reduction* is not a str.
- **TypeError** –If neither *input* nor *target* is a tensor.
- **TypeError** –If dtype of *input* or *target* is not currently supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> x = ms.Tensor([[0.3, 0.7], [0.5, 0.5]])
>>> target = ms.Tensor([[1.0, 2.0], [3.0, 4.0]])
>>> loss = nn.PoissonNLLLoss()
>>> output = loss(x, target)
>>> print(output.asnumpy())
0.3652635
```

3.14.22 mindspore.nn.RMSELoss

class mindspore.nn.**RMSELoss**

RMSELoss creates a criterion to measure the root mean square error between x and y element-wise, where x is the input and y is the labels.

For simplicity, let x and y be 1-dimensional Tensor with length N, the loss of x and y is given as:

$$loss = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(x_i - y_i)^2}$$

Inputs:

- **logits** (Tensor) - Tensor of shape $(N, *)$ where $*$ means, any number of additional dimensions.
- **labels** (Tensor) - Tensor of shape $(N, *)$, same shape as the *logits* in common cases. However, it supports the shape of *logits* is different from the shape of *labels* and they should be broadcasted to each other.

Outputs:

Tensor, weighted loss float tensor and its shape is ().

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> # Case 1: logits.shape = labels.shape = (3,)
>>> loss = nn.RMSELoss()
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([1, 2, 2]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
0.57735026
>>> # Case 2: logits.shape = (3,), labels.shape = (2, 3)
>>> loss = nn.RMSELoss()
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([[1, 1, 1], [1, 2, 2]]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
1.0
```

3.14.23 mindspore.nn.SampledSoftmaxLoss

class mindspore.nn.**SampledSoftmaxLoss**(*num_sampled*, *num_classes*, *num_true=1*, *sampled_values=None*, *remove_accidental_hits=True*, *seed=0*, *reduction='none'*)

Computes the sampled softmax training loss. This operator can accelerate the training of the softmax classifier over a large number of classes. It is generally an underestimate of the full softmax loss.

Parameters

- **num_sampled** (*int*) –The number of classes to randomly sample per batch.
- **num_classes** (*int*) –The number of possible classes.
- **num_true** (*int*) –The number of labels classes per training example. Default: `1` .
- **sampled_values** (*Union[list, tuple]*) –List or tuple of (*sampled_candidates*, *true_expected_count*, *sampled_expected_count*) returned by a **CandidateSampler* function. Default to None, *UniformCandidateSampler* is applied. Default: `None` .
- **remove_accidental_hits** (*bool*) –Whether to remove "accidental hits" where a sampled class equals to one of the labels classes. Default: `True` .
- **seed** (*int*) –Random seed for candidate sampling. Default: `0`.
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'none'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **weights** (Tensor) - The weights of input. Tensor of shape (C, dim).
- **bias** (Tensor) - Tensor of shape $(C,)$. The class biases.
- **labels** (Tensor) - Tensor of shape (N, num_true), type *int64, int32*. The labels classes.
- **logits** (Tensor) - Tensor of shape (N, dim). The forward activations of the input network.

Outputs:

Tensor or Scalar, if *reduction* is `'none'`, then output is a tensor with shape $(N,)$. Otherwise, the output is a scalar.

Raises

- **TypeError** –If *sampled_values* is not a list or tuple.
- **TypeError** –If dtype of *labels* is neither int32 nor int64.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.
- **ValueError** –If *num_sampled* or *num_true* is greater than *num_classes*.
- **ValueError** –If length of *sampled_values* is not equal to 3.

Supported Platforms:

`GPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> mindspore.set_seed(1)
>>> loss = nn.SampledSoftmaxLoss(num_sampled=4, num_classes=7, num_true=1)
>>> weights = Tensor(np.random.randint(0, 9, [7, 10]), mindspore.float32)
>>> biases = Tensor(np.random.randint(0, 9, [7]), mindspore.float32)
>>> labels = Tensor([0, 1, 2])
>>> logits = Tensor(np.random.randint(0, 9, [3, 10]), mindspore.float32)
>>> output = loss(weights, biases, labels, logits)
>>> print(output)
[4.6051701e+01 1.4000047e+01 6.1989022e-06]
```

3.14.24 mindspore.nn.SmoothL1Loss

class mindspore.nn.**SmoothL1Loss**(*beta=1.0*, *reduction='none'*)

SmoothL1 loss function. Compare the error value element-wise and if the absolute error between the predicted value and the target value is less than the set threshold *beta*, the square term is used, otherwise the absolute error term is used.

Given two input x, y, the SmoothL1Loss can be described as follows:

$$L_i = \begin{cases} \frac{0.5(x_i - y_i)^2}{\text{beta}}, & \text{if } |x_i - y_i| < \text{beta} \\ |x_i - y_i| - 0.5 * \text{beta}, & \text{otherwise.} \end{cases}$$

Where beta represents the threshold *beta*.

If *reduction* is not *none*, then:

$$L = \begin{cases} \text{mean}(L_i), & \text{if reduction = 'mean';} \\ \text{sum}(L_i), & \text{if reduction = 'sum'.} \end{cases}$$

Note:

- SmoothL1Loss can be regarded as modified version of *mindspore.nn.L1Loss* or a combination of *mindspore.nn.L1Loss* and *mindspore.ops.L2Loss*.
- *mindspore.nn.L1Loss* computes the element-wise absolute difference between two input tensor while *mindspore.ops.L2Loss* computes the
- squared difference between two input tensors. *mindspore.ops.L2Loss* often leads to faster convergence but it is less robust to outliers, and the loss function has better robustness.

Parameters

- **beta** (*number, optional*) – The loss function calculates the threshold of the transformation between L1Loss and L2Loss. Default: `1.0`.
  - Ascend: The value should be equal to or greater than zero.
  - CPU/GPU: The value should be greater than zero.
- **reduction** (*str, optional*) – Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'none'`.
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - Predictive value. Tensor of any dimension. Supported dtypes:
  - Ascend: float16, float32, bfloat16.
  - CPU/GPU: float16, float32, float64.
- **labels** (Tensor) - Ground truth data.
  - CPU/Ascend: has the same shape as the *logits*, *logits* and *labels* comply with the implicit type conversion rules to make the data types consistent.
  - GPU: has the same shape and dtype as the *logits*.

Outputs:

Tensor, if *reduction* is `'none'`, then output is a tensor with the same shape as *logits*. Otherwise the shape of output tensor is ().

Raises

- **TypeError** – If input *logits* or *labels* are not Tensor.
- **RuntimeError** – If dtype of *logits* or *labels* is not one of float16, float32, float64, bfloat16.
- **ValueError** – If shape of *logits* is not the same as *labels*.
- **ValueError** – If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.
- **TypeError** – If *beta* is not a float, int or bool.

- **RuntimeError** –If *beta* is less than or equal to 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> loss = nn.SmoothL1Loss()
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([1, 2, 2]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
[0.  0.  0.5]
```

3.14.25 mindspore.nn.SoftMarginLoss

class mindspore.nn.**SoftMarginLoss**(*reduction='mean'*)

A loss class for two-class classification problems.

SoftMarginLoss creates a criterion that optimizes a two-class classification logistic loss between input tensor x and labels tensor y (containing 1 or -1).

$$\text{loss}(x, y) = \sum_i \frac{\log(1 + \exp(-y[i] * x[i]))}{x.nelement()}$$

$x.nelement()$ represents the number of element of x .

Parameters

reduction (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .

- `'none'`: no reduction will be applied.
- `'mean'`: compute and return the mean of elements in the output.
- `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - Predict data. Data type must be float16, float32, bfloat16 (Among them, the Atlas training series products do not support bfloat16).
- **labels** (Tensor) - Ground truth data, with the same shape as *logits*. In GE mode, the data type should be the same as *logits*.

Outputs:

Tensor or Scalar, if *reduction* is `'none'`, its shape is the same as *logits*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** –If *logits* or *labels* is not a Tensor.

- **TypeError** –If dtype of *logits* or *labels* is not float16, float32, bfloat16 (Among them, the Atlas training series products do not support bfloat16).
- **ValueError** –If shape of *logits* is not the same as *labels*.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> loss = nn.SoftMarginLoss()
>>> logits = Tensor(np.array([[0.3, 0.7], [0.5, 0.5]]), mindspore.float32)
>>> labels = Tensor(np.array([[-1, 1], [1, -1]]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
0.6764238
```

3.14.26 mindspore.nn.SoftmaxCrossEntropyWithLogits

class mindspore.nn.**SoftmaxCrossEntropyWithLogits**(*sparse=False*, *reduction='none'*)

Computes softmax cross entropy between logits and labels.

Measures the distribution error between the probabilities of the input (computed with softmax function) and the labels where the classes are mutually exclusive (only one class is positive) using cross entropy loss.

Typical input into this function is unnormalized scores denoted as x whose shape is (N, C) , and the corresponding targets.

Typically, the input to this function is the fractional value of each category and the corresponding target value, and the input format is (N, C) .

For each instance x_i, i ranges from 0 to N-1, the loss is given as:

$$\ell(x_i, c) = -\log\left(\frac{\exp(x_i[c])}{\sum_j \exp(x_i[j])}\right) = -x_i[c] + \log\left(\sum_j \exp(x_i[j])\right)$$

where x_i is a 1D score Tensor, c is the index of 1 in one-hot.

Note: While the labels classes are mutually exclusive, i.e., only one class is positive in the labels, the predicted probabilities does not need to be exclusive. It is only required that the predicted probability distribution of entry is a valid one.

Parameters

- **sparse** (*bool, optional*) –Specifies whether labels use sparse format or not. Default: `False` .
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'none'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.

  - `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - Tensor of shape (N, C) . Data type must be float16 or float32.
- **labels** (Tensor) - Tensor of shape $(N,)$. If *sparse* is True, The type of *labels* is int32 or int64. Otherwise, the type of *labels* is the same as the type of *logits*.

Outputs:

Tensor, a tensor of the same shape and type as logits with the component-wise logistic losses.

Raises

- **TypeError** –If *sparse* is not a bool.
- **TypeError** –If *sparse* is `True` and dtype of *labels* is neither int32 nor int64.
- **TypeError** –If *sparse* is `False` and dtype of *labels* is neither float16 not float32.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> # case 1: sparse=True
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> logits = Tensor(np.array([[3, 5, 6, 9, 12, 33, 42, 12, 32, 72]]), mindspore.float32)
>>> labels_np = np.array([1]).astype(np.int32)
>>> labels = Tensor(labels_np)
>>> output = loss(logits, labels)
>>> print(output)
[67.]
>>> # case 2: sparse=False
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=False)
>>> logits = Tensor(np.array([[3, 5, 6, 9, 12, 33, 42, 12, 32, 72]]), mindspore.float32)
>>> labels_np = np.array([[0, 0, 0, 0, 0, 0, 1, 0, 0, 0]]).astype(np.float32)
>>> labels = Tensor(labels_np)
>>> output = loss(logits, labels)
>>> print(output)
[30.]
```

3.14.27 mindspore.nn.TripletMarginLoss

class mindspore.nn.**TripletMarginLoss**(*p=2*, *swap=False*, *eps=1e-06*, *reduction='mean'*, *margin=1.*)

TripletMarginLoss operation.

Triple loss is used to measure the relative similarity between samples, which is measured by a triplet and a *margin* with a value greater than 0 . The triplet is composed by a, p, n in the following formula.

The shapes of all input tensors should be $(N, *)$, where N is batch size and $*$ means any number of additional dimensions.

The distance swap is described in detail in the paper Learning local feature descriptors with triplets and shallow convolutional neural networks by V. Balntas, E. Riba et al.

The loss function for each sample in the mini-batch is:

$$L(a, p, n) = \max\{d(a_i, p_i) - d(a_i, n_i) + \text{margin}, 0\}$$

where

$$d(x_i, y_i) = \|\mathbf{x}_i - \mathbf{y}_i\|_p$$

Parameters

- **p** (*int, optional*) –The degree of norm for pairwise distance. Default: `2` .
- **eps** (*float, optional*) –Add small value to avoid division by zero. Default: `1e-06` .
- **swap** (*bool, optional*) –The distance swap change the negative distance to the distance between positive sample and negative sample. Default: `False` .
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **margin** (*Union[Tensor, float]*) –Make a margin between the positive pair and the negative pair. The length of shape of *margin* must be 0. Default: `1.0` .

Inputs:

- **x** (Tensor) - A sample randomly selected from the training set. Data type must be BasicType. a in the above formula.
- **positive** (Tensor) - A sample belonging to the same category as x, with the same type and shape as x. p in the above formula.
- **negative** (Tensor) - A sample belonging to the different class from x, with the same type and shape as x. n in the above formula.
- **margin** (Union[Tensor, float]) - Make a margin between the positive pair and the negative pair. The length of shape of *margin* must be 0. Default: `1.0` .

Outputs:

Tensor. If *reduction* is `"none"`, its shape is (N). Otherwise, a scalar value will be returned.

Raises

- **TypeError** –If x or *positive* or 'negative' is not a Tensor.
- **TypeError** –If dtype of x, *positive* and *negative* is not the same.

- **TypeError** – If *p* is not an int.
- **TypeError** – If *eps* is not a float.
- **TypeError** – If *swap* is not a bool.
- **ValueError** – If dimensions of input *x*, *positive* and *negative* are less than or equal to 1 at the same time.
- **ValueError** – If the dimension of input *x* or *positive* or *negative* is bigger than or equal to 8.
- **ValueError** – If length of shape of *margin* is not 0.
- **ValueError** – If shape of *x*, *positive* and *negative* cannot broadcast.
- **ValueError** – If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`GPU`

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> import numpy as np
>>> loss = nn.TripletMarginLoss()
>>> x = ms.Tensor(np.array([[0.3, 0.7], [0.5, 0.5]]), ms.float32)
>>> positive = ms.Tensor(np.array([[0.4, 0.6], [0.4, 0.6]]), ms.float32)
>>> negative = ms.Tensor(np.array([[0.2, 0.9], [0.3, 0.7]]), ms.float32)
>>> output = loss(x, positive, negative)
>>> print(output)
0.8881968
```

3.15 Optimizer

API Name	Description	Supported Platforms
mindspore.nn.Adadelta	Implements the Adadelta algorithm.	`Ascend` `GPU` `CPU`
mindspore.nn.Adagrad	Implements the Adagrad algorithm.	`Ascend` `GPU` `CPU`
mindspore.nn.Adam	Implements the Adaptive Moment Estimation (Adam) algorithm.	`Ascend` `GPU` `CPU`
mindspore.nn.AdaMax	Implements the AdaMax algorithm, a variant of Adaptive Movement Estimation (Adam) based on the infinity norm.	`Ascend` `GPU` `CPU`
mindspore.nn.AdamWeightDecay	Implements the Adam algorithm with weight decay.	`Ascend` `GPU` `CPU`
mindspore.nn.AdaSumByDeltaWeightWrapCell	Enable the adasum in "auto_parallel/semi_auto_parallel" mode.	`Ascend` `GPU`
mindspore.nn.AdaSumByGradWrapCell	Enable the adasum in "auto_parallel/semi_auto_parallel" mode.	`Ascend` `GPU`
mindspore.nn.ASGD	Implements Average Stochastic Gradient Descent.	`Ascend` `GPU` `CPU`
mindspore.nn.FTRL	Implements the FTRL algorithm.	`Ascend` `GPU`
mindspore.nn.Lamb	Implements the Lamb(Layer-wise Adaptive Moments optimizer for Batching training) algorithm.	`Ascend` `GPU`
mindspore.nn.LARS	Implements the LARS algorithm.	`Ascend`

continues on next page

Table 15 – continued from previous page

mindspore.nn.LazyAdam	Implements the Adaptive Moment Estimation (Adam) algorithm.	Ascend GPU CPU
mindspore.nn.Momentum	Implements the Momentum algorithm.	Ascend GPU CPU
mindspore.nn.OptTFTWrapper	Implements TFT optimizer wrapper, this wrapper is used to report status to MindIO TFT before optimizer updating.	Ascend
mindspore.nn.ProximalAdagrad	Implements the ProximalAdagrad algorithm that is an online Learning and Stochastic Optimization.	Ascend GPU
mindspore.nn.RMSProp	Implements Root Mean Squared Propagation (RMSProp) algorithm.	Ascend GPU CPU
mindspore.nn.Rprop	Implements Resilient backpropagation.	Ascend GPU CPU
mindspore.nn.SGD	Implements stochastic gradient descent.	Ascend GPU CPU

3.15.1 mindspore.nn.Adadelta

class mindspore.nn.**Adadelta**(*params*, *learning_rate=1.0*, *rho=0.9*, *epsilon=1e-6*, *loss_scale=1.0*, *weight_decay=0.0*)

Implements the Adadelta algorithm.

Adadelta is an online Learning and Stochastic Optimization. Refer to paper ADADELTA: AN ADAPTIVE LEARNING RATE METHOD.

$$
\begin{aligned}
accum_t &= \rho * accum_{t-1} + (1-\rho) * g_t^2 \\
update_t &= \sqrt{accum\_update_{t-1} + \epsilon} * \frac{g_t}{\sqrt{accum_t + \epsilon}} \\
accum\_update_t &= \rho * accum\_update_{t-1} + (1-\rho) * update_t^2 \\
w_t &= w_{t-1} - \gamma * update_t
\end{aligned}
$$

where g represents *grads*, γ represents *learning_rate*, ρ represents *rho*, ϵ represents *epsilon*, w represents *params*, $accum$ represents accumulation, $accum\_update$ represents accumulation update, t represents current step.

Note: If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) – Must be list of *Parameter* or list of *dict*. When the *params* is a list of *dict*, the string *"params"*, *"lr"*, *"weight_decay"*, *"grad_centralization"* and *"order_params"* are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.
  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is `False` by default. This configuration only works on the convolution layer.

  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.

- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule], optional*) – Default: `1.0`.
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.
  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of current step.
- **rho** (*float, optional*) – Decay rate, must be in range [0.0, 1.0]. Default: `0.9`.
- **epsilon** (*float, optional*) – A small value added for numerical stability, must be non-negative. Default: `1e-6`.
- **loss_scale** (*float, optional*) – Value for the loss scale. It must be greater than 0.0. In general, use the default value. Only when *FixedLossScaleManager* is used for training and the *drop_overflow_update* in *FixedLossScaleManager* is set to `False`, then this value needs to be the same as the *loss_scale* in *FixedLossScaleManager*. Refer to class *mindspore.amp.FixedLossScaleManager* for more details. Default: `1.0`.
- **weight_decay** (*Union[float, int, Cell], optional*) – Weight decay (L2 penalty). Default: `0.0`.
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.
  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.

Inputs:

- **grads** (tuple[Tensor]) - The gradients of *params* in the optimizer, has the same shape and data type as the *params* in optimizer. With float16 or float32 data type.

Outputs:

Tensor[bool], the value is `True`.

Raises

- **TypeError** – If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** – If element of *params* is neither Parameter nor dict.
- **TypeError** – If *rho*, *epsilon* or *loss_scale* is not a float.
- **TypeError** – If *weight_decay* is not float, int or cell.
- **ValueError** – if *rho* is not in range [0.0, 1.0].
- **ValueError** – If *loss_scale* is less than or equal to 0.
- **ValueError** – If *learning_rate*, *epsilon* or *weight_decay* is less than 0.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>>
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.conv = nn.Conv1d(120, 240, 4)
...         self.fc = nn.Dense(4, 1)
...     def construct(self, x):
...          x = self.conv(x)
...          x = self.fc(x)
...          return x
>>> net = Net()
>>> #1) All parameters use the same learning rate and weight decay
>>> optim = nn.Adadelta(params=net.trainable_params())
>>>
>>> #2) Use parameter groups and set different values
>>> conv_params = list(filter(lambda x: 'conv' in x.name, net.trainable_params()))
>>> no_conv_params = list(filter(lambda x: 'conv' not in x.name, net.trainable_params()))
>>> group_params = [{'params': conv_params, 'weight_decay': 0.01, 'grad_centralization':True}
 ↪,
...                 {'params': no_conv_params, 'lr': 0.01},
...                 {'order_params': net.trainable_params()}]
>>> optim = nn.Adadelta(group_params, learning_rate=0.1, weight_decay=0.0)
>>> # The conv_params's parameters will use default learning rate of 0.1 and weight decay of␣
 ↪0.01 and grad
>>> # centralization of True.
>>> # The no_conv_params's parameters will use learning rate of 0.01 and default weight␣
 ↪decay of 0.0 and grad
>>> # centralization of False.
>>> # The final parameters order in which the optimizer will be followed is the value of
 ↪'order_params'.
>>>
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> model = ms.train.Model(net, loss_fn=loss, optimizer=optim)
```

3.15.2 mindspore.nn.Adagrad

class mindspore.nn.**Adagrad**(*params*, *accum=0.1*, *learning_rate=0.001*, *update_slots=True*, *loss_scale=1.0*, *weight_decay=0.0*)

Implements the Adagrad algorithm.

Adagrad is an online Learning and Stochastic Optimization. Refer to paper Efficient Learning using Forward-Backward Splitting. Adagrad can adaptively assign different learning rates to each parameter in response to the uneven number of samples for different parameters.

The updating Pseudo codes are as follows:

Parameters : learning rate γ, params w_0, weight decay λ,
initial accumulator value $state\_sum$
Init : $state\_sum_0 \leftarrow 0$

---

for $t = 1$ **to** ... **do**
$g_t \leftarrow \nabla_w f_t(w_{t-1})$
if $\lambda \neq 0$
$g_t \leftarrow g_t + \lambda w_{t-1}$
$state\_sum_t \leftarrow state\_sum_{t-1} + g_t^2$
$w_t \leftarrow w_{t-1} - \gamma * \frac{g_t}{\sqrt{state\_sum_t}+\epsilon}$

---

return $\mathbf{w_t}$

---

state_sum stands for the accumulated squared sum of the gradients $accum$. g stands for *grads*, λ stands for *weight_decay*. γ stands for *learning_rate*, w stands for *params*. t represents current *step*.

Note: If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) – Must be list of *Parameter* or list of *dict*. When the *params* is a list of *dict*, the string "params", "lr", "weight_decay", "grad_centralization" and "order_params" are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.
  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.
- **accum** (*float, optional*) – The starting value for h, must be zero or positive values. Default: `0.1`.
- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule], optional*) – Default: `0.001`.

  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.
  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of current step.

- **update_slots** (*bool, optional*) – Whether the *h* will be updated. Default: `True` .
- **loss_scale** (*float, optional*) – Value for the loss scale. It must be greater than 0.0. In general, use the default value. Only when *FixedLossScaleManager* is used for training and the *drop_overflow_update* in *FixedLossScaleManager* is set to False, then this value needs to be the same as the *loss_scale* in *FixedLossScaleManager*. Refer to class *mindspore.amp.FixedLossScaleManager* for more details. Default: `1.0` .
- **weight_decay** (*Union[float, int, Cell], optional*) – Weight decay (L2 penalty). Default: `0.0` .
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.
  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.

Inputs:

- **grads** (tuple[Tensor]) - The gradients of *params* in the optimizer, the shape is the same as the *params* in optimizer.

Outputs:

Tensor[bool], the value is `True` .

Raises

- **TypeError** – If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** – If element of *parameters* is neither Parameter nor dict.
- **TypeError** – If *accum* or *loss_scale* is not a float.
- **TypeError** – If *update_slots* is not a bool.
- **TypeError** – If *weight_decay* is neither float nor int.
- **ValueError** – If *loss_scale* is less than or equal to 0.
- **ValueError** – If *accum* or *weight_decay* is less than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import train
>>> import mindspore.nn as nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> #1) All parameters use the same learning rate and weight decay
>>> optim = nn.Adagrad(params=net.trainable_params())
>>>
>>> #2) Use parameter groups and set different values
>>> conv_params = list(filter(lambda x: 'conv' in x.name, net.trainable_params()))
>>> no_conv_params = list(filter(lambda x: 'conv' not in x.name, net.trainable_params()))
>>> group_params = [{'params': conv_params, 'weight_decay': 0.01, 'grad_centralization':True}
 ↪,
...                 {'params': no_conv_params, 'lr': 0.01},
...                 {'order_params': net.trainable_params()}]
>>> optim = nn.Adagrad(group_params, learning_rate=0.1, weight_decay=0.0)
>>> # The conv_params's parameters will use default learning rate of 0.1 and weight decay of␣
 ↪0.01 and grad
>>> # centralization of True.
>>> # The no_conv_params's parameters will use learning rate of 0.01 and default weight␣
 ↪decay of 0.0 and grad
>>> # centralization of False.
>>> # The final parameters order in which the optimizer will be followed is the value of
 ↪'order_params'.
>>>
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> model = train.Model(net, loss_fn=loss, optimizer=optim)
```

3.15.3 mindspore.nn.Adam

class mindspore.nn.**Adam**(*params*, *learning_rate=1e-3*, *beta1=0.9*, *beta2=0.999*, *eps=1e-8*, *use_locking=False*, *use_nesterov=False*, *weight_decay=0.0*, *loss_scale=1.0*, *use_amsgrad=False*, ***kwargs*)

Implements the Adaptive Moment Estimation (Adam) algorithm.

The Adam optimizer can dynamically adjust the learning rate of each parameter using the first-order moment estimation and the second-order moment estimation of the gradient. The Adam algorithm is proposed in Adam: A Method for Stochastic Optimization.

The updating formulas are as follows:

Parameters : 1^{st} moment vector m, 2^{nd} moment vector v,

gradients g, learning rate γ, exponential decay rates for the moment estimates β_1 β_2,

parameter vector w_0, timestep t, weight decay λ

Init : $m_0 \leftarrow 0$, $v_0 \leftarrow 0$, $t \leftarrow 0$, init parameter vector w_0

---

while w_t not converged **do**

$\boldsymbol{g}_t \leftarrow \nabla_w \boldsymbol{f}_t\left(\boldsymbol{w}_{t-1}\right)$

if $\lambda \neq 0$

$\boldsymbol{g}_t \leftarrow \boldsymbol{g}_t + \lambda \boldsymbol{w}_{t-1}$

$\boldsymbol{m}_t \leftarrow \beta_1 \boldsymbol{m}_{t-1} + (1-\beta_1)\, \boldsymbol{g}_t$

$\boldsymbol{v}_t \leftarrow \beta_2 \boldsymbol{v}_{t-1} + (1-\beta_2)\, \boldsymbol{g}_t^2$

$\hat{\boldsymbol{m}}_t \leftarrow \boldsymbol{m}_t / \left(1-\beta_1^t\right)$

$\hat{\boldsymbol{v}}_t \leftarrow \boldsymbol{v}_t / \left(1-\beta_2^t\right)$

$\boldsymbol{w}_t \leftarrow \boldsymbol{w}_{t-1} - \gamma \hat{\boldsymbol{m}}_t / (\sqrt{\hat{\boldsymbol{v}}_t} + \epsilon)$

end while

---

return $\boldsymbol{w}_t$

---

m represents the 1st moment vector, v represents the 2nd moment vector, g represents *gradients*, β_1, β_2 represent *beta1* and *beta2*, t represents the current step while $beta_1^t$ and $beta_2^t$ represent *beta1_power* and *beta2_power*, γ represents *learning_rate*, w represents *params*, ϵ represents *eps*.

Note: On Ascend, when *use_amsgrad* is set to True, it might have slightly larger accuracy error.

The sparse strategy is applied while the SparseGatherV2 operator is used for forward network. If the sparse strategy wants to be executed on the host, set the target to the CPU. The sparse feature is under continuous development.

If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

When using Adam with use_lazy=True:

Please note, the optimizer only updates the current index position of the network parameters when the gradient is sparse. The sparse behavior is not equivalent to the original Adam algorithm. If you want to execute a sparse policy, target needs to be set to CPU.

When using Adam with use_offload=True:

This optimizer only supports *GRAPH_MODE* and don't support GE backend.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) –Must be list of *Parameter* or list of *dict*. When the *params* is a list of *dict*, the string "params", "lr", "weight_decay", "grad_centralization" and "order_params" are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.
  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.
- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule], optional*) –Default: `1e-3`.
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.
  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of current step.
- **beta1** (*float, optional*) –The exponential decay rate for the 1st moment estimations. Should be in range (0.0, 1.0). Default: `0.9`.
- **beta2** (*float, optional*) –The exponential decay rate for the 2nd moment estimations. Should be in range (0.0, 1.0). Default: `0.999`.
- **eps** (*float, optional*) –Term added to the denominator to improve numerical stability. Should be greater than 0. Default: `1e-8`.
- **use_locking** (*bool, optional*) –Whether to enable a lock to protect the updating process of variable tensors. If `true`, updates of the *w*, *m*, and *v* tensors will be protected by a lock. If `false`, the result is unpredictable. Default: `False`.

- **use_nesterov** (*bool, optional*) – Whether to use Nesterov Accelerated Gradient (NAG) algorithm to update the gradients. If `true` , update the gradients using NAG. If `false` , update the gradients without using NAG. Default: `False` .
- **use_amsgrad** (*bool, optional*) – Whether to use Amsgrad algorithm to update the gradients. If `true` , update the gradients using Amsgrad. If `false` , update the gradients without using Amsgrad. Default: `False` .
- **weight_decay** (*Union[float, int, Cell], optional*) – Weight decay (L2 penalty). Default: `0.0` .
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.
  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.
- **loss_scale** (*float, optional*) – A floating point value for the loss scale. Should be greater than 0. In general, use the default value. Only when *FixedLossScaleManager* is used for training and the *drop_overflow_update* in *FixedLossScaleManager* is set to False, then this value needs to be the same as the *loss_scale* in *FixedLossScaleManager*. Refer to class *mindspore.amp.FixedLossScaleManager* for more details. Default: `1.0`.
- **kwargs** –
  - use_lazy (bool): Whether to use Lazy Adam algorithm. Default: `False` . If `true` , apply lazy adam algorithm. If `false` , apply normal adam algorithm.
  - use_offload (bool): Whether to offload adam optimizer to host CPU and keep parameters being updated on the device in order to minimize the memory cost. Default: `False` . If `true` , apply offload adam. If `false` , apply normal adam.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*, the shape is the same as *params*.

Outputs:

Tensor[bool], the value is True.

Raises

- **KeyError** – If kwargs got keys other than 'use_lazy' or 'use_offload'.
- **TypeError** – If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** – If element of *params* is neither Parameter nor dict.
- **TypeError** – If *beta1*, *beta2*, *eps* or *loss_scale* is not a float.
- **TypeError** – If *weight_decay* is neither float nor int.
- **TypeError** – If *use_locking*, *use_nesterov*, *use_amsgrad*, *use_lazy* or *use_offload* is not a bool.
- **ValueError** – If *loss_scale* or *eps* is less than or equal to 0.
- **ValueError** – If *beta1*, *beta2* is not in range (0.0, 1.0).
- **ValueError** – If *weight_decay* is less than 0.
- **ValueError** – If *use_lazy* and *use_offload* are both `true` .
- **ValueError** – If *use_amsgrad* is `true`, *use_lazy* or *use_offload* is `true` .
- **ValueError** – If *use_amsgrad* is `True` while using distributed training.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> #1) All parameters use the same learning rate and weight decay
>>> optim = nn.Adam(params=net.trainable_params())

```

3.15.4 mindspore.nn.AdaMax

class mindspore.nn.**AdaMax**(*params*, *learning_rate=0.001*, *beta1=0.9*, *beta2=0.999*, *eps=1e-08*, *weight_decay=0.0*, *loss_scale=1.0*)

Implements the AdaMax algorithm, a variant of Adaptive Movement Estimation (Adam) based on the infinity norm.

The AdaMax algorithm is proposed in Adam: A Method for Stochastic Optimization.

The updating formulas are as follows,

$$
\begin{aligned}
m_{t+1} &= \beta_1 * m_t + (1 - \beta_1) * g \\
v_{t+1} &= \max(\beta_2 * v_t, |g|) \\
w &= w - \frac{l}{1-\beta_1^{t+1}} * \frac{m_{t+1}}{v_{t+1}+\epsilon}
\end{aligned}
$$

m represents the 1st moment vector, v represents the 2nd moment vector, g represents *gradients*, β_1, β_2 represent *beta1* and *beta2*, t represents the current step, $beta_1^t$ represent *beta1_power*, l represents *learning_rate*, w represents *params*, ϵ represents *eps*.

Note: If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped,

each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) –Must be list of *Parameter* or list of *dict*. When the *params* is a list of *dict*, the string "params", "lr", "weight_decay", "grad_centralization" and "order_params" are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.
  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.
- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule]*) –Default: `0.001`.
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.
  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of current step.
- **beta1** (*float, optional*) –The exponential decay rate for the 1st moment estimations. Should be in range (0.0, 1.0). Default: `0.9`.
- **beta2** (*float, optional*) –The exponential decay rate for the 2nd moment estimations. Should be in range (0.0, 1.0). Default: `0.999`.
- **eps** (*float, optional*) –Term added to the denominator to improve numerical stability. Should be greater than 0. Default: `1e-08`.
- **weight_decay** (*Union[float, int, Cell]*) –Weight decay (L2 penalty). Default: `0.0`.
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.
  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.

- **loss_scale** (*float, optional*) – A floating point value for the loss scale. Should be greater than 0. In general, use the default value. Only when *FixedLossScaleManager* is used for training and the *drop_overflow_update* in *FixedLossScaleManager* is set to `False` , then this value needs to be the same as the *loss_scale* in *FixedLossScaleManager*. Refer to class *mindspore.amp.FixedLossScaleManager* for more details. Default: `1.0` .

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*, the shape is the same as *params*.

Outputs:

Tensor[bool], the value is True.

Raises

- **TypeError** – If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** – If element of *parameters* is neither Parameter nor dict.
- **TypeError** – If *beta1*, *beta2*, *eps* or *loss_scale* is not a float.
- **TypeError** – If *weight_decay* is neither float nor int.
- **ValueError** – If *loss_scale* or *eps* is less than or equal to 0.
- **ValueError** – If *beta1*, *beta2* is not in range (0.0, 1.0).
- **ValueError** – If *weight_decay* is less than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

3.15.5 mindspore.nn.AdamWeightDecay

class mindspore.nn.**AdamWeightDecay**(*params*, *learning_rate=1e-3*, *beta1=0.9*, *beta2=0.999*, *eps=1e-6*, *weight_decay=0.0*)

Implements the Adam algorithm with weight decay.

Parameters : 1^{st} moment vector m, 2^{nd} moment vector v,

$gradients\ g$, learning rate γ, exponential decay rates for the moment estimates β_1 β_2,

parameter vector w_0, timestep t, weight decay λ

Init : $m_0 \leftarrow 0$, $v_0 \leftarrow 0$, $t \leftarrow 0$, init parameter vector w_0

---

repeat

$t \leftarrow t + 1$

$\boldsymbol{g}_t \leftarrow \nabla f_t\left(\boldsymbol{w}_{t-1}\right)$

$\boldsymbol{m}_t \leftarrow \beta_1 \boldsymbol{m}_{t-1} + \left(1 - \beta_1\right) \boldsymbol{g}_t$

$\boldsymbol{v}_t \leftarrow \beta_2 \boldsymbol{v}_{t-1} + \left(1 - \beta_2\right) \boldsymbol{g}_t^2$

$\boldsymbol{w}_t \leftarrow \boldsymbol{w}_{t-1} - \gamma \left(\boldsymbol{m}_t / \left(\sqrt{\boldsymbol{v}_t} + \epsilon\right) + \lambda \boldsymbol{w}_{t-1}\right)$

until stopping criterion is met

---

return $\boldsymbol{w}_t$

---

m represents the 1st moment vector *moment1*, v represents the 2nd moment vector *moment2*, g represents *gradients*, γ represents *learning_rate*, β_1, β_2 represent *beta1* and *beta2*, t represents the current step, w represents *params*, λ represents *weight_decay*.

Note: There is usually no connection between a optimizer and mixed precision. But when *FixedLossScaleManager* is used and *drop_overflow_update* in *FixedLossScaleManager* is set to False, optimizer needs to set the 'loss_scale'. As this optimizer has no argument of *loss_scale*, so *loss_scale* needs to be processed by other means, refer document LossScale to process *loss_scale* correctly.

If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) –Must be list of *Parameter* or list of *dict*. When the *params* is a list of *dict*, the string "params", "lr", "weight_decay", and "order_params" are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.
  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.
- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule]*) –Default: `1e-3`.
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.
  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of current step.
- **beta1** (*float*) –The exponential decay rate for the 1st moment estimations. Default: `0.9`. Should be in range (0.0, 1.0).
- **beta2** (*float*) –The exponential decay rate for the 2nd moment estimations. Default: `0.999`. Should be in range (0.0, 1.0).
- **eps** (*float*) –Term added to the denominator to improve numerical stability. Default: `1e-6`. Should be greater than 0.
- **weight_decay** (*Union[float, int, Cell]*) –Weight decay (L2 penalty). Default: `0.0`.
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.
  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*, the shape is the same as *params*.

Outputs:

tuple[bool], all elements are True.

Raises

- **TypeError** – If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** – If element of *parameters* is neither Parameter nor dict.
- **TypeError** – If *beta1*, *beta2* or *eps* is not a float.
- **TypeError** – If *weight_decay* is neither float nor int.
- **ValueError** – If *eps* is less than or equal to 0.
- **ValueError** – If *beta1*, *beta2* is not in range (0.0, 1.0).
- **ValueError** – If *weight_decay* is less than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> #1) All parameters use the same learning rate and weight decay
>>> optim = nn.AdamWeightDecay(params=net.trainable_params())
>>>
>>> #2) Use parameter groups and set different values
>>> conv_params = list(filter(lambda x: 'conv' in x.name, net.trainable_params()))
>>> no_conv_params = list(filter(lambda x: 'conv' not in x.name, net.trainable_params()))
>>> group_params = [{'params': conv_params, 'weight_decay': 0.01},
...                 {'params': no_conv_params, 'lr': 0.01},
...                 {'order_params': net.trainable_params()}]
>>> optim = nn.AdamWeightDecay(group_params, learning_rate=0.1, weight_decay=0.0)
>>> # The conv_params's parameters will use default learning rate of 0.1 and weight decay of␣
↪0.01.
>>> # The no_conv_params's parameters will use learning rate of 0.01 and default weight␣
↪decay of 0.0.
>>> # The final parameters order in which the optimizer will be followed is the value of
↪'order_params'.
>>>
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> model = ms.Model(net, loss_fn=loss, optimizer=optim)
```

3.15.6 mindspore.nn.AdaSumByDeltaWeightWrapCell

class mindspore.nn.**AdaSumByDeltaWeightWrapCell**(*optimizer*)

Enable the adasum in "auto_parallel/semi_auto_parallel" mode. The implementation of the Adaptive Summation (AdaSum) algorithm is calculated based on the difference of weights before and after the updating of optimizer. See the paper AdaSum: Scaling Distributed Training with Adaptive Summation.

$$w_{t+1} = w_t - \alpha \cdot Adasum(g_1, g_2)$$
$$w_{t+1} = w_t - \alpha \cdot [(1 - \frac{g_2^T \cdot g_1}{2 \cdot \|g_1\|^2}) \cdot g_1 + (1 - \frac{g_1^T \cdot g_2}{2 \cdot \|g_2\|^2}) \cdot g_2]$$

In this implementation, g represents the weight difference before and after the updating of optimizer, and the subscripts represent different devices in the data parallel dimension.

Note: When using AdaSum, the number of traning cards needs to be a power of 2 and at least 16 cards are required. Currently, the optimizer sharding and pipeline parallel is not supported when using AdaSum. It is recommended to using AdaSumByDeltaWeightWrapCell in semi auto parallel/auto parallel mode. In data parallel mode, we recommend to using mindspore.boost to applying AdaSum.

Parameters

optimizer (*Union[Cell]*) – Optimizer for updating the weights. The construct function of the optimizer requires only one input.

Inputs:

- **grads** (Tuple(Tensor)) - Tuple of gradients, same with the input of passed optimizer.

Raises

- **RuntimeError** – If *parallel_mode* uses *stand_alone* mode, AdaSum only supports use in distributed scenarios.
- **RuntimeError** – If the optimizer parallel is used when using AdaSum.
- **RuntimeError** – If the pipeline parallel is used when using AdaSum.
- **RuntimeError** – If *device_num* is not a power of 2, or less than 16.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> optim = nn.AdaSumByDeltaWeightWrapCell(nn.Momentum(params=net.trainable_params(),
...                                                    learning_rate=0.1, momentum=0.9))
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> model = ms.train.Model(net, loss_fn=loss, optimizer=optim, metrics=None)
```

3.15.7 mindspore.nn.AdaSumByGradWrapCell

class mindspore.nn.**AdaSumByGradWrapCell**(*optimizer*)

Enable the adasum in "auto_parallel/semi_auto_parallel" mode. The implementation of the Adaptive Summation (AdaSum) algorithm is calculated by gradients. See the paper AdaSum: Scaling Distributed Training with Adaptive Summation.

$$w_{t+1} = w_t - \alpha \cdot Adasum(g_1, g_2)$$
$$w_{t+1} = w_t - \alpha \cdot [(1 - \frac{g_2^T \cdot g_1}{2 \cdot \|g_1\|^2}) \cdot g_1 + (1 - \frac{g_1^T \cdot g_2}{2 \cdot \|g_2\|^2}) \cdot g_2]$$

In this implementation, g represents the gradient of the weights, and the subscripts represent different devices in the data-parallel dimension.

Note:

- It is recommended to using AdaSumByGradWrapCell in semi auto parallel/auto parallel mode. In data parallel mode, we recommend to using mindspore.boost to applying AdaSum.
- When using AdaSum, the number of traning cards needs to be a power of 2 and at least 16 cards are required. Currently, the optimizer sharding and pipeline parallel is not supported when using AdaSum.

Parameters

optimizer (*Union[Cell]*) – Optimizer for updating the weights. The construct function of the optimizer requires only one input.

Inputs:

- **grads** (Tuple[Tensor]) - Tuple of gradients, same with the input of passed optimizer.

Raises

- **RuntimeError** – If *parallel_mode* uses *stand_alone* mode, AdaSum only supports use in distributed scenarios.
- **RuntimeError** – If the optimizer parallel is used when using AdaSum.
- **RuntimeError** – If the pipeline parallel is used when using AdaSum.
- **RuntimeError** – If *device_num* is not a power of 2, or less than 16.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> optim = nn.AdaSumByGradWrapCell(nn.Momentum(params=net.trainable_params(), learning_
↪rate=0.1, momentum=0.9))
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> model = ms.train.Model(net, loss_fn=loss, optimizer=optim, metrics=None)
```

3.15.8 mindspore.nn.ASGD

class mindspore.nn.**ASGD**(*params*, *learning_rate=0.1*, *lambd=1e-4*, *alpha=0.75*, *t0=1e6*, *weight_decay=0.0*)

Implements Average Stochastic Gradient Descent.

Introduction to ASGD can be found at Acceleration of stochastic approximation by average.

The updating formulas are as follows:

$$
\begin{aligned}
w_t &= w_{t-1} * (1 - \lambda * \eta_{t-1}) - \eta_{t-1} * g_t \\
ax_t &= (w_t - ax_{t-1}) * \mu_{t-1} \\
\eta_t &= \frac{1.}{(1+\lambda * lr * t)^{\alpha}} \\
\mu_t &= \frac{1}{\max(1, t-t0)}
\end{aligned}
$$

λ represents the decay term, μ and η are tracked to update ax and w, $t0$ represents the point of starting averaging, α represents the power for η update, ax represents the averaged parameter value, t represents the current step, g represents *gradients*, w represents *params*.

Note: This optimizer don't support GE backend.

If parameters are not grouped, the *weight_decay* in optimizer will be applied on the parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*, if not, the *weight_decay* in optimizer will be applied.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) – Must be list of *Parameter* or list of *dict*. When the *parameters* is a list of *dict*, the "params", "lr", "weight_decay", "grad_centralization" and "order_params" are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.
  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.
- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule]*) – learning_rate. Default: 0.1 .
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.

  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of current step.

- **lambd** (*float*) –The decay term. Default: `1e-4` .
- **alpha** (*float*) –The power for η update. Default: `0.75` .
- **t0** (*float*) –The point of starting averaging. Default: `1e6` .
- **weight_decay** (*Union[float, int, Cell]*) –Weight decay (L2 penalty). Default: `0.0` .
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.
  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*, the shape is the same as *params*.

Outputs:

Tensor[bool], the value is True.

Raises

- **TypeError** –If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** –If element of *parameters* is neither Parameter nor dict.
- **TypeError** –If *lambd*, *alpha* or *t0* is not a float.
- **TypeError** –If *weight_decay* is neither float nor int.
- **ValueError** –If *weight_decay* is less than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> #1) All parameters use the same learning rate and weight decay
>>> optim = nn.ASGD(params=net.trainable_params())
>>>
>>> #2) Use parameter groups and set different values
>>> conv_params = list(filter(lambda x: 'conv' in x.name, net.trainable_params()))
>>> no_conv_params = list(filter(lambda x: 'conv' not in x.name, net.trainable_params()))
>>> group_params = [{'params': conv_params,'grad_centralization':True},
...                 {'params': no_conv_params, 'lr': 0.01},
...                 {'order_params': net.trainable_params()}]
>>> optim = nn.ASGD(group_params, learning_rate=0.1, weight_decay=0.0)
>>> # The conv_params's parameters will use default learning rate of 0.1 default weight␣
↪decay of 0.0 and grad
```

(continues on next page)

(continued from previous page)

```
>>> # centralization of True.
>>> # The no_conv_params's parameters will use learning rate of 0.01 and default weight␣
↪decay of 0.0 and grad
>>> # centralization of False.
>>> # The final parameters order in which the optimizer will be followed is the value of
↪'order_params'.
>>>
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> model = ms.train.Model(net, loss_fn=loss, optimizer=optim)
```

3.15.9 mindspore.nn.FTRL

class mindspore.nn.**FTRL**(*params*, *initial_accum=0.1*, *learning_rate=0.001*, *lr_power=- 0.5*, *l1=0.0*, *l2=0.0*, *use_locking=False*, *loss_scale=1.0*, *weight_decay=0.0*)

Implements the FTRL algorithm.

FTRL is an online convex optimization algorithm that adaptively chooses its regularization function based on the loss functions. Refer to paper Adaptive Bound Optimization for Online Convex Optimization.

The updating formulas are as follows,

$$
\begin{aligned}
m_{t+1} &= m_t + g^2 \\
u_{t+1} &= u_t + g - \frac{m_{t+1}^{-p} - m_t^{-p}}{\alpha} * \omega_t \\
\omega_{t+1} &= \begin{cases} \frac{(sign(u_{t+1}) * l1 - u_{t+1})}{\frac{m_{t+1}^{-p}}{\alpha} + 2 * l2} & \text{if } |u_{t+1}| > l1 \\ 0.0 & \text{otherwise} \end{cases}
\end{aligned}
$$

m represents accumulators, g represents *grads*, t represents the current step, u represents the linear coefficient to be updated, p represents *lr_power*, α represents *learning_rate*, ω represents *params*.

Note: The sparse strategy is applied while the SparseGatherV2 operator is used for forward network. If the sparse strategy wants to be executed on the host, set the target to the CPU. The sparse feature is under continuous development.

If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) –Must be list of *Parameter* or list of *dict*. When the *params* is a list of *dict*, the string "params", "weight_decay", "grad_centralization" and "order_params" are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Using different learning rate by grouping parameters is currently not supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.

  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.

- **initial_accum** (*float, optional*) – The starting value for accumulators *m*, must be zero or positive values. Default: `0.1`.
- **learning_rate** (*float, optional*) – The learning rate value, must be zero or positive, dynamic learning rate is currently not supported. Default: `0.001`.
- **lr_power** (*float, optional*) – Learning rate power controls how the learning rate decreases during training, must be less than or equal to zero. Use fixed learning rate if lr_power is zero. Default: `-0.5`.
- **l1** (*float, optional*) – l1 regularization strength, must be greater than or equal to zero. Default: `0.0`.
- **l2** (*float, optional*) – l2 regularization strength, must be greater than or equal to zero. Default: `0.0`.
- **use_locking** (*bool, optional*) – If true, use locks for updating operation. Default: `False`.
- **loss_scale** (*float, optional*) – Value for the loss scale. It must be greater than 0.0. In general, use the default value. Only when *FixedLossScaleManager* is used for training and the *drop_overflow_update* in *FixedLossScaleManager* is set to `False`, then this value needs to be the same as the *loss_scale* in *FixedLossScaleManager*. Refer to class *mindspore.amp.FixedLossScaleManager* for more details. Default: `1.0`.
- **weight_decay** (*Union[float, int, Cell], optional*) – Weight decay (L2 penalty). Default: `0.0`.
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.
  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.

Inputs:

- **grads** (tuple[Tensor]) - The gradients of *params* in the optimizer, the shape is the same as the *params* in optimizer.

Outputs:

Tuple[Parameter], the updated parameters, the shape is the same as *params*.

Raises

- **TypeError** – If *initial_accum*, *learning_rate*, *lr_power*, *l1*, *l2* or *loss_scale* is not a float.
- **TypeError** – If element of *parameters* is neither Parameter nor dict.
- **TypeError** – If *weight_decay* is neither float nor int.
- **TypeError** – If *use_nesterov* is not a bool.
- **ValueError** – If *lr_power* is greater than 0.
- **ValueError** – If *loss_scale* is less than or equal to 0.
- **ValueError** – If *initial_accum*, *l1* or *l2* is less than 0.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> #1) All parameters use the same learning rate and weight decay
>>> optim = nn.FTRL(params=net.trainable_params())
>>>
>>> #2) Use parameter groups and set different values
>>> conv_params = list(filter(lambda x: 'conv' in x.name, net.trainable_params()))
>>> no_conv_params = list(filter(lambda x: 'conv' not in x.name, net.trainable_params()))
>>> group_params = [{'params': conv_params, 'weight_decay': 0.01, 'grad_centralization':True}
 ↪,
...                 {'params': no_conv_params},
...                 {'order_params': net.trainable_params()}]
>>> optim = nn.FTRL(group_params, learning_rate=0.1, weight_decay=0.0)
>>> # The conv_params's parameters will use default learning rate of 0.1 and weight decay of␣
 ↪0.01 and grad
>>> # centralization of True.
>>> # The no_conv_params's parameters will use default learning rate of 0.1 will use default␣
 ↪weight decay
>>> # of 0.0 and grad centralization of False.
>>> # The final parameters order in which the optimizer will be followed is the value of
 ↪'order_params'.
>>>
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> model = ms.train.Model(net, loss_fn=loss, optimizer=optim)
```

3.15.10 mindspore.nn.Lamb

class mindspore.nn.**Lamb**(*params*, *learning_rate*, *beta1=0.9*, *beta2=0.999*, *eps=1e-6*, *weight_decay=0.0*)

Implements the Lamb(Layer-wise Adaptive Moments optimizer for Batching training) algorithm.

LAMB is an optimization algorithm employing a layerwise adaptive large batch optimization technique. Refer to the paper LARGE BATCH OPTIMIZATION FOR DEEP LEARNING: TRAINING BERT IN 76 MINUTES.

The LAMB optimizer aims to increase the training batch size without reducing the accuracy, and it supports adaptive element-by-element update and accurate layered correction.

The updating of parameters follows:

Parameters : 1^{st} moment vector m, 2^{nd} moment vector v,

learning rate $\{\gamma_t\}_{t=1}^{T}$, exponential decay rates for the moment estimates β_1 β_2,

scaling function ϕ

Init : $\boldsymbol{m}_0 \leftarrow 0$, $\boldsymbol{v}_0 \leftarrow 0$

---

for t=1 to T **do**

Draw b samples S_t from $\mathbb{P}$.

Compute $g_t = \frac{1}{|\mathbb{S}_t|} \sum_{s_t \in \mathbb{S}_t} \nabla \ell \left(x_t, s_t \right)$.

$\boldsymbol{m}_t \leftarrow \beta_1 \boldsymbol{m}_{t-1} + \left(1 - \beta_1 \right) \boldsymbol{g}_t$

$\boldsymbol{v}_t \leftarrow \beta_2 \boldsymbol{v}_{t-1} + \left(1 - \beta_2 \right) \boldsymbol{g}_t^2$

$\hat{\boldsymbol{m}}_t \leftarrow \boldsymbol{m}_t / \left(1 - \beta_1^t \right)$

$\hat{\boldsymbol{v}}_t \leftarrow \boldsymbol{v}_t / \left(1 - \beta_2^t \right)$

Compute ratio $\boldsymbol{r}_t = \hat{\boldsymbol{m}}_t / (\sqrt{\hat{\boldsymbol{v}}_t} + \epsilon)$

$$\boldsymbol{w}_{t+1}^{(i)} = \boldsymbol{w}_t^{(i)} - \gamma_t \frac{\boldsymbol{\phi}\left(\left\| \boldsymbol{w}_t^{(i)} \right\| \right)}{\left\| \boldsymbol{r}_t^{(i)} + \lambda \boldsymbol{w}_t^{(i)} \right\|} \left(\boldsymbol{r}_t^{(i)} + \lambda \boldsymbol{w}_t^{(i)} \right)$$

end for

---

return $\boldsymbol{w}_{t+1}$

---

m represents the 1st moment vector *moment1*, v represents the 2nd moment vector *moment2*, g represents *gradients*, β_1, β_2 represent *beta1* and *beta2*, t represents the current step while $beta_1^t$ and $beta_2^t$ represent *beta1_power* and *beta2_power*, γ represents *learning_rate*, w represents *params*, ϵ represents *eps*, λ represents *weight_decay*.

Note: There is usually no connection between a optimizer and mixed precision. But when *FixedLossScaleManager* is used and *drop_overflow_update* in *FixedLossScaleManager* is set to False, optimizer needs to set the 'loss_scale'. As this optimizer has no argument of *loss_scale*, so *loss_scale* needs to be processed by other means. Refer document LossScale to process *loss_scale* correctly.

If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma'

in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Warning: The update process of the Lamb optimizer is not completely elementwise, and the sharding of weights in distributed parallel may affect the update result.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) –Must be list of *Parameter* or list of *dict*. When the *params* is a list of *dict*, the string "params", "lr", "weight_decay", "grad_centralization" and "order_params" are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.
  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.
- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule]*) –
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.
  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of current step.
- **beta1** (*float*) –The exponential decay rate for the 1st moment estimations. Default: `0.9`. Should be in range (0.0, 1.0).
- **beta2** (*float*) –The exponential decay rate for the 2nd moment estimations. Default: `0.999`. Should be in range (0.0, 1.0).
- **eps** (*float*) –Term added to the denominator to improve numerical stability. Default: `1e-6`. Should be greater than 0.
- **weight_decay** (*Union[float, int, Cell]*) –Weight decay (L2 penalty). Default: `0.0`.
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.

  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*, the shape is the same as *params*.

Outputs:

tuple[bool], all elements are `True` .

Raises

- **TypeError** –If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** –If element of *parameters* is neither Parameter nor dict.
- **TypeError** –If *beta1*, *beta2* or *eps* is not a float.
- **TypeError** –If *weight_decay* is neither float nor int.
- **ValueError** –If *eps* is less than or equal to 0.
- **ValueError** –If *beta1*, *beta2* is not in range (0.0, 1.0).
- **ValueError** –If *weight_decay* is less than 0.
