3.15.11 mindspore.nn.LARS

class mindspore.nn.**LARS**(*optimizer*, *epsilon=1e-05*, *coefficient=0.001*, *use_clip=False*, *lars_filter=lambda x: ...*)

Implements the LARS algorithm.

LARS is an optimization algorithm employing a large batch optimization technique. Refer to paper LARGE BATCH TRAINING OF CONVOLUTIONAL NETWORKS.

The updating formulas are as follows,

Parameters : base learning rate γ_0, momentum m, weight decay λ,
LARS coefficient η, number of steps T
Init : t=0, v=0, init weight w_0^l for each layer l

---

while t<T for each layer l **do**
$g_t^l \leftarrow \nabla L\left(w_t^l\right)$
$\gamma_t \leftarrow \gamma_0 * \left(1-\frac{t}{T}\right)^2$
$\gamma^l \leftarrow \eta * \frac{\|w_t^l\|}{\|g_t^l\|+\lambda\|w_t^l\|}$(compute the local LR $\gamma^{l)}$
$v_{t+1}^l \leftarrow m v_t^l + \gamma_{t+1} * \gamma^l * \left(g_t^l + \lambda w_t^l\right)$
$w_{t+1}^l \leftarrow w_t^l - v_{t+1}^l$
end while

---

w represents the network's params, g represents *gradients*, t represents the current step, λ represents *weight_decay* in *optimizer*, γ represents *learning_rate* in *optimizer*, η represents *coefficient*.

Parameters

- **optimizer** (*mindspore.nn.Optimizer*) –MindSpore optimizer for which to wrap and modify gradients.
- **epsilon** (*float*) –Term added to the denominator to improve numerical stability. Default: `1e-05` .
- **coefficient** (*float*) –Trust coefficient for calculating the local learning rate. Default: `0.001` .
- **use_clip** (*bool*) –Whether to use clip operation for calculating the local learning rate. Default: `False` .
- **lars_filter** (*Function*) –A function to determine which of the network parameters to use LARS algorithm. Default: `lambda x: 'LayerNorm' not in x.name and 'bias' not in x.name`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params* in the optimizer, the shape is the as same as the *params* in the optimizer.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> opt = nn.Momentum(net.trainable_params(), 0.1, 0.9)
>>> opt_lars = nn.LARS(opt, epsilon=1e-08, coefficient=0.02)
>>> model = ms.train.Model(net, loss_fn=loss, optimizer=opt_lars, metrics=None)
```

3.15.12 mindspore.nn.LazyAdam

class mindspore.nn.**LazyAdam**(*params*, *learning_rate=1e-3*, *beta1=0.9*, *beta2=0.999*, *eps=1e-8*, *use_locking=False*, *use_nesterov=False*, *weight_decay=0.0*, *loss_scale=1.0*)

Implements the Adaptive Moment Estimation (Adam) algorithm. The Adam algorithm is proposed in Adam: A Method for Stochastic Optimization.

This optimizer will apply a lazy adam algorithm when gradient is sparse.

The updating formulas are as follows,

$$
\begin{aligned}
m_{t+1} &= \beta_1 * m_t + (1 - \beta_1) * g \\
v_{t+1} &= \beta_2 * v_t + (1 - \beta_2) * g * g \\
\widehat{m_{t+1}} &= \frac{m_{t+1}}{1-\beta_1^t} \\
\widehat{v_{t+1}} &= \frac{v_{t+1}}{1-\beta_2^t} \\
w_{t+1} &= w_t - \gamma * \frac{\widehat{m_{t+1}}}{\sqrt{\widehat{v_{t+1}}}+\epsilon}
\end{aligned}
$$

m represents the 1st moment vector *moment1*, v represents the 2nd moment vector *moment2*, g represents *gradients*, γ represents *learning_rate*, β_1, β_2 represent *beta1* and *beta2*, t represents the current step while $beta_1^t$ and $beta_2^t$ represent *beta1_power* and *beta2_power*, w represents *params*, ϵ represents *eps*.

Note: The sparse strategy is applied while the SparseGatherV2 operator is used for forward network. If the sparse strategy wants to be executed on the host, set the target to the CPU. Please note, the optimizer only updates the current index position of the network parameters when the gradient is sparse. The sparse behavior is not equivalent to the original Adam algorithm. If you want to execute a sparse policy, target needs to be set to CPU.

If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) –Must be list of *Parameter* or list of *dict*. When the *params* is a list of *dict*, the string "params", "lr", "weight_decay", "grad_centralization" and "order_params" are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.

  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.
  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.

- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule], optional*) – Default: `1e-3`.
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.
  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of current step.
- **beta1** (*float, optional*) – The exponential decay rate for the 1st moment estimations. Should be in range (0.0, 1.0). Default: `0.9`.
- **beta2** (*float, optional*) – The exponential decay rate for the 2nd moment estimations. Should be in range (0.0, 1.0). Default: `0.999`.
- **eps** (*float, optional*) – Term added to the denominator to improve numerical stability. Should be greater than 0. Default: `1e-8`.
- **use_locking** (*bool, optional*) – Whether to enable a lock to protect the updating process of variable tensors. If `true`, updates of the *w*, *m*, and *v* tensors will be protected by a lock. If `false`, the result is unpredictable. Default: `False`.
- **use_nesterov** (*bool, optional*) – Whether to use Nesterov Accelerated Gradient (NAG) algorithm to update the gradients. If `true`, update the gradients using NAG. If `false`, update the gradients without using NAG. Default: `False`.
- **weight_decay** (*Union[float, int, Cell], optional*) – Weight decay (L2 penalty). Default: `0.0`.
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.
  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.
- **loss_scale** (*float, optional*) – A floating point value for the loss scale. Should be equal to or greater than 1. In general, use the default value. Only when *FixedLossScaleManager* is used for training and the *drop_overflow_update* in *FixedLossScaleManager* is set to `False`, then this value needs to be the same as the *loss_scale* in *FixedLossScaleManager*. Refer to class *mindspore.amp.FixedLossScaleManager* for more details. Default: `1.0`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*, the shape is the same as *params*.

Outputs:

Tensor[bool], the value is `True` .

Raises

- **TypeError** – If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** – If element of *parameters* is neither Parameter nor dict.
- **TypeError** – If *beta1*, *beta2*, *eps* or *loss_scale* is not a float.
- **TypeError** – If *weight_decay* is neither float nor int.
- **TypeError** – If *use_locking* or *use_nesterov* is not a bool.
- **ValueError** – If *loss_scale* or *eps* is less than or equal to 0.
- **ValueError** – If *beta1*, *beta2* is not in range (0.0, 1.0).
- **ValueError** – If *weight_decay* is less than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> #1) All parameters use the same learning rate and weight decay
>>> optim = nn.LazyAdam(params=net.trainable_params())
>>>
>>> #2) Use parameter groups and set different values
>>> conv_params = list(filter(lambda x: 'conv' in x.name, net.trainable_params()))
>>> no_conv_params = list(filter(lambda x: 'conv' not in x.name, net.trainable_params()))
>>> group_params = [{'params': conv_params, 'weight_decay': 0.01, 'grad_centralization':True}

...                 {'params': no_conv_params, 'lr': 0.01},
...                 {'order_params': net.trainable_params()}]
>>> optim = nn.LazyAdam(group_params, learning_rate=0.1, weight_decay=0.0)
>>> # The conv_params's parameters will use default learning rate of 0.1 and weight decay of␣
 ↪0.01 and grad
>>> # centralization of True.
>>> # The no_conv_params's parameters will use learning rate of 0.01 and default weight␣
 ↪decay of 0.0 and grad
>>> # centralization of False.
>>> # The final parameters order in which the optimizer will be followed is the value of
 ↪'order_params'.
>>>
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> model = ms.train.Model(net, loss_fn=loss, optimizer=optim)
```

3.15.13 mindspore.nn.Momentum

class mindspore.nn.**Momentum**(*params*, *learning_rate*, *momentum*, *weight_decay=0.0*, *loss_scale=1.0*, *use_nesterov=False*)

Implements the Momentum algorithm.

Refer to the paper On the importance of initialization and momentum in deep learning for more details.

$$v_{t+1} = v_t * u + grad$$

If use_nesterov is True:

$$p_{t+1} = p_t - (grad * lr + v_{t+1} * u * lr)$$

If use_nesterov is False:

$$p_{t+1} = p_t - lr * v_{t+1}$$

Here: where $grad$, lr, p, v and u denote the gradients, learning_rate, params, moments, and momentum respectively.

Note: If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) – Must be list of *Parameter* or list of *dict*. When the *params* is a list of *dict*, the string "params", "lr", "weight_decay", "grad_centralization" and "order_params" are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.
  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.
- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule], optional*) –
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.

  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of current step.

- **momentum** (*float, optional*) – Hyperparameter of type float, means momentum for the moving average. It must be at least 0.0.
- **weight_decay** (*Union[float, int, Cell], optional*) – Weight decay (L2 penalty). Default: `0.0`.
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.
  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.
- **loss_scale** (*float, optional*) – A floating point value for the loss scale. It must be greater than 0.0. In general, use the default value. Only when *FixedLossScaleManager* is used for training and the *drop_overflow_update* in *FixedLossScaleManager* is set to `False`, then this value needs to be the same as the *loss_scale* in *FixedLossScaleManager*. Refer to class *mindspore.amp.FixedLossScaleManager* for more details. Default: `1.0`.
- **use_nesterov** (*bool, optional*) – Enable Nesterov momentum. Default: `False`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*, the shape is the same as *params*.

Outputs:

tuple[bool]. All elements are `True`.

Raises

- **TypeError** – If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** – If element of *parameters* is neither Parameter nor dict.
- **TypeError** – If *loss_scale* or *momentum* is not a float.
- **TypeError** – If *weight_decay* is neither float nor int.
- **TypeError** – If *use_nesterov* is not a bool.
- **ValueError** – If *loss_scale* is less than or equal to 0.
- **ValueError** – If *weight_decay* or *momentum* is less than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

```

3.15.14 mindspore.nn.OptTFTWrapper

class mindspore.nn.**OptTFTWrapper**(*opt*, ***kwargs*)

Implements TFT optimizer wrapper, this wrapper is used to report status to MindIO TFT before optimizer updating.

Note: This optimizer is depend on MindIO TFT feature. Currently only support ascend graph mode and sink_size must be less than 1.

Parameters

opt (Optimizer) – Must be sub-class of Optimizer.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of opt's *params*, the shape is the same as opt's *params*.

Outputs:

Tensor, result of executing optimizer 'opt'.

Raises

- **TypeError** – If the parameter opt is not an subclass of Optimizer.
- **ValueError** – If the platform is not Ascend graph mode, or customer doesn't switch on TFT feature.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> #1) All parameters use the same learning rate and weight decay
>>> optim = nn.SGD(params=net.trainable_params())
>>> optim_wrapper = nn.OptTFTWrapper(optim)
>>>
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> model = ms.train.Model(net, loss_fn=loss, optimizer=optim)
```

3.15.15 mindspore.nn.ProximalAdagrad

class mindspore.nn.**ProximalAdagrad**(*params*, *accum=0.1*, *learning_rate=0.001*, *l1=0.0*, *l2=0.0*, *use_locking=False*, *loss_scale=1.0*, *weight_decay=0.0*)

Implements the ProximalAdagrad algorithm that is an online Learning and Stochastic Optimization. Refer to paper Efficient Learning using Forward-Backward Splitting.

$$accum_{t+1} = accum_t + g * g$$

$$\text{prox\_v} = w_t - \gamma * g * \frac{1}{\sqrt{accum_{t+1}}}$$

$$w_{t+1} = \frac{sign(\text{prox\_v})}{1 + \gamma * l2} * \max(|\text{prox\_v}| - \gamma * l1, 0)$$

Here : where g , γ, w , $accum$ and t denote the *grads*, *learning_rate*, *params*, accumulation and current step respectively.

Note: The sparse strategy is applied while the SparseGatherV2 operator is used for forward network. If the sparse strategy wants to be executed on the host, set the target to the CPU. The sparse feature is under continuous development.

If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) –Must be list of *Parameter* or list of *dict*. When the *params* is a list of *dict*, the string *"params"*, *"lr"*, *"weight_decay"*, *"grad_centralization"* and *"order_params"* are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.

  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters are grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.

- **accum** (*float, optional*) – The starting value for accumulators *accum*, must be zero or positive values. Default: `0.1`.
- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule], optional*) – Default: `0.001`.
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.
  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of the current step.
- **l1** (*float, optional*) – l1 regularization strength, must be greater than or equal to zero. Default: `0.0`.
- **l2** (*float, optional*) – l2 regularization strength, must be greater than or equal to zero. Default: `0.0`.
- **use_locking** (*bool, optional*) – If `True`, use locks for updating operation. Default: `False`.
- **loss_scale** (*float, optional*) – Value for the loss scale. It must be greater than 0.0. In general, use the default value. Only when *FixedLossScaleManager* is used for training and the *drop_overflow_update* in *FixedLossScaleManager* is set to `False` , then this value needs to be the same as the *loss_scale* in *FixedLossScaleManager*. Refer to class *mindspore.amp.FixedLossScaleManager* for more details. Default: `1.0`.
- **weight_decay** (*Union[float, int, Cell], optional*) – Weight decay (L2 penalty). Default: `0.0`.
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.
  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.

Inputs:

- **grads** (tuple[Tensor]) - The gradients of *params* in the optimizer, the shape is the same as the *params* in optimizer.

Outputs:

Tensor[bool], the value is True.

Raises

- **TypeError** – If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** – If element of *parameters* is neither Parameter nor dict.
- **TypeError** – If *accum*, *l1*, *l2* or *loss_scale* is not a float.
- **TypeError** – If *weight_decay* is neither float nor int.
- **ValueError** – If *loss_scale* is less than or equal to 0.

- **ValueError** – If *accum*, *l1*, *l2* or *weight_decay* is less than 0.

Supported Platforms:

`Ascend` `GPU`

```

3.15.16 mindspore.nn.RMSProp

class mindspore.nn.**RMSProp**(*params*, *learning_rate=0.1*, *decay=0.9*, *momentum=0.0*, *epsilon=1e-10*, *use_locking=False*, *centered=False*, *loss_scale=1.0*, *weight_decay=0.0*)

Implements Root Mean Squared Propagation (RMSProp) algorithm.

Update *params* according to the RMSProp algorithm. The 29th of the original presentation slide proposes RMSProp. The equation is as follows:

$$s_{t+1} = \rho s_t + (1-\rho)(\nabla Q_i(w))^2$$

$$m_{t+1} = \beta m_t + \frac{\eta}{\sqrt{s_{t+1} + \epsilon}} \nabla Q_i(w)$$

$$w = w - m_{t+1}$$

The first equation calculates moving average of the squared gradient for each weight. Then dividing the gradient by $\sqrt{ms_{t+1} + \epsilon}$.

If centered is True:

$$g_{t+1} = \rho g_t + (1 - \rho)\nabla Q_i(w)$$

$$s_{t+1} = \rho s_t + (1 - \rho)(\nabla Q_i(w))^2$$

$$m_{t+1} = \beta m_t + \frac{\eta}{\sqrt{s_{t+1} - g_{t+1}^2 + \epsilon}}\nabla Q_i(w)$$

$$w = w - m_{t+1}$$

where w represents *params*, which will be updated. g_{t+1} is mean gradients. s_{t+1} is the mean square gradients. m_{t+1} is moment, the delta of w. ρ represents *decay*. β is the momentum term, represents *momentum*. ϵ is a smoothing term to avoid division by zero, represents *epsilon*. η is learning rate, represents *learning_rate*. $\nabla Q_i(w)$ is gradients, represents *gradients*. t represents the current step.

Note: If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) – Must be list of *Parameter* or list of *dict*. When the *params* is a list of *dict*, the string "params", "lr", "weight_decay", "grad_centralization" and "order_params" are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.
  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters are grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.
- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule], optional*) – Default: `0.1`.
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.
  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of the current step.

- **decay** (*float, optional*) –Decay rate. Should be equal to or greater than 0. Default: `0.9`.
- **momentum** (*float, optional*) –Hyperparameter of type float, means momentum for the moving average. Should be equal to or greater than 0. Default: `0.0`.
- **epsilon** (*float, optional*) –Term added to the denominator to improve numerical stability. Should be greater than 0. Default: `1e-10`.
- **use_locking** (*bool, optional*) –Whether to enable a lock to protect the updating process of variable tensors. Default: `False`.
- **centered** (*bool, optional*) –If True, gradients are normalized by the estimated variance of the gradient. Default: `False`.
- **loss_scale** (*float, optional*) –A floating point value for the loss scale. Should be greater than 0. In general, use the default value. Only when *FixedLossScaleManager* is used for training and the *drop_overflow_update* in *FixedLossScaleManager* is set to `False`, then this value needs to be the same as the *loss_scale* in *FixedLossScaleManager*. Refer to class *mindspore.amp.FixedLossScaleManager* for more details. Default: `1.0`.
- **weight_decay** (*Union[float, int, Cell], optional*) –Weight decay (L2 penalty). Default: `0.0`.
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.
  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*, the shape is the same as *params*.

Outputs:

Tensor[bool], the value is `True`.

Raises

- **TypeError** –If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** –If *decay*, *momentum*, *epsilon* or *loss_scale* is not a float.
- **TypeError** –If element of *parameters* is neither Parameter nor dict.
- **TypeError** –If *weight_decay* is neither float nor int.
- **TypeError** –If *use_locking* or *centered* is not a bool.
- **ValueError** –If *epsilon* is less than or equal to 0.
- **ValueError** –If *decay* or *momentum* is less than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> #1) All parameters use the same learning rate and weight decay
>>> optim = nn.RMSProp(params=net.trainable_params(), learning_rate=0.1)
>>>
>>> #2) Use parameter groups and set different values
>>> conv_params = list(filter(lambda x: 'conv' in x.name, net.trainable_params()))
>>> no_conv_params = list(filter(lambda x: 'conv' not in x.name, net.trainable_params()))
>>> group_params = [{'params': conv_params, 'weight_decay': 0.01, 'grad_centralization':True}
 ↪,
...                 {'params': no_conv_params, 'lr': 0.01},
...                 {'order_params': net.trainable_params()}]
>>> optim = nn.RMSProp(group_params, learning_rate=0.1, weight_decay=0.0)
>>> # The conv_params's parameters will use default learning rate of 0.1 and weight decay of␣
 ↪0.01 and grad
>>> # centralization of True.
>>> # The no_conv_params's parameters will use learning rate of 0.01 and default weight␣
 ↪decay of 0.0 and grad
>>> # centralization of False.
>>> # The final parameters order in which the optimizer will be followed is the value of
 ↪'order_params'.
>>>
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> model = ms.train.Model(net, loss_fn=loss, optimizer=optim)
```

3.15.17 mindspore.nn.Rprop

class mindspore.nn.**Rprop**(*params*, *learning_rate=0.1*, *etas=(0.5, 1.2)*, *step_sizes=(1e-6, 50.)*, *weight_decay=0.*)

Implements Resilient backpropagation.

Further information about this implementation can be found at A Direct Adaptive Method for Faster Backpropagation Learning: The RPROP Algorithm.

The updating formulas are as follows:

$$
\begin{aligned}
&\textbf{if } g_{t-1} g_t > 0 \\
&\qquad \Delta_t \leftarrow \min(\Delta_{t-1} \eta_+, \Delta_{max}) \\
&\qquad \textbf{else if } g_{t-1} g_t < 0 \\
&\qquad \Delta_t \leftarrow \max(\Delta_{t-1} \eta_-, \Delta_{min}) \\
&\textbf{else} \\
&\qquad \Delta_t \leftarrow \Delta_{t-1} \\
&\qquad w_t \leftarrow w_{t-1} - \Delta_t \operatorname{sign}(g_t)
\end{aligned}
$$

g represents *gradients*, w represents *parameters*, $\Delta_{min/max}$ represents the min/max step size, $\eta_{+/-}$ represents the factors of etaminus and etaplus.

Note: If parameters are not grouped, the *weight_decay* in optimizer will be applied on the parameters without 'beta' or 'gamma' in their names.

Users can group parameters to change the strategy of decaying weight.

When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) –Must be list of *Parameter* or list of *dict*. When the *parameters* is a list of *dict*, the *"params"*, *"lr"*, *"weight_decay"*, *"grad_centralization"* and *"order_params"* are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay can be a constant value or a Cell. It is a Cell only when dynamic weight decay is applied. Dynamic weight decay is similar to dynamic learning rate, users need to customize a weight decay schedule only with global step as input, and during training, the optimizer calls the instance of WeightDecaySchedule to get the weight decay value of current step.
  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.
- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule], optional*) –Learning_rate. Default: `0.1`.
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.
  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of current step.
- **etas** (*tuple[float, float], optional*) –The factor of multiplicative increasing or descreasing(etaminus, etaplus). Default: `(0.5, 1.2)`.
- **step_sizes** (*tuple[float, float], optional*) –The allowed minimal and maximal step size(min_step_sizes, max_step_size). Default: `(1e-6, 50.)`.
- **weight_decay** (*Union[float, int, Cell], optional*) –Weight decay (L2 penalty). Default: `0.0`.
  - float: The fixed weight decay value. Must be equal to or greater than 0.
  - int: The fixed weight decay value. Must be equal to or greater than 0. It will be converted to float.
  - Cell: Weight decay is dynamic. During training, the optimizer calls the instance of the Cell with step as the input to get the weight decay value of current step.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*, the shape is the same as *params*.

Outputs:

Tensor[bool], the value is True.

Raises

- **TypeError** – If *learning_rate* is not one of int, float, Tensor, Iterable, LearningRateSchedule.
- **TypeError** – If element of *parameters* is neither Parameter nor dict.
- **TypeError** – If *step_sizes* or *etas* is not a tuple.
- **ValueError** – If maximal step size is less than minimal step size.
- **ValueError** – If the length of *step_sizes* or *etas* is not equal to 2.
- **TypeError** – If the element in *etas* or *step_sizes* is not a float.
- **ValueError** – If *etaminus* is not in the range of (0, 1) or *etaplus* is not greater than 1.
- **TypeError** – If *weight_decay* is neither float nor int.
- **ValueError** – If *weight_decay* is less than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> #1) All parameters use the same learning rate and weight decay
>>> optim = nn.Rprop(params=net.trainable_params())
>>>
>>> #2) Use parameter groups and set different values
>>> conv_params = list(filter(lambda x: 'conv' in x.name, net.trainable_params()))
>>> no_conv_params = list(filter(lambda x: 'conv' not in x.name, net.trainable_params()))
>>> group_params = [{'params': conv_params,'grad_centralization':True},
...                 {'params': no_conv_params, 'lr': 0.01},
...                 {'order_params': net.trainable_params()}]
>>> optim = nn.Rprop(group_params, learning_rate=0.1, weight_decay=0.0)
>>> # The conv_params's parameters will use default learning rate of 0.1 default weight␣
↪decay of 0.0 and grad
>>> # centralization of True.
>>> # The no_conv_params's parameters will use learning rate of 0.01 and default weight␣
↪decay of 0.0 and grad
>>> # centralization of False.
>>> # The final parameters order in which the optimizer will be followed is the value of
↪'order_params'.
>>>
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> model = ms.train.Model(net, loss_fn=loss, optimizer=optim)
```

3.15.18 mindspore.nn.SGD

class mindspore.nn.**SGD**(*params*, *learning_rate=0.1*, *momentum=0.0*, *dampening=0.0*, *weight_decay=0.0*, *nesterov=False*, *loss_scale=1.0*)

Implements stochastic gradient descent. Momentum is optional.

Introduction to SGD can be found at SGD . Nesterov momentum is based on the formula from paper On the importance of initialization and momentum in deep learning.

$$v_{t+1} = u * v_t + gradient * (1 - dampening)$$

If nesterov is True:

$$p_{t+1} = p_t - lr * (gradient + u * v_{t+1})$$

If nesterov is False:

$$p_{t+1} = p_t - lr * v_{t+1}$$

To be noticed, for the first step, $v_{t+1} = gradient$.

Here : where p, v and u denote the parameters, accum, and momentum respectively.

Note: If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied.

Parameters

- **params** (*Union[list[Parameter], list[dict]]*) – Must be list of *Parameter* or list of *dict*. When the *params* is a list of *dict*, the string "params", "lr", "grad_centralization" and "order_params" are the keys can be parsed.
  - params: Required. Parameters in current group. The value must be a list of *Parameter*.
  - lr: Optional. If "lr" in the keys, the value of corresponding learning rate will be used. If not, the *learning_rate* in optimizer will be used. Fixed and dynamic learning rate are supported.
  - weight_decay: Optional. If "weight_decay" in the keys, the value of corresponding weight decay will be used. If not, the *weight_decay* in the optimizer will be used. It should be noted that weight decay must be float, dynamic weight decay is currently not supported.
  - grad_centralization: Optional. Must be Boolean. If "grad_centralization" is in the keys, the set value will be used. If not, the *grad_centralization* is False by default. This configuration only works on the convolution layer.
  - order_params: Optional. When parameters is grouped, this usually is used to maintain the order of parameters that appeared in the network to improve performance. The value should be parameters whose order will be followed in optimizer. If *order_params* in the keys, other keys will be ignored and the element of 'order_params' must be in one group of *params*.
- **learning_rate** (*Union[float, int, Tensor, Iterable, LearningRateSchedule], optional*) – Default: `0.1`.
  - float: The fixed learning rate value. Must be equal to or greater than 0.
  - int: The fixed learning rate value. Must be equal to or greater than 0. It will be converted to float.
  - Tensor: Its value should be a scalar or a 1-D vector. For scalar, fixed learning rate will be applied. For vector, learning rate is dynamic, then the i-th step will take the i-th value as the learning rate.
  - Iterable: Learning rate is dynamic. The i-th step will take the i-th value as the learning rate.

  - LearningRateSchedule: Learning rate is dynamic. During training, the optimizer calls the instance of LearningRateSchedule with step as the input to get the learning rate of current step.

- **momentum** (*float, optional*) – A floating point value the momentum. must be at least 0.0. Default: `0.0`.
- **dampening** (*float, optional*) – A floating point value of dampening for momentum. must be at least 0.0. Default: `0.0`.
- **weight_decay** (*float, optional*) – Weight decay (L2 penalty). It must be equal to or greater than 0. Default: `0.0`.
- **nesterov** (*bool, optional*) – Enables the Nesterov momentum. If use nesterov, momentum must be positive, and dampening must be equal to 0.0. Default: `False`.
- **loss_scale** (*float, optional*) – A floating point value for the loss scale, which must be larger than 0.0. In general, use the default value. Only when *FixedLossScaleManager* is used for training and the *drop_overflow_update* in *FixedLossScaleManager* is set to `False`, then this value needs to be the same as the *loss_scale* in *FixedLossScaleManager*. Refer to class *mindspore.amp.FixedLossScaleManager* for more details. Default: `1.0`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*, the shape is the same as *params*.

Outputs:

Tensor[bool], the value is `True`.

Raises

ValueError – If the momentum, dampening or weight_decay value is less than 0.0.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py

```

3.16 Dynamic Learning Rate

3.16.1 LearningRateSchedule Class

The dynamic learning rates in this module are all subclasses of LearningRateSchedule. Pass the instance of LearningRateSchedule to an optimizer. During the training process, the optimizer calls the instance taking current step as input to get the current learning rate.

```
import mindspore.nn as nn

min_lr = 0.01
max_lr = 0.1
decay_steps = 4
cosine_decay_lr = nn.CosineDecayLR(min_lr, max_lr, decay_steps)

net = Net()
optim = nn.Momentum(net.trainable_params(), learning_rate=cosine_decay_lr, momentum=0.9)
```

API Name	Description	Supported Platforms
mindspore.nn.CosineDecayLR	Calculates learning rate based on cosine decay function.	Ascend GPU
mindspore.nn.ExponentialDecayLR	Calculates learning rate based on exponential decay function.	Ascend GPU CPU
mindspore.nn.InverseDecayLR	Calculates learning rate base on inverse-time decay function.	Ascend GPU CPU
mindspore.nn.NaturalExpDecayLR	Calculates learning rate base on natural exponential decay function.	Ascend GPU CPU
mindspore.nn.PolynomialDecayLR	Calculates learning rate base on polynomial decay function.	Ascend GPU
mindspore.nn.WarmUpLR	Gets learning rate warming up.	Ascend GPU CPU

mindspore.nn.CosineDecayLR

class mindspore.nn.**CosineDecayLR**(*min_lr*, *max_lr*, *decay_steps*)

Calculates learning rate based on cosine decay function.

For current step, the formula of computing decayed learning rate is:

$$decayed\_learning\_rate = min\_lr + 0.5 * (max\_lr - min\_lr) * (1 + cos(\frac{current\_step}{decay\_steps}\pi))$$

Parameters

- **min_lr** (*float*) – The minimum value of learning rate.
- **max_lr** (*float*) – The maximum value of learning rate.

- **decay_steps** (*int*) –Number of steps to decay over.

Inputs:

- **global_step** (Tensor) - The current step number.

Outputs:

Tensor. The learning rate value for the current step with shape ().

Raises

- **TypeError** –If *min_lr* or *max_lr* is not a float.
- **TypeError** –If *decay_steps* is not an int.
- **ValueError** –If *min_lr* is less than 0 or *decay_steps* is less than 1.
- **ValueError** –If *max_lr* is less than or equal to 0.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>>
>>> min_lr = 0.01
>>> max_lr = 0.1
>>> decay_steps = 4
>>> global_steps = Tensor(2, mindspore.int32)
>>> cosine_decay_lr = nn.CosineDecayLR(min_lr, max_lr, decay_steps)
>>> lr = cosine_decay_lr(global_steps)
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

mindspore.nn.ExponentialDecayLR

class mindspore.nn.**ExponentialDecayLR**(*learning_rate*, *decay_rate*, *decay_steps*, *is_stair=False*)

Calculates learning rate based on exponential decay function.

For current step, the formula of computing decayed learning rate is:

$$decayed\_learning\_rate = learning\_rate * decay\_rate^{p}$$

Where :

$$p = \frac{current\_step}{decay\_steps}$$

If *is_stair* is True, the formula is :

$$p = floor(\frac{current\_step}{decay\_steps})$$

Parameters

- **learning_rate** (*float*) –The initial value of learning rate.

- **decay_rate** (*float*) –The decay rate.
- **decay_steps** (*int*) –Number of steps to decay over.
- **is_stair** (*bool, optional*) –If `True`, learning rate is decayed once every *decay_steps* time. Default: `False` .

Inputs:

- **global_step** (Tensor) - The current step number. $current\_step$ in the above formula.

Outputs:

Tensor. The learning rate value for the current step with shape ().

Raises

- **TypeError** –If *learning_rate* or *decay_rate* is not a float.
- **TypeError** –If *decay_steps* is not an int or *is_stair* is not a bool.
- **ValueError** –If *decay_steps* is less than 1.
- **ValueError** –If *learning_rate* or *decay_rate* is less than or equal to 0.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>>
>>> learning_rate = 0.1
>>> decay_rate = 0.9
>>> decay_steps = 4
>>> global_step = Tensor(2, mindspore.int32)
>>> exponential_decay_lr = nn.ExponentialDecayLR(learning_rate, decay_rate, decay_steps)
>>> lr = exponential_decay_lr(global_step)
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

mindspore.nn.InverseDecayLR

class mindspore.nn.**InverseDecayLR**(*learning_rate*, *decay_rate*, *decay_steps*, *is_stair=False*)

Calculates learning rate base on inverse-time decay function.

For current step, the formula of computing decayed learning rate is:

$$decayed\_learning\_rate = learning\_rate/(1 + decay\_rate * p)$$

Where :

$$p = \frac{current\_step}{decay\_steps}$$

If *is_stair* is True, the formula is :

$$p = floor(\frac{current\_step}{decay\_steps})$$

Parameters

- **learning_rate** (*float*) –The initial value of learning rate.
- **decay_rate** (*float*) –The decay rate.
- **decay_steps** (*int*) –Number of steps to decay over.
- **is_stair** (*bool, optional*) –If true, learning rate decay once every *decay_steps* times. If False, the learning rate decays for every step. Default: `False` .

Inputs:

- **global_step** (Tensor) - The current step number.

Outputs:

Tensor. The learning rate value for the current step with shape ().

Raises

- **TypeError** –If *learning_rate* or *decay_rate* is not a float.
- **TypeError** –If *decay_steps* is not an int or *is_stair* is not a bool.
- **ValueError** –If *decay_steps* is less than 1.
- **ValueError** –If *learning_rate* or *decay_rate* is less than or equal to 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>>
>>> learning_rate = 0.1
>>> decay_rate = 0.9
>>> decay_steps = 4
>>> global_step = Tensor(2, mindspore.int32)
>>> inverse_decay_lr = nn.InverseDecayLR(learning_rate, decay_rate, decay_steps, True)
>>> lr = inverse_decay_lr(global_step)
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

mindspore.nn.NaturalExpDecayLR

class mindspore.nn.**NaturalExpDecayLR**(*learning_rate*, *decay_rate*, *decay_steps*, *is_stair=False*)

Calculates learning rate base on natural exponential decay function.

For current step, the formula of computing decayed learning rate is:

$$decayed\_learning\_rate = learning\_rate * e^{-decay\_rate*p}$$

Where :

$$p = \frac{current\_step}{decay\_steps}$$

If *is_stair* is True, the formula is :

$$p = floor(\frac{current\_step}{decay\_steps})$$

Parameters

- **learning_rate** (*float*) –The initial value of learning rate.
- **decay_rate** (*float*) –The decay rate.
- **decay_steps** (*int*) –Number of steps to decay over.
- **is_stair** (*bool*) –If `true` , learning rate is decayed once every *decay_steps* time. Default: `False` .

Inputs:

- **global_step** (Tensor) - The current step number.

Outputs:

Tensor. The learning rate value for the current step with shape ().

Raises

- **TypeError** –If *learning_rate* or *decay_rate* is not a float.
- **TypeError** –If *decay_steps* is not an int or *is_stair* is not a bool.
- **ValueError** –If *decay_steps* is less than 1.
- **ValueError** –If *learning_rate* or *decay_rate* is less than or equal to 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>>
>>> learning_rate = 0.1
>>> decay_rate = 0.9
>>> decay_steps = 4
>>> global_step = Tensor(2, mindspore.int32)
>>> natural_exp_decay_lr = nn.NaturalExpDecayLR(learning_rate, decay_rate, decay_steps, True)
>>> lr = natural_exp_decay_lr(global_step)
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

mindspore.nn.PolynomialDecayLR

class mindspore.nn.**PolynomialDecayLR**(*learning_rate*, *end_learning_rate*, *decay_steps*, *power*, *update_decay_steps=False*)

Calculates learning rate base on polynomial decay function.

For current step, the formula of computing decayed learning rate is:

$$\begin{aligned} decayed\_learning\_rate =& (learning\_rate - end\_learning\_rate) * \\ & (1 - tmp\_step / tmp\_decay\_steps)^{power} \\ & + end\_learning\_rate \end{aligned}$$

Where :

$$tmp\_step = \min(current\_step, decay\_steps)$$

If *update_decay_steps* is true, update the value of tmp_decay_steps every *decay_steps*. The formula is :

$$tmp\_decay\_steps = decay\_steps * ceil(current\_step / decay\_steps)$$

Parameters

- **learning_rate** (*float*) –The initial value of learning rate.
- **end_learning_rate** (*float*) –The end value of learning rate.
- **decay_steps** (*int*) –Number of steps to decay over.
- **power** (*float*) –The power of polynomial. It must be greater than 0.
- **update_decay_steps** (*bool*) –If `true` , learning rate is decayed once every *decay_steps* time. Default: `False` .

Inputs:

- **global_step** (Tensor) - The current step number. Shape is ().

Outputs:

Tensor. The learning rate value for the current step with shape ().

Raises

- **TypeError** –If *learning_rate*, *end_learning_rate* or *power* is not a float.
- **TypeError** –If *decay_steps* is not an int or *update_decay_steps* is not a bool.
- **ValueError** –If *end_learning_rate* is less than 0 or *decay_steps* is less than 1.
- **ValueError** –If *learning_rate* or *power* is less than or equal to 0.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>>
>>> learning_rate = 0.1
>>> end_learning_rate = 0.01
>>> decay_steps = 4
>>> power = 0.5
>>> global_step = Tensor(2, mindspore.int32)
>>> polynomial_decay_lr = nn.PolynomialDecayLR(learning_rate, end_learning_rate, decay_steps,
 ↪ power)
>>> lr = polynomial_decay_lr(global_step)
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

mindspore.nn.WarmUpLR

class mindspore.nn.**WarmUpLR**(*learning_rate*, *warmup_steps*)

Gets learning rate warming up.

For current step, the formula of computing warmup learning rate is:

$$warmup\_learning\_rate = learning\_rate * tmp\_step / warmup\_steps$$

Where

$$tmp\_step = \min(current\_step, warmup\_steps)$$

Parameters

- **learning_rate** (*float*) –The initial value of learning rate. The value of *learning_rate* must be greater than 0.
- **warmup_steps** (*int*) –The warm up steps of learning rate. The value of *warmup_steps* must be greater than or equal to 1.

Inputs:

- **global_step** (Tensor) - The current step number. Shape is ().

Outputs:

Tensor. The learning rate value for the current step with shape ().

Raises

- **TypeError** –If *learning_rate* is not a float.
- **TypeError** –If *warmup_steps* is not an int.
- **ValueError** –If *warmup_steps* is less than 1.
- **ValueError** –If *learning_rate* is less than or equal to 0.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>>
>>> learning_rate = 0.1
>>> warmup_steps = 2
>>> global_step = Tensor(2, mindspore.int32)
>>> warmup_lr = nn.WarmUpLR(learning_rate, warmup_steps)
>>> lr = warmup_lr(global_step)
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

3.16.2 Dynamic LR Function

The dynamic learning rates in this module are all functions. Call the function and pass the result to an optimizer. During the training process, the optimizer takes result[current step] as current learning rate.

```
import mindspore.nn as nn

min_lr = 0.01
max_lr = 0.1
total_step = 6
step_per_epoch = 1
decay_epoch = 4

lr= nn.cosine_decay_lr(min_lr, max_lr, total_step, step_per_epoch, decay_epoch)

net = Net()
optim = nn.Momentum(net.trainable_params(), learning_rate=lr, momentum=0.9)
```

API Name	Description	Supported Platforms
mindspore.nn.cosine_decay_lr	Calculates learning rate base on cosine decay function.	Ascend GPU CPU
mindspore.nn.exponential_decay_lr	Calculates learning rate base on exponential decay function.	Ascend GPU CPU
mindspore.nn.inverse_decay_lr	Calculates learning rate base on inverse-time decay function.	Ascend GPU CPU
mindspore.nn.natural_exp_decay_lr	Calculates learning rate base on natural exponential decay function.	Ascend GPU CPU
mindspore.nn.piecewise_constant_lr	Get piecewise constant learning rate.	Ascend GPU CPU
mindspore.nn.polynomial_decay_lr	Calculates learning rate base on polynomial decay function.	Ascend GPU CPU
mindspore.nn.warmup_lr	Gets learning rate warming up.	Ascend GPU CPU

mindspore.nn.cosine_decay_lr

mindspore.nn.**cosine_decay_lr**(*min_lr*, *max_lr*, *total_step*, *step_per_epoch*, *decay_epoch*)

Calculates learning rate base on cosine decay function. The learning rate for each step will be stored in a list.

For the i-th step, the formula of computing decayed_learning_rate[i] is:

$$decayed\_learning\_rate[i] = min\_lr + 0.5 * (max\_lr - min\_lr) * (1 + cos(\frac{current\_epoch}{decay\_epoch}\pi))$$

Where $current\_epoch = floor(\frac{i}{step\_per\_epoch})$.

Parameters

- **min_lr** (*float*) –The minimum value of learning rate.
- **max_lr** (*float*) –The maximum value of learning rate.
- **total_step** (*int*) –The total number of steps.
- **step_per_epoch** (*int*) –The number of steps in per epoch.
- **decay_epoch** (*int*) –Number of epochs to decay over.

Returns

list[float]. The size of list is *total_step*.

Raises

- **TypeError** –If *min_lr* or *max_lr* is not a float.
- **TypeError** –If *total_step* or *step_per_epoch* or *decay_epoch* is not an int.
- **ValueError** –If *max_lr* is not greater than 0 or *min_lr* is less than 0.
- **ValueError** –If *total_step* or *step_per_epoch* or *decay_epoch* is less than 0.
- **ValueError** –If *min_lr* is greater than or equal to *max_lr*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.nn as nn
>>>
>>> min_lr = 0.01
>>> max_lr = 0.1
>>> total_step = 6
>>> step_per_epoch = 2
>>> decay_epoch = 2
>>> lr = nn.cosine_decay_lr(min_lr, max_lr, total_step, step_per_epoch, decay_epoch)
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

mindspore.nn.exponential_decay_lr

mindspore.nn.**exponential_decay_lr**(*learning_rate*, *decay_rate*, *total_step*, *step_per_epoch*, *decay_epoch*, *is_stair=False*)

Calculates learning rate base on exponential decay function. The learning rate for each step will be stored in a list.

For the i-th step, the formula of computing decayed_learning_rate[i] is:

$$decayed\_learning\_rate[i] = learning\_rate * decay\_rate^{\frac{current\_epoch}{decay\_epoch}}$$

Where $current\_epoch = floor(\frac{i}{step\_per\_epoch})$.

Parameters

- **learning_rate** (*float*) –The initial value of learning rate.
- **decay_rate** (*float*) –The decay rate.
- **total_step** (*int*) –The total number of steps.
- **step_per_epoch** (*int*) –The number of steps in per epoch.
- **decay_epoch** (*int*) –Number of epochs to decay over.
- **is_stair** (*bool*) –If true, learning rate is decayed once every *decay_epoch* times. Default: `False`.

Returns

list[float]. The size of list is *total_step*.

Raises

- **TypeError** –If *total_step* or *step_per_epoch* or *decay_epoch* is not an int.
- **TypeError** –If *is_stair* is not a bool.
- **TypeError** –If *learning_rate* or *decay_rate* is not a float.
- **ValueError** –If *learning_rate* or *decay_rate* is less than or equal to 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.nn as nn
>>>
>>> learning_rate = 0.1
>>> decay_rate = 0.9
>>> total_step = 6
>>> step_per_epoch = 2
>>> decay_epoch = 1
>>> lr = nn.exponential_decay_lr(learning_rate, decay_rate, total_step, step_per_epoch,␣
↪decay_epoch)
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

mindspore.nn.inverse_decay_lr

mindspore.nn.**inverse_decay_lr**(*learning_rate*, *decay_rate*, *total_step*, *step_per_epoch*, *decay_epoch*, *is_stair=False*)

Calculates learning rate base on inverse-time decay function. The learning rate for each step will be stored in a list.

For the i-th step, the formula of computing decayed_learning_rate[i] is:

$$decayed\_learning\_rate[i] = learning\_rate/(1 + decay\_rate * current\_epoch/decay\_epoch)$$

Where $current\_epoch = floor(\frac{i}{step\_per\_epoch})$.

Parameters

- **learning_rate** (*float*) –The initial value of learning rate.
- **decay_rate** (*float*) –The decay rate.
- **total_step** (*int*) –The total number of steps.
- **step_per_epoch** (*int*) –The number of steps in per epoch.
- **decay_epoch** (*int*) –Number of epochs to decay over.
- **is_stair** (*bool*) –If true, learning rate is decayed once every *decay_epoch* times. If False, the learning rate decays for every epoch. Default: `False` .

Returns

list[float]. The size of list is *total_step*.

Raises

- **TypeError** –If *total_step* or *step_per_epoch* or *decay_epoch* is not an int.
- **TypeError** –If *is_stair* is not a bool.
- **TypeError** –If *learning_rate* or *decay_rate* is not a float.
- **ValueError** –If *learning_rate* or *decay_rate* is less than or equal to 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.nn as nn
>>>
>>> learning_rate = 0.1
>>> decay_rate = 0.5
>>> total_step = 6
>>> step_per_epoch = 1
>>> decay_epoch = 1
>>> lr = nn.inverse_decay_lr(learning_rate, decay_rate, total_step, step_per_epoch, decay_
↪epoch, True)
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

mindspore.nn.natural_exp_decay_lr

mindspore.nn.**natural_exp_decay_lr**(*learning_rate*, *decay_rate*, *total_step*, *step_per_epoch*, *decay_epoch*, *is_stair=False*)

Calculates learning rate base on natural exponential decay function. The learning rate for each step will be stored in a list.

For the i-th step, the formula of computing decayed_learning_rate[i] is:

$$decayed\_learning\_rate[i] = learning\_rate * e^{-decay\_rate*current\_epoch}$$

Where $current\_epoch = floor(\frac{i}{step\_per\_epoch})$.

Parameters

- **learning_rate** (*float*) –The initial value of learning rate.
- **decay_rate** (*float*) –The decay rate.
- **total_step** (*int*) –The total number of steps.
- **step_per_epoch** (*int*) –The number of steps in per epoch.
- **decay_epoch** (*int*) –Number of epochs to decay over.
- **is_stair** (*bool*) –If true, learning rate is decayed once every *decay_epoch* times. Default: `False` .

Returns

list[float]. The size of list is *total_step*.

Raises

- **TypeError** –If *total_step* or *step_per_epoch* or *decay_epoch* is not an int.
- **TypeError** –If *is_stair* is not a bool.
- **TypeError** –If *learning_rate* or *decay_rate* is not a float.
- **ValueError** –If *learning_rate* or *decay_rate* is less than or equal to 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.nn as nn
>>>
>>> learning_rate = 0.1
>>> decay_rate = 0.9
>>> total_step = 6
>>> step_per_epoch = 2
>>> decay_epoch = 2
>>> lr = nn.natural_exp_decay_lr(learning_rate, decay_rate, total_step, step_per_epoch,␣
↪decay_epoch, True)
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

mindspore.nn.piecewise_constant_lr

mindspore.nn.**piecewise_constant_lr**(*milestone*, *learning_rates*)

Get piecewise constant learning rate. The learning rate for each step will be stored in a list.

Calculate learning rate by the given *milestone* and *learning_rates*. Let the value of *milestone* be $(M_1, M_2, ..., M_t, ..., M_N)$ and the value of *learning_rates* be $(x_1, x_2, ..., x_t, ..., x_N)$. N is the length of *milestone*. Let the output learning rate be $y[i]$, then for the i-th step, the formula of computing decayed_learning_rate[i] is:

$$y[i] = x_t, \ for \ i \in [M_{t-1}, M_t)$$

Parameters

- **milestone** (*Union[list[int], tuple[int]]*) – A list of milestone. When the specified step is reached, use the corresponding *learning_rates*. This list is a monotone increasing list. Every element in the list must be greater than 0.
- **learning_rates** (*Union[list[float], tuple[float]]*) – A list of learning rates.

Returns

list[float]. The size of list is M_N.

Raises

- **TypeError** – If *milestone* or *learning_rates* is neither a tuple nor a list.
- **ValueError** – If the length of *milestone* and *learning_rates* is not same.
- **ValueError** – If the value in *milestone* is not monotonically decreasing.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.nn as nn
>>>
>>> milestone = [2, 5, 10]
>>> learning_rates = [0.1, 0.05, 0.01]
>>> lr = nn.piecewise_constant_lr(milestone, learning_rates)
>>> # learning_rates = 0.1  if step <= 2
>>> # learning_rates = 0.05  if 2 < step <= 5
>>> # learning_rates = 0.01  if 5 < step <= 10
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

mindspore.nn.polynomial_decay_lr

mindspore.nn.**polynomial_decay_lr**(*learning_rate*, *end_learning_rate*, *total_step*, *step_per_epoch*, *decay_epoch*, *power*, *update_decay_epoch=False*)

Calculates learning rate base on polynomial decay function. The learning rate for each step will be stored in a list.

For the i-th step, the formula of computing decayed_learning_rate[i] is:

$$decayed\_learning\_rate[i] = (learning\_rate - end\_learning\_rate) * (1 - tmp\_epoch/tmp\_decay\_epoch)^{power} + end\_learning\_$$

Where:

$$tmp\_epoch = \min(current\_epoch, decay\_epoch)$$

$$current\_epoch = floor(\frac{i}{step\_per\_epoch})$$

$$tmp\_decay\_epoch = decay\_epoch$$

If *update_decay_epoch* is true, update the value of tmp_decay_epoch every epoch. The formula is:

$$tmp\_decay\_epoch = decay\_epoch * ceil(current\_epoch/decay\_epoch)$$

Parameters

- **learning_rate** (*float*) –The initial value of learning rate.
- **end_learning_rate** (*float*) –The end value of learning rate.
- **total_step** (*int*) –The total number of steps.
- **step_per_epoch** (*int*) –The number of steps in per epoch.
- **decay_epoch** (*int*) –Number of epochs to decay over.
- **power** (*float*) –The power of polynomial. It must be greater than 0.
- **update_decay_epoch** (*bool*) –If `true`, update *decay_epoch*. Default: `False` .

Returns

list[float]. The size of list is *total_step*.

Raises

- **TypeError** –If *learning_rate* or *end_learning_rate* or *power* is not a float.
- **TypeError** –If *total_step* or *step_per_epoch* or *decay_epoch* is not an int.
- **TypeError** –If *update_decay_epoch* is not a bool.
- **ValueError** –If *learning_rate* or *power* is not greater than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.nn as nn
>>>
>>> lr = 0.1
>>> end_learning_rate = 0.01
>>> total_step = 6
>>> step_per_epoch = 2
>>> decay_epoch = 2
>>> power = 0.5
>>> lr = nn.polynomial_decay_lr(lr, end_learning_rate, total_step, step_per_epoch, decay_
↪epoch, power)
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

mindspore.nn.warmup_lr

mindspore.nn.**warmup_lr**(*learning_rate*, *total_step*, *step_per_epoch*, *warmup_epoch*)

Gets learning rate warming up. The learning rate for each step will be stored in a list.

For the i-th step, the formula of computing warmup_learning_rate[i] is:

$$warmup\_learning\_rate[i] = learning\_rate * tmp\_epoch / warmup\_epoch$$

Where $tmp\_epoch = \min(current\_epoch, warmup\_epoch)$, $current\_epoch = floor(\frac{i}{step\_per\_epoch})$

Parameters

- **learning_rate** (*float*) –The initial value of learning rate.
- **total_step** (*int*) –The total number of steps.
- **step_per_epoch** (*int*) –The number of steps in per epoch.
- **warmup_epoch** (*int*) –A value that determines the epochs of the learning rate is warmed up.

Returns

list[float]. The size of list is *total_step*.

Raises

- **TypeError** –If *learning_rate* is not a float.
- **TypeError** –If *total_step* or *step_per_epoch* or *decay_epoch* is not an int.
- **ValueError** –If *learning_rate* is less than 0.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.nn as nn
>>>
>>> learning_rate = 0.1
>>> total_step = 6
>>> step_per_epoch = 2
>>> warmup_epoch = 2
>>> lr = nn.warmup_lr(learning_rate, total_step, step_per_epoch, warmup_epoch)
>>> net = nn.Dense(2, 3)
>>> optim = nn.SGD(net.trainable_params(), learning_rate=lr)
```

3.17 Image Processing Layer

API Name	Description	Supported Platforms
mindspore.nn.PixelShuffle	Applies the PixelShuffle operation over input which implements sub-pixel convolutions with stride $1/r$.	Ascend GPU CPU
mindspore.nn.PixelUnshuffle	Applies the PixelUnshuffle operation over input which is the inverse of PixelShuffle.	Ascend GPU CPU

continues on next page

Table 18 – continued from previous page

mindspore.nn.Upsample	For details, please refer to *mindspore.ops.interpolate()*.	Ascend GPU CPU

3.17.1 mindspore.nn.PixelShuffle

class mindspore.nn.**PixelShuffle**(*upscale_factor*)

Applies the PixelShuffle operation over input which implements sub-pixel convolutions with stride $1/r$. For more details, refer to Real-Time Single Image and Video Super-Resolution Using an Efficient Sub-Pixel Convolutional Neural Network .

Typically, the input is of shape $(*, C \times r^2, H, W)$, and the output is of shape $(*, C, H \times r, W \times r)$, where r is an upscale factor and $*$ is zero or more batch dimensions.

Note: The dimension of input Tensor on Ascend should be less than 7.

Parameters

upscale_factor (*int*) –factor to shuffle the input, and is a positive integer. *upscale_factor* is the above-mentioned r.

Inputs:

- **input** (Tensor) - Tensor of shape $(*, C \times r^2, H, W)$. The dimension of x is larger than 2, and the length of third to last dimension can be divisible by *upscale_factor* squared.

Outputs:

- **output** (Tensor) - Tensor of shape $(*, C, H \times r, W \times r)$.

Raises

- **ValueError** –If *upscale_factor* is not a positive integer.
- **ValueError** –If the length of third to last dimension of *input* is not divisible by *upscale_factor* squared.
- **ValueError** –If the dimension of *input* is less than 3.
- **TypeError** –If *input* is not a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> input_x = np.arange(3 * 2 * 8 * 4 * 4).reshape((3, 2, 8, 4, 4))
>>> input_x = ms.Tensor(input_x, ms.dtype.int32)
>>> pixel_shuffle = ms.nn.PixelShuffle(2)
>>> output = pixel_shuffle(input_x)
>>> print(output.shape)
(3, 2, 2, 8, 8)
```

3.17.2 mindspore.nn.PixelUnshuffle

class mindspore.nn.**PixelUnshuffle**(*downscale_factor*)

Applies the PixelUnshuffle operation over input which is the inverse of PixelShuffle. For more details, refer to Real-Time Single Image and Video Super-Resolution Using an Efficient Sub-Pixel Convolutional Neural Network .

Typically, the input is of shape $(*, C, H \times r, W \times r)$, and the output is of shape $(*, C \times r^2, H, W)$, where r is a downscale factor and $*$ is zero or more batch dimensions.

Parameters

downscale_factor (*int*) –factor to unshuffle the input, and is a positive integer. *downscale_factor* is the above-mentioned r.

Inputs:

- **input** (Tensor) - Tensor of shape $(*, C, H \times r, W \times r)$. The dimension of *input* is larger than 2, and the length of second to last dimension or last dimension can be divisible by *downscale_factor* .

Outputs:

- **output** (Tensor) - Tensor of shape $(*, C \times r^2, H, W)$.

Raises

- **ValueError** –If *downscale_factor* is not a positive integer.
- **ValueError** –If the length of second to last dimension or last dimension is not divisible by *downscale_factor* .
- **ValueError** –If the dimension of *input* is less than 3.
- **TypeError** –If *input* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> pixel_unshuffle = ms.nn.PixelUnshuffle(2)
>>> input_x = np.arange(8 * 8).reshape((1, 1, 8, 8))
>>> input_x = ms.Tensor(input_x, ms.dtype.int32)
>>> output = pixel_unshuffle(input_x)
>>> print(output.shape)
(1, 4, 4, 4)
```

3.17.3 mindspore.nn.Upsample

class mindspore.nn.**Upsample**(*size=None*, *scale_factor=None*, *mode='nearest'*, *align_corners=None*, *recompute_scale_factor=None*)

For details, please refer to *mindspore.ops.interpolate()*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> x = ms.Tensor([[[[1.0, 2.0, 3.0, 4.0], [5.0, 6.0, 7.0, 8.0]]]])
>>> upsample = ms.nn.Upsample(size=(5, 5))
>>> out = upsample(x)
>>> print(x.asnumpy())
[[[[1. 2. 3. 4.]
   [5. 6. 7. 8.]]]]
>>> print(out.asnumpy())
[[[[1. 1. 2. 3. 4.]
   [1. 1. 2. 3. 4.]
   [1. 1. 2. 3. 4.]
   [5. 5. 6. 7. 8.]
   [5. 5. 6. 7. 8.]]]]
>>> print(out.shape)
(1, 1, 5, 5)
```

3.18 Common Layer

API Name	Description	Supported Platforms
mindspore.nn.ChannelShuffle	Divide the channels in a tensor of shape $(*, C, H, W)$ into g group and rearrange them as $(*, \frac{C}{g}, g, H * W)$, while retaining the original tensor shape in the final output.	`Ascend` `GPU` `CPU`
mindspore.nn.Flatten	Flatten the input Tensor along dimensions from *start_dim* to *end_dim*.	`Ascend` `GPU` `CPU`
mindspore.nn.Identity	A placeholder identity operator that returns the same as input.	`Ascend` `GPU` `CPU`
mindspore.nn.Unflatten	Unflattens a Tensor dim according to *axis* and *unflattened_size*.	`Ascend` `GPU` `CPU`

3.18.1 mindspore.nn.ChannelShuffle

class mindspore.nn.**ChannelShuffle**(*groups*)

Divide the channels in a tensor of shape $(*, C, H, W)$ into g group and rearrange them as $(*, \frac{C}{g}, g, H * W)$, while retaining the original tensor shape in the final output.

Parameters

groups (*int*) –Number of groups to divide channels in, must be greater than 0. Refer to g in the above formula.

Inputs:

- **x** (Tensor) - Tensor of shape $(*, C_{in}, H_{in}, W_{in})$.

Outputs:

Tensor, with the same type and shape as the *x*.

Raises

- **TypeError** –If *groups* is not a positive integer.
- **ValueError** –If *groups* is less than 1.
- **ValueError** –If dims of *x* is less than 3.
- **ValueError** –If number of channels can not be divisible by groups.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> channel_shuffle = ms.nn.ChannelShuffle(2)
>>> x = ms.Tensor(np.arange(16).astype(np.int32).reshape(1, 4, 2, 2))
>>> print(x)
[[[[ 0  1]
   [ 2  3]]
  [[ 4  5]
   [ 6  7]]
  [[ 8  9]
   [10 11]]
  [[12 13]
   [14 15]]]]
>>> output = channel_shuffle(x)
>>> print(output)
[[[[ 0  1]
   [ 2  3]]
  [[ 8  9]
   [10 11]]
  [[ 4  5]
   [ 6  7]]
  [[12 13]
   [14 15]]]]
```

3.18.2 mindspore.nn.Flatten

class mindspore.nn.**Flatten**(*start_dim=1*, *end_dim=-1*)

Flatten the input Tensor along dimensions from *start_dim* to *end_dim*.

Parameters

- **start_dim** (*int, optional*) – The first dimension to flatten. Default: `1`.
- **end_dim** (*int, optional*) – The last dimension to flatten. Default: `-1`.

Inputs:

- **x** (Tensor) - The input Tensor to be flattened.

Outputs:

Tensor. If no dimensions are flattened, returns the original *x*, otherwise return the flattened Tensor. If *x* is a 0-dimensional Tensor, a 1-dimensional Tensor will be returned.

Raises

- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If *start_dim* or *end_dim* is not int.
- **ValueError** – If *start_dim* is greater than *end_dim* after canonicalized.
- **ValueError** – If *start_dim* or *end_dim* is not in range of [-x.dim, x.dim-1]. For example, the default values are used for the args and the input is a 0-dimensional or 1-dimensional Tensor.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> x = Tensor(np.array([[[1.2, 1.2], [2.1, 2.1]], [[2.2, 2.2], [3.2, 3.2]]]), mindspore.
↪float32)
>>> net = nn.Flatten()
>>> output = net(x)
>>> print(output)
[[1.2 1.2 2.1 2.1]
 [2.2 2.2 3.2 3.2]]
>>> print(f"before flatten the x shape is {x.shape}")
before flatten the x shape is  (2, 2, 2)
>>> print(f"after flatten the output shape is {output.shape}")
after flatten the output shape is (2, 4)
```

3.18.3 mindspore.nn.Identity

class mindspore.nn.**Identity**(**args*, ***kwargs*)

A placeholder identity operator that returns the same as input.

Parameters

- **args** (*Any*) – Any argument.
- **kwargs** (*Any*) – Any keyword argument.

Inputs:

- **input** (Any) - The input of Identity.

Outputs:

The same as *input*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> input = Tensor(np.array([1, 2, 3, 4]), mindspore.int64)
>>> net = nn.Identity()
>>> output = net(input)
>>> print(output)
[1 2 3 4]
```

3.18.4 mindspore.nn.Unflatten

class mindspore.nn.**Unflatten**(*axis*, *unflattened_size*)

Unflattens a Tensor dim according to *axis* and *unflattened_size*.

Parameters

- **axis** (*int*) – specifies the dimension of the input Tensor to be unflattened.
- **unflattened_size** (*Union(tuple[int], list[int])*) – the new shape of the unflattened dimension of the Tensor and it can be a tuple of ints or a list of ints. The product of *unflattened_size* must equal to input_shape[axis].

Inputs:

- **input** (Tensor) - The input Tensor to be unflattened.

Outputs:

Tensor that has been unflattend.

Raises

- **TypeError** – If *axis* is not int.
- **TypeError** – If *unflattened_size* is neither tuple of ints nor list of ints.

- **TypeError** – The product of *unflattened_size* does not equal to input_shape[axis].

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, nn
>>> import numpy as np
>>> input = Tensor(np.arange(0, 100).reshape(2, 10, 5), mindspore.float32)
>>> net = nn.Unflatten(1, (2, 5))
>>> output = net(input)
>>> print(f"before unflatten the input shape is {input.shape}")
before unflatten the input shape is  (2, 10, 5)
>>> print(f"after unflatten the output shape is {output.shape}")
after unflatten the output shape is (2, 2, 5, 5)
```

3.19 Tools

mindspore.nn.utils.no_init_parameters	This interface is used to skip parameter initialization.

3.19.1 mindspore.nn.utils.no_init_parameters

mindspore.nn.utils.**no_init_parameters**()

This interface is used to skip parameter initialization.

In scenarios where a checkpoint is loaded, parameters within the network instantiation will be instantiated and occupy physical memory. Loading a checkpoint will replace the parameter values. Decorator can be applied during network instantiation to add an attribute *init_param* to all parameters within the current Cell, setting it to *init_param=False* . When *init_param=False* is detected, the initialization of the parameters is skipped, and the parameters are assigned values directly from the checkpoint during loading, which can optimize performance and reduce physical memory usage.

Note: Initialization of parameters created with *initializer* can only be skipped. Parameters created by *Tensor* or *numpy* cannot be skipped.

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn, ops, load_checkpoint
>>> from mindspore.common.initializer import initializer
>>> from mindspore.nn.utils import no_init_parameters
>>> # 1. Add a decorator to the network that requires delayed initialization
>>> class Net(nn.Cell):
...     def __init__(self, in_channels, out_channels):
...         super().__init__()
...         self.weight = ms.Parameter(initializer("normal", [in_channels, out_channels], ms.
↪float32))
```

(continues on next page)

(continued from previous page)

```
...         self.bias = ms.Parameter(initializer("normal", [out_channels], ms.float32))
...         self.matmul = ops.MatMul()
...         self.add = ops.Add()
...
...     def construct(self, x):
...         x = self.matmul(x, self.weight)
...         x = self.add(x, self.bias)
...         return x
>>> with no_init_parameters():
...     # After instantiation, all parameters in the net are not initialized
...     net = Net(28*28, 64)
>>> # 2. Load checkpoint parameters to the net
>>> load_checkpoint('./checkpoint/test_net.ckpt', net=net)
>>> # 3. After loading the checkpoint, manually call init_parameters_data() to initialize
>>> #    the uninitialized parameters in the net if need. If the network is executed,
>>> #    the framework will automatically call this interface.
>>> net.init_parameters_data()
```

CHAPTER

FOUR

MINDSPORE.MINT

mindspore.mint provides a large number of functional, nn, optimizer interfaces. The API usages and functions are consistent with the mainstream usage in the industry for easy reference. The mint interface is currently an experimental interface and performs better than ops in graph mode of O0 and PyNative mode. Currently, the O2 (graph sinking mode) and CPU/GPU backend are not supported, and it will be gradually improved in the future.

The module import method is as follows:

```
from mindspore import mint
```

Compared with the previous version, the added, deleted and supported platforms change information of *mindspore.mint* operators in MindSpore, please refer to the link mindspore.mint API Interface Change .

4.1 Tensor

4.1.1 Creation Operations

API Name	Description	Supported Platforms
mindspore.mint.arange	Creates a sequence of numbers that begins at *start* and extends by increments of *step* up to but not including *end*.	Ascend
mindspore.mint.bernoulli	Sample from the Bernoulli distribution and randomly set the i^{th} element of the *output* to (0 or 1) according to the i^{th} probability value given in the *input*.	Ascend
mindspore.mint.bincount	Count the occurrences of each value in the input.	Ascend
mindspore.mint.clone	Returns a copy of the input tensor.	Ascend
mindspore.mint.eye	Returns a tensor with ones on the diagonal and zeros in the rest.	Ascend
mindspore.mint.einsum	According to the Einstein summation Convention (Einsum), the product of the input tensor elements is summed along the specified dimension.	Ascend
mindspore.mint.empty	Creates a tensor with uninitialized data, whose shape, dtype and device are described by the argument *size*, *dtype* and *device* respectively.	Ascend
mindspore.mint.empty_like	Returns an uninitialized Tensor with the same shape as the *input*.	Ascend
mindspore.mint.full	Create a Tensor of the specified shape and fill it with the specified value.	Ascend

continues on next page

Table 1 – continued from previous page

mindspore.mint.full_like	Return a Tensor of the same shape as *input* and filled with *fill_value*.	Ascend
mindspore.mint.linspace	Generate a one-dimensional tensor with *steps* elements, evenly distributed in the interval [start, end].	Ascend
mindspore.mint.ones	Creates a tensor filled with value ones.	Ascend
mindspore.mint.ones_like	Creates a tensor filled with 1, with the same shape as input, and its data type is determined by the given dtype.	Ascend
mindspore.mint.randint	Returns a new tensor filled with integer numbers from the uniform distribution over an interval $[low, high)$ based on the given shape and dtype.	Ascend
mindspore.mint.randint_like	Returns a new tensor filled with integer numbers from the uniform distribution over an interval $[low, high)$ based on the given dtype and shape of the input tensor.	Ascend
mindspore.mint.randn	Returns a new tensor filled with numbers from the normal distribution over an interval $[0, 1)$ based on the given shape and dtype.	Ascend
mindspore.mint.randn_like	Returns a new tensor filled with numbers from the normal distribution over an interval $[0, 1)$ based on the given dtype and shape of the input tensor.	Ascend
mindspore.mint.randperm	Generates random permutation of integers from 0 to n-1.	Ascend
mindspore.mint.zeros	Creates a tensor filled with 0 with shape described by *size* and fills it with value 0 in type of *dtype*.	Ascend
mindspore.mint.zeros_like	Creates a tensor filled with 0, with the same size as input.	Ascend

mindspore.mint.arange

mindspore.mint.**arange**(*start=0*, *end=None*, *step=1*, *, *dtype=None*)

Creates a sequence of numbers that begins at *start* and extends by increments of *step* up to but not including *end*.

Parameters

- **start** (*Union[float, int], optional*) – The start of the interval. Default: 0 .
- **end** (*Union[float, int], optional*) – The end of the interval, exclusive. Default: None . If None , it defaults to the value of *start*, and 0 is used as the starting value.
- **step** (*Union[float, int], optional*) – The step size with which the array element increments. Default: 1 .

Keyword Arguments

dtype (mindspore.dtype, *optional*) – The required data type of returned Tensor. Default: None . When *dtype* is not specified or None:

If *start*, *end*, and *step* are all integers, the dtype of output is int64,

If *start*, *end*, and *step* contain at least one floating-point number, the dtype of output is float32.

Returns

A 1-D Tensor, cast to *dtype* if provided, may potentially lose precision due to casting.

Raises

- **TypeError** – If *start*, *end* or *step* are not of type int or float.

- **ValueError** –If *step* = 0.
- **ValueError** –If *start* >= *end* when *step* > 0.
- **ValueError** –If *start* <= *end* when *step* < 0.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, mint
>>> output = mint.arange(1, 6)
>>> print(output)
[1 2 3 4 5]
>>> print(output.dtype)
Int64
>>> output = mint.arange(0, 3, 1.2)
>>> print(output)
[0.  1.2 2.4]
>>> print(output.dtype)
Float32
>>> output = mint.arange(7, 1, -2)
>>> print(output)
[7 5 3]
>>> print(output.dtype)
Int64
>>> output = mint.arange(12, 2, -1, dtype=ms.bfloat16)
>>> print(output)
[12. 11. 10.  9.  8.  7.  6.  5.  4.  3.]
>>> print(output.dtype)
BFloat16
```

mindspore.mint.bernoulli

mindspore.mint.**bernoulli**(*input*, *, *generator=None*)

Sample from the Bernoulli distribution and randomly set the i^{th} element of the *output* to (0 or 1) according to the i^{th} probability value given in the *input*.

$$output_i \sim Bernoulli(p = input_i)$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

input (Tensor) –The input tensor of Bernoulli distribution, where the i^{th} element 'input_{i}' represents the probability that the corresponding output element 'output_{i}' is set to '1', therefore each element in 'input' have to be in the range '[0,1]'. Supported dtype: float16, float32, float64, bfloat16 (only supported by Atlas A2 training series products).

Keyword Arguments

generator (*mindspore.Generator*, optional) –a pseudorandom number generator. Default: None, uses the default pseudorandom number generator.

Returns

output (Tensor), The output tensor, with the same shape and dtype as *input*.

Raises

- **TypeError** –If dtype of *input* is not one of: float16, float32, float64, bfloat16.
- **ValueError** –If any element of the *input* is not in the range [0, 1].

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> input_x = Tensor(np.ones((3, 3)), mindspore.float32)
>>> output = mint.bernoulli(input_x)
>>> print(output)
[[ 1. 1. 1.]
 [ 1. 1. 1.]
 [ 1. 1. 1.]]
>>> input_x = Tensor(np.zeros((3, 3)), mindspore.float32)
>>> output = mint.bernoulli(input_x)
>>> print(output)
[[ 0. 0. 0.]
 [ 0. 0. 0.]
 [ 0. 0. 0.]]
```

mindspore.mint.bincount

`mindspore.mint.`**`bincount`**(*input*, *weights=None*, *minlength=0*)

Count the occurrences of each value in the input.

If *minlength* is not specified, the length of the output Tensor is the maximum value in the input plus one. If *minlength* is specified, the length of the output Tensor is the maximum value between *minlength* or the maximum value in the input plus one.

Each value in the output Tensor represents the number of occurrences of that index value in the input. If *weights* is specified, the output results are weighted, i.e., $out[n] += weight[i]$ instead of $out[n] += 1$.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (`Tensor`) –A one-dimensional Tensor.
- **weights** (`Tensor, optional`) –Weights with the same shape as the input. Default: `None`.
- **minlength** (`int, optional`) –The minimum length of output Tensor. Should be non-negative. Default: `0`.

Returns

Tensor, If input is non-empty, the output shape is $(max(max(input) + 1, minlength),)$, otherwise the shape is $(0,)$.

Raises

- **TypeError** –If *input* or *weights* is not a Tensor.
- **ValueError** –If *input* contains negative values.
- **ValueError** –If *input* is not one-dimensional or *input* and *weights* do not have the same shape.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import mint, Tensor
>>> print(mint.bincount(Tensor(np.arange(5))))
[1 1 1 1 1]
>>> print(mint.bincount(Tensor(np.array([0, 1, 1, 3, 2, 1, 7]))))
[1 3 1 1 0 0 0 1]
>>> w = Tensor(np.array([0.3, 0.5, 0.2, 0.7, 1., -0.6])) # weights
>>> x = Tensor(np.array([0, 1, 1, 2, 2, 2]))
>>> print(mint.bincount(x,  weights=w, minlength=5))
[0.3 0.7 1.1 0.  0. ]
```

mindspore.mint.clone

`mindspore.mint.clone(input)`

Returns a copy of the input tensor.

Warning: This is an experimental API that is subject to change or deletion.

Note: This function is differentiable, and gradients will flow back directly from the calculation result of the function to the *input*.

Parameters

input (Tensor) –A tensor to be copied.

Returns

Tensor, with the same data, shape and type as *input*.

Raises

TypeError –If *input* is not a Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.ones((3,3)).astype("float32"))
>>> output = mint.clone(input)
>>> print(output)
[[1. 1. 1.]
 [1. 1. 1.]
 [1. 1. 1.]]
```

mindspore.mint.eye

mindspore.mint.**eye**(*n*, *m=None*, *dtype=None*)

Returns a tensor with ones on the diagonal and zeros in the rest.

Parameters

- **n** (*int*) –The number of rows returned.
- **m** (*int, optional*) –The number of columns returned. If None , the number of columns is as the same as n.
- **dtype** (mindspore.dtype, *optional*) –The data type returned.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> output = mindspore.mint.eye(3)
>>> print(output)
[[1. 0. 0.]
 [0. 1. 0.]
 [0. 0. 1.]]
>>>
>>> output = mindspore.mint.eye(3, 4)
>>> print(output)
[[1. 0. 0. 0.]
 [0. 1. 0. 0.]
 [0. 0. 1. 0.]]
```

mindspore.mint.einsum

mindspore.mint.**einsum**(*equation*, **operands*)

According to the Einstein summation Convention (Einsum), the product of the input tensor elements is summed along the specified dimension. You can use this operator to perform diagonal, reducesum, transpose, matmul, mul, inner product operations, etc.

Note: The sublist format is also supported. For example, einsum_ext(op1, sublist1, op2, sublist2, ···, sublist_out). In this format, equation can be derived by the sublists which are made up of Python's Ellipsis and list of integers in [0, 52). Each operand is followed by a sublist and an output sublist is at the end. Dynamic shape, dynamic rank input is not supported in graph mode (mode=mindspore.GRAPH_MODE).

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **equation** (*str*) −Notation based on the Einstein summation convention, represent the operation you want to do. the value can contain only letters, commas, ellipsis and arrow. The letters(must be in [a-zA-Z]) represent input tensor dimension, commas(,) represent separate tensors, ellipsis indicates the tensor dimension that you do not care about, the left of the arrow indicates the input tensors, and the right of it indicates the desired output dimension. If there are no arrows in the equation, the letters that appear exactly once in the equation will be part of the output, sorted in increasing alphabetical order. The output is computed by multiplying the input operands element-wise, with their dimensions aligned based on the letters, and then summing out the dimensions whose letters are not part of the output. If there is one arrow in the equation, the output letters must appear at least once for some input operand and at most once for the output.
- **operands** (Tensor) −Input tensor used for calculation. The dtype of the tensor must be the same.

Returns

Tensor, the shape of it can be obtained from the *equation* , and the dtype is the same as input tensors.

Raises

- **TypeError** −If *equation* is invalid, or the *equation* does not match the input tensor.
- **ValueError** −If the number in sublist is not in [0, 52) in sublist format.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([1.0, 2.0, 4.0]), mindspore.float32)
>>> equation = "i->"
>>> output = mint.einsum(equation, x)
>>> print(output)
7.0
>>> x = Tensor(np.array([1.0, 2.0, 4.0]), mindspore.float32)
>>> y = Tensor(np.array([2.0, 4.0, 3.0]), mindspore.float32)
>>> equation = "i,i->i"
```

(continues on next page)

(continued from previous page)

```
>>> output = mint.einsum(equation, x, y)
>>> print(output)
[ 2. 8. 12.]
>>> x = Tensor(np.array([[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]]), mindspore.float32)
>>> y = Tensor(np.array([[2.0, 3.0], [1.0, 2.0], [4.0, 5.0]]), mindspore.float32)
>>> equation = "ij,jk->ik"
>>> output = mint.einsum(equation, x, y)
>>> print(output)
[[16. 22.]
 [37. 52.]]
>>> x = Tensor(np.array([[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]]), mindspore.float32)
>>> equation = "ij->ji"
>>> output = mint.einsum(equation, x)
>>> print(output)
[[1. 4.]
 [2. 5.]
 [3. 6.]]
>>> x = Tensor(np.array([[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]]), mindspore.float32)
>>> equation = "ij->j"
>>> output = mint.einsum(equation, x)
>>> print(output)
[5. 7. 9.]
>>> x = Tensor(np.array([[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]]), mindspore.float32)
>>> equation = "...->"
>>> output = mint.einsum(equation, x)
>>> print(output)
21.0
>>> x = Tensor(np.array([1.0, 2.0, 3.0]), mindspore.float32)
>>> y = Tensor(np.array([2.0, 4.0, 1.0]), mindspore.float32)
>>> equation = "j,i->ji"
>>> output = mint.einsum(equation, x, y)
>>> print(output)
[[ 2. 4. 1.]
 [ 4. 8. 2.]
 [ 6. 12. 3.]]
>>> x = mindspore.Tensor([1, 2, 3, 4], mindspore.float32)
>>> y = mindspore.Tensor([1, 2], mindspore.float32)
>>> output = mint.einsum(x, [..., 1], y, [..., 2], [..., 1, 2])
>>> print(output)
[[1. 2.]
 [2. 4.]
 [3. 6.]
 [4. 8.]]
```

mindspore.mint.empty

mindspore.mint.**empty**(**size*, *dtype=None*, *device=None*) → *Tensor*

Creates a tensor with uninitialized data, whose shape, dtype and device are described by the argument *size*, *dtype* and *device* respectively.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

size (*Union[tuple[int], list[int], int]*) –The specified shape of output tensor. Can be variable numbers of positive integers or tupled or list containing positive integers.

Keyword Arguments

- **dtype** (*mindspore.dtype*, optional) –The specified type of output tensor. If *dtype* is `None` , *mindspore.float32* will be used. Default: `None` .
- **device** (*string, optional*) –The specified device of the output tensor. Support `CPU` and `Ascend`. If *device* = *None*, *mindspore.context.device_target* will be used. Default `None`.

Returns

Tensor, whose dtype and size are defined by input.

Raises

TypeError –If *size* is neither an int nor a tuple or list of int.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import mint
>>> output = mint.empty((2, 3), dtype=mindspore.float32)
>>> print(output)
[[0. 0. 0.]
 [0. 0. 0.]]
```

mindspore.mint.empty_like

`mindspore.mint.`**empty_like**(*input*, *, *dtype=None*, *device=None*)

Returns an uninitialized Tensor with the same shape as the *input*. Its dtype is specified by *dtype* and its device is specified by *device*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

input (`Tensor`) –Tensor of any dimension.

Keyword Arguments

- **dtype** (*mindspore.dtype*, optional) –The specified dtype of the output tensor. If *dtype* = *None*, the tensor will have the same dtype as input *input*. Default `None`.
- **device** (*string, optional*) –The specified device of the output tensor. Support `CPU` and `Ascend`. If *device* = *None*, the tensor will have the same device as input *input* and if the device of the input tensor is not defined, the value set by *mindspore.set_device()* will be used. Default `None`.

Returns

Tensor, has the same shape, type and device as *input* but with uninitialized data (May be a random value).

Raises

TypeError –If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import mint, Tensor
>>> x = Tensor([[1, 2, 3], [4, 5, 6]])
>>> output1 = mint.empty_like(x)
>>> print(output1)
[[0 0 0]
 [0 0 0]]
>>> output2 = mint.empty_like(x, dtype=mindspore.float64)
>>> print(output2)
[[0. 0. 0.]
 [0. 0. 0.]]
```

mindspore.mint.full

mindspore.mint.**full**(*size*, *fill_value*, *, *dtype=None*)

Create a Tensor of the specified shape and fill it with the specified value.

Parameters

- **size** (*Union(tuple[int], list[int])*) – The specified shape of output tensor.
- **fill_value** (*Union(number.Number, Tensor)*) – Value to fill the returned tensor. It can be a Scalar number, a 0-D Tensor, or a 1-D Tensor with only one element.

Keyword Arguments

dtype (mindspore.dtype, *optional*) – The specified type of output tensor. *bool_* and *number* are supported, for details, please refer to *mindspore.dtype* . Default: None .

Returns

Tensor.

Raises

- **TypeError** – If *size* is not a tuple or list.
- **ValueError** – The element in *size* is less than 0.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import mint
>>> output = mint.full((2, 2), 1)
>>> print(output)
[[1. 1.]
 [1. 1.]]
>>> output = mint.full((3, 3), 0)
>>> print(output)
[[0. 0. 0.]
 [0. 0. 0.]
 [0. 0. 0.]]
```

mindspore.mint.full_like

mindspore.mint.**full_like**(*input*, *fill_value*, *, *dtype=None*)

Return a Tensor of the same shape as *input* and filled with *fill_value*.

Parameters

- **input** (Tensor) – input Tensor and the output Tensor have the same shape as *input*.
- **fill_value** (*Number*) – Value to fill the returned tensor. Complex numbers are not supported for now.

Keyword Arguments

dtype (mindspore.dtype, *optional*) – The specified type of output tensor. *bool_* and *number* are supported, for details, please refer to *mindspore.dtype* . Default: None .

Returns

Tensor.

Raises

TypeError – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input = Tensor([[0, 1], [2, 1]], dtype=mindspore.int32)
>>> output = mint.full_like(input, 1)
>>> print(output)
[[1 1]
 [1 1]]
>>> input = Tensor([[0, 1, 1], [2, 1, 2], [1, 3, 4]], dtype=mindspore.int32)
>>> output = mint.full_like(input, 0, dtype=mindspore.float32)
>>> print(output)
[[0. 0. 0.]
 [0. 0. 0.]
 [0. 0. 0.]]
```

mindspore.mint.linspace

mindspore.mint.**linspace**(*start*, *end*, *steps*, *, *dtype=None*)

Generate a one-dimensional tensor with *steps* elements, evenly distributed in the interval [start, end].

$$step = (end - start)/(steps - 1)$$
$$output = [start, start + step, start + 2 * step, ..., end]$$

Warning: Atlas training series does not support int16 dtype currently.

Parameters

- **start** (*Union[float, int]*) –Start value of interval.
- **end** (*Union[float, int]*) –Last value of interval.
- **steps** (*int*) –Number of elements.

Keyword Arguments

dtype (mindspore.dtype, *optional*) –The data type returned.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> output = mindspore.mint.linspace(3, 10, 5)
>>> print(output)
[ 3.    4.75  6.5   8.25 10.  ]
>>> output = mindspore.mint.linspace(-10, 10, 5)
>>> print(output)
[-10.  -5.   0.   5.  10.]
>>> output = mindspore.mint.linspace(-10, 10, 1)
>>> print(output)
[-10.]
```

mindspore.mint.ones

mindspore.mint.**ones**(*size*, *, *dtype=None*)

Creates a tensor filled with value ones.

Creates a tensor with shape described by the first argument and fills it with value ones in type of the second argument.

Parameters

size (*Union[tuple[int], list[int], int, Tensor]*) –The specified shape of output tensor. Only positive integer or tuple or Tensor containing positive integers are allowed. If it is a Tensor, it must be a 0-D or 1-D Tensor with int32 or int64 dtypes.

Keyword Arguments

dtype (*mindspore.dtype*, optional) – The specified type of output tensor. If *dtype* is `None` , *mindspore.float32* will be used. Default: `None` .

Returns

Tensor, whose dtype and size are defined by input.

Raises

TypeError – If *size* is neither an int nor a tuple/list/Tensor of int.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import mint
>>> output = mint.ones((2, 2), dtype=mindspore.float32)
>>> print(output)
[[1. 1.]
 [1. 1.]]
```

mindspore.mint.ones_like

mindspore.mint.**ones_like**(*input*, *, *dtype=None*)

Creates a tensor filled with 1, with the same shape as input, and its data type is determined by the given dtype.

If *dtype* = *None*, the tensor will have the same dtype as input *input*.

Parameters

input (`Tensor`) – Tensor of any dimension.

Keyword Arguments

dtype (*mindspore.dtype*, optional) – The specified dtype of the output tensor. If *dtype* is `None` , the dtype of the input tensor will be used. Default: `None` .

Returns

Tensor, has the same shape as *input* but filled with ones.

Raises

TypeError – If *input* is not a Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[0, 1], [2, 1]]).astype(np.int32))
>>> output = mint.ones_like(x)
>>> print(output)
[[1 1]
 [1 1]]
```

mindspore.mint.randint

mindspore.mint.**randint**(*low=0*, *high*, *size*, ***, *generator=None*, *dtype=None*) → *Tensor*

Returns a new tensor filled with integer numbers from the uniform distribution over an interval $[low, high)$ based on the given shape and dtype.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **low** (*int, optional*) – the lower bound of the generated random number. Default: 0.
- **high** (*int*) – the upper bound of the generated random number
- **size** (*Union[tuple(int), list(int)]*) – Shape of the new tensor, e.g. $(2, 3)$.

Keyword Arguments

- **generator** (*mindspore.Generator*, optional) – a pseudorandom number generator. Default: None, uses the default pseudorandom number generator.
- **dtype** (*mindspore.dtype*, optional) – Designated tensor dtype. If None, *mindspore.int64* will be applied. Default: None .

Returns

Tensor, with the designated shape and dtype, filled with random numbers from the uniform distribution on the interval $[low, high)$.

Raises

- **TypeError** – If *size* is not a tuple.
- **TypeError** – If *low* or *high* is not integer.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import mint
>>> print(mint.randint(0, 5, (2, 3)).shape)
(2, 3)
```

mindspore.mint.randint_like

mindspore.mint.**randint_like**(*input*, *low=0*, *high*, ***, *dtype=None*) → *Tensor*

Returns a new tensor filled with integer numbers from the uniform distribution over an interval $[low, high)$ based on the given dtype and shape of the input tensor.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) −Input Tensor to specify the output shape and its default dtype.
- **low** (*int, optional*) −the lower bound of the generated random number. Default: 0.
- **high** (*int*) −the upper bound of the generated random number

Keyword Arguments

dtype (*mindspore.dtype*, optional) −Designated tensor dtype. If None, the same dtype of *input* will be applied. Default: None .

Returns

Tensor, with the designated shape and dtype, filled with random numbers from the uniform distribution on the interval $[low, high)$.

Raises

TypeError −If *low* or *high* is not integer.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, mint
>>> a = Tensor([[2, 3, 4], [1, 2, 3]])
>>> low = 0
>>> high = 5
>>> print(mint.randint_like(a, low, high, dtype=ms.int32).shape)
(2, 3)
```

mindspore.mint.randn

mindspore.mint.**randn**(**size*, *generator=None*, *dtype=None*)

Returns a new tensor filled with numbers from the normal distribution over an interval $[0, 1)$ based on the given shape and dtype.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

size (*Union[int, tuple(int), list(int)]*) –Shape of the new tensor, e.g. $(2, 3)$ or 2.

Keyword Arguments

- **generator** (*mindspore.Generator*, optional) –a pseudorandom number generator. Default: `None`, uses the default pseudorandom number generator.
- **dtype** (*mindspore.dtype*, optional) –Designated tensor dtype. If None, *mindspore.float32* will be applied. Default: `None` .

Returns

Tensor, with the designated shape and dtype, filled with random numbers from the normal distribution on the interval $[0, 1)$.

Raises

ValueError –If *size* contains negative numbers.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import mint
>>> print(mint.randn(2, 3).shape)
(2, 3)
```

mindspore.mint.randn_like

mindspore.mint.**randn_like**(*input*, ***, *dtype=None*)

Returns a new tensor filled with numbers from the normal distribution over an interval $[0, 1)$ based on the given dtype and shape of the input tensor.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

input (`Tensor`) –Input Tensor to specify the output shape and its default dtype.

Keyword Arguments

dtype (*mindspore.dtype*, optional) –Designated Tensor dtype, it must be float type. If `None`, the same dtype of *input* will be applied. Default: `None` .

Returns

Tensor, with the designated shape and dtype, filled with random numbers from the normal distribution on the interval $[0, 1)$.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, mint
>>> a = Tensor([[2, 3, 4], [1, 2, 3]])
>>> print(mint.randn_like(a, dtype=ms.float32).shape)
(2, 3)
```

mindspore.mint.randperm

`mindspore.mint.`**`randperm`**(*n*, ***, *generator=None*, *dtype=mstype.int64*)

Generates random permutation of integers from 0 to n-1.

Warning:

- This is an experimental API that is subject to change or deletion.

Parameters

n (*Union[Tensor, int]*) – size of the permutation. int or Tensor with shape: () or (1,) and data type int64. The value of *n* must be greater than zero.

Keyword Arguments

- **generator** (*mindspore.Generator*, optional) – a pseudorandom number generator. Default: `None`, uses the default pseudorandom number generator.
- **dtype** (*mindspore.dtype, optional*) – The type of output. Default: mstype.int64.

Returns

Tensor with shape (n,) and type *dtype*.

Raises

- **TypeError** – If *dtype* is not supported.
- **ValueError** – If *n* is a negative or 0 element.
- **ValueError** – If *n* is larger than the maximal data of the set dtype.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import mint
>>> from mindspore import dtype as mstype
>>> n = 4
>>> output = mint.randperm(n, dtype=mstype.int64)
>>> print(output.shape)
(4,)
```

mindspore.mint.zeros

mindspore.mint.**zeros**(*size*, *, *dtype=None*)

Creates a tensor filled with 0 with shape described by *size* and fills it with value 0 in type of *dtype*.

Parameters

size (*Union[tuple[int], list[int], int, Tensor]*) – The specified shape of output tensor. Only positive integer or tuple or Tensor containing positive integers are allowed. If it is a Tensor, it must be a 0-D or 1-D Tensor with int32 or int64 dtypes.

Keyword Arguments

dtype (*mindspore.dtype*, optional) – The specified type of output tensor. If *dtype* is `None` , mindspore.float32 will be used. Default: `None` .

Returns

Tensor, whose dtype and size are defined by input.

Raises

TypeError – If *size* is neither an int nor a tuple/list/Tensor of int.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import mint
>>> output = mint.zeros((2, 2), dtype=mindspore.float32)
>>> print(output)
[[0. 0.]
 [0. 0.]]
```

mindspore.mint.zeros_like

mindspore.mint.**zeros_like**(*input*, *, *dtype=None*)

Creates a tensor filled with 0, with the same size as input. Its data type is determined by the given dtype.

If *dtype* = *None*, the tensor will have the same dtype as input *input*.

Parameters

input (Tensor) –Tensor of any dimension.

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The specified dtype of the output tensor. If *dtype* is None , the dtype of the input tensor will be used. Default: None .

Returns

Tensor, filled with 0.

Raises

TypeError –If dtype is not a MindSpore dtype.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.arange(4).reshape(2, 2))
>>> output = mint.zeros_like(x, dtype=mindspore.float32)
>>> print(output)
[[0. 0.]
 [0. 0.]]
```

4.1.2 Indexing, Slicing, Joining, Mutating Operations

API Name	Description	Supported Platforms
mindspore.mint.cat	Connect input tensors along with the given dimension.	Ascend
mindspore.mint.chunk	Cut the input Tensor into *chunks* sub-tensors along the specified axis.	Ascend
mindspore.mint.concat	Alias for *mindspore.mint.cat()*.	Ascend
mindspore.mint.count_nonzero	Count the number of non-zero elements in the Tensor *input* on a given dimension *dim*.	Ascend
mindspore.mint.gather	Gather data from a tensor by indices.	Ascend
mindspore.mint.index_add	Accumulate the elements of *alpha* times *source* into the *input* by adding to the index in the order given in *index*.	Ascend

continues on next page

Table 2 – continued from previous page

mindspore.mint.index_select	Generates a new Tensor that accesses the values of *input* along the specified *dim* dimension using the indices specified in *index*.	Ascend
mindspore.mint.masked_select	Return a new 1-D tensor which indexes the *input* tensor according to the boolean *mask*.	Ascend
mindspore.mint.permute	Permutes the dimensions of the input tensor according to input *dims* .	Ascend
mindspore.mint.reshape	Reshape the input tensor based on the given shape.	Ascend
mindspore.mint.scatter	Update the value in *src* to *input* according to the specified index.	Ascend
mindspore.mint.scatter_add	Add all elements in *src* to the index specified by *index* to *input* along dimension specified by *dim*.	Ascend
mindspore.mint.split	Splits the Tensor into chunks along the given dim.	Ascend
mindspore.mint.narrow	Obtains a tensor of a specified length at a specified start position along a specified axis.	Ascend
mindspore.mint.nonzero	Return the positions of all non-zero values.	Ascend
mindspore.mint.tile	Creates a new tensor by repeating the elements in the input tensor *dims* times.	Ascend
mindspore.mint.tril	Zero the input tensor above the diagonal specified.	Ascend
mindspore.mint.select	Slices the input tensor along the selected dimension at the given index.	Ascend
mindspore.mint.squeeze	Return the Tensor after deleting the dimension of size 1 in the specified *dim*.	Ascend
mindspore.mint.stack	Stacks a list of tensors in specified dim.	Ascend
mindspore.mint.swapaxes	Alias for mindspore.mint.transpose() .	Ascend
mindspore.mint.transpose	Interchange two axes of a tensor.	Ascend
mindspore.mint.triu	Zero the input tensor below the diagonal specified.	Ascend
mindspore.mint.unbind	Unbind a tensor dimension in specified axis.	Ascend
mindspore.mint.unique_consecutive	Returns the elements that are unique in each consecutive group of equivalent elements in the input tensor.	Ascend
mindspore.mint.unsqueeze	Adds an additional dimension to the input tensor at the given dimension.	Ascend
mindspore.mint.where	Selects elements from *input* or *other* based on *condition* and returns a tensor.	Ascend

mindspore.mint.cat

mindspore.mint.**cat**(*tensors*, *dim=0*)

Connect input tensors along with the given dimension.

The input data is a tuple or a list of tensors. These tensors have the same rank R. Set the given dimension as m, and $0 \le m < R$. Set the number of input tensors as N. For the i-th tensor t_i, it has the shape of $(x_1, x_2, ..., x_{mi}, ..., x_R)$. x_{mi} is the m-th dimension of the t_i. Then, the shape of the output tensor is

$$(x_1, x_2, ..., \sum_{i=1}^{N} x_{mi}, ..., x_R)$$

Parameters

- **tensors** (*Union[tuple, list]*) −A tuple or a list of input tensors. Suppose there are two tensors in this tuple or list, namely t1 and t2. To perform *concat* in the dimension 0 direction, except for the 0-th dimension, all other

dimensions should be equal, that is, $t1.shape[1] = t2.shape[1], t1.shape[2] = t2.shape[2], ..., t1.shape[R-1] = t2.shape[R-1]$, where R represents the rank of tensor.

- **dim** (*int, optional*) –The specified dimension, whose value is in range $[-R, R)$. Default: `0` .

Returns

Tensor, the shape is $(x_1, x_2, ..., \sum_{i=1}^{N} x_{mi}, ..., x_R)$. The data type is the same with *tensors*.

Raises

- **TypeError** –If *dim* is not an int.
- **ValueError** –If *tensors* have different dimension of tensor.
- **ValueError** –If *dim* not in range $[-R, R)$.
- **ValueError** –If tensor's shape in *tensors* except for *dim* are different.
- **ValueError** –If *tensors* is an empty tuple or list.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> input_x1 = Tensor(np.array([[0, 1], [2, 1]]).astype(np.float32))
>>> input_x2 = Tensor(np.array([[0, 1], [2, 1]]).astype(np.float32))
>>> output = mint.cat((input_x1, input_x2))
>>> print(output)
[[0. 1.]
 [2. 1.]
 [0. 1.]
 [2. 1.]]
>>> output = mint.cat((input_x1, input_x2), 1)
>>> print(output)
[[0. 1. 0. 1.]
 [2. 1. 2. 1.]]
```

mindspore.mint.chunk

mindspore.mint.**chunk**(*input*, *chunks*, *dim=0*)

Cut the input Tensor into *chunks* sub-tensors along the specified axis.

Note: This function may return less than the specified number of chunks!

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –A Tensor to be cut.
- **chunks** (*int*) –Number of sub-tensors to cut.
- **dim** (*int, optional*) –Specify the dimensions that you want to split. Default: 0 .

Returns

A tuple of sub-tensors.

Raises

- **TypeError** –If argument *input* is not Tensor.
- **TypeError** –The sum of *chunks* is not int.
- **TypeError** –If argument *dim* is not int.
- **ValueError** –If argument *dim* is out of range of $[-input.ndim, input.ndim)$.
- **ValueError** –If argument *chunks* is not positive number.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> input_x = np.arange(9).astype("float32")
>>> output = mindspore.mint.chunk(Tensor(input_x), 3)
>>> print(output)
(Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  1.00000000e+00,  2.
↪00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value= [ 3.00000000e+00,  4.00000000e+00,  5.
↪00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value= [ 6.00000000e+00,  7.00000000e+00,  8.
↪00000000e+00]))
```

mindspore.mint.concat

mindspore.mint.**concat**(*tensors*, *dim=0*)

Alias for *mindspore.mint.cat()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Supported Platforms:

Ascend

mindspore.mint.count_nonzero

mindspore.mint.**count_nonzero**(*input*, *dim=None*)

Count the number of non-zero elements in the Tensor *input* on a given dimension *dim*. If no dim is specified then all non-zeros in the tensor are counted.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –Input data is used to count non-zero numbers. With shape $(*)$ where $*$ means, any number of additional dimensions.
- **dim** (*Union[None, int, tuple(int), list(int)], optional*) –Count the dimension of the number of non-zero elements. Default value: None, which indicates that the number of non-zero elements is calculated. If *dim* is None, all elements in the tensor are summed up.

Returns

Tensor, number of nonzero element across dim specified by *dim*.

Raises

- **TypeError** –If *input* is not tensor.
- **TypeError** –If *dim* is not int, tuple(int), list(int) or None.
- **ValueError** –If any value in *dim* is not in range $[-input.ndim, input.ndim)$.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> import mindspore
>>> # case 1: each value specified.
>>> x = Tensor(np.array([[0, 1, 0], [1, 1, 0]]).astype(np.float32))
>>> nonzero_num = mint.count_nonzero(input=x, dim=[0, 1])
>>> print(nonzero_num)
3
>>> # case 2: all value is default.
>>> nonzero_num = mint.count_nonzero(input=x)
>>> print(nonzero_num)
3
>>> # case 3: dim value was specified 0.
>>> nonzero_num = mint.count_nonzero(input=x, dim=[0,])
>>> print(nonzero_num)
[1 2 0]
>>> # case 4: dim value was specified 1.
>>> nonzero_num = mint.count_nonzero(input=x, dim=[1,])
>>> print(nonzero_num)
[1 2]
```

mindspore.mint.gather

mindspore.mint.**gather**(*input*, *dim*, *index*)

Gather data from a tensor by indices.

$$output[(i_0, i_1, ..., i_{dim}, i_{dim+1}, ..., i_n)] = input[(i_0, i_1, ..., index[(i_0, i_1, ..., i_{dim}, i_{dim+1}, ..., i_n)], i_{dim+1}, ..., i_n)]$$

Warning: On Ascend, the behavior is unpredictable in the following cases:

- the value of *index* is not in the range *[-input.shape[dim], input.shape[dim])* in forward;
- the value of *index* is not in the range *[0, input.shape[dim])* in backward.

Parameters

- **input** (Tensor) –The target tensor to gather values.
- **dim** (*int*) –the axis to index along, must be in range *[-input.rank, input.rank)*.
- **index** (Tensor) –The index tensor, with int32 or int64 data type. A valid *index* should be:
  - *index.rank == input.rank*;
  - for *axis != dim*, *index.shape[axis] <= input.shape[axis]*;
  - the value of *index* is in range *[-input.shape[dim], input.shape[dim])*.

Returns

Tensor, has the same type as *input* and the same shape as *index*.

Raises

- **ValueError** –If the shape of *index* is illegal.
- **ValueError** –If *dim* is not in *[-input.rank, input.rank)*.
- **ValueError** –If the value of *index* is out of the valid range.
- **TypeError** –If the type of *index* is illegal.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]), mindspore.float32)
>>> index = Tensor(np.array([[0, 0], [1, 1]]), mindspore.int32)
>>> output = mint.gather(input, 1, index)
>>> print(output)
[[-0.1 -0.1]
 [0.5   0.5]]
```

mindspore.mint.index_add

mindspore.mint.**index_add**(*input*, *dim*, *index*, *source*, *alpha=1*)

Accumulate the elements of *alpha* times *source* into the *input* by adding to the index in the order given in *index*. For example, if `dim == 0`, `index[i] == j`, and `alpha = -1`, then the *i* th row of *source* is subtracted from the *j* th row of *input*. The *dim* th dimension of *source* must have the same size as the length of *index*, and all other dimensions must match *input*, or an error will be raised. For a 3-D tensor, the output is defined as follows:

$$
\begin{aligned}
input[index[i],\ :,\ :] &+= alpha * source[i,\ :,\ :] \quad \#if\ dim == 0 \\
input[:,\ index[i],\ :] &+= alpha * source[:,\ i,\ :] \quad \#if\ dim == 1 \\
input[:,\ :,\ index[i]] &+= alpha * source[:,\ :,\ i] \quad \#if\ dim == 2
\end{aligned}
$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input Tensor.
- **dim** (*int*) –The dimension along which to index.
- **index** (Tensor) –Add the value of "input Tensor" and *source* along the dimension of the *dim* according to the specified index value, with data type int32. The *index* must be 1D with the same size as the size of *source* in the *dim* dimension. The values of *index* should be in [0, b), where the b is the size of "input Tensor" in the *dim* dimension.
- **source** (Tensor) –The input tensor with the value to add. Must have same data type as "input Tensor". The shape must be the same as "input Tensor" except the *dim* th dimension.
- **alpha** (*number, optional*) –The scalar multiplier for source. Default: `1`.

Returns

Tensor, has the same shape and dtype as *input*.

Raises

- **TypeError** –If neither *index* nor *source* is a Tensor.
- **ValueError** –If the value of *dim* is out of the dimension range of *source* shape.
- **ValueError** –If *index* rank is not the same as *source* rank.
- **ValueError** –If shape of *index* is not 1D or size of *index* is not equal to dimension of source[dim].
- **ValueError** –If the shape of *source* is not the same as that of *input* except the *dim* axis.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), mindspore.float32)
>>> index = Tensor(np.array([0, 2]), mindspore.int32)
>>> y = Tensor(np.array([[0.5, 1.0], [1.0, 1.5], [2.0, 2.5]]), mindspore.float32)
>>> output = mint.index_add(x, 1, index, y, alpha=1)
```

(continues on next page)

(continued from previous page)

```
>>> print(output)
[[ 1.5  2.   4. ]
 [ 5.   5.   7.5]
 [ 9.   8.  11.5]]
```

mindspore.mint.index_select

mindspore.mint.**index_select**(*input*, *dim*, *index*)

Generates a new Tensor that accesses the values of *input* along the specified *dim* dimension using the indices specified in *index*. The new Tensor has the same number of dimensions as *input*, with the size of the *dim* dimension being equal to the length of *index*, and the size of all other dimensions will be unchanged from the original *input* Tensor.

Note: The value of index must be in the range of *[0, input.shape[dim])*, the result is undefined out of range.

Parameters

- **input** (Tensor) –The input Tensor.
- **dim** (*int*) –The dimension to be indexed.
- **index** (Tensor) –A 1-D Tensor with the indices.

Returns

Tensor, has the same dtype as input Tensor.

Raises

- **TypeError** –If *input* or *index* is not a Tensor.
- **TypeError** –If *dim* is not int number.
- **ValueError** –If the value of *dim* is out the range of *[-input.ndim, input.ndim - 1]*.
- **ValueError** –If the dimension of *index* is not equal to 1.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.arange(16).astype(np.float32).reshape(2, 2, 4))
>>> print(input)
[[[ 0.  1.  2.  3.]
[ 4.  5.  6.  7.]]
[[ 8.  9. 10. 11.]
[12. 13. 14. 15.]]]
>>> index = Tensor([0,], mindspore.int32)
>>> y = mint.index_select(input, 1, index)
>>> print(y)
```

(continued from previous page)

```
[[[ 0.  1.  2.  3.]]
[[ 8.  9. 10. 11.]]]
```

mindspore.mint.masked_select

mindspore.mint.**masked_select**(*input*, *mask*)

Return a new 1-D tensor which indexes the *input* tensor according to the boolean *mask*.

Support broadcast.

Parameters

- **input** (Tensor) – The input tensor.
- **mask** (Tensor[bool]) – The input mask.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1, 2, 3, 4], mindspore.int64)
>>> mask = mindspore.tensor([1, 0, 1, 0], mindspore.bool_)
>>> output = mindspore.mint.masked_select(x, mask)
>>> print(output)
[1 3]
```

mindspore.mint.permute

mindspore.mint.**permute**(*input*, *dims*)

Permutes the dimensions of the input tensor according to input *dims* .

Parameters

- **input** (Tensor) – Input Tensor.
- **dims** (tuple(int)) – The order of the dimensions. Permute rearranges the *input* according to the order of the *dims*.

Returns

Tensor, has the same dimension as input tensor, with *axis* suitably permuted.

Raises

- **ValueError** – If *dims* is None.
- **ValueError** – If the number of elements of *dims* is not equal to *input* ndim.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input_x = Tensor(np.array([[[1, 2, 3], [4, 5, 6]], [[7, 8, 9], [10, 11, 12]]]),␣
↪mindspore.float32)
>>> input_perm = (0, 2, 1)
>>> print(mint.permute(input_x, input_perm))
[[[ 1.  4.]
  [ 2.  5.]
  [ 3.  6.]]
 [[ 7. 10.]
  [ 8. 11.]
  [ 9. 12.]]]
```

mindspore.mint.reshape

mindspore.mint.**reshape**(*input*, *shape*)

Reshape the input tensor based on the given shape.

Note: The -1 in the parameter *shape* indicates that the size of that dimension is inferred from the other dimensions and the total number of elements in input tensor.

Parameters

- **input** (Tensor) –The input tensor.
- **shape** (*Union[tuple[int], list[int], Tensor[int]]*) –New shape.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]], mindspore.float32)
>>> # case1: Parameter `shape` does not contain -1.
>>> output = mindspore.mint.reshape(input, (3, 2))
>>> print(output)
[[-0.1  0.3]
 [ 3.6  0.4]
 [ 0.5 -3.2]]
>>> # case2: Parameter `shape` contains -1.
>>> output = mindspore.mint.reshape(input, (-1, 6))
>>> print(output)
[[-0.1  0.3  3.6  0.4  0.5 -3.2]]
```

mindspore.mint.scatter

mindspore.mint.**scatter**(*input*, *dim*, *index*, *src*)

Update the value in *src* to *input* according to the specified index. For a 3-D tensor, the output will be:

```
output[index[i][j][k]][j][k] = src[i][j][k]  # if dim == 0

output[i][index[i][j][k]][k] = src[i][j][k]  # if dim == 1

output[i][j][index[i][j][k]] = src[i][j][k]  # if dim == 2
```

Note: The backward is supported only for the case *src.shape* == *index.shape* when *src* is a tensor.

Parameters

- **input** (Tensor) −The target tensor. The rank of *input* must be at least 1.
- **dim** (*int*) −Which axis to scatter. Accepted range is [-r, r) where r = rank(input).
- **index** (Tensor) −The index to do update operation whose data must be positive number with type of mindspore.int32 or mindspore.int64. Same rank as *input* . And accepted range is [-s, s) where s is the size along axis.
- **src** (Tensor, *float*) −The data doing the update operation with *input*. Can be a tensor with the same data type as *input* or a float number to scatter.

Returns

Tensor, has the same shape and type as *input* .

Raises

- **TypeError** −If *index* is neither int32 nor int64.
- **ValueError** −If rank of any of *input* , *index* and *src* is less than 1.
- **ValueError** −If the rank of *src* is not equal to the rank of *input* .
- **TypeError** −If the data types of *input* and *src* have different dtypes.
- **RuntimeError** −If *index* has negative elements.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[1, 2, 3, 4, 5]]), dtype=ms.float32)
>>> src = Tensor(np.array([[8, 8]]), dtype=ms.float32)
>>> index = Tensor(np.array([[2, 4]]), dtype=ms.int64)
>>> out = mint.scatter(input=input, dim=1, index=index, src=src)
>>> print(out)
[[1. 2. 8. 4. 8.]]
>>> input = Tensor(np.zeros((5, 5)), dtype=ms.float32)
>>> src = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), dtype=ms.float32)
```

(continues on next page)

(continued from previous page)

```
>>> index = Tensor(np.array([[0, 0, 0], [2, 2, 2], [4, 4, 4]]), dtype=ms.int64)
>>> out = mint.scatter(input=input, dim=0, index=index, src=src)
>>> print(out)
[[1. 2. 3. 0. 0.]
[0. 0. 0. 0. 0.]
[4. 5. 6. 0. 0.]
[0. 0. 0. 0. 0.]
[7. 8. 9. 0. 0.]]
>>> input = Tensor(np.zeros((5, 5)), dtype=ms.float32)
>>> src = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), dtype=ms.float32)
>>> index = Tensor(np.array([[0, 2, 4], [0, 2, 4], [0, 2, 4]]), dtype=ms.int64)
>>> out = mint.scatter(input=input, dim=1, index=index, src=src)
>>> print(out)
[[1. 0. 2. 0. 3.]
[4. 0. 5. 0. 6.]
[7. 0. 8. 0. 9.]
[0. 0. 0. 0. 0.]
[0. 0. 0. 0. 0.]]
```

mindspore.mint.scatter_add

mindspore.mint.**scatter_add**(*input*, *dim*, *index*, *src*)

Add all elements in *src* to the index specified by *index* to *input* along dimension specified by *dim*. It takes three inputs *input*, *src* and *index* of the same rank r >= 1.

For a 3-D tensor, the operation updates input as follows:

```
input[index[i][j][k]][j][k] += src[i][j][k]  # if dim == 0

input[i][index[i][j][k]][k] += src[i][j][k]  # if dim == 1

input[i][j][index[i][j][k]] += src[i][j][k]  # if dim == 2
```

Parameters

- **input** (Tensor) −The target tensor. The rank must be at least 1.
- **dim** (*int*) −Which dim to scatter. Accepted range is [-r, r) where r = rank(*input*).
- **index** (Tensor) −The index of *input* to do scatter operation whose data type must be mindspore.int32 or mindspore.int64. Same rank as *input*. Except for the dimension specified by *dim*, the size of each dimension of *index* must be less than or equal to the size of the corresponding dimension of *input*.
- **src** (Tensor) −The tensor doing the scatter operation with *input*, has the same type as *input* and the size of each dimension must be greater than or equal to that of *index*.

Returns

Tensor, has the same shape and type as *input*.

Raises

- **TypeError** −If *index* is neither int32 nor int64.
- **ValueError** −If anyone of the rank among *input*, *index* and *src* is less than 1.
- **ValueError** −If the rank of *input*, *index* and *src* is not the same.

- **ValueError** –The size of any dimension of *index* except the dimension specified by *dim* is greater than the size of the corresponding dimension of *input*.
- **ValueError** –If the size of any dimension of *src* is less than that of *index*.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[1, 2, 3, 4, 5]]), dtype=ms.float32)
>>> src = Tensor(np.array([[8, 8]]), dtype=ms.float32)
>>> index = Tensor(np.array([[2, 4]]), dtype=ms.int64)
>>> out = mint.scatter_add(input=input, dim=1, index=index, src=src)
>>> print(out)
[[1. 2. 11. 4. 13.]]
>>> input = Tensor(np.zeros((5, 5)), dtype=ms.float32)
>>> src = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), dtype=ms.float32)
>>> index = Tensor(np.array([[0, 0, 0], [2, 2, 2], [4, 4, 4]]), dtype=ms.int64)
>>> out = mint.scatter_add(input=input, dim=0, index=index, src=src)
>>> print(out)
[[1. 2. 3. 0. 0.]
 [0. 0. 0. 0. 0.]
 [4. 5. 6. 0. 0.]
 [0. 0. 0. 0. 0.]
 [7. 8. 9. 0. 0.]]
>>> input = Tensor(np.zeros((5, 5)), dtype=ms.float32)
>>> src = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), dtype=ms.float32)
>>> index = Tensor(np.array([[0, 2, 4], [0, 2, 4], [0, 2, 4]]), dtype=ms.int64)
>>> out = mint.scatter_add(input=input, dim=1, index=index, src=src)
>>> print(out)
[[1. 0. 2. 0. 3.]
 [4. 0. 5. 0. 6.]
 [7. 0. 8. 0. 9.]
 [0. 0. 0. 0. 0.]
 [0. 0. 0. 0. 0.]]
```

mindspore.mint.split

mindspore.mint.**split**(*tensor*, *split_size_or_sections*, *dim=0*)

Splits the Tensor into chunks along the given dim.

Parameters

- **tensor** (Tensor) –A Tensor to be divided.
- **split_size_or_sections** (*Union[int, tuple(int), list(int)]*) –If *split_size_or_sections* is an int type, *tensor* will be split into equally sized chunks, each chunk with size *split_size_or_sections*. Last chunk will be smaller than *split_size_or_sections* if *tensor.shape[dim]* is not divisible by *split_size_or_sections*. If *split_size_or_sections* is a list type, then *tensor* will be split into len(split_size_or_sections) chunks with sizes *split_size_or_sections* along the given *dim*.
- **dim** (*int, optional*) –The dim along which to split. Default: `0` .

Returns

A tuple of sub-tensors.

Raises

- **TypeError** –If argument *tensor* is not Tensor.
- **TypeError** –If argument *dim* is not int.
- **ValueError** –If argument *dim* is out of range of [-tensor.ndim, tensor.ndim).
- **TypeError** –If each element in *split_size_or_sections* is not integer.
- **TypeError** –If argument *split_size_or_sections* is not int, tuple(int) or list(int).
- **ValueError** –The sum of *split_size_or_sections* is not equal to tensor.shape[dim].

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import mint, Tensor
>>> input_x = np.arange(9).astype("float32")
>>> output = mint.split(Tensor(input_x), 3)
>>> print(output)
(Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  1.00000000e+00,  2.
↪00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value= [ 3.00000000e+00,  4.00000000e+00,  5.
↪00000000e+00]),
 Tensor(shape=[3], dtype=Float32, value= [ 6.00000000e+00,  7.00000000e+00,  8.
↪00000000e+00]))
```

mindspore.mint.narrow

mindspore.mint.**narrow**(*input*, *dim*, *start*, *length*)

Obtains a tensor of a specified length at a specified start position along a specified axis.

Parameters

- **input** (Tensor) –the tensor to narrow.
- **dim** (*int*) –the axis along which to narrow.
- **start** (*Union[int, Tensor[int]]*) –the starting dimension.
- **length** (*int*) –the distance to the ending dimension.

Returns

output (Tensors) - The narrowed tensor.

Raises

- **ValueError** –the rank of *input* is 0.
- **ValueError** –the value of *dim* is out the range [-input.ndim, input.ndim).
- **ValueError** –the value of *start* is out the range [-input.shape[dim], input.shape[dim]].

- **ValueError** –the value of *length* is out the range [0, input.shape[dim]-start].

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import mint
>>> from mindspore import Tensor
>>> x = Tensor([[1, 2, 3], [4, 5, 6], [7, 8, 9]], mindspore.int32)
>>> output = mint.narrow(x, 0, 0, 2)
>>> print(output)
[[ 1 2 3]
 [ 4 5 6]]
>>> output = mint.narrow(x, 1, 1, 2)
>>> print(output)
[[ 2 3]
 [ 5 6]
 [ 8 9]]
```

mindspore.mint.nonzero

mindspore.mint.**nonzero**(*input*, *, *as_tuple=False*)

Return the positions of all non-zero values.

Parameters

input (Tensor) –The input tensor.

Note:

- Ascend: Rank of Input tensor can be equal to 0 except jit level O2 mode.

Keyword Arguments

as_tuple (bool, *optional*) –Whether the output is tuple. Default False .

Returns

Tensor or tuple of tensors

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([[[1,  0], [-5, 0]]], mindspore.int32)
>>> output = mindspore.mint.nonzero(x)
>>> print(output)
[[0 0 0]
 [0 1 0]]
>>> x = mindspore.tensor([1, 0, 2, 0, 3], mindspore.int32)
>>> output = mindspore.mint.nonzero(x, as_tuple=False)
>>> print(output)
[[0]
 [2]
 [4]]
>>> x = mindspore.tensor([[[1,  0], [-5, 0]]], mindspore.int32)
>>> output = mindspore.mint.nonzero(x, as_tuple=True)
>>> print(output)
(Tensor(shape=[2], dtype=Int64, value=[0, 0]),
 Tensor(shape=[2], dtype=Int64, value=[0, 1]),
 Tensor(shape=[2], dtype=Int64, value=[0, 0]))
>>> x = mindspore.tensor([1, 0, 2, 0, 3], mindspore.int32)
>>> output = mindspore.mint.nonzero(x, as_tuple=True)
>>> print(output)
(Tensor(shape=[3], dtype=Int64, value=[0, 2, 4]), )
```

mindspore.mint.tile

mindspore.mint.**tile**(*input*, *dims*)

Creates a new tensor by repeating the elements in the input tensor *dims* times.

The i'th dimension of output tensor has *input.shape[i] * dims[i]* elements, and the values of *input* are repeated *dims[i]* times along the i'th dimension.

Note:

- On Ascend, the number of *dims* should not exceed 8, and currently does not support scenarios where more than 4 dimensions are repeated simultaneously.
- If *input.dim* = d, then the shape of their corresponding positions can be multiplied, and the shape of Outputs is $(x_1 * y_1, x_2 * y_2, ..., x_S * y_S)$.
- If *input.dim* < d, prepend 1 to the shape of *input* until their lengths are consistent. Such as set the shape of *input* as $(1, ..., x_1, x_2, ..., x_S)$, then the shape of their corresponding positions can be multiplied, and the shape of Outputs is $(1 * y_1, ..., x_R * y_R, x_S * y_S)$.
- If *input.dim* > d, prepend 1 to *dims* until their lengths are consistent. Such as set the *dims* as $(1, ..., y_1, y_2, ..., y_S)$, then the shape of their corresponding positions can be multiplied, and the shape of Outputs is $(x_1 * 1, ..., x_R * y_R, x_S * y_S)$.

Parameters

- **input** (Tensor) –The input tensor.
- **dims** (*tuple[int]*) –The specified number of repetitions in each dimension.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1, 2], [3, 4]])
>>> mindspore.mint.tile(input, (2, 3))
Tensor(shape=[4, 6], dtype=Int64, value=
[[1, 2, 1, 2, 1, 2],
 [3, 4, 3, 4, 3, 4],
 [1, 2, 1, 2, 1, 2],
 [3, 4, 3, 4, 3, 4]])
>>> mindspore.mint.tile(input, (2, 3, 2))
Tensor(shape=[2, 6, 4], dtype=Int64, value=
[[[1, 2, 1, 2],
  [3, 4, 3, 4],
  [1, 2, 1, 2],
  [3, 4, 3, 4],
  [1, 2, 1, 2],
  [3, 4, 3, 4]],
 [[1, 2, 1, 2],
  [3, 4, 3, 4],
  [1, 2, 1, 2],
  [3, 4, 3, 4],
  [1, 2, 1, 2],
  [3, 4, 3, 4]]])
```

mindspore.mint.tril

mindspore.mint.**tril**(*input*, *diagonal=0*)

Zero the input tensor above the diagonal specified.

Parameters

- **input** (Tensor) –The input tensor. The rank must be at least 2.
- **diagonal** (*int, optional*) –The diagonal specified of 2-D tensor. Default 0 represents the main diagonal.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[ 1,  2,  3,  4],
...                           [ 5,  6,  7,  8],
...                           [10, 11, 12, 13],
...                           [14, 15, 16, 17]])
>>> mindspore.mint.tril(input)
Tensor(shape=[4, 4], dtype=Int64, value=
[[ 1,  0,  0,  0],
 [ 5,  6,  0,  0],
 [10, 11, 12,  0],
 [14, 15, 16, 17]])
>>> mindspore.mint.tril(input, 1)
Tensor(shape=[4, 4], dtype=Int64, value=
[[ 1,  2,  0,  0],
 [ 5,  6,  7,  0],
 [10, 11, 12, 13],
 [14, 15, 16, 17]])
>>> mindspore.mint.tril(input, -1)
Tensor(shape=[4, 4], dtype=Int64, value=
[[ 0,  0,  0,  0],
 [ 5,  0,  0,  0],
 [10, 11,  0,  0],
 [14, 15, 16,  0]])
>>> input = mindspore.tensor([[[ 1,  2,  3],
...                            [ 5,  6,  7],
...                            [10, 11, 12]],
...                           [[ 1,  2,  3],
...                            [ 5,  6,  7],
...                            [10, 11, 12]]])
>>> mindspore.mint.tril(input)
Tensor(shape=[2, 3, 3], dtype=Int64, value=
[[[ 1,  0,  0],
  [ 5,  6,  0],
  [10, 11, 12]],
 [[ 1,  0,  0],
  [ 5,  6,  0],
  [10, 11, 12]]])
```

mindspore.mint.select

mindspore.mint.**select**(*input*, *dim*, *index*)

Slices the input tensor along the selected dimension at the given index.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) – the input tensor.
- **dim** (*int*) – the dimension to slice.
- **index** (*int*) – the index to select with.

Returns

Tensor.

Raises

TypeError –If input is not a Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor, mint
>>> input = Tensor([[2, 3, 4, 5],[3, 2, 4, 5]])
>>> y = mint.select(input, 0, 0)
>>> print(y)
[2 3 4 5]
```

mindspore.mint.squeeze

`mindspore.mint.`**`squeeze`**(*input*, *dim*)

Return the Tensor after deleting the dimension of size 1 in the specified *dim*.

If $dim = ()$, it will remove all the dimensions of size 1. If *dim* is specified, it will remove the dimensions of size 1 in the given *dim*. For example, if the dimension is not specified $dim = ()$, input shape is (A, 1, B, C, 1, D), then the shape of the output Tensor is (A, B, C, D). If the dimension is specified, the squeeze operation is only performed in the specified dimension. If input shape is (A, 1, B), when $dim = 0$ or $dim = 2$, the input tensor is not changed, while when $dim = 1$, the input tensor shape is changed to (A, B).

Note:

- Please note that in dynamic graph mode, the output Tensor will share data with the input Tensor, and there is no Tensor data copy process.
- The dimension index starts at 0 and must be in the range *[-input.ndim, input.ndim]*.
- In GE mode, only support remove dimensions of size 1 from the shape of input tensor.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (`Tensor`) –Used to calculate Squeeze. The shape of tensor is $(x_1, x_2, ..., x_R)$.
- **dim** (*`Union[int, tuple(int)]`*) –Specifies the dimension indexes of shape to be removed, which will remove all the dimensions of size 1 in the given dim parameter. If specified, it must be int32 or int64.

Returns

Tensor, the shape of tensor is $(x_1, x_2, ..., x_S)$.

Raises

- **TypeError** –If *input* is not a tensor.
- **TypeError** –If *dim* is not an int, tuple.

- **TypeError** –If *dim* is a tuple whose elements are not all int.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.ones(shape=[3, 2, 1]), mindspore.float32)
>>> output = mint.squeeze(input, 2)
>>> print(output)
[[1. 1.]
 [1. 1.]
 [1. 1.]]
```

mindspore.mint.stack

mindspore.mint.**stack**(*tensors*, *dim=0*)

Stacks a list of tensors in specified dim.

Stacks the list of input tensors with the same rank *R*, output is a tensor of rank *(R+1)*.

Given input tensors of shape $(x_1, x_2, ..., x_R)$. Set the number of input tensors as *N*. If $dim \geq 0$, the shape of the output tensor is $(x_1, x_2, ..., x_{dim}, N, x_{dim+1}, ..., x_R)$.

Parameters

- **tensors** (*Union[tuple, list]*) –A Tuple or list of Tensor objects with the same shape and type.
- **dim** (*int, optional*) –Dimension to stack. The range is [-(R+1), R+1). Default: 0 .

Returns

Tensor. A stacked Tensor with the same type as *tensors*.

Raises

- **TypeError** –If the data types of elements in *tensors* are not the same.
- **ValueError** –If *dim* is out of the range [-(R+1), R+1); or if the shapes of elements in *tensors* are not the same.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> data1 = Tensor(np.array([0, 1]).astype(np.float32))
>>> data2 = Tensor(np.array([2, 3]).astype(np.float32))
>>> output = mint.stack([data1, data2], 0)
>>> print(output)
[[0. 1.]
 [2. 3.]]
```

mindspore.mint.swapaxes

mindspore.mint.**swapaxes**(*input*, *axis0*, *axis1*)

Alias for *mindspore.mint.transpose()* . The *input* corresponds to the *input* in the reference interface, and the parameters *axis0* and *axis1* correspond to *dim0* and *dim1* in the reference interface respectively.

For more details, see *mindspore.mint.transpose()* .

Warning: This is an experimental API that is subject to change or deletion.

Examples

```
>>> import numpy as np
>>> from mindspore import mint
>>> from mindspore import Tensor
>>> input = Tensor(np.ones((2,3,4), dtype=np.float32))
>>> output = mint.swapaxes(input, 0, 2)
>>> print(output.shape)
(4, 3, 2)
```

mindspore.mint.transpose

mindspore.mint.**transpose**(*input*, *dim0*, *dim1*)

Interchange two axes of a tensor.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (*Tensor*) –Input tensor.
- **dim0** (*int*) –First axis.
- **dim1** (*int*) –Second axis.

Returns

Transposed tensor, has the same data type as *input*.

Raises

- **TypeError** –If argument *input* is not Tensor.
- **TypeError** –If *dim0* or *dim1* is not integer.
- **ValueError** –If *dim0* or *dim1* is not in the range of $[-ndim, ndim - 1]$.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.ones((2, 3, 4), dtype=np.float32))
>>> output = mint.transpose(input, 0, 2)
>>> print(output.shape)
(4, 3, 2)
```

mindspore.mint.triu

mindspore.mint.**triu**(*input*, *diagonal=0*)

Zero the input tensor below the diagonal specified.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input tensor.
- **diagonal** (*int, optional*) –The diagonal specified of 2-D tensor. Default 0 represents the main diagonal.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[ 1,  2,  3,  4],
...                           [ 5,  6,  7,  8],
...                           [10, 11, 12, 13],
...                           [14, 15, 16, 17]])
>>> mindspore.mint.triu(input)
Tensor(shape=[4, 4], dtype=Int64, value=
[[ 1,  2,  3,  4],
 [ 0,  6,  7,  8],
 [ 0,  0, 12, 13],
 [ 0,  0,  0, 17]])
>>> mindspore.mint.triu(input, 1)
```

(continues on next page)

(continued from previous page)

```
Tensor(shape=[4, 4], dtype=Int64, value=
[[ 0,  2,  3,  4],
 [ 0,  0,  7,  8],
 [ 0,  0,  0, 13],
 [ 0,  0,  0,  0]])
>>> mindspore.mint.triu(input, -1)
Tensor(shape=[4, 4], dtype=Int64, value=
[[ 1,  2,  3,  4],
 [ 5,  6,  7,  8],
 [ 0, 11, 12, 13],
 [ 0,  0, 16, 17]])
>>> input = mindspore.tensor([[[ 1,  2,  3],
...                            [ 5,  6,  7],
...                            [10, 11, 12]],
...                           [[ 1,  2,  3],
...                            [ 5,  6,  7],
...                            [10, 11, 12]]])
>>> mindspore.mint.triu(input)
Tensor(shape=[2, 3, 3], dtype=Int64, value=
[[[ 1,  2,  3],
  [ 0,  6,  7],
  [ 0,  0, 12]],
 [[ 1,  2,  3],
  [ 0,  6,  7],
  [ 0,  0, 12]]])
```

mindspore.mint.unbind

mindspore.mint.**unbind**(*input*, *dim=0*)

Unbind a tensor dimension in specified axis.

Given a tensor of shape $(n_1, n_2, ..., n_R)$ and unbinding it in the specified *dim*, multiple tensors with shape $(n_1, n_2, ..., n_{dim}, n_{dim+2}, ..., n_R)$ are returned.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input tensor to unbind, with a shape of $(n_1, n_2, ..., n_R)$. The rank of the tensor must be greater than 0.
- **dim** (*int, optional*) –Dimension along which to unbind. The range is [-R, R). Default: `0` .

Returns

A tuple of tensors, the shape of each objects is the same.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *dim* is not an int.
- **ValueError** –If *dim* is out of the range [-R, R).

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]))
>>> output = mint.unbind(input, dim=0)
>>> print(output)
(Tensor(shape=[3], dtype=Int64, value=[1, 2, 3]), Tensor(shape=[3], dtype=Int64, value=[4, 5,
 ↪ 6]),
Tensor(shape=[3], dtype=Int64, value=[7, 8, 9]))
```

mindspore.mint.unique_consecutive

mindspore.mint.**unique_consecutive**(*input*, *return_inverse=False*, *return_counts=False*, *dim=None*)

Returns the elements that are unique in each consecutive group of equivalent elements in the input tensor.

When *return_inverse=True* , it returns a tensor containing the indices of the elements in the input tensor within the output tensor.

When *return_counts=True* , it returns a tensor representing the number of occurrences of each output element in the input.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input tensor.
- **return_inverse** (*bool, optional*) –Whether to return the index of where the element in the original input maps to the position in the output. Default: False .
- **return_counts** (*bool, optional*) –Whether to return the counts of each unique element. Default: False .
- **dim** (*int, optional*) –The dimension to apply unique. If None , the unique of the flattened input is returned. If the dimension is specified, it must be int32 or int64. Default: None .

Returns

A tensor or a tuple of tensors containing tensor objects (*output*, *inverse_indices*, *counts*).

- **output** (Tensor): the output tensor has the same type as *input* and represents the output list of unique scalar elements.
- **inverse_indices** (Tensor, optional): if *return_inverse* is True, there will be an additional returned tensor *inverse_indices*. *inverse_indices* has the same shape as *input* and represents the index of where the element in the original input maps to the position in the output.
- **counts** (Tensor, optional): if *return_counts* is True, there will be an additional returned tensor *counts*. *counts* has the same shape as *output* or *output.shape[dim]* if dim was specified and represents the number of occurrences for each unique value or tensor.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If dtype of *input* is not supported.
- **TypeError** –If *return_inverse* is not a bool.

- **TypeError** – If *return_counts* is not a bool.
- **TypeError** – If *dim* is not an int.
- **ValueError** – If *dim* is not in the range of $[-ndim, ndim - 1]$.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> from mindspore import dtype as mstype
>>> x = Tensor(np.array([1, 1, 2, 2, 3, 1, 1, 2]), mstype.int64)
>>> output, inverse_indices, counts = mint.unique_consecutive(x, True, True, None)
>>> print(output)
[1 2 3 1 2]
>>> print(inverse_indices)
[0 0 1 1 2 3 3 4]
>>> print(counts)
[2 2 1 2 1]
```

mindspore.mint.unsqueeze

mindspore.mint.**unsqueeze**(*input*, *dim*)

Adds an additional dimension to the input tensor at the given dimension.

Parameters

- **input** (Tensor) – The input tensor.
- **dim** (*int*) – The dimension specified.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 2, 3, 4])
>>> mindspore.mint.unsqueeze(input, 0)
Tensor(shape=[1, 4], dtype=Int64, value=
[[1, 2, 3, 4]])
>>> mindspore.mint.unsqueeze(input, 1)
Tensor(shape=[4, 1], dtype=Int64, value=
[[1],
 [2],
 [3],
 [4]])
```

mindspore.mint.where

mindspore.mint.**where**(*condition*, *input*, *other*) → *Tensor*

Selects elements from *input* or *other* based on *condition* and returns a tensor.

$$output_i = \begin{cases} input_i, & if\ condition_i \\ other_i, & otherwise \end{cases}$$

Parameters

- **condition** (*Tensor[bool]*) – If true, yield *input*, otherwise yield *other*.
- **input** (*Union[Tensor, Scalar]*) – When *condition* is true, values to select from.
- **other** (*Union[Tensor, Scalar]*) – When *condition* is false, values to select from.

Returns

Tensor, elements are selected from *input* and *other*.

Raises

- **TypeError** – If *condition* is not a tensor.
- **TypeError** – If both *input* and *other* are scalars.
- **ValueError** – If *condition*, *input* and *other* can not broadcast to each other.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import tensor, mint
>>> from mindspore import dtype as mstype
>>> a = tensor(np.arange(4).reshape((2, 2)), mstype.float32)
>>> b = tensor(np.ones((2, 2)), mstype.float32)
>>> condition = a < 3
>>> output = mint.where(condition, a, b)
>>> print(output)
[[0. 1.]
 [2. 1.]]
```

mindspore.mint.**where**(*condition*) → *Tensor*

Identical to *mindspore.ops.nonzero()* with input *condition* and *as_tuple* being True.

Supported Platforms:

Ascend

4.2 Random Sampling

API Name	Description	Supported Platforms
mindspore.mint.multinomial	Returns a tensor sampled from the multinomial probability distribution located in the corresponding row of the input tensor.	Ascend
mindspore.mint.normal	Generates random numbers according to the standard Normal (or Gaussian) random number distribution.	Ascend
mindspore.mint.rand_like	Returns a new tensor that fills numbers from the uniform distribution over an interval $[0, 1)$ based on the given dtype and shape of the input tensor.	Ascend
mindspore.mint.rand	Returns a new tensor that fills numbers from the uniform distribution over an interval $[0, 1)$ based on the given shape and dtype.	Ascend

4.2.1 mindspore.mint.multinomial

mindspore.mint.**multinomial**(*input*, *num_samples*, *replacement=False*, ***, *generator=None*)

Returns a tensor sampled from the multinomial probability distribution located in the corresponding row of the input tensor.

The polynomial distribution is a probability distribution that generalizes the binomial distribution formula to multiple states. In the polynomial distribution, each event has a fixed probability, and the sum of these probabilities is 1. The purpose of the *mindspore.mint.multinomial()* interface is to perform *num_samples* sampling on the input *input*, and the output tensor is the index of the input tensor for each sampling. The values in *input* represent the probability of selecting the corresponding index for each sampling.

Here is an extreme example for better understanding. Suppose we have an input probability tensor with values *Tensor([90 / 100, 10 / 100, 0], mindspore.float32)*, which means we can sample three indices, namely index 0, index 1, and index 2, with probabilities of 90%, 10%, and 0%, respectively. We perform n samplings, and the resulting sequence is the calculation result of the polynomial distribution, with a length equal to the number of samplings.

In case 1 of the sample code, we perform two non-replacement samplings (*replacement* is *False*). The calculation result is most likely *[0, 1]*, and less likely *[1, 0]*. Since the probability of selecting index 0 is 90% for each sampling, the first result is most likely to be index 0. Since the probability of selecting index 2 is 0, index 2 cannot appear in the sampling result. Therefore, the second result must be index 1, and the resulting sequence is *[0, 1]*.

In case 2 of the sample code, we perform 10 replacement samplings (*replacement* is *True*). As expected, about 90% of the sampling results are index 0.

In case 3 of the sample code, we extend the input to 2 dimensions, and the sampling results in each dimension also match our sampling expectations.

Note: The rows of input do not need to sum to one (in which case we use the values as weights), but must be non-negative, finite and have a non-zero sum. When using values as weights, it can be understood as normalizing the input along the last dimension.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input tensor containing probabilities, must be 1 or 2 dimensions, with float32 data type.

- **num_samples** (*int*) –Number of samples to draw.
- **replacement** (*bool, optional*) –Whether to draw with replacement or not. Default: `False`.

Keyword Arguments

generator (*generator, optional*) –MindSpore generator. Default: `None`.

Returns

Tensor, dtype is Int64. If *input* is a vector, out is a vector of size *num_samples*. If *input* is a matrix with m rows, out is an matrix of shape(m * num_samples).

Raises

- **TypeError** –If *input* is not a Tensor whose dtype is not in float16, float32, float64 or bfloat16.
- **TypeError** –If *num_samples* is not an int, a Scalar of int or a Tensor with shape[1,] and only one int element.
- **RuntimeError** –If num_samples <= 0.
- **RuntimeError** –If *replacement* is False, num_samples > *shape* of the last dimension of *input*.
- **RuntimeError** –If shape of the last dimension of *input* exceeds `2^24`.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> from mindspore import dtype as mstype
>>> # case 1: The output is random, and the length of the output is the same as num_sample.
>>> # replacement is False.
>>> input1 = Tensor([90 / 100, 10 / 100, 0], mindspore.float32)
>>> input2 = Tensor([90, 10, 0], mindspore.float32)
>>> # input1 and input2 have the same meaning.
>>> output1 = mint.multinomial(input1, 2)
>>> output2 = mint.multinomial(input2, 2)
>>> # print(output1)
>>> # [0 1]
>>> # print(output2)
>>> # [0 1]
>>> print(len(output1))
2
>>> print(len(output2))
2
>>> # case 2: The output is random, and the length of the output is the same as num_sample.
>>> # replacement is True.
>>> output3 = mint.multinomial(input1, 10, replacement=True)
>>> # print(output3)
>>> # [0 0 1 0 0 0 0 0 0 0]
>>> print(len(output3))
10
>>> # case 3: The output is random, and the length of the output is the same as num_sample.
>>> # replacement is True.
>>> # rank is 2
>>> input4 = Tensor([[90, 10, 0], [10, 90, 0]], mstype.float32)
```

(continues on next page)

(continued from previous page)

```
>>> output4 = mint.multinomial(input4, 10, replacement=True)
>>> # print(output4)
>>> # [[0 0 0 0 0 0 0 0 1 0]
>>> #  [1 1 1 1 1 0 1 1 1 1]]
```

4.2.2 mindspore.mint.normal

mindspore.mint.**normal**(*mean*, *std*, *, *generator=None*) → *Tensor*

Generates random numbers according to the standard Normal (or Gaussian) random number distribution.

Parameters

- **mean** (*Union[float, Tensor]*) –Mean value of each element, the shape of the *mean* tensor should be the same as that of the *std* tensor.
- **std** (*Union[float, Tensor]*) –Standard deviation for each element, the shape of the *std* tensor should be the same as that of the *mean* tensor. The value of *std* should be greater than or equal to 0.

Keyword Arguments

generator (*generator, optional*) –MindSpore generator. Default: `None`.

Returns

Outputs a tensor with the same shape as *mean*.

Raises

TypeError –If *mean* or *std* is not Union[float, Tensor].

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import mint
>>> from mindspore import Tensor
>>> mean = Tensor(np.array([1.0, 2.0, 3.0]), mindspore.float32)
>>> std = Tensor(np.array([1.0, 2.0, 3.0]), mindspore.float32)
>>> output = mint.normal(mean, std)
>>> print(output.shape)
(3,)
```

mindspore.mint.**normal**(*mean*, *std=1.0*) → *Tensor*

Similar to the function above, but the standard deviations are shared among all drawn elements.

Parameters

- **mean** (`Tensor`) –Mean value of each element.
- **std** (*float, optional*) –Standard deviation for each element. The value of *std* should be greater than or equal to 0. Default: `1.0`.

Returns

Outputs a tensor with the same shape as *mean*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import mint
>>> from mindspore import Tensor
>>> mean = Tensor(np.array([1.0, 2.0, 3.0]), mindspore.float32)
>>> output = mint.normal(mean, 1.0)
>>> print(output.shape)
(3,)
```

`mindspore.mint.`**`normal`**(*mean*, *std*, *size*) → *Tensor*

Similar to the function above, but the means and standard deviations are shared among all drawn elements. The result tensor has size given by *size*.

Parameters

- **`mean`** (*float*) –Mean value of each element.
- **`std`** (*float*) –Standard deviation for each element.
- **`size`** (*tuple*) –output shape.

Returns

Outputs a tensor. The shape is specified as *size*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import mint
>>> from mindspore import Tensor
>>> output = mint.normal(1.0, 2.0, (2, 4))
>>> print(output.shape)
(2, 4)
```

4.2.3 mindspore.mint.rand_like

mindspore.mint.**rand_like**(*input*, *, *dtype=None*)

Returns a new tensor that fills numbers from the uniform distribution over an interval $[0, 1)$ based on the given dtype and shape of the input tensor.

Parameters

input (Tensor) −Input Tensor to specify the output shape and its default dtype.

Keyword Arguments

dtype (*mindspore.dtype*, optional) −Designated tensor dtype, it must be float type. If None, the same dtype of *input* will be applied. Default: None .

Returns

Tensor, with the designated shape and dtype, filled with random numbers from the uniform distribution on the interval $[0, 1)$.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore as ms
>>> from mindspore import Tensor, mint
>>> a = Tensor([[2, 3, 4], [1, 2, 3]])
>>> print(mint.rand_like(a, dtype=ms.float32).shape)
(2, 3)
```

4.2.4 mindspore.mint.rand

mindspore.mint.**rand**(**size*, *generator=None*, *dtype=None*)

Returns a new tensor that fills numbers from the uniform distribution over an interval $[0, 1)$ based on the given shape and dtype.

Parameters

size (*Union[int, tuple(int), list(int)]*) −Shape of the new tensor, e.g. $(2, 3)$ or 2.

Keyword Arguments

- **generator** (*mindspore.Generator*, optional) −a pseudorandom number generator. Default: None, uses the default pseudorandom number generator.
- **dtype** (*mindspore.dtype*, optional) −Designated tensor dtype. If None, *mindspore.float32* will be applied. Default: None .

Returns

Tensor, with the designated shape and dtype, filled with random numbers from the uniform distribution on the interval $[0, 1)$.

Raises

ValueError −If *size* contains negative numbers.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import mint
>>> print(mint.rand(2, 3).shape)
(2, 3)
```

4.3 Math Operations

4.3.1 Pointwise Operations

API Name	Description	Supported Platforms
mindspore.mint.abs	Compute the absolute value of a tensor element-wise.	Ascend
mindspore.mint.add	Adds scaled other value to *self*.	Ascend
mindspore.mint.addmv	Performs a matrix-vector product of *mat* and *vec*, and add the input vector *input* to the final result.	Ascend
mindspore.mint.acos	Computes arccosine of input tensors element-wise.	Ascend
mindspore.mint.acosh	Computes inverse hyperbolic cosine of the inputs element-wise.	Ascend
mindspore.mint.arccos	Alias for mindspore.mint.acos() .	Ascend
mindspore.mint.arccosh	Alias for mindspore.mint.acosh().	Ascend
mindspore.mint.arcsin	Alias for mindspore.mint.asin().	Ascend
mindspore.mint.arcsinh	Alias for mindspore.mint.asinh().	Ascend
mindspore.mint.arctan	Alias for mindspore.mint.atan().	Ascend
mindspore.mint.arctan2	Alias for mindspore.mint.atan2().	Ascend
mindspore.mint.arctanh	Alias for mindspore.mint.atanh().	Ascend
mindspore.mint.asin	Computes arcsine of input tensors element-wise.	Ascend
mindspore.mint.asinh	Computes inverse hyperbolic sine of the input element-wise.	Ascend
mindspore.mint.atan	Computes the trigonometric inverse tangent of the input element-wise.	Ascend
mindspore.mint.atan2	Returns arctangent of input/other element-wise.	Ascend
mindspore.mint.atanh	Computes inverse hyperbolic tangent of the input element-wise.	Ascend
mindspore.mint.bitwise_and	Returns bitwise *and* of two tensors element-wise.	Ascend
mindspore.mint.bitwise_or	Returns bitwise *or* of two tensors element-wise.	Ascend
mindspore.mint.bitwise_xor	Returns bitwise *xor* of two tensors element-wise.	Ascend
mindspore.mint.ceil	Rounds a tensor up to the closest integer element-wise.	Ascend
mindspore.mint.clamp	Clamps tensor values between the specified minimum value and maximum value.	Ascend
mindspore.mint.cos	Computes cosine of input element-wise.	Ascend
mindspore.mint.cosh	Computes hyperbolic cosine of input element-wise.	Ascend
mindspore.mint.cross	Compute the cross product of two input tensors along the specified dimension.	Ascend
mindspore.mint.diff	Computes the n-th forward difference along the given dimension.	Ascend
mindspore.mint.div	Divides each element of the *input* by the corresponding element of the *other* .	Ascend

continues on next page

Table 4 – continued from previous page

mindspore.mint.divide	Alias for mindspore.mint.div() .	Ascend
mindspore.mint.erf	Compute the Gauss error of input tensor element-wise.	Ascend
mindspore.mint.erfc	Compute the complementary error function of input tensor element-wise.	Ascend
mindspore.mint.erfinv	Compute the inverse error of input tensor element-wise.	Ascend
mindspore.mint.exp	Compute exponential of the input tensor element-wise.	Ascend
mindspore.mint.exp2	Calculates the base-2 exponent of the Tensor *input* element by element.	Ascend
mindspore.mint.expm1	Compute exponential of the input tensor, then minus 1, element-wise.	Ascend
mindspore.mint.fix	Alias for mindspore.mint.trunc() .	Ascend
mindspore.mint.float_power	Computes *input* to the power of *exponent* element-wise in double precision, and always returns a mindspore.float64 tensor.	Ascend
mindspore.mint.floor	Rounds a tensor down to the closest integer element-wise.	Ascend
mindspore.mint.fmod	Computes the floating-point remainder of the division operation input/other.	Ascend
mindspore.mint.frac	Calculates the fractional part of each element in the input.	Ascend
mindspore.mint.lerp	Perform a linear interpolation of two tensors input and end based on a float or tensor weight.	Ascend
mindspore.mint.log	Compute the natural logarithm of the input tensor element-wise.	Ascend
mindspore.mint.log1p	Compute the natural logarithm of (tensor + 1) element-wise.	Ascend
mindspore.mint.log2	Returns the logarithm to the base 2 of a tensor element-wise.	Ascend
mindspore.mint.log10	Returns the logarithm to the base 10 of a tensor element-wise.	Ascend
mindspore.mint.logaddexp	Computes the logarithm of the sum of exponentiations of the inputs.	Ascend
mindspore.mint.logaddexp2	Logarithm of the sum of exponentiations of the inputs in base of 2.	Ascend
mindspore.mint.logical_and	Compute the "logical AND" of two tensors element-wise.	Ascend
mindspore.mint.logical_not	Compute the "logical NOT" of the input tensor element-wise.	Ascend
mindspore.mint.logical_or	Compute the "logical OR" of two tensors element-wise.	Ascend
mindspore.mint.logical_xor	Compute the "logical XOR" of two tensors element-wise.	Ascend
mindspore.mint.mul	Multiply other value by input Tensor.	Ascend
mindspore.mint.mv	Multiply matrix *input* and vector *vec*.	Ascend
mindspore.mint.nansum	Computes sum of *input* over a given dimension, treating NaNs as zero.	Ascend

continues on next page

Table 4 – continued from previous page

mindspore.mint.nan_to_num	Replace the *NaN*, positive infinity and negative infinity values in *input* with the specified values in *nan*, *posinf* and *neginf* respectively.	Ascend
mindspore.mint.neg	Returns a tensor with negative values of the input tensor element-wise.	Ascend
mindspore.mint.negative	Alias for mindspore.mint.neg() .	Ascend
mindspore.mint.pow	Calculates the *exponent* power of each element in *input*.	Ascend
mindspore.mint.polar	Converts polar coordinates to Cartesian coordinates.	Ascend
mindspore.mint.ravel	Expand the multidimensional Tensor into 1D along the 0 axis direction.	Ascend
mindspore.mint.reciprocal	Returns reciprocal of a tensor element-wise.	Ascend
mindspore.mint.remainder	Computes the remainder of *input* divided by *other* element-wise.	Ascend
mindspore.mint.roll	Roll the elements of a tensor along a dimension.	Ascend
mindspore.mint.round	Round elements of input to the nearest integer.	Ascend
mindspore.mint.rsqrt	Compute reciprocal of square root of input tensor element-wise.	Ascend
mindspore.mint.sigmoid	Computes Sigmoid of input element-wise.	Ascend
mindspore.mint.sign	Return an element-wise indication of the sign of a number.	Ascend
mindspore.mint.sin	Compute sine of the input tensor element-wise.	Ascend
mindspore.mint.sinc	Compute the normalized sinc of input.	Ascend
mindspore.mint.sinh	Compute hyperbolic sine of the input element-wise.	Ascend
mindspore.mint.softmax	Alias for mindspore.mint.nn.functional.softmax().	Ascend
mindspore.mint.sqrt	Returns sqrt of a tensor element-wise.	Ascend
mindspore.mint.square	Return square of a tensor element-wise.	Ascend
mindspore.mint.sub	Subtracts scaled other value from self Tensor.	Ascend
mindspore.mint.t	Transpose the input tensor.	Ascend
mindspore.mint.tan	Computes tangent of *input* element-wise.	Ascend
mindspore.mint.tanh	Computes hyperbolic tangent of input element-wise.	Ascend
mindspore.mint.trunc	Returns a tensor with the truncated integer values of the elements of the input tensor.	Ascend
mindspore.mint.xlogy	Computes the first input multiplied by the logarithm of second input element-wise.	Ascend

mindspore.mint.abs

mindspore.mint.**abs**(*input*)

Compute the absolute value of a tensor element-wise.

$$out_i = |input_i|$$

Parameters

input (Tensor) −The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> output = mindspore.mint.abs(mindspore.tensor([-1.0, 1.0, 0.0]))
>>> print(output)
[1. 1. 0.]
```

mindspore.mint.add

mindspore.mint.**add**(*input*, *other*, *, *alpha=1*) → *Tensor*

Adds scaled other value to *self*.

$$out_i = self_i + alpha \times other_i$$

Note:

- When *self* and *other* have different shapes, they must be able to broadcast to a common shape.
- *self*, *other* and *alpha* comply with the implicit type conversion rules to make the data types consistent.

Parameters

- **input** (*Union[Tensor, number.Number, bool]*) – *input* is a number.Number or a bool or a tensor whose data type is number or bool_.
- **other** (*Union[Tensor, number.Number, bool]*) – *other* is a number.Number or a bool or a tensor whose data type is number or bool_.

Keyword Arguments

alpha (*number.Number, optional*) – A scaling factor applied to *other*, default 1.

Returns

Tensor with a shape that is the same as the broadcasted shape of the *self* and *other*, and the data type is the one with higher precision or higher digits among *self*, *other* and *alpha*.

Raises

- **TypeError** – If the type of *other* or *alpha* is not one of the following: Tensor, number.Number, bool.
- **TypeError** – If *alpha* is of type float but *self* and *other* are not of type float.
- **TypeError** – If *alpha* is of type bool but *self* and *other* are not of type bool.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> x = Tensor(1, mindspore.int32)
>>> y = Tensor(np.array([4, 5, 6]).astype(np.float32))
>>> alpha = 0.5
>>> output = mint.add(x, y, alpha=alpha)  # x.add(y, alpha=alpha)
>>> print(output)
[3. 3.5 4.]
>>> # the data type of x is int32, the data type of y is float32,
>>> # alpha is a float, and the output is the data format of higher precision float32.
>>> print(output.dtype)
Float32
```

mindspore.mint.addmv

mindspore.mint.**addmv**(*input*, *mat*, *vec*, *, *beta=1*, *alpha=1*)

Performs a matrix-vector product of *mat* and *vec*, and add the input vector *input* to the final result.

If *mat* is a tensor of size (N, M) , *vec* is a 1-D tensor of size M , then *input* must be broadcastable with a 1-D tensor of size N . In this case, *output* is a 1-D Tensor of size N .

$$output = \beta input + \alpha(mat@vec)$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –Vector to be added.
- **mat** (Tensor) –The first tensor needs to be multiplied.
- **vec** (Tensor) –The second tensor needs to be multiplied.

Keyword Arguments

- **beta** (*Union[float, int], optional*) –Coefficient of *input*. Default: 1.
- **alpha** (*Union[float, int], optional*) –Coefficient of $mat@vec$. Default: 1.

Returns

Tensor, with a shape of $(N,)$, and its dtype is the same as *input*.

Raises

- **TypeError** –If dtype of *input*, *mat* or *vec* is not tensor.
- **TypeError** –If dtypes of *mat* and *vec* are not the same.
- **ValueError** –If *mat* is not a 2-D tensor.
- **ValueError** –If *vec* is not a 1-D tensor.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([2., 3.]).astype(np.float32))
>>> mat = Tensor(np.array([[2., 5., 3.], [4., 2., 2.]]).astype(np.float32))
>>> vec = Tensor(np.array([3., 2., 4.]).astype(np.float32))
>>> output = mint.addmv(input, mat, vec)
>>> print(output)
[30. 27.]
```

mindspore.mint.acos

mindspore.mint.**acos**(*input*)

Computes arccosine of input tensors element-wise.

$$out_i = \cos^{-1}(input_i)$$

Parameters

input (Tensor) −The shape of tensor is $(N, *)$, where $*$ means any number of additional dimensions.

Returns

Tensor, has the same shape as *input*. The dtype of output is float32 when dtype of *input* is in [bool, int8, uint8, int16, int32, int64]. Otherwise output has the same dtype as *input*.

Raises

TypeError −If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([0.74, 0.04, 0.30, 0.56]), mindspore.float32)
>>> output = mint.acos(input)
>>> print(output)
[0.7377037  1.5307857 1.2661037 0.9764114]
```

mindspore.mint.acosh

mindspore.mint.**acosh**(*input*)

Computes inverse hyperbolic cosine of the inputs element-wise.

$$out_i = \cosh^{-1}(input_i)$$

Note: Given an input tensor input, the function computes inverse hyperbolic cosine of every element. Input range is [1, inf].

Parameters

input (Tensor) – The input tensor of inverse hyperbolic cosine function.

Returns

Tensor, has the same shape as *input*. The dtype of output is float32 when dtype of *input* is in [bool, int8, uint8, int16, int32, int64]. Otherwise output has the same dtype as *input*.

Raises

TypeError – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([1.0, 1.5, 3.0, 100.0]), mindspore.float32)
>>> output = mint.acosh(input)
>>> print(output)
[0.        0.9624236 1.7627472 5.298292 ]
```

mindspore.mint.arccos

mindspore.mint.**arccos**(*input*)

Alias for *mindspore.mint.acos()*.

Supported Platforms:

Ascend

mindspore.mint.arccosh

mindspore.mint.**arccosh**(*input*)

Alias for *mindspore.mint.acosh()*.

Supported Platforms:

Ascend

mindspore.mint.arcsin

mindspore.mint.**arcsin**(*x*)

Alias for *mindspore.mint.asin()*.

Supported Platforms:

Ascend

mindspore.mint.arcsinh

mindspore.mint.**arcsinh**(*input*)

Alias for *mindspore.mint.asinh()*.

Supported Platforms:

Ascend

mindspore.mint.arctan

mindspore.mint.**arctan**(*input*)

Alias for *mindspore.mint.atan()*.

Supported Platforms:

Ascend

mindspore.mint.arctan2

mindspore.mint.**arctan2**(*input*, *other*)

Alias for *mindspore.mint.atan2()*.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> x = Tensor(np.array([0, 1]), mindspore.float32)
>>> y = Tensor(np.array([1, 1]), mindspore.float32)
>>> output = mint.arctan2(x, y)
>>> print(output)
[0.        0.7853982]
```

mindspore.mint.arctanh

mindspore.mint.**arctanh**(*input*)

Alias for *mindspore.mint.atanh()*.

Supported Platforms:

Ascend

mindspore.mint.asin

mindspore.mint.**asin**(*input*)

Computes arcsine of input tensors element-wise.

$$out_i = \sin^{-1}(input_i)$$

Parameters

input (Tensor) –The shape of tensor is $(N, *)$, where $*$ means any number of additional dimensions.

Returns

Tensor, has the same shape as *input*. The dtype of output is float32 when dtype of *input* is in [bool, int8, uint8, int16, int32, int64]. Otherwise output has the same dtype as *input*.

Raises

TypeError –If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([0.74, 0.04, 0.30, 0.56]), mindspore.float32)
>>> output = mint.asin(input)
>>> print(output)
[0.8330927  0.04001068  0.30469266  0.59438497 ]
```

mindspore.mint.asinh

mindspore.mint.**asinh**(*input*)

Computes inverse hyperbolic sine of the input element-wise.

$$out_i = \sinh^{-1}(input_i)$$

Parameters

input (Tensor) –The input tensor of inverse hyperbolic sine function.

Returns

Tensor, has the same shape as *input*. The dtype of output is float32 when dtype of *input* is in [bool, int8, uint8, int16, int32, int64]. Otherwise output has the same dtype as *input*.

Raises

TypeError –If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([-5.0, 1.5, 3.0, 100.0]), mindspore.float32)
>>> output = mint.asinh(input)
>>> print(output)
[-2.3124385  1.1947632  1.8184465  5.298342 ]
```

mindspore.mint.atan

mindspore.mint.**atan**(*input*)

Computes the trigonometric inverse tangent of the input element-wise.

$$out_i = \tan^{-1}(input_i)$$

Parameters

input (Tensor) – The shape of tensor is $(N, *)$ where $*$ means, any number of additional dimensions.

Returns

Tensor, has the same shape as *input*. The dtype of output is float32 when dtype of *input* is in [bool, int8, uint8, int16, int32, int64]. Otherwise output has the same dtype as *input*.

Raises

TypeError – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([1.0, 0.0]), mindspore.float32)
>>> output = mint.atan(input)
>>> print(output)
[0.7853982 0.       ]
```

mindspore.mint.atan2

mindspore.mint.**atan2**(*input*, *other*)

Returns arctangent of input/other element-wise.

It returns $\theta \in [-\pi, \pi]$ such that $input = r * \sin(\theta), other = r * \cos(\theta)$, where $r = \sqrt{input^2 + other^2}$.

Note:

- Arg *input* and *other* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower precision data type will be converted to relatively the highest precision data type.

Parameters

- **input** (Tensor, *Number.number*) –The input tensor or scalar.
- **other** (Tensor, *Number.number*) –The input tensor or scalar. It has the same shape with *input* or its shape is able to broadcast with *input*.

Returns

Tensor, the shape is the same as the one after broadcasting. The dtype of output is float32 when dtype of *input* is in [bool, int8, uint8, int16, int32, int64]. Otherwise output has the same dtype as *input*.

Raises

- **TypeError** –If *input* or *other* is not a Tensor or scalar.
- **RuntimeError** –If the data type of *input* and *other* conversion of Parameter is required when data type conversion of Parameter is not supported.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([0, 1]), mindspore.float32)
>>> other = Tensor(np.array([1, 1]), mindspore.float32)
>>> output = mint.atan2(input, other)
>>> print(output)
[0.        0.7853982]
```

mindspore.mint.atanh

mindspore.mint.**atanh**(*input*)

Computes inverse hyperbolic tangent of the input element-wise.

$$out_i = \tanh^{-1}(input_i)$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> output = mindspore.mint.atanh(mindspore.tensor([0, -0.5]))
>>> print(output)
[ 0.         -0.54930615]
```

mindspore.mint.bitwise_and

mindspore.mint.**bitwise_and**(*input*, *other*)

Returns bitwise *and* of two tensors element-wise.

$$out_i = input_i \wedge other_i$$

Note: Args of *input* and *other* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower precision data type will be converted to the relatively highest precision data type.

Parameters

- **input** (Tensor) – The input tensor.
- **other** (Tensor, *Number.number*) – The input tensor or scalar. It has the same shape with *input* or its shape is able to broadcast with *input*.

Returns

Tensor, the shape is the same as the one after broadcasting, and the data type is same as *input*.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([0, 0, 1, -1, 1, 1, 1]), mindspore.int16)
>>> other = Tensor(np.array([0, 1, 1, -1, -1, 2, 3]), mindspore.int16)
>>> output = mint.bitwise_and(input, other)
>>> print(output)
[ 0  0  1 -1  1  0  1]
```

mindspore.mint.bitwise_or

mindspore.mint.**bitwise_or**(*input*, *other*)

Returns bitwise *or* of two tensors element-wise.

$$out_i = input_i \mid other_i$$

Note: Args of *input* and *other* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower precision data type will be converted to the relatively highest precision data type.

Parameters

- **input** (Tensor) – The input tensor.
- **other** (Tensor, *Number.number*) – The input tensor or scalar. It has the same shape with *input* or its shape is able to broadcast with *input*.

Returns

Tensor, the shape is the same as the one after broadcasting, and the data type is same as *input*.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([0, 0, 1, -1, 1, 1, 1]), mindspore.int16)
>>> other = Tensor(np.array([0, 1, 1, -1, -1, 2, 3]), mindspore.int16)
>>> output = mint.bitwise_or(input, other)
>>> print(output)
[ 0  1  1 -1 -1  3  3]
```

mindspore.mint.bitwise_xor

mindspore.mint.**bitwise_xor**(*input*, *other*)

Returns bitwise *xor* of two tensors element-wise.

$$out_i = input_i \oplus other_i$$

Note: Args of *input* and *other* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower precision data type will be converted to the relatively highest precision data type.

Parameters

- **input** (Tensor) – The input tensor.

- **other** (Tensor, *Number.number*) –The input tensor or scalar. It has the same shape with *input* or its shape is able to broadcast with *input*.

Returns

Tensor, the shape is the same as the one after broadcasting, and the data type is same as *input*.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([0, 0, 1, -1, 1, 1, 1]), mindspore.int16)
>>> other = Tensor(np.array([0, 1, 1, -1, -1, 2, 3]), mindspore.int16)
>>> output = mint.bitwise_xor(input, other)
>>> print(output)
[ 0  1  0  0 -2  3  2]
```

mindspore.mint.ceil

mindspore.mint.**ceil**(*input*)

Rounds a tensor up to the closest integer element-wise.

$$out_i = \lceil input_i \rceil$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1.1, 2.5, -1.5])
>>> output = mindspore.mint.ceil(input)
>>> print(output)
[ 2.  3. -1.]
```

mindspore.mint.clamp

mindspore.mint.**clamp**(*input*, *min=None*, *max=None*) → *Tensor*

Clamps tensor values between the specified minimum value and maximum value.

Limits the value of $input$ to a range, whose lower limit is *min* and upper limit is *max* .

$$out_i = \begin{cases} max & \text{if } input_i \geq max \\ input_i & \text{if } min < input_i < max \\ min & \text{if } input_i \leq min \end{cases}$$

Note:

- *min* and *max* cannot be None at the same time;
- When *min* is None and *max* is not None, the elements in Tensor larger than *max* will become *max*;
- When *min* is not None and *max* is None, the elements in Tensor smaller than *min* will become *min*;
- If *min* is greater than *max*, the value of all elements in Tensor will be set to *max*;
- The data type of *input*, *min* and *max* should support implicit type conversion and cannot be bool type.

Parameters

- **input** (Tensor) –Input data, which type is Tensor. Tensors of arbitrary dimensions are supported.
- **min** (*Union(Tensor, float, int), optional*) –The minimum value. Default: None .
- **max** (*Union(Tensor, float, int), optional*) –The maximum value. Default: None .

Returns

Tensor, a clipped Tensor. The data type and shape are the same as input.

Raises

- **ValueError** –If both *min* and *max* are None.
- **TypeError** –If the type of *input* is not Tensor.
- **TypeError** –If the type of *min* is not in None, Tensor, float or int.
- **TypeError** –If the type of *max* is not in None, Tensor, float or int.

Supported Platforms:

Ascend

Examples

```
>>> # case 1: the data type of input is Tensor
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> min_value = Tensor(5, mindspore.float32)
>>> max_value = Tensor(20, mindspore.float32)
>>> input = Tensor(np.array([[1., 25., 5., 7.], [4., 11., 6., 21.]]), mindspore.float32)
>>> output = mint.clamp(input, min_value, max_value)
```

(continues on next page)

(continued from previous page)

```
>>> print(output)
[[ 5. 20.  5.  7.]
 [ 5. 11.  6. 20.]]
>>> # case 2: the data type of input is number
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> min_value = 5
>>> max_value = 20
>>> input = Tensor(np.array([[1., 25., 5., 7.], [4., 11., 6., 21.]]), mindspore.float32)
>>> output = mint.clamp(input, min_value, max_value)
>>> print(output)
[[ 5. 20.  5.  7.]
 [ 5. 11.  6. 20.]]
```

mindspore.mint.cos

mindspore.mint.**cos**(*input*)

Computes cosine of input element-wise.

$$out_i = \cos(x_i)$$

Warning: Using float64 may cause a problem of missing precision.

Parameters

input (Tensor) −The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> # The datatype of output will be float32 when datatype of input is in [bool, int8, uint8,
 ↪ int16, int32, int64](Datatype only supported on Ascend).
>>> input = mindspore.tensor([0, 1, 2], mindspore.int32)
>>> mindspore.mint.cos(input)
Tensor(shape=[3], dtype=Float32, value= [ 1.00000000e+00,  5.40302306e-01, -4.16146837e-01])
>>>
>>> # Otherwise output has the same dtype as the `input`.
>>> input = mindspore.tensor([0.74, 0.04, 0.30, 0.56], mindspore.float64)
>>> mindspore.mint.cos(input)
Tensor(shape=[4], dtype=Float64, value= [ 7.38468559e-01,  9.99200107e-01,  9.55336489e-01, ␣
 ↪8.47255111e-01])
```

mindspore.mint.cosh

mindspore.mint.**cosh**(*input*)

Computes hyperbolic cosine of input element-wise.

$$out_i = \cosh(input_i)$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.74, 0.04, 0.30, 0.56])
>>> output = mindspore.mint.cosh(input)
>>> print(output)
[1.2865248 1.0008001 1.0453385 1.1609408]
```

mindspore.mint.cross

mindspore.mint.**cross**(*input*, *other*, *dim=None*)

Compute the cross product of two input tensors along the specified dimension.

Note: *input* and *other* must have the same shape, and the size of their *dim* dimension should be *3*. If *dim* is not specified, it is set to be the first dimension found with the size *3*.

Parameters

- **input** (Tensor) –The first input tensor.
- **other** (Tensor) –The second input tensor.
- **dim** (*int, optional*) –Specify the dimension for computation. Default None.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1, 2, 3], [1, 2, 3], [1, 2, 3]])
>>> other = mindspore.tensor([[4, 5, 6], [4, 5, 6], [4, 5, 6]])
>>> mindspore.mint.cross(input, other)
Tensor(shape=[3, 3], dtype=Int64, value=
[[0, 0, 0],
 [0, 0, 0],
 [0, 0, 0]])
>>> mindspore.mint.cross(input, other, dim=1)
Tensor(shape=[3, 3], dtype=Int64, value=
[[-3,  6, -3],
 [-3,  6, -3],
 [-3,  6, -3]])
```

mindspore.mint.diff

mindspore.mint.**diff**(*input*, *n=1*, *dim=- 1*, *prepend=None*, *append=None*)

Computes the n-th forward difference along the given dimension.

The first-order differences are given by $out[i] = input[i+1] - input[i]$. Higher-order differences are calculated by using *diff* recursively.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) – the tensor to compute the differences on.
- **n** (*int, optional*) – the number of times to recursively compute the difference. Default: `1` .
- **dim** (*int, optional*) – the dimension to compute the difference along. Default is the last dimension. Default: `0` .
- **prepend** (Tensor, *optional*) – values to prepend or append to *input* along *dim* before computing the difference. Their dimensions must be equivalent to that of input, and their shapes must match input's shape except on *dim*. Default: `None` .
- **append** (Tensor, *optional*) – values to prepend or append to *input* along *dim* before computing the difference. Their dimensions must be equivalent to that of input, and their shapes must match input's shape except on *dim*. Default: `None` .

Returns

Tensor, the result of n-th forward difference computation.

Raises

- **TypeError** – If *input* is not a tensor.
- **TypeError** – If *n* is not a scalar or scalar tensor.
- **TypeError** – If *dim* is not a scalar or scalar tensor.
- **TypeError** – If *input* type is complex64, complex128, float64, int16.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor, mint
>>> x = Tensor([1, 3, -1, 0, 4])
>>> out = mint.diff(x)
>>> print(out.asnumpy())
[ 2 -4  1  4]
```

mindspore.mint.div

mindspore.mint.**div**(*input*, *other*, *, *rounding_mode=None*) → *Tensor*

Divides each element of the *input* by the corresponding element of the *other* .

$$out_i = input_i / other_i$$

Note:

- When the two inputs have different shapes, they must be able to broadcast to a common shape.
- The two inputs can not be bool type at the same time, [True, Tensor(True, bool_), Tensor(np.array([True]), bool_)] are all considered bool type.
- The two inputs comply with the implicit type conversion rules to make the data types consistent.

Parameters

- **input** (*Union[Tensor, Number, bool]*) – The dividend.
- **other** (*Union[Tensor, Number, bool]*) – The divisor.

Keyword Arguments

rounding_mode (*str, optional*) – Type of rounding applied to the result. Default: None . Three types are defined as,

- None: Default behavior, which is the same as true division in Python or *true_divide* in NumPy.
- "floor": Rounds the division of the inputs down, which is the same as floor division in Python or *floor_divide* in NumPy.
- "trunc": Rounds the division of the inputs towards zero, which is the same as C-style integer division.

Returns

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Raises

- **TypeError** – If *input* and *other* is not one of the following: Tensor, Number, bool.
- **ValueError** – If *rounding_mode* value is not None, "floor" or "trunc".

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([1.0, 2.0, 3.0]), mindspore.float32)
>>> y = Tensor(np.array([4.0, 5.0, 6.0]), mindspore.float32)
>>> output = mint.div(x, y)
>>> print(output)
[0.25 0.4 0.5]
```

mindspore.mint.divide

mindspore.mint.**divide**(*input*, *other*, *, *rounding_mode=None*)

Alias for *mindspore.mint.div()* .

Supported Platforms:

Ascend

mindspore.mint.erf

mindspore.mint.**erf**(*input*)

Compute the Gauss error of input tensor element-wise.

$$\text{erf}(x) = \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> # The datatype of output will be float32 when datatype of input is in [int64,␣
↪bool](Datatype only supported on Ascend).
>>> input = mindspore.tensor([-1, 0, 1, 2, 3], mindspore.int64)
>>> mindspore.mint.erf(input)
Tensor(shape=[5], dtype=Float32, value= [-8.42700793e-01,  0.00000000e+00,  8.42700793e-01, ␣
↪9.95322265e-01,  9.99977910e-01])
>>>
>>> # Otherwise output has the same dtype as the input.
>>> input = mindspore.tensor([-1, 0, 1, 2, 3], mindspore.float64)
>>> mindspore.mint.erf(input)
Tensor(shape=[5], dtype=Float64, value= [-8.42700793e-01,  0.00000000e+00,  8.42700793e-01, ␣
↪9.95322265e-01,  9.99977910e-01])
```

mindspore.mint.erfc

mindspore.mint.**erfc**(*input*)

Compute the complementary error function of input tensor element-wise.

$$\operatorname{erfc}(x) = 1 - \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> # The datatype of output will be float32 when datatype of input is in [int64,␣
↪bool](Datatype only supported on Ascend).
>>> input = mindspore.tensor([-1, 0, 1, 2, 3], mindspore.int64)
>>> mindspore.mint.erfc(input)
Tensor(shape=[5], dtype=Float32, value= [ 1.84270079e+00,  1.00000000e+00,  1.57299207e-01, ␣
↪4.67773498e-03,  2.20904970e-05])
>>>
>>> # Otherwise output has the same dtype as the input.
>>> input = mindspore.tensor([-1, 0, 1, 2, 3], mindspore.float64)
>>> mindspore.mint.erfc(input)
Tensor(shape=[5], dtype=Float64, value= [ 1.84270079e+00,  1.00000000e+00,  1.57299207e-01, ␣
↪4.67773498e-03,  2.20904970e-05])
```

mindspore.mint.erfinv

mindspore.mint.**erfinv**(*input*)

Compute the inverse error of input tensor element-wise.

It is defined in the range *(-1, 1)* as:

$$erfinv(erf(x)) = x$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> # When the `input` is int8, int16, int32, int64, uint8 or bool, the return value type is␣
↪float32.
>>> input = mindspore.tensor([0, 0.5, -0.9], mindspore.int64)
>>> mindspore.mint.erfinv(input)
Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  0.00000000e+00,  0.00000000e+00])
>>> # Otherwise, the return value type is the same as the input type.
>>> input = mindspore.tensor([0, 0.5, -0.9], mindspore.float32)
>>> mindspore.mint.erfinv(input)
Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  4.76936132e-01, -1.16308689e+00])
```

mindspore.mint.exp

mindspore.mint.**exp**(*input*)

Compute exponential of the input tensor element-wise.

$$out_i = e^{x_i}$$

Parameters

input (Tensor) −The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.0, 1.0, 3.0], mindspore.float32)
>>> output = mindspore.mint.exp(input)
>>> print(output)
[ 1.        2.7182817 20.085537]
```

mindspore.mint.exp2

mindspore.mint.**exp2**(*input*)

Calculates the base-2 exponent of the Tensor *input* element by element.

$$out_i = 2^{input_i}$$

Parameters

input (Tensor) −The input Tensor.

Returns

Tensor, which has the same shape as the *input*.

Raises

TypeError – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([0.0, 1.0, 2.0, 4.0]), mindspore.float32)
>>> output = mint.exp2(x)
>>> print(output)
[ 1. 2. 4. 16.]
```

mindspore.mint.expm1

mindspore.mint.**expm1**(*input*)

Compute exponential of the input tensor, then minus 1, element-wise.

$$out_i = e^{x_i} - 1$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.0, 1.0, 3.0], mindspore.float32)
>>> output = mindspore.mint.expm1(input)
>>> print(output)
[ 0.         1.7182817 19.085537 ]
```

mindspore.mint.fix

mindspore.mint.**fix**(*input*)

Alias for *mindspore.mint.trunc()*.

For more details, see *mindspore.mint.trunc()*.

Supported Platforms:

Ascend

mindspore.mint.float_power

mindspore.mint.**float_power**(*input*, *exponent*)

Computes *input* to the power of *exponent* element-wise in double precision, and always returns a mindspore.float64 tensor.

$$out_i = input_i^{exponent_i}$$

Warning: This is an experimental API that is subject to change or deletion.

Note: Unlike *ops.pow*, this function always uses double precision for calculations, while the precision of *ops.pow* depends on type promotion. Currently, this function does not support complex number calculations. Since float64 calculations are significantly slower on ascend devices compared to other data types, it is strongly recommended to use this function only in scenarios where double precision is required and performance is not a priority. Otherwise, using *ops.pow* is a better choice.

Parameters

- **input** (*Union[Tensor, Number]*) – The first input is a tensor or a number.
- **exponent** (*Union[Tensor, Number]*) – The second input, if the first input is Tensor, the second input can be Number or Tensor. Otherwise, it must be a Tensor.

Returns

Tensor, the shape is the same as the one after broadcasting, the return value type is mindspore.float64.

Raises

- **TypeError** – If neither *input* nor *exponent* is a Tensor.
- **TypeError** – If the data type of *input* or *exponent* is neither a tensor nor a number, or it contains complex numbers.
- **ValueError** – If *input* and *exponent* have different shapes and cannot be broadcasted to each other.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import Tensor, mint
>>> input = Tensor([1, 2, 3])
>>> mint.float_power(input, 2)
Tensor(shape=[3], dtype=Float64, value= [ 1.00000000e+00,  4.00000000e+00,  9.00000000e+00])
>>>
>>> exp = Tensor([2, -3, -4])
>>> mint.float_power(input, exp)
Tensor(shape=[3], dtype=Float64, value= [ 1.00000000e+00,  1.25000000e-01,  1.23456790e-02])
```

mindspore.mint.floor

mindspore.mint.**floor**(*input*)

Rounds a tensor down to the closest integer element-wise.

$$out_i = \lfloor input_i \rfloor$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1.1, 2.5, -1.5])
>>> output = mindspore.mint.floor(input)
>>> print(output)
[ 1.  2. -2.]
```

mindspore.mint.fmod

mindspore.mint.**fmod**(*input*, *other*) → *Tensor*

Computes the floating-point remainder of the division operation input/other.

$$out = input - n * other$$

Where n is $input/other$ with its fractional part truncated. The returned value has the same sign as *input* and is less than *other* in magnitude.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) – the dividend.
- **other** (*Union[Tensor, Number]*) – the divisor.

Returns

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Raises

TypeError – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([-4., -3.5, 0, 3.5, 4]), mindspore.float32)
>>> output = mint.fmod(input, 2.5)
>>> print(output)
[-1.5 -1.   0.   1.   1.5]
```

mindspore.mint.frac

mindspore.mint.**frac**(*input*)

Calculates the fractional part of each element in the input.

$$out_i = input_i - \lfloor |input_i| \rfloor * sgn(input_i)$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

input (Tensor) – The input Tensor.

Returns

Tensor, has the same shape and type as input.

Raises

TypeError – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor([2, 4.2, -2.5], mindspore.float16)
>>> output = mint.frac(x)
>>> print(output)
  [ 0.      0.1992 -0.5   ]
```

mindspore.mint.lerp

mindspore.mint.**lerp**(*input*, *end*, *weight*) → *Tensor*

Perform a linear interpolation of two tensors input and end based on a float or tensor weight.

If *weight* is a tensor, the shapes of three inputs need to be broadcast; If *weight* is a float, the shapes of *input* and *end* need to be broadcast. If *weight* is a float and platform is Ascend, the types of *input* and *end* need to be float32.

Warning: This is an experimental API that is subject to change or deletion.

$$output_i = input_i + weight_i * (end_i - input_i)$$

Parameters

- **input** (Tensor) –The tensor with the starting points. Data type must be float16 or float32.
- **end** (Tensor) –The tensor with the ending points. Data type must be the same as *input*.
- **weight** (*Union[float, Tensor]*) –The weight for the interpolation formula. Must be a float scalar or a tensor with float16 or float32 data type.

Returns

Tensor, has the same type and shape as input *input*.

Raises

- **TypeError** –If *input* or *end* is not a tensor.
- **TypeError** –If *weight* is neither scalar(float) nor tensor.
- **TypeError** –If dtype of *input* or *end* is neither float16 nor float32.
- **TypeError** –If dtype of *weight* is neither float16 nor float32 when it is a tensor.
- **TypeError** –If *input* and *end* have different data types.
- **TypeError** –If *input*, *end* and *weight* have different data types when *weight* is a tensor.
- **ValueError** –If *end* could not be broadcast to a tensor with shape of *input*.
- **ValueError** –If *weight* could not be broadcast to tensors with shapes of *input* and *end* when it is a tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> start = Tensor(np.array([1., 2., 3., 4.]), mindspore.float32)
>>> end = Tensor(np.array([10., 10., 10., 10.]), mindspore.float32)
>>> output = mint.lerp(start, end, 0.5)
>>> print(output)
[5.5 6. 6.5 7. ]
```

mindspore.mint.log

mindspore.mint.**log**(*input*)

Compute the natural logarithm of the input tensor element-wise.

$$y_i = \log_e(x_i)$$

Warning: If the input value of operator Log is within the range (0, 0.01] or [0.95, 1.05], the output accuracy may be affacted.

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1.0, 2.0, 4.0], mindspore.float32)
>>> output = mindspore.mint.log(x)
>>> print(output)
[0.        0.6931472 1.3862944]
```

mindspore.mint.log1p

mindspore.mint.**log1p**(*input*)

Compute the natural logarithm of (tensor + 1) element-wise.

$$out_i = \log_e(input_i + 1)$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1.0, 2.0, 4.0], mindspore.float32)
>>> output = mindspore.mint.log1p(x)
>>> print(output)
[0.6931472 1.0986123 1.609438 ]
```

mindspore.mint.log2

mindspore.mint.**log2**(*input*)

Returns the logarithm to the base 2 of a tensor element-wise.

$$y_i = \log_2(x_i)$$

Warning:

- If the input value of operator Log2 is within the range (0, 0.01] or [0.95, 1.05], the output accuracy may be affacted.

Parameters

input (Tensor) – Input Tensor of any dimension. The value must be greater than 0.

Returns

Tensor, has the same shape as the *input*. If *input.dtype* is of integer or boolean type, the output dtype will be float32. Otherwise, the output dtype will be the same as *input.dtype*.

Raises

TypeError – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([3.0, 5.0, 7.0]), mindspore.float32)
>>> output = mint.log2(x)
>>> print(output)
[1.5849625 2.321928  2.807355 ]
```

mindspore.mint.log10

mindspore.mint.**log10**(*input*)

Returns the logarithm to the base 10 of a tensor element-wise.

$$y_i = \log_{10}(x_i)$$

Warning:

- This is an experimental API that is subject to change or deletion.
- If the input value of operator Log10 is within the range (0, 0.01] or [0.95, 1.05], the output accuracy may be affacted.

Parameters

input (Tensor) – Input Tensor of any dimension. The value must be greater than 0.

Returns

Tensor, has the same shape as the *input*, and the dtype changes according to the *input.dtype*.

- if *input.dtype* is in [float16, float32, float64, bfloat16], the output dtype is the same as the *input.dtype*.
- if *input.dtype* is integer or boolean type, the output dtype is float32.

Raises

TypeError – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([3.0, 5.0, 7.0]), mindspore.float32)
>>> output = mint.log10(x)
>>> print(output)
[0.47712136 0.69897    0.845098  ]
```

mindspore.mint.logaddexp

mindspore.mint.**logaddexp**(*input*, *other*)

Computes the logarithm of the sum of exponentiations of the inputs. This function is useful in statistics where the calculated probabilities of events may be so small as to exceed the range of normal floating point numbers.

$$out_i = \log(exp(input_i) + \exp(other_i))$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –Input Tensor. The dtype of *input* must be float.
- **other** (Tensor) –Input Tensor. The dtype of *other* must be float. If the shape of *input* is not equal to the shape of *other*, they must be broadcastable to a common shape.

Returns

Tensor, with the same dtype as *input* and *other*.

Raises

- **TypeError** –If *input* or *other* is not a Tensor.
- **TypeError** –The dtype of *input* or *other* is not float.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x1 = Tensor(np.array([1, 2, 3]).astype(np.float16))
>>> x2 = Tensor(np.array(2).astype(np.float16))
>>> output = mint.logaddexp(x1, x2)
>>> print(output)
[2.312 2.693 3.312]
```

mindspore.mint.logaddexp2

mindspore.mint.**logaddexp2**(*input*, *other*)

Logarithm of the sum of exponentiations of the inputs in base of 2.

$$out_i = \log_2(2^{input_i} + 2^{other_i})$$

Parameters

- **input** (Tensor) –Input Tensor. The dtype of *input* must be float.
- **other** (Tensor) –Input Tensor. The dtype of *other* must be float. If the shape of *input* is not equal to the shape of *other*, they must be broadcastable to a common shape (which becomes the shape of the output).

Returns

Tensor, with the same dtype as *input* and *other*.

Raises

- **TypeError** –If *input* or *other* is not a Tensor.
- **TypeError** –The dtype of *input* or *other* is not float.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x1 = Tensor(np.array([1, 2, 3]).astype(np.float16))
>>> x2 = Tensor(np.array(2).astype(np.float16))
>>> output = mint.logaddexp2(x1, x2)
>>> print(output)
[2.586 3. 3.586]
```

mindspore.mint.logical_and

mindspore.mint.**logical_and**(*input*, *other*)

Compute the "logical AND" of two tensors element-wise.

$$out_i = input_i \wedge other_i$$

Note:

- Broadcasting is supported.
- Support implicit type conversion.

Parameters

- **input** (*Union[Tensor, bool]*) – The first input.
- **other** (*Union[Tensor, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([True, False, True], mindspore.bool_)
>>> y = mindspore.tensor([True, True, False], mindspore.bool_)
>>> output = mindspore.mint.logical_and(x, y)
>>> print(output)
[ True False False]
>>> x = mindspore.tensor(1, mindspore.bool_)
>>> y = mindspore.tensor(0, mindspore.bool_)
>>> output = mindspore.mint.logical_and(x, y)
>>> print(output)
False
>>> x = True
>>> y = mindspore.tensor(0, mindspore.bool_)
>>> output = mindspore.mint.logical_and(x, y)
```

(continues on next page)

(continued from previous page)

```
>>> print(output)
False
>>> x = True
>>> y = mindspore.tensor([True, False], mindspore.bool_)
>>> output = mindspore.mint.logical_and(x, y)
>>> print(output)
[True False]
```

mindspore.mint.logical_not

mindspore.mint.**logical_not**(*input*)

Compute the "logical NOT" of the input tensor element-wise.

$$out_i = \neg input_i$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([True, False, True], mindspore.bool_)
>>> output = mindspore.mint.logical_not(x)
>>> print(output)
[False  True False]
```

mindspore.mint.logical_or

mindspore.mint.**logical_or**(*input*, *other*)

Compute the "logical OR" of two tensors element-wise.

$$out_i = input_i \vee other_i$$

Note:

- Broadcasting is supported.
- Support implicit type conversion.

Parameters

- **input** (*Union[Tensor, bool]*) – The first input.

- **other** (*Union[Tensor, bool]*) –The second input.

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([True, False, True], mindspore.bool_)
>>> y = mindspore.tensor([True, True, False], mindspore.bool_)
>>> output = mindspore.mint.logical_or(x, y)
>>> print(output)
[ True  True  True]
>>> x = mindspore.tensor(1, mindspore.bool_)
>>> y = mindspore.tensor(0, mindspore.bool_)
>>> output = mindspore.mint.logical_or(x, y)
>>> print(output)
True
>>> x = True
>>> y = mindspore.tensor(0, mindspore.bool_)
>>> output = mindspore.mint.logical_or(x, y)
>>> print(output)
True
>>> x = True
>>> y = mindspore.tensor([True, False], mindspore.bool_)
>>> output = mindspore.mint.logical_or(x, y)
>>> print(output)
[True True]
```

mindspore.mint.logical_xor

mindspore.mint.**logical_xor**(*input*, *other*)

Compute the "logical XOR" of two tensors element-wise.

$$out_i = input_i \oplus other_i$$

Note:

- Broadcasting is supported.
- Support implicit type conversion.

Parameters

- **input** (Tensor) –The first input tensor.
- **other** (Tensor) –The second input tensor.

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([True, False, True], mindspore.bool_)
>>> y = mindspore.tensor([True, True, False], mindspore.bool_)
>>> output = mindspore.mint.logical_xor(x, y)
>>> print(output)
[False  True  True]
>>> x = mindspore.tensor(1, mindspore.bool_)
>>> y = mindspore.tensor(0, mindspore.bool_)
>>> output = mindspore.mint.logical_xor(x, y)
>>> print(output)
True
>>> x = True
>>> y = mindspore.tensor(0, mindspore.bool_)
>>> output = mindspore.mint.logical_xor(x, y)
>>> print(output)
True
>>> x = True
>>> y = mindspore.tensor([True, False], mindspore.bool_)
>>> output = mindspore.mint.logical_xor(x, y)
>>> print(output)
[False  True]
```

mindspore.mint.mul

`mindspore.mint.`**`mul`**(*input*, *other*)

Multiply other value by input Tensor.

$$out_i = input_i \times other_i$$

Note:

- When the two inputs have different shapes, they must be able to broadcast to a common shape.
- The two inputs comply with the implicit type conversion rules to make the data types consistent.

Parameters

- **`input`** (*Union[Tensor, number.Number, bool]*) – The first input is a number.Number or a bool or a tensor whose data type is number or bool_.
- **`other`** (*Union[Tensor, number.Number, bool]*) – The second input, is a number.Number or a bool or a tensor whose data type is number or bool_.

Returns

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Raises

TypeError –If the type of *input*, *other* is not one of the following: Tensor, number.Number, bool.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> x = Tensor(np.array([2, 6, 9]).astype(np.int32))
>>> y = Tensor(np.array([4, 5, 6]).astype(np.float32))
>>> output = mint.mul(x, y)
>>> print(output)
[8. 30. 54.]
>>> # the data type of x is int32, the data type of y is float32,
>>> # and the output is the data format of higher precision float32.
>>> print(output.dtype)
Float32
```

mindspore.mint.mv

mindspore.mint.**mv**(*input*, *vec*)

Multiply matrix *input* and vector *vec*. If *input* is a tensor with shape (N, M) and *vec* is a tensor with shape $(M,)$, The output is a 1-D tensor which shape is $(N,)$.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input matrix which shape is (N, M) and the rank must be 2-D.
- **vec** (Tensor) –The input vector which shape is $(M,)$ and the rank is 1-D.

Returns

Tensor, the shape is $(N,)$.

Raises

- **TypeError** –If *input* or *vec* is not a tensor.
- **TypeError** –If the dtype of *input* or *vec* is not float16 or float32.
- **TypeError** –If the dtypes of *input* and *vec* are different.
- **ValueError** –If the *input* is not a 2-D tensor or the *vec* is not a 1-D tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[3., 4.], [1., 6.], [1., 3.]]).astype(np.float32))
>>> vec = Tensor(np.array([1., 2.]).astype(np.float32))
>>> output = mint.mv(input, vec)
>>> print(output)
[11. 13. 7.]
```

mindspore.mint.nansum

mindspore.mint.**nansum**(*input*, *dim=None*, *keepdim=False*, *, *dtype=None*) → *Tensor*

Computes sum of *input* over a given dimension, treating NaNs as zero.

> **Warning:** It is only supported on Atlas A2 Training Series Products. This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input Tensor.
- **dim** (*Union[int, tuple(int)], optional*) –The dimensions to sum. Dim must be in the range [-rank(input), rank(input)). Default: None, which indicates the sum of all elements in a tensor.
- **keepdim** (*bool, optional*) –Whether the output Tensor keeps dimensions or not. Default: False, indicating that no dimension is kept.

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The dtype of output Tensor. Default: None.

Returns

Tensor, the sum of input *input* in the given dimension dim, treating NaNs as zero.

- If dim is None, keepdim is False, the output is a 0-D Tensor representing the sum of all elements in the input Tensor.
- If dim is int, set as 2, and keepdim is False, the shape of output is $(input_1, input_3, ..., input_R)$.
- If dim is tuple(int) or list(int), set as (2, 3), and keepdim is False, the shape of output is $(input_1, input_4, ..., input_R)$.

Raises

- **TypeError** –If *input* is not Tensor.
- **TypeError** –If *keepdim* is not a bool.
- **TypeError** –If the dtype of *input* or *dtype* is complex type.
- **ValueError** –If *dim* is not in [-rank(input), rank(input)).

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[float("nan"), 2, 3], [1, 2, float("nan")]]), mindspore.float32)
>>> output1 = mint.nansum(x, dim=0, keepdim=False, dtype=mindspore.float32)
>>> output2 = mint.nansum(x, dim=0, keepdim=True, dtype=mindspore.float32)
>>> print(output1)
[1. 4. 3.]
>>> print(output2)
[[1. 4. 3.]]
```

mindspore.mint.nan_to_num

mindspore.mint.**nan_to_num**(*input*, *nan=None*, *posinf=None*, *neginf=None*)

Replace the *NaN*, positive infinity and negative infinity values in *input* with the specified values in *nan*, *posinf* and *neginf* respectively.

Warning: For Ascend, it is only supported on Atlas A2 Training Series Products. This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input tensor.
- **nan** (*number, optional*) –The replace value of *NaN*. Default None.
- **posinf** (*number, optional*) –the value to replace *posinf* values with. Default None, replacing *posinf* with the maximum value supported by the data type of *input*.
- **neginf** (*number, optional*) –the value to replace *neginf* values with. Default None, replacing *neginf* with the minimum value supported by the data type of *input*.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([float('nan'), float('inf'), -float('inf'), 5.0], mindspore.
↪float32)
>>> output = mindspore.mint.nan_to_num(input)
>>> print(output)
[ 0.0000000e+00  3.4028235e+38 -3.4028235e+38  5.0000000e+00]
>>> output = mindspore.mint.nan_to_num(input, 1.0)
>>> print(output)
[ 1.0000000e+00  3.4028235e+38 -3.4028235e+38  5.0000000e+00]
>>> output = mindspore.mint.nan_to_num(input, 1.0, 2.0)
```

(continues on next page)

(continued from previous page)

```
>>> print(output)
[ 1.0000000e+00  2.0000000e+00 -3.4028235e+38  5.0000000e+00]
>>> output = mindspore.mint.nan_to_num(input, 1.0, 2.0, 3.0)
>>> print(output)
[1.  2.  3.  5.0]
```

mindspore.mint.neg

mindspore.mint.**neg**(*input*)

Returns a tensor with negative values of the input tensor element-wise.

$$out_i = -input_i$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 2, -1, 2, 0, -3.5], mindspore.float32)
>>> output = mindspore.mint.neg(input)
>>> print(output)
[-1.  -2.   1.  -2.   0.   3.5]
```

mindspore.mint.negative

mindspore.mint.**negative**(*input*)

Alias for *mindspore.mint.neg()*.

Supported Platforms:

Ascend

mindspore.mint.pow

mindspore.mint.**pow**(*input*, *exponent*)

Calculates the *exponent* power of each element in *input*.

When *exponent* is a Tensor, the shapes of *input* and *exponent* must be broadcastable.

$$out_i = input_i^{exponent_i}$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (*Union[Tensor, Number]*) –The first input is a Number or a tensor whose data type is number or bool_.
- **exponent** (*Union[Tensor, Number]*) –The second input is a Number or a tensor whose data type is number or bool_.

Returns

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Raises

- **TypeError** –If types of *input* and *exponent* are bool.
- **TypeError** –The *input* is tensor and of type int or bool, while the *exponent* is negative int.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([1.0, 2.0, 4.0]), mindspore.float32)
>>> exponent = 3.0
>>> output = mint.pow(input, exponent)
>>> print(output)
[ 1.  8. 64.]
>>>
>>> input = Tensor(np.array([1.0, 2.0, 4.0]), mindspore.float32)
>>> exponent = Tensor(np.array([2.0, 4.0, 3.0]), mindspore.float32)
>>> output = mint.pow(input, exponent)
>>> print(output)
[ 1. 16. 64.]
```

mindspore.mint.polar

mindspore.mint.**polar**(*abs*, *angle*)

Converts polar coordinates to Cartesian coordinates.

Returns a complex tensor, its elements are Cartesian coordinates constructed with the polar coordinates which is specified by radial distance *abs* and polar angle *angle*.

$$y_i = abs_i * \cos(angle_i) + abs_i * \sin(angle_i) * j$$

Parameters

- **abs** (*Tensor, float*) –Radial distance.
- **angle** (*Tensor, float*) –Polar angle.

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> abs = mindspore.tensor([1, 2], mindspore.float32)
>>> angle = mindspore.tensor([np.pi / 2, 5 * np.pi / 4], mindspore.float32)
>>> output = mindspore.mint.polar(abs, angle)
>>> print(output)
[ -4.3711388e-08+1.j         -1.4142137e+00-1.4142134j]
```

mindspore.mint.ravel

mindspore.mint.**ravel**(*input*)

Expand the multidimensional Tensor into 1D along the 0 axis direction.

Parameters

input (Tensor) – A tensor to be flattened.

Returns

Tensor, a 1-D tensor, containing the same elements of the input.

Raises

TypeError – If argument *input* is not Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[0, 1], [2, 1]]).astype(np.float32))
>>> output = mint.ravel(x)
>>> print(output)
[0. 1. 2. 1.]
>>> print(output.shape)
(4,)
```

mindspore.mint.reciprocal

mindspore.mint.**reciprocal**(*input*)

Returns reciprocal of a tensor element-wise.

$$out_i = \frac{1}{x_i}$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1.0, 2.0, 4.0], mindspore.float32)
>>> output = mindspore.mint.reciprocal(input)
>>> print(output)
[1.   0.5  0.25]
```

mindspore.mint.remainder

mindspore.mint.**remainder**(*input*, *other*) → *Tensor*

Computes the remainder of *input* divided by *other* element-wise. The result has the same sign as the divisor and its absolute value is less than that of *other*.

Supports broadcasting to a common shape and implicit type promotion.

```
remainder(input, other) == input - input.div(other, rounding_mode="floor") * other
```

Note: Complex inputs are not supported. At least one input need to be tensor, but not both are bool tensors.

Parameters

- **input** (*Union[Tensor, numbers.Number, bool]*) –The dividend is a numbers.Number or a bool or a tensor whose data type is number or bool_.
- **other** (*Union[Tensor, numbers.Number, bool]*) –The divisor is a numbers.Number or a bool or a tensor whose data type is number or bool_ when the dividend is a tensor. When the dividend is Scalar, the divisor must be a Tensor whose data type is number or bool_.

Returns

Tensor, with dtype promoted and shape broadcasted.

Raises

- **TypeError** –If *input* and *other* are not of types: (tensor, tensor), (tensor, number), (tensor, bool), (number, tensor) or (bool, tensor).

- **ValueError** –If *input* and *other* are not broadcastable.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([-4.0, 5.0, 6.0]).astype(np.float32))
>>> y = Tensor(np.array([3.0, 2.0, 3.0]).astype(np.float64))
>>> output = mint.remainder(x, y)
>>> print(output)
[2.  1.  0.]
```

mindspore.mint.roll

mindspore.mint.**roll**(*input*, *shifts*, *dims=None*)

Roll the elements of a tensor along a dimension.

Parameters

- **input** (Tensor) –The input tensor.
- **shifts** (*Union[list(int), tuple(int), int]*) –The amount of element shifting.
- **dims** (*Union[list(int), tuple(int), int], optional*) –Specify the dimension to move. Default None , which means the input tensor will be flattened before computation, and the result will be reshaped back to the original input shape.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0, 1, 2, 3, 4], mindspore.float32)
>>> # case1: Parameter `shifts` is positive
>>> output = mindspore.mint.roll(input, shifts=2, dims=0)
>>> print(output)
[3. 4. 0. 1. 2.]
>>> # case2: Parameter `shifts` is negative
>>> output = mindspore.mint.roll(input, shifts=-2, dims=0)
>>> print(output)
[2. 3. 4. 0. 1.]
```

mindspore.mint.round

mindspore.mint.**round**(*input*, *, *decimals=0*)

Round elements of input to the nearest integer.

$$out_i \approx input_i$$

Note: The input data types supported by the Ascend platform include bfloat16 (Atlas training series products are not supported), float16, float32, float64, int32, and int64.

Parameters

input (Tensor) −The input tensor.

Keyword Arguments

decimals (int, *optional*) −Number of decimal places to round. If decimals is negative, it specifies the number of positions to the left of the decimal point. Default 0 .

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> output = mindspore.mint.round(mindspore.tensor([4.7, -2.3, 9.1, -7.7]))
>>> print(output)
[ 5. -2.  9. -8.]
>>> # Values equidistant from two integers are rounded towards the
>>> # the nearest even value (zero is treated as even)
>>> output = mindspore.mint.round(mindspore.tensor([-0.5, 0.5, 1.5, 2.5]))
>>> print(output)
[0. 0.  2.  2.]
>>> # A positive decimals argument rounds to the to that decimal place
>>> output = mindspore.mint.round(mindspore.tensor([0.1234567]), decimals=3)
>>> print(output)
[0.123]
>>> # A negative decimals argument rounds to the left of the decimal
>>> output = mindspore.mint.round(mindspore.tensor([1200.1234567]), decimals=-3)
>>> print(output)
[1000.]
```

mindspore.mint.rsqrt

mindspore.mint.**rsqrt**(*input*)

Compute reciprocal of square root of input tensor element-wise.

$$out_i = \frac{1}{\sqrt{input_i}}$$

Parameters

input (Tensor) −The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([-0.0370,  0.2970,  1.5420, -0.9105])
>>> output = mindspore.mint.rsqrt(input)
>>> print(output)
[       nan 1.8349396  0.8053002        nan]
```

mindspore.mint.sigmoid

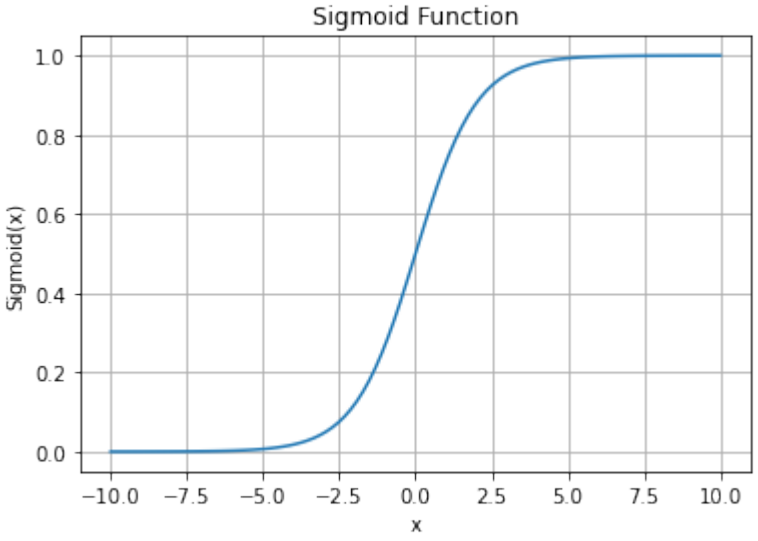
mindspore.mint.**sigmoid**(*input*)

Computes Sigmoid of input element-wise. The Sigmoid function is defined as:

$$\text{sigmoid}(x_i) = \frac{1}{1 + \exp(-x_i)}$$

where x_i is an element of x.

Sigmoid Function Graph:



Parameters

input (Tensor) – *input* is x in the preceding formula. Tensor of any dimension, the data type is float16, float32, float64, complex64 or complex128.

Returns

Tensor, with the same type and shape as the input.

Raises

- **TypeError** – If dtype of *input* is not float16, float32, float64, complex64 or complex128.
- **TypeError** – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> output = mint.sigmoid(input)
>>> print(output)
[0.7310586  0.880797   0.95257413 0.98201376 0.9933072 ]
```

mindspore.mint.sign

mindspore.mint.**sign**(*input*)

Return an element-wise indication of the sign of a number.

$$\text{out}_i = \begin{cases} -1 & \text{input}_i < 0 \\ 0 & \text{input}_i = 0 \\ 1 & \text{input}_i > 0 \end{cases}$$

Note: When the input is NaN and dtype is float64, the output of this operator is NaN.

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[-1, 0, 2, 4, 6], [2, 3, 5, -6, 0]])
>>> output = mindspore.mint.sign(input)
>>> print(output)
[[-1  0  1  1  1]
 [ 1  1  1 -1  0]]
>>> mindspore.set_device(device_target="CPU")
>>> x = mindspore.tensor([[-1, 0, float('inf'), 4, float('nan')], [2, 3, float('-inf'), -6,␣
↪0]])
>>> output = mindspore.mint.sign(x)
>>> print(output)
[[-1.  0.  1.  1.  0.]
 [ 1.  1. -1. -1.  0.]]
```

mindspore.mint.sin

mindspore.mint.**sin**(*input*)

Compute sine of the input tensor element-wise.

$$output_i = \sin(input_i)$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.62, 0.28, 0.43, 0.62], mindspore.float32)
>>> output = mindspore.mint.sin(input)
>>> print(output)
[0.58103514 0.27635565 0.4168708 0.58103514]
```

mindspore.mint.sinc

mindspore.mint.**sinc**(*input*)

Compute the normalized sinc of input.

$$out_i = \begin{cases} \frac{sin(\pi input_i)}{\pi input_i} & input_i \neq 0 \\ 1 & input_i = 0 \end{cases}$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.62, 0.28, 0.43, 0.62], mindspore.float32)
>>> output = mindspore.mint.sinc(input)
>>> print(output)
[0.47735003 0.8759357  0.7224278  0.47735003]
```

mindspore.mint.sinh

`mindspore.mint.`**`sinh`**(*input*)

Compute hyperbolic sine of the input element-wise.

$$output_i = \sinh(input_i)$$

Parameters

`input` (`Tensor`) −The input tensor.

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.62, 0.28, 0.43, 0.62], mindspore.float32)
>>> output = mindspore.mint.sinh(input)
>>> print(output)
[0.6604918  0.28367308 0.44337422 0.6604918 ]
```

mindspore.mint.softmax

`mindspore.mint.`**`softmax`**(*input*, *dim*, *, *dtype=None*)

Alias for *`mindspore.mint.nn.functional.softmax()`*.

Supported Platforms:

`Ascend`

mindspore.mint.sqrt

mindspore.mint.**sqrt**(*input*)

Returns sqrt of a tensor element-wise.

$$out_i = \sqrt{input_i}$$

Parameters

input (Tensor) −The input tensor with a dtype of number.Number.

Returns

Tensor, has the same shape as the *input*.

Raises

TypeError −If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([1.0, 4.0, 9.0]), mindspore.float32)
>>> output = mint.sqrt(input)
>>> print(output)
[1. 2. 3.]
```

mindspore.mint.square

mindspore.mint.**square**(*input*)

Return square of a tensor element-wise.

$$y_i = input_i^2$$

Parameters

input (Tensor) −The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1.0, 2.0, 3.0], mindspore.float32)
>>> output = mindspore.mint.square(input)
>>> print(output)
[1. 4. 9.]
```

mindspore.mint.sub

mindspore.mint.**sub**(*input*, *other*, *, *alpha=1*) → *Tensor*

Subtracts scaled other value from self Tensor.

$$out_i = self_i - alpha \times other_i$$

Note:

- When the two inputs have different shapes, they must be able to broadcast to a common shape.
- The two inputs and alpha comply with the implicit type conversion rules to make the data types consistent.

Parameters

- **input** (*Union[Tensor, number.Number, bool]*) – *input* is a number.Number or a bool or a tensor whose data type is number or bool_.
- **other** (*Union[Tensor, number.Number, bool]*) – *other* is a number.Number or a bool or a tensor whose data type is number or bool_.

Keyword Arguments

alpha (*number.Number, optional*) – A scaling factor applied to *other*, default 1.

Returns

Tensor with a shape that is the same as the broadcasted shape of the self *self* and *other*, and the data type is the one with higher precision or higher digits among the two inputs and alpha.

Raises

- **TypeError** – If the type of *other* or *alpha* is not one of the following: Tensor, number.Number, bool.
- **TypeError** – If *alpha* is of type float but *input* and *other* are not of type float.
- **TypeError** – If *alpha* is of type bool but *input* and *other* are not of type bool.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([4, 5, 6]).astype(np.float32))
>>> y = Tensor(1, mindspore.int32)
>>> alpha = 0.5
>>> output = mint.sub(x, y, alpha=alpha)
>>> print(output)
[3.5 4.5 5.5]
>>> # the data type of x is float32, the data type of y is int32,
>>> # alpha is a float, and the output is the data format of higher precision float32.
>>> print(output.dtype)
Float32
```

mindspore.mint.t

mindspore.mint.**t**(*input*)

Transpose the input tensor.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

input (Tensor) – The input tensor.

Returns

Tensor, transpose 2D tensor, return 1D tensor as it is.

Raises

- **ValueError** – If the dimension of *input* is greater than 2.
- **ValueError** – If *input* is empty.
- **TypeError** – If *input* is not a tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[1, 2, 3], [4, 5, 6]]), mindspore.float32)
>>> output = mint.t(input)
>>> print(output)
[[ 1. 4.]
 [ 2. 5.]
 [ 3. 6.]]
```

mindspore.mint.tan

mindspore.mint.**tan**(*input*)

Computes tangent of *input* element-wise.

$$out_i = \tan(input_i)$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> output = mindspore.mint.tan(mindspore.tensor([-1.0, 0.0, 1.0]))
>>> print(output)
[-1.5574077 0. 1.5574077]
```

mindspore.mint.tanh

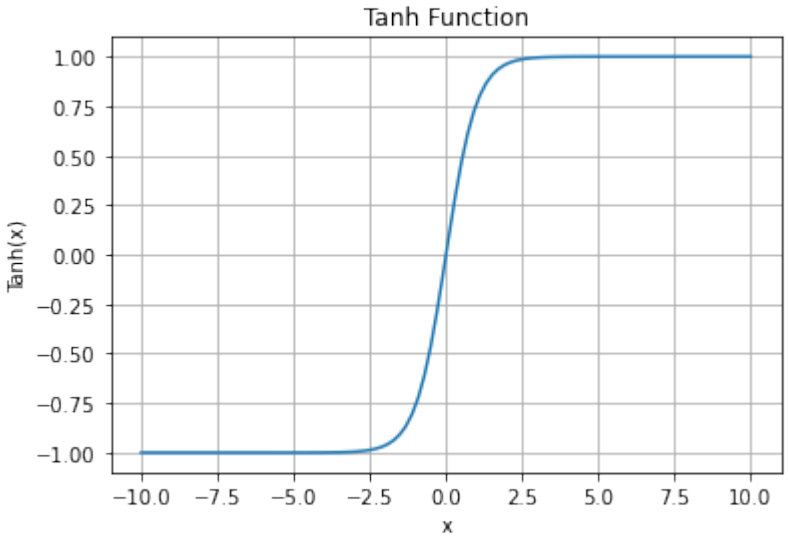
mindspore.mint.**tanh**(*input*)

Computes hyperbolic tangent of input element-wise. The Tanh function is defined as:

$$tanh(x_i) = \frac{\exp(x_i) - \exp(-x_i)}{\exp(x_i) + \exp(-x_i)} = \frac{\exp(2x_i) - 1}{\exp(2x_i) + 1},$$

where x_i is an element of the input Tensor.

Tanh Activation Function Graph:



Parameters

input (Tensor) –Input of Tanh.

Returns

Tensor, with the same type and shape as the *input*.

Raises

TypeError –If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> output = mint.tanh(input)
>>> print(output)
[0.7615941 0.9640276 0.9950547 0.9993293 0.9999092]
```

mindspore.mint.trunc

mindspore.mint.**trunc**(*input*)

Returns a tensor with the truncated integer values of the elements of the input tensor.

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> output = mindspore.mint.trunc(mindspore.tensor([3.4742, 0.5466, -0.8008, -3.9079]))
>>> print(output)
[3. 0. 0. -3.]
```

mindspore.mint.xlogy

mindspore.mint.**xlogy**(*input*, *other*) → *Tensor*

Computes the first input multiplied by the logarithm of second input element-wise. Returns zero when *input* is zero.

$$out_i = input_i \log other_i$$

Inputs of *input* and *other* comply with the implicit type conversion rules to make the data types consistent. The inputs must be two tensors or one tensor and one scalar. When the inputs are two tensors, the shapes of them could be broadcast.

Parameters

- **input** (*Union[Tensor, numbers.Number, bool]*) – The first input is a numbers.Number or a bool or a tensor whose data type is number or bool_.
- **other** (*Union[Tensor, numbers.Number, bool]*) – The second input is a numbers.Number or a bool or a tensor whose data type is number or bool when the first input is a tensor. When the first input is Scalar, the second input must be a Tensor whose data type is number or bool.

Returns

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Raises

- **TypeError** – If *input* and *other* is not a numbers.Number or a bool or a Tensor.
- **ValueError** – If *input* could not be broadcast to a tensor with shape of *other*.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([-5, 0, 4]), mindspore.float32)
>>> other = Tensor(np.array([2, 2, 2]), mindspore.float32)
>>> output = mint.xlogy(input, other)
>>> print(output)
[-3.465736   0.        2.7725887]
```

4.3.2 Reduction Operations

API Name	Description	Supported Platforms
mindspore.mint.amax	Computes the maximum value of of all elements along the specified *dim* dimension of the *input*, and retains the dimension based on the *keepdim* parameter.	Ascend
mindspore.mint.amin	Computes the minimum value of of all elements along the specified *dim* dimension of the *input*, and retains the dimension based on the *keepdim* parameter.	Ascend

continues on next page

Table 5 – continued from previous page

mindspore.mint.argmax	Return the indices of the maximum values of a tensor.	Ascend
mindspore.mint.argmin	Return the indices of the minimum values of a tensor across a dimension.	Ascend
mindspore.mint.argsort	Sorts the input tensor along the given dimension in specified order and return the sorted indices.	Ascend
mindspore.mint.all	Tests if all element in *input* evaluates to *True*.	Ascend
mindspore.mint.any	Tests if any element in *input* evaluates to *True* along the given axes.	Ascend
mindspore.mint.cumprod	Return the cumulative product along the given dimension of the tensor.	Ascend
mindspore.mint.histc	Computes the histogram of a tensor.	Ascend
mindspore.mint.logsumexp	Computes the logarithm of the sum of exponentiations of all elements along the specified *dim* dimension of the *input* (with numerical stabilization), and retains the dimension based on the *keepdim* parameter.	Ascend
mindspore.mint.max	Returns the maximum value of the input tensor.	Ascend
mindspore.mint.mean	Reduces all dimension of a tensor by averaging all elements.	Ascend
mindspore.mint.median	Output the median on the specified dimension `dim` and its corresponding index.	Ascend
mindspore.mint.min	Returns the minimum value of the input tensor.	Ascend
mindspore.mint.norm	Returns the matrix norm or vector norm of a given tensor.	Ascend
mindspore.mint.prod	Multiplying all elements of input.	Ascend
mindspore.mint.sum	Calculate sum of all elements in Tensor.	Ascend
mindspore.mint.std	Calculates the standard deviation over the dimensions specified by *dim*.	Ascend
mindspore.mint.std_mean	By default, return the standard deviation and mean of each dimension in Tensor.	Ascend
mindspore.mint.unique	Returns the unique elements of input tensor.	Ascend
mindspore.mint.var	Calculates the variance over the dimensions specified by *dim*.	Ascend
mindspore.mint.var_mean	By default, return the variance and mean of each dimension in Tensor.	Ascend

mindspore.mint.amax

mindspore.mint.**amax**(*input*, *dim=()*, *keepdim=False*)

Computes the maximum value of of all elements along the specified *dim* dimension of the *input*, and retains the dimension based on the *keepdim* parameter.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) – Input tensor.
- **dim** (*Union[int, tuple(int), list(int)], optional*) – The dimension to be reduced, the value should be within *[-len(input.shape), len(input.shape) - 1]*, when the *dim* is *()*, all dimensions are reduced, default: `()`.

- **keepdim** (*bool, optional*) –Whether the output tensor retains the dimension *dim*, default: `False`.

Returns

Tensor, has same type as *input*, and the shape changes according to the values of *dim* and *keepdim*.

- If *dim* is *()*, and *keepdim* is False, the output is a 0-D tensor representing the maximum value of all elements in the *input* tensor.
- If *dim* is *1*, and *keepdim* is False, the shape of output is $(input.shape[0], input.shape[2], ..., input.shape[n])$.
- If *dim* is *(1, 2)*, and *keepdim* is False, the shape of output is $(input.shape[0], input.shape[3], ..., input.shape[n])$.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *dim* is not an int or tuple(int) or list(int).
- **TypeError** –If *keepdim* is not a bool.
- **ValueError** –If the value of any elements of *dim* is not in the range *[-len(input.shape), len(input.shape) - 1]*.
- **RuntimeError** –If any element of *dim* is repeated.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> x = Tensor(np.random.randn(3, 4, 5, 6).astype(np.float32))
>>> output = mint.amax(x, 1, keepdim=True)
>>> result = output.shape
>>> print(result)
(3, 1, 5, 6)
>>> # case 1: Reduces a dimension by the maximum value of all elements in the dimension.
>>> x = Tensor(np.array([[[1, 1, 1, 1, 1, 1], [2, 2, 2, 2, 2, 2], [3, 3, 3, 3, 3, 3]],
... [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
... [[7, 7, 7, 7, 7, 7], [8, 8, 8, 8, 8, 8], [9, 9, 9, 9, 9, 9]]]),
... mindspore.float32)
>>> output = mint.amax(x)
>>> print(output)
9.0
>>> print(output.shape)
()
>>> # case 2: Reduces a dimension along axis 0.
>>> output = mint.amax(x, 0, True)
>>> print(output)
[[[7. 7. 7. 7. 7. 7.]
  [8. 8. 8. 8. 8. 8.]
  [9. 9. 9. 9. 9. 9.]]]
>>> # case 3: Reduces a dimension along axis 1.
>>> output = mint.amax(x, 1, True)
>>> print(output)
```

(continues on next page)

(continued from previous page)

```
[[[3. 3. 3. 3. 3. 3.]]

mindspore.mint.amin

mindspore.mint.**amin**(*input*, *dim=()*, *keepdim=False*)

Computes the minimum value of of all elements along the specified *dim* dimension of the *input*, and retains the dimension based on the *keepdim* parameter.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –Input tensor.
- **dim** (*Union[int, tuple(int), list(int)], optional*) –The dimension to be reduced, the value should be within *[-len(input.shape), len(input.shape) - 1]*, when the *dim* is *()*, all dimensions are reduced, default: `()`.
- **keepdim** (*bool, optional*) –Whether the output tensor retains the dimension *dim*, default: `False`.

Returns

Tensor, has same type as *input*, and the shape changes according to the values of *dim* and *keepdim*.

- If *dim* is *()*, and *keepdim* is False, the output is a 0-D tensor representing the minimum value of all elements in the *input* tensor.
- If *dim* is *1*, and *keepdim* is False, the shape of output is $(input.shape[0], input.shape[2], ..., input.shape[n])$.
- If *dim* is *(1, 2)*, and *keepdim* is False, the shape of output is $(input.shape[0], input.shape[3], ..., input.shape[n])$.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *dim* is not an int or tuple(int) or list(int).
- **TypeError** –If *keepdim* is not a bool.
- **ValueError** –If the value of any elements of *dim* is not in the range *[-len(input.shape), len(input.shape) - 1]*.
- **RuntimeError** –If any element of *dim* is repeated.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> x = Tensor(np.random.randn(3, 4, 5, 6).astype(np.float32))
>>> output = mint.amin(x, 1, keepdim=True)
>>> result = output.shape
>>> print(result)
(3, 1, 5, 6)
>>> # case 1: Reduces a dimension by the minimum value of all elements in the dimension.
>>> x = Tensor(np.array([[[1, 1, 1, 1, 1, 1], [2, 2, 2, 2, 2, 2], [3, 3, 3, 3, 3, 3]],
... [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
... [[7, 7, 7, 7, 7, 7], [8, 8, 8, 8, 8, 8], [9, 9, 9, 9, 9, 9]]]),
... mindspore.float32)
>>> output = mint.amin(x)
>>> print(output)
1.0
>>> print(output.shape)
()
>>> # case 2: Reduces a dimension along axis 0.
>>> output = mint.amin(x, 0, True)
>>> print(output)
[[[1. 1. 1. 1. 1. 1.]
  [2. 2. 2. 2. 2. 2.]
  [3. 3. 3. 3. 3. 3.]]]
>>> # case 3: Reduces a dimension along axis 1.
>>> output = mint.amin(x, 1, True)
>>> print(output)
[[[1. 1. 1. 1. 1. 1.]]
 [[4. 4. 4. 4. 4. 4.]]
 [[7. 7. 7. 7. 7. 7.]]]
>>> # case 4: Reduces a dimension along axis 2.

  [3.]]
 [[4.]
  [5.]
  [6.]]
 [[7.]
  [8.]
  [9.]]]
```

mindspore.mint.argmax

mindspore.mint.**argmax**(*input*) → *Tensor*

Return the indices of the maximum values of a tensor.

Parameters

input (Tensor) – Input tensor.

Returns

Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> x = Tensor(np.array([[1, 20, 5], [67, 8, 9], [130, 24, 15]]).astype(np.float32))
>>> output = mint.argmax(x)
>>> print(output)
6
```

mindspore.mint.**argmax**(*input*, *dim*, *keepdim=False*) → *Tensor*

Return the indices of the maximum values of a tensor across a dimension.

Parameters

- **input** (Tensor) – Input tensor.
- **dim** (*int*) – The dimension to reduce.
- **keepdim** (*bool, optional*) – Whether the output tensor retains the specified dimension. Default: False .

Returns

Tensor, indices of the maximum values across a dimension.

Raises

- **TypeError** – If *keepdim* is not bool.
- **ValueError** – If *dim* is out of range.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> x = Tensor(np.array([[1, 20, 5], [67, 8, 9], [130, 24, 15]]).astype(np.float32))
>>> output = mint.argmax(x, dim=-1)
>>> print(output)
[1 0 0]
```

mindspore.mint.argmin

mindspore.mint.**argmin**(*input*, *dim=None*, *keepdim=False*)

Return the indices of the minimum values of a tensor across a dimension.

Parameters

- **input** (Tensor) –Input tensor.
- **dim** (*Union[int, None], optional*) –Specify the axis for calculation. If *dim* is None , the indices of the minimum value within the flattened input will be returned. Default: None .
- **keepdim** (*bool, optional*) –Whether the output tensor retains the specified dimension. Ignored if *dim* is None. Default: False .

Returns

Tensor, indices of the minimum values of the input tensor across a dimension.

Raises

- **TypeError** –If *keepdim* is not bool.
- **ValueError** –If *dim* is out of range.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> x = Tensor(np.array([[1, 20, 5], [67, 8, 9], [130, 24, 15]]).astype(np.float32))
>>> output = mint.argmin(x, dim=-1)
>>> print(output)
[0 1 2]
```

mindspore.mint.argsort

mindspore.mint.**argsort**(*input*, *dim=- 1*, *descending=False*, *stable=False*)

Sorts the input tensor along the given dimension in specified order and return the sorted indices.

> **Warning:** This is an experimental optimizer API that is subject to change.

Parameters

- **input** (Tensor) – The input tensor to sort.
- **dim** (*int, optional*) – The dim to sort along. Default: -1 , means the last dimension. The Ascend backend only supports sorting the last dimension.
- **descending** (*bool, optional*) – The sort order. If *descending* is True then the elements are sorted in descending order by value. Otherwise sort in ascending order. Default: False .
- **stable** (*bool, optional*) – Whether to use stable sorting algorithm. Default: False.

Returns

Tensor, the indices of sorted input tensor. Data type is int64.

Raises

- **ValueError** – If *dim* is out of range.
- **TypeError** – If dtype of *dim* is not int32.
- **TypeError** – If dtype of *descending* is not bool.
- **TypeError** – If dtype of *stable* is not bool.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[8, 2, 1], [5, 9, 3], [4, 6, 7]]), mindspore.float16)
>>> sort = mint.argsort(x)
>>> print(sort)
[[2 1 0]
 [2 0 1]
 [0 1 2]]
```

mindspore.mint.all

mindspore.mint.**all**(*input*) → *Tensor*

Tests if all element in *input* evaluates to *True*.

Parameters

input (Tensor) –The input Tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[True, False], [True, True]])
>>> output = mindspore.mint.all(input)
>>> print(output)
False
```

mindspore.mint.**all**(*input*, *dim*, *keepdim=False*) → *Tensor*

Tests if all element in *input* evaluates to *True* along the given axes.

Parameters

- **input** (Tensor) –The input tensor.
- **dim** (*Union[int, tuple(int), list(int), Tensor]*) –The dimensions to reduce. If None , all dimensions are reduced. Default None .
- **keepdim** (*bool, optional*) –Whether the output tensor has dim retained or not. Default False .

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[True, False], [True, True]])
>>>
>>> # case 1: Reduces a dimension along dim 1, with keepdim False.
>>> mindspore.mint.all(input, dim=1)
Tensor(shape=[2], dtype=Bool, value= [False,  True])
>>>
>>> # case 2: Reduces a dimension along dim (0, 1), with keepdim False.
>>> mindspore.mint.all(input, dim=(0,1))
Tensor(shape=[], dtype=Bool, value= False)
>>>
```

(continues on next page)

(continued from previous page)

```
>>> # case 3: Reduces a dimension along dim [0, 1], with keepdim True.
>>> mindspore.mint.all(input, dim=[0,1], keepdim=True)
Tensor(shape=[1, 1], dtype=Bool, value=
[[False]])
```

mindspore.mint.any

mindspore.mint.**any**(*input*, *dim=None*, *keepdim=False*)

Tests if any element in *input* evaluates to *True* along the given axes.

Parameters

- **input** (Tensor) – The input tensor.
- **dim** (*Union[int, tuple(int), list(int), Tensor], optional*) – The dimensions to reduce. If None , all dimensions are reduced. Default None .
- **keepdim** (*bool, optional*) – Whether the output tensor has dim retained or not. Default False .

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[True, False], [True, True]])
>>>
>>> # case 1:  By default, mindspore.mint.any tests along all the axes.
>>> mindspore.mint.any(input)
Tensor(shape=[], dtype=Bool, value= True)
>>>
>>> # case 2: Reduces a dimension along dim 1, with keepdim False.
>>> mindspore.mint.any(input, dim=1)
Tensor(shape=[2], dtype=Bool, value= [ True,  True])
>>>
>>> # case 3: Reduces a dimension along dim (0, 1), with keepdim False.
>>> mindspore.mint.any(input, dim=(0,1))
Tensor(shape=[], dtype=Bool, value= True)
>>>
>>> # case 4: Reduces a dimension along dim [0, 1], with keepdim True.
>>> mindspore.mint.any(input, dim=[0,1], keepdim=True)
Tensor(shape=[1, 1], dtype=Bool, value=
[[ True]])
```

mindspore.mint.cumprod

mindspore.mint.**cumprod**(*input*, *dim*, *dtype=None*)

Return the cumulative product along the given dimension of the tensor.

$$y_i = x_1 * x_2 * x_3 * ... * x_i$$

Parameters

- **input** (Tensor) –The input tensor.
- **dim** (*int*) –Specify the dimension for computation.
- **dtype** (*mindspore.dtype*, optional) –The data type returned. Default None .

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([[1, 2, 3],
...                           [4, 5, 6]])
>>> mindspore.mint.cumprod(input, dim=0)
Tensor(shape=[2, 3], dtype=Int64, value=
[[ 1,  2,  3],
 [ 4, 10, 18]])
>>> mindspore.mint.cumprod(input, dim=1)
Tensor(shape=[2, 3], dtype=Int64, value=
[[  1,   2,   6],
 [  4,  20, 120]])
```

mindspore.mint.histc

mindspore.mint.**histc**(*input*, *bins=100*, *min=0*, *max=0*)

Computes the histogram of a tensor.

The elements are sorted into equal width bins between *min* and *max*. If *min* and *max* are both zero, the minimum and maximum values of the data are used.

Elements lower than min or higher than max are ignored.

> **Warning:** This is an experimental API that is subject to change or deletion. If input is int64, valid values fit within int32; exceeding this may cause precision errors.

Parameters

- **input** (Tensor) –the input tensor.
- **bins** (*int, optional*) –Number of histogram bins, optional. If specified, must be positive. Default: 100 .
- **min** (*int, float, optional*) –the lower end of the range (inclusive), optional. Default: 0 .

- **max** (*int, float, optional*) –the upper end of the range (inclusive), optional. Default: `0` .

Returns

A 1-D Tensor, has the same type as *input* with the shape $(bins,)$.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *input* datatype is not in support list.
- **TypeError** –If attr *min* or *max* is not float or int.
- **TypeError** –If attr *bins* is not int.
- **ValueError** –If attr value *min* > *max*.
- **ValueError** –If attr *bins* <= 0.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor, mint
>>> x = Tensor([1., 2, 1])
>>> y = mint.histc(x, bins=4, min=0, max=3)
>>> print(y)
[0 2 1 0]
```

mindspore.mint.logsumexp

`mindspore.mint.`**`logsumexp`**(*input*, *dim*, *keepdim=False*)

Computes the logarithm of the sum of exponentiations of all elements along the specified *dim* dimension of the *input* (with numerical stabilization), and retains the dimension based on the *keepdim* parameter.

$$logsumexp(input) = \log(\sum(e^{input - input_{max}})) + input_{max}$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (`Tensor`) –Input Tensor.
- **dim** (*Union[int, tuple(int), list(int)], optional*) –The dimension to be reduced (the value should be within *[0, len(input.shape) - 1]*), when the *dim* is *()*, all dimensions are reduced.
- **keepdim** (*bool, optional*) –Whether the output tensor retains the dimension *dim*, default: *False*.

Returns

Tensor, the dtype changes according to the *input.dtype*, and the shape changes according to the values of *dim* and *keepdim*.

- If *input.dtype* is in [float16, float32, bfloat16], the output dtype is the same as the *input.dtype*.

- If *input.dtype* is an integer or boolean type, the output dtype is float32.
- If *dim* is (), and *keepdim* is False, the output is a 0-D tensor representing the logarithm of the sum of exponentiations of all elements in the *input* tensor.
- If *dim* is *1*, and *keepdim* is False, the shape of output is $(input.shape[0], input.shape[2], ..., input.shape[n])$.
- If *dim* is *(1, 2)*, and *keepdim* is False, the shape of output is $(input.shape[0], input.shape[3], ..., input.shape[n])$.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If dtype of *input* is not one of: bool, int8, int16, int32, int64, uint8, float16, float32, bfloat16.
- **TypeError** –If *dim* is not an int or tuple(int) or list(list).
- **TypeError** –If *keepdim* is not a bool.
- **ValueError** –If the value of any elements of *dim* is not in the range *[0, len(input.shape) - 1]*.
- **RuntimeError** –If any element of *dim* is repeated.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.random.randn(3, 4, 5, 6).astype(np.float32))
>>> output = mint.logsumexp(x, 1, keepdim=True)
>>> print(output.shape)
(3, 1, 5, 6)
```

mindspore.mint.max

mindspore.mint.**max**(*input*) → *Tensor*

Returns the maximum value of the input tensor.

Parameters

input (Tensor) –The input tensor.

Returns

Scalar Tensor with the same dtype as *input*, the maximum value of the input.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([0.0, 0.4, 0.6, 0.7, 0.1]), mindspore.float32)
>>> output = mint.max(x)
>>> print(output)
0.7
```

mindspore.mint.**max**(*input*, *dim*, *keepdim=False*)

Calculates the maximum value along with the given dim for the input tensor, and returns the maximum values and indices.

Parameters

- **input** (Tensor) –The input tensor, can be any dimension. Set the shape of input tensor as $(input_1, input_2, ..., input_N)$, Complex tensor is not supported.
- **dim** (*int*) –The dimension to reduce.
- **keepdim** (*bool, optional*) –Whether to reduce dimension, if `True` the output will keep the same dimension as the *input* , the output will reduce dimension if `False`. Default: `False`.

Returns

tuple (Tensor), tuple of 2 tensors, containing the maximum value of the self tensor along the given dimension *dim* and the corresponding index.

- **values** (Tensor) - The maximum value of input tensor, with the same shape as *index*, and same dtype as *input*.
- **index** (Tensor) - The index for the maximum value of the input tensor, with dtype int64. If *keepdim* is `True` , the shape of output tensors is $(input_1, input_2, ..., input_{dim-1}, 1, input_{dim+1}, ..., input_N)$. Otherwise, the shape is $(input_1, input_2, ..., input_{dim-1}, input_{dim+1}, ..., input_N)$.

Raises

- **TypeError** –If *input* is not Tensor.
- **TypeError** –If *keepdim* is not a bool.
- **TypeError** –If *dim* is not an int.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([0.0, 0.4, 0.6, 0.7, 0.1]), mindspore.float32)
>>> output, index = mint.max(x, 0, keepdim=True)
>>> print(output, index)
[0.7] [3]
```

mindspore.mint.**max**(*input*, *other*) → *Tensor*

For details, please refer to *mindspore.mint.maximum()*.

mindspore.mint.mean

mindspore.mint.**mean**(*input*, *, *dtype=None*) → *Tensor*

Reduces all dimension of a tensor by averaging all elements.

Parameters

input (*Tensor[Number]*) –The input tensor. The dtype of the tensor to be reduced is number. $(N, *)$ where $*$ means, any number of additional dimensions.

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The desired data type of returned Tensor. Default: None .

Returns

Tensor.

Raises

TypeError –If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[[2, 2, 2, 2, 2, 2], [2, 2, 2, 2, 2, 2], [2, 2, 2, 2, 2, 2]],
... [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
... [[6, 6, 6, 6, 6, 6], [8, 8, 8, 8, 8, 8], [10, 10, 10, 10, 10, 10]]]),
... mindspore.float32)
>>> output = mint.mean(x)
>>> print(output)
5.0
>>> print(output.shape)
()
```

mindspore.mint.**mean**(*input*, *dim*, *keepdim=False*, *, *dtype=None*) → *Tensor*

Reduces all dimension of a tensor by averaging all elements in the dimension, by default. And reduce a dimension of *input* along the specified *dim*. *keepdim* determines whether the dimensions of the output and input are the same.

Note: The *dim* with tensor type is only used for compatibility with older versions and is not recommended.

Parameters

- **input** (*Tensor[Number]*) –The input tensor. The dtype of the tensor to be reduced is number. $(N, *)$ where $*$ means, any number of additional dimensions.
- **dim** (*Union[int, tuple(int), list(int), Tensor]*) –The dimensions to reduce. Only constant value is allowed. Assume the rank of *input* is r, and the value range is [-r,r).
- **keepdim** (*bool*) –If True , keep these reduced dimensions and the length is 1. If False , don't keep these dimensions. Default: False .

Keyword Arguments

dtype (*mindspore.dtype*, optional) −The desired data type of returned Tensor. Default: `None` .

Returns

Tensor.

- If *dim* is int, set as 1, and *keepdim* is `False` , the shape of output is $(input_0, input_2, ..., input_R)$.
- If *dim* is tuple(int) or list(int), set as (1, 2), and *keepdim* is `False` , the shape of output is $(input_0, input_3, ..., input_R)$.
- If *dim* is 1-D Tensor, set as [1, 2], and *keepdim* is `False` , the shape of output is $(input_0, input_3, ..., input_R)$.

Raises

- **TypeError** −If *input* is not a Tensor.
- **TypeError** −If *dim* is not one of the following: int, tuple, list or Tensor.
- **TypeError** −If *keepdim* is not a bool.
- **ValueError** −If *dim* is out of range.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[[2, 2, 2, 2, 2, 2], [2, 2, 2, 2, 2, 2], [2, 2, 2, 2, 2, 2]],
... [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
... [[6, 6, 6, 6, 6, 6], [8, 8, 8, 8, 8, 8], [10, 10, 10, 10, 10, 10]]]),
... mindspore.float32)
>>> output = mint.mean(x, 0, True)
>>> print(output)
[[[4. 4. 4. 4. 4. 4.]
  [5. 5. 5. 5. 5. 5.]
  [6. 6. 6. 6. 6. 6.]]]
```

mindspore.mint.median

`mindspore.mint.`**median**(*input*, *dim=None*, *keepdim=False*)

Output the median on the specified dimension `dim` and its corresponding index. If `dim` is None, calculate the median of all elements in the Tensor.

Parameters

- **input** (`Tensor`) −A Tensor of any dimension whose data type is uint8, int16, int32, int64, float16 or float32.
- **dim** (*int, optional*) −Specify the axis for calculation. Default: `None` .
- **keepdim** (*bool, optional*) −Whether the output tensor need to retain `dim` dimension or not. Default: `False` .

Returns

- y (Tensor) - Output median, with the same data type as `input` .

- If `dim` is `None` , `y` only has one element.
- If `keepdim` is `True` , the `y` has the same shape as the `input` except the shape of `y` in dimension *dim* is size 1.
- Otherwise, the `y` lacks *dim* dimension than input.

- indices (Tensor) - The index of the median. Shape is consistent with `y` , with a data type of int64.

Raises

- **TypeError** –If dtype of `input` is not one of the following: uint8, int16, int32, int64, float16 or float32.
- **TypeError** –If input `input` is not a Tensor.
- **TypeError** –If `dim` is not an int.
- **TypeError** –If `keepdim` is not a bool.
- **ValueError** –If `dim` is not in range of [-x.dim, x.dim-1].

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[0.57, 0.11, 0.21],[0.38, 0.50, 0.57], [0.36, 0.16, 0.44]]).
↪astype(np.float32))
>>> y = mint.median(x, dim=0, keepdim=False)
>>> print(y)
(Tensor(shape=[3], dtype=Float32, value= [ 3.79999995e-01,  1.59999996e-01,  4.39999998e-
↪01]),
Tensor(shape=[3], dtype=Int64, value= [1, 2, 2]))
```

mindspore.mint.min

mindspore.mint.**min**(*input*) → *Tensor*

Returns the minimum value of the input tensor.

Parameters

input (Tensor) –The input tensor.

Returns

Scalar Tensor with the same dtype as *input*, the minimum value of the input.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([0.0, 0.4, 0.6, 0.7, 0.1]), mindspore.float32)
>>> output = mint.min(x)
>>> print(output)
0.0
```

mindspore.mint.**min**(*input*, *dim*, *keepdim=False*) → *Tensor*

Calculates the minimum value along with the given dim for the input tensor, and returns the minimum values and indices.

Parameters

- **input** (Tensor) –$(input_1, input_2, ..., input_N)$, Complex tensor is not supported.
- **dim** (*int*) –The dimension to reduce.
- **keepdim** (*bool, optional*) –Whether to reduce dimension, if `True` the output will keep the same dimension as the input, the output will reduce dimension if `False`. Default: `False`.

Returns

tuple (Tensor), tuple of 2 tensors, containing the minimum value of the self tensor along the given dimension *dim* and the corresponding index.

- **values** (Tensor) - The minimum value of input tensor, with the same shape as *index*, and same dtype as *input*.
- **index** (Tensor) - The index for the minimum value of the input tensor, with dtype int64. If *keepdim* is `True` , the shape of output tensors is $(input_1, input_2, ..., input_{dim-1}, 1, input_{dim+1}, ..., input_N)$. Otherwise, the shape is $(input_1, input_2, ..., input_{dim-1}, input_{dim+1}, ..., input_N)$.

Raises

- **TypeError** –If *input* is not Tensor.
- **TypeError** –If *keepdim* is not a bool.
- **TypeError** –If *dim* is not an int.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([0.0, 0.4, 0.6, 0.7, 0.1]), mindspore.float32)
>>> output, index = mint.min(x, 0, keepdim=True)
>>> print(output, index)
[0.0] [0]
```

mindspore.mint.**min**(*input*, *other*) → *Tensor*

For details, please refer to *mindspore.mint.minimum()*.

mindspore.mint.norm

mindspore.mint.**norm**(*input*, *p='fro'*, *dim=None*, *keepdim=False*, *, *dtype=None*)

Returns the matrix norm or vector norm of a given tensor.

p is the calculation mode of norm. The following norm modes are supported.

p	norm for matrices	norm for vectors
'fro'	Frobenius norm	−not supported −
'nuc'	nuclear norm	−not supported −
other *int* or *float*	−not supported −	$sum(abs(x)^p)^{(1/p)}$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) −The shape is $(*)$ or $(*, m, n)$ where $*$ means, any number of additional dimensions.
- **p** (*Union[bool, int, float, inf, -inf, 'fro', 'nuc'], optional*) −norm's mode. refer to the table above for behavior. Default: `fro` .
- **dim** (*Union[int, List(int), Tuple(int)], optional*) −calculate the dimension of vector norm or matrix norm. Default: `None` .
- **keepdim** (*bool, optional*) −whether the output Tensor retains the original dimension. Default: `False` .

Keyword Arguments

dtype (*mindspore.dtype*, optional) −When set, *input* will be converted to the specified type, *dtype*, before execution, and dtype of returned Tensor will also be *dtype*. Default: `None` .

Returns

Tensor, the result of norm calculation on the specified dimension, *dim*.

Raises

- **TypeError** −If *input* is not a Tensor.
- **ValueError** −If *dim* is out of range.
- **TypeError** −If *dim* is neither an int nor a tuple of int.
- **ValueError** −If two elements of *dim* is same after normalized.
- **ValueError** −If any elements of *dim* is out of range.

Note: Dynamic shape, Dynamic rank and mutable input is not supported in graph mode (mode=mindspore.GRAPH_MODE).

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint, ops
>>> data_range = ops.arange(-13, 13, dtype=ms.float32)
>>> x = data_range[data_range != 0]
>>> y = x.reshape(5, 5)
>>> print(mint.norm(x, 2.0))
38.327538
```

mindspore.mint.prod

mindspore.mint.**prod**(*input*, *, *dtype=None*) → *Tensor*

Multiplying all elements of input.

Parameters

input (Tensor[*Number*]) – The input tensor. The dtype of the tensor to be reduced is number. $(N, *)$ where $*$ means, any number of additional dimensions.

Keyword Arguments

dtype (*mindspore.dtype*, optional) – The desired data type of returned Tensor. Default: None .

Returns

Tensor.

Raises

TypeError – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[[1, 1, 1, 1, 1, 1], [2, 2, 2, 2, 2, 2], [3, 3, 3, 3, 3, 3]],
...                      [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
...                      [[7, 7, 7, 7, 7, 7], [8, 8, 8, 8, 8, 8], [9, 9, 9, 9, 9, 9]]]),␣
↪mindspore.float32)
>>> output = mint.prod(x)
>>> print(output)
2.2833798e+33
>>> print(output.shape)
()
```

mindspore.mint.**prod**(*input*, *dim*, *keepdim=False*, *, *dtype=None*) → *Tensor*

Reduces a dimension of a tensor by multiplying all elements in the dimension, by default. And also can reduce a dimension of *input* along the *dim*. Determine whether the dimensions of the output and input are the same by controlling *keepdim*.

Parameters

- **input** (*Tensor[Number]*) –The input tensor. The dtype of the tensor to be reduced is number. $(N, *)$ where $*$ means, any number of additional dimensions.
- **dim** (*int*) –The dimensions to reduce. Only constant value is allowed. Assume the rank of x is r, and the value range is [-r,r).
- **keepdim** (*bool*) –If `True` , keep these reduced dimensions and the length is 1. If `False` , don't keep these dimensions. Default: `False` .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The desired data type of returned Tensor. Default: `None` .

Returns

Tensor.

- If *dim* is int, set as 1, and *keepdim* is `False` , the shape of output is $(input_0, input_2, ..., input_R)$.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *dim* is not int.
- **TypeError** –If *keepdim* is not a bool.
- **ValueError** –If *dim* is out of range.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[[1, 1, 1, 1, 1, 1], [2, 2, 2, 2, 2, 2], [3, 3, 3, 3, 3, 3]],
...                      [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
...                      [[7, 7, 7, 7, 7, 7], [8, 8, 8, 8, 8, 8], [9, 9, 9, 9, 9, 9]]]),␣
↪mindspore.float32)
>>> output = mint.prod(x, 0, True)
>>> print(output)
[[[ 28.  28.  28.  28.  28.  28.]
  [ 80.  80.  80.  80.  80.  80.]
  [162. 162. 162. 162. 162. 162.]]]
```

mindspore.mint.sum

mindspore.mint.**sum**(*input*, *, *dtype=None*) → *Tensor*

Calculate sum of all elements in Tensor.

Parameters

input (Tensor) –The input tensor.

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The desired data type of returned Tensor. Default: None .

Returns

A Tensor, sum of all elements in *input*.

Raises

TypeError –If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> from mindspore import dtype as mstype
>>> x = Tensor(np.array([[[1, 1, 1, 1, 1, 1], [2, 2, 2, 2, 2, 2], [3, 3, 3, 3, 3, 3]],
...                      [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
...                      [[7, 7, 7, 7, 7, 7], [8, 8, 8, 8, 8, 8], [9, 9, 9, 9, 9, 9]]]),␣
↪mstype.float32)
>>> out = mint.sum(x)
>>> print(out)
270.0
```

mindspore.mint.**sum**(*input*, *dim*, *keepdim=False*, *, *dtype=None*) → *Tensor*

Calculate sum of Tensor elements over a given dim.

Note: The *dim* with tensor type is only used for compatibility with older versions and is not recommended.

Parameters

- **input** (Tensor) –The input tensor.
- **dim** (*Union[int, tuple(int), list(int), Tensor]*) –Dimensions along which a sum is performed. If the *dim* is a tuple or list of ints, a sum is performed on all the dimensions specified in the tuple. Must be in the range $[-input.ndim, input.ndim)$.
- **keepdim** (*bool*) –Whether the output tensor has *dim* retained or not. If True , keep these reduced dimensions and the length is 1. If False , don't keep these dimensions. Default: False .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The desired data type of returned Tensor. Default: None .

Returns

A Tensor, sum of elements over a given *dim* in *input*.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If *dim* is not an int, tulpe(int), list(int) or Tensor.
- **ValueError** – If *dim* is not in the range $[-input.ndim, input.ndim)$.
- **TypeError** – If *keepdim* is not a bool.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> from mindspore import dtype as mstype
>>> x = Tensor(np.array([[[1, 1, 1, 1, 1, 1], [2, 2, 2, 2, 2, 2], [3, 3, 3, 3, 3, 3]],
...                      [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
...                      [[7, 7, 7, 7, 7, 7], [8, 8, 8, 8, 8, 8], [9, 9, 9, 9, 9, 9]]]),␣
↪mstype.float32)
>>> out = mint.sum(x)
>>> print(out)
270.0
>>> out = mint.sum(x, dim=2)
>>> print(out)
[[ 6. 12. 18.]
 [24. 30. 36.]
 [42. 48. 54.]]
>>> out = mint.sum(x, dim=2, keepdim=True)
>>> print(out)
[[[ 6.]
  [12.]
  [18.]]
 [[24.]
  [30.]
  [36.]]
 [[42.]
  [48.]
  [54.]]]
```

mindspore.mint.std

mindspore.mint.**std**(*input*, *dim=None*, *, *correction=1*, *keepdim=False*)

Calculates the standard deviation over the dimensions specified by *dim*. *dim* can be a single dimension, list of dimensions, or None to reduce over all dimensions.

The standard deviation (σ) is calculated as:

$$\sigma = \sqrt{\frac{1}{N - \delta N}\sum_{j-1}^{N-1}\left(self_{ij} - \overline{x_i}\right)^2}$$

where x is the sample set of elements, $\bar{x}$ is the sample mean, N is the number of samples and δN is the *correction*.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) −The tensor used to calculate the standard deviation.
- **dim** (*None, int, tuple(int), optional*) −The dimension or dimensions to reduce. Defaults to None. If None, all dimensions are reduced.

Keyword Arguments

- **correction** (int, *optional*) −The difference between the sample size and sample degrees of freedom. Defaults to Bessel' s correction. Defaults to 1.
- **keepdim** (bool, *optional*) −Whether the output tensor has dim retained or not. If True , keep these reduced dimensions and the length is 1. If False, don't keep these dimensions. Defaults to False.

Returns

Tensor, the standard deviation. Suppose the shape of *input* is $(x_0, x_1, ..., x_R)$:

- If *dim* is () and *keepdim* is set to False , returns a 0-D Tensor, indicating the standard deviation of all elements in *input*.
- If *dim* is int, e.g. 1 and *keepdim* is set to False , then the returned Tensor has shape $(x_0, x_2, ..., x_R)$.
- If *dim* is tuple(int) or list(int), e.g. (1, 2) and *keepdim* is set to False , then the returned Tensor has shape $(x_0, x_3, ..., x_R)$.

Raises

- **TypeError** −If *input* is not a Tensor.
- **TypeError** −If *input* is not in bfloat16, float16, float32.
- **TypeError** −If *dim* is not one of the followings: None, int, tuple.
- **TypeError** −If *correction* is not an int.
- **TypeError** −If *keepdim* is not a bool.
- **ValueError** −If *dim* is out of range $[-input.ndim, input.ndim)$.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import mint, Tensor
>>> input = Tensor(np.array([[1, 2, 3], [-1, 1, 4]]).astype(np.float32))
>>> output = mint.std(input, dim=1, correction=1, keepdim=False)
>>> print(output)
[1.      2.5166113]
```

mindspore.mint.std_mean

mindspore.mint.**std_mean**(*input*, *dim=None*, *, *correction=1*, *keepdim=False*)

By default, return the standard deviation and mean of each dimension in Tensor. If dim is a dimension list, calculate the standard deviation and mean of the corresponding dimension.

The standard deviation (σ) is calculated as:

$$\sigma = \sqrt{\frac{1}{N-\delta N}\sum_{j=0}^{N-1}\left(self_{ij} - \overline{x_i}\right)^2}$$

where is x the sample set of elements, $\bar{x}$ is the sample mean, N is the number of samples and δN is the *correction* .

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input tensor. Supported dtypes: float16, float32.
- **dim** (*Union[int, tuple(int), list(int)], optional*) –Specify the dimensions for calculating standard deviation and mean. Default value: None.

Keyword Arguments

- **correction** (int, *optional*) –Difference between the sample size and sample degrees of freedom. Defaults to Bessel's correction. Default: 1.
- **keepdim** (bool, *optional*) –Whether to preserve the dimensions of the output Tensor. If True, retain the reduced dimension with a size of 1. Otherwise, remove the dimensions. Default value: False.

Returns

A tuple of standard deviation and mean.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *dim* is not one of the following data types: int, tuple, list, or Tensor.
- **TypeError** –If *keepdim* is not a bool.
- **ValueError** –If *dim* is out of range.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore as ms
>>> input = ms.Tensor([[1, 2, 3, 4], [-1, 1, 4, -10]], ms.float32)
>>> output_std, output_mean = ms.mint.std_mean(input, 1, correction=2, keepdim=True)
>>> print(output_std)
[[1.5811388]
 [7.3824115]]
>>> print(output_mean)
[[ 2.5]
 [-1.5]]
```

mindspore.mint.unique

mindspore.mint.**unique**(*input*, *sorted=True*, *return_inverse=False*, *return_counts=False*, *dim=None*)

Returns the unique elements of input tensor.

when *return_inverse=True*, also return a tensor containing the index of each value of input tensor corresponding to the output unique tensor. when *return_counts=True*, also return a tensor containing the number of occurrences for each unique value or tensor.

Parameters

- **input** (Tensor) –The input tensor.
- **sorted** (*bool, optional*) –Whether to sort the unique elements in ascending order before returning as output. Default: True .
- **return_inverse** (*bool, optional*) –Whether to also return the indices for where elements in the original input ended up in the returned unique list. Default: False .
- **return_counts** (*bool, optional*) –Whether to also return the counts for each unique element. Default: False .
- **dim** (*int, optional*) –the dimension to operate upon. If None, the unique of the flattened input is returned. Otherwise, each of the tensors indexed by the given dimension is treated as one of the elements to apply the unique operation upon. Default: None .

Returns

A tensor or a tuple of tensors containing some of tensor objects (*output*, *inverse_indices*, *counts*).

- output(Tensor) - The output tensor including the unique elements of input tensor, it has same dtype as input.
- inverse_indices(Tensor) - Return when return_inverse is True. It represents the indices for where elements in the original input map to in the output. When dim is None, it has same shape as input, otherwise, the shape is input.shape[dim].
- counts(Tensor) - Return when return_counts is True. It represents the number of occurrences for each unique value or tensor. When dim is None, it has same shape as output, otherwise, the shape is output.shape(dim).

Raises

TypeError –If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> from mindspore import mint
>>> x = Tensor(np.array([1, 2, 5, 2]), mindspore.int32)
>>> output = mint.unique(x, return_inverse=True)
>>> print(output)
(Tensor(shape=[3], dtype=Int32, value= [1, 2, 5]), Tensor(shape=[4], dtype=Int64, value= [0,␣
↪1, 2, 1]))
>>> y = output[0]
>>> print(y)
[1 2 5]
>>> idx = output[1]
>>> print(idx)
[0 1 2 1]
```

mindspore.mint.var

mindspore.mint.**var**(*input*, *dim=None*, *, *correction=1*, *keepdim=False*)

Calculates the variance over the dimensions specified by *dim*. *dim* can be a single dimension, list of dimensions, or None to reduce over all dimensions.

The variance (δ^2) is calculated as:

$$\delta^2 = \frac{1}{\max(0, N - \delta N)} \sum_{i=0}^{N-1} (x_i - \bar{x})^2$$

where x is the sample set of elements, $\bar{x}$ is the sample mean, N is the number of samples and δN is the *correction*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The tensor used to calculate the variance.
- **dim** (*None, int, tuple(int), optional*) –The dimension or dimensions to reduce. Defaults to None. If None, all dimensions are reduced.

Keyword Arguments

- **correction** (int, *optional*) –The difference between the sample size and sample degrees of freedom. Defaults to Bessel' s correction. Defaults to 1.
- **keepdim** (bool, *optional*) –Whether the output tensor has dim retained or not. If True , keep these reduced dimensions and the length is 1. If False, don't keep these dimensions. Defaults to False.

Returns

Tensor, the variance. Suppose the shape of *input* is $(x_0, x_1, ..., x_R)$:

- If *dim* is () and *keepdim* is set to False , returns a 0-D Tensor, indicating the variance of all elements in *input*.
- If *dim* is int, e.g. 1 and *keepdim* is set to False , then the returned Tensor has shape $(x_0, x_2, ..., x_R)$.

- If *dim* is tuple(int) or list(int), e.g. `(1, 2)` and *keepdim* is set to `False` , then the returned Tensor has shape $(x_0, x_3, ..., x_R)$.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *input* is not in bfloat16, float16, flaot32.
- **TypeError** –If *dim* is not one of the followings: None, int, list, tuple.
- **TypeError** –If *correction* is not an int.
- **TypeError** –If *keepdim* is not a bool.
- **ValueError** –If *dim* is out of range $[-input.ndim, input.ndim)$.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input = Tensor([[8, 2, 1], [5, 9, 3], [4, 6, 7]], mindspore.float32)
>>> output = mint.var(input, dim=0, correction=1, keepdim=True)
>>> print(output)
[[ 4.333333, 12.333333, 9.333333]]
```

mindspore.mint.var_mean

mindspore.mint.**var_mean**(*input*, *dim=None*, ***, *correction=1*, *keepdim=False*)

By default, return the variance and mean of each dimension in Tensor. If dim is a dimension list, calculate the variance and mean of the corresponding dimension.

The variance (σ^2) is calculated as:

$$\sigma^2 = \frac{1}{N - \delta N} \sum_{j=0}^{N-1} \left(self_{ij} - \overline{x_i}\right)^2$$

where is x the sample set of elements, $\bar{x}$ is the sample mean, N is the number of samples and δN is the *correction* .

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input tensor. Supported dtypes: float16, float32.
- **dim** (*Union[int, tuple(int), list(int)], optional*) –Specify the dimensions for calculating variance and mean. Default value: `None`.

Keyword Arguments

- **correction** (int, *optional*) –Difference between the sample size and sample degrees of freedom. Defaults to Bessel's correction. Default: `1`.

- **keepdim** (bool, optional) –Whether to preserve the dimensions of the output Tensor. If True, retain the reduced dimension with a size of 1. Otherwise, remove the dimensions. Default value: False.

Returns

A tuple of variance and mean.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *dim* is not one of the following data types: int, tuple, list, or Tensor.
- **TypeError** –If *keepdim* is not a bool.
- **ValueError** –If *dim* is out of range.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore as ms
>>> input = ms.Tensor([[1, 2, 3, 4], [-1, 1, 4, -10]], ms.float32)
>>> output_var, output_mean = ms.mint.var_mean(input, 1, correction=2, keepdim=True)
>>> print(output_var)
[[ 2.5]
 [54.5]]
>>> print(output_mean)
[[ 2.5]
 [-1.5]]
```

4.3.3 Comparison Operations

API Name	Description	Supported Platforms
mindspore.mint.allclose	Returns a new Tensor with boolean elements representing if each element of *input* is "close" to the corresponding element of *other*.	Ascend
mindspore.mint.argsort	Sorts the input tensor along the given dimension in specified order and return the sorted indices.	Ascend
mindspore.mint.eq	Compute the equivalence of the two inputs element-wise.	Ascend
mindspore.mint.equal	Computes the equivalence between two tensors.	Ascend
mindspore.mint.greater	Compute the value of $input > other$ element-wise.	Ascend
mindspore.mint.greater_equal	Computes the boolean value of $input >= other$ element-wise.	Ascend
mindspore.mint.gt	Compute the value of $input > other$ element-wise.	Ascend
mindspore.mint.isclose	Return a boolean tensor where two tensors are element-wise equal within a tolerance.	Ascend
mindspore.mint.isfinite	Determine which elements are finite for each position.	Ascend

continues on next page

Table 6 – continued from previous page

mindspore.mint.isinf	Return a boolean tensor indicating which elements are +/- inifnity.	Ascend
mindspore.mint.isneginf	Determines which elements are -inf for each position.	Ascend
mindspore.mint.le	Compute the value of *input* <= *other* element-wise.	Ascend
mindspore.mint.less	Compute the value of *input* < *other* element-wise.	Ascend
mindspore.mint.less_equal	Compute the value of *input* <= *other* element-wise.	Ascend
mindspore.mint.lt	Alias for mindspore.mint.less() .	Ascend
mindspore.mint.maximum	Compute the maximum of the two input tensors element-wise.	Ascend
mindspore.mint.minimum	Compute the minimum of the two input tensors element-wise.	Ascend
mindspore.mint.ne	Compute the non-equivalence of two inputs element-wise.	Ascend
mindspore.mint.not_equal	Alias for mindspore.mint.ne() .	Ascend
mindspore.mint.topk	Finds values and indices of the *k* largest or smallest entries along a given dimension.	Ascend
mindspore.mint.sort	Sorts the elements of the input tensor along the given dimension in the specified order.	Ascend

mindspore.mint.allclose

mindspore.mint.**allclose**(*input*, *other*, *rtol=1e-05*, *atol=1e-08*, *equal_nan=False*)

Returns a new Tensor with boolean elements representing if each element of *input* is "close" to the corresponding element of *other*. Closeness is defined as:

$$|input - other| atol + rtol » |other|$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) – First tensor to compare. Support dtype: float16, float32, float64, int8, int16, int32, int64 and uint8. On Ascend, more dtypes are support: bool and bfloat16.
- **other** (Tensor) – Second tensor to compare. Dtype must be same as *input*.
- **rtol** (*Union[float, int, bool], optional*) – Relative tolerance. Default: 1e-05 .
- **atol** (*Union[float, int, bool], optional*) – Absolute tolerance. Default: 1e-08 .
- **equal_nan** (*bool, optional*) – If True , then two NaNs will be considered equal. Default: False.

Returns

A bool Scalar.

Raises

- **TypeError** – *input* or *other* is not Tensor.

- **TypeError** – *input* or *other* dtype is not support.
- **TypeError** – *atol* or *rtol* is not float, int or bool.
- **TypeError** – *equal_nan* is not bool.
- **TypeError** – *input* and *other* have different dtypes.
- **ValueError** – *input* and *other* cannot broadcast.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([1.3, 2.1, 3.2, 4.1, 5.1]), mindspore.float16)
>>> other = Tensor(np.array([1.3, 3.3, 2.3, 3.1, 5.1]), mindspore.float16)
>>> output = mint.allclose(input, other)
>>> print(output)
False
```

mindspore.mint.eq

mindspore.mint.**eq**(*input*, *other*)

Compute the equivalence of the two inputs element-wise.

$$out_i = \begin{cases} \text{True, if } input_i = other_i \\ \text{False, if } input_i \neq other_i \end{cases}$$

Note:

- Support implicit type conversion.
- The input must be two Tensors, or a Tensor and a Scalar.
- The shapes of the inputs can be broadcasted to each other.

Parameters

- **input** (*Union[Tensor, Number]*) – The first input.
- **other** (*Union[Tensor, Number]*) – The second input.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> x = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.mint.eq(x, 2.0)
>>> print(output)
[False  True False]
>>> # case 2: The shape of two inputs are the same
>>> x = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> y = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.mint.eq(x, y)
>>> print(output)
[ True  True False]
```

mindspore.mint.equal

mindspore.mint.**equal**(*input*, *other*)

Computes the equivalence between two tensors.

Note: *input* and *other* comply with the implicit type conversion rules to make the data types consistent.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The first input.
- **other** (Tensor) –The second input.

Returns

bool.

Raises

TypeError –If *input* or *other* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> x = Tensor([1, 2, 3], mindspore.int32)
>>> y = Tensor([1, 2, 4], mindspore.int32)
>>> output = mint.equal(x, y)
>>> print(output)
False
```

mindspore.mint.greater

mindspore.mint.**greater**(*input*, *other*)

Compute the value of $input > other$ element-wise.

Parameters

- **input** (*Union[Tensor, Number]*) – The first input.
- **other** (*Union[Tensor, Number]*) – The second input.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.mint.greater(input, 2.0)
>>> print(output)
[False False True]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.mint.greater(input, other)
>>> print(output)
[ False False False]
```

mindspore.mint.greater_equal

mindspore.mint.**greater_equal**(*input*, *other*) → *Tensor*

Computes the boolean value of $input >= other$ element-wise.

$$out_i = \begin{cases} \text{True, if } input_i >= other_i \\ \text{False, if } input_i < other_i \end{cases}$$

Note:

- Inputs of *input* and *other* comply with the implicit type conversion rules to make the data types consistent.
- The inputs must be two tensors or one tensor and one scalar.
- When the inputs are two tensors, dtypes of them cannot be bool at the same time, and the shapes of them can be broadcast.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.
- Broadcasting is supported.
- If the input Tensor can be broadcast, the low dimension will be extended to the corresponding high dimension in another input by copying the value of the dimension.

Parameters

- **input** (*Union[Tensor, Number]*) –The first input is a number or a tensor whose data type is number or bool_.
- **other** (*Union[Tensor, Number]*) –Second input. When the first input is a Tensor, the second input should be a Number, or a Tensor of the number or **bool_** data type. When the first input is a Scalar, the second input must be a Tensor of number or **bool_** data type.

Returns

Tensor, the shape is the same as the one after broadcasting, and the data type is bool.

Raises

TypeError –If neither *input* nor *other* is a Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([1, 2, 3]), mindspore.int32)
>>> other = Tensor(np.array([1, 1, 4]), mindspore.int32)
>>> output = mint.greater_equal(input, other)
>>> print(output)
[True True False]
>>> y = 2.1
>>> output = mint.greater_equal(input, y)
>>> print(output)
[False False True]
```

mindspore.mint.gt

`mindspore.mint.gt(input, other)`

Compute the value of $input > other$ element-wise.

$$out_i = \begin{cases} \text{True, if } input_i > other_i \\ \text{False, if } input_i <= other_i \end{cases}$$

Note:

- Support implicit type conversion.
- The inputs must be two tensors or one tensor and one scalar.
- When the inputs are two tensors, dtypes of them cannot be bool at the same time, and the shapes of them can be broadcast.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.
- Broadcasting is supported.
- If the input Tensor can be broadcast, the low dimension will be extended to the corresponding high dimension in another input by copying the value of the dimension.

Parameters

- **input** (*Union[Tensor, number.Number, bool]*) –The first input.
- **other** (*Union[Tensor, number.Number, bool]*) –The second input.

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.mint.gt(input, 2.0)
>>> print(output)
[False False True]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.mint.gt(input, other)
>>> print(output)
[ False False False]
```

mindspore.mint.isclose

`mindspore.mint.`**`isclose`**(*input*, *other*, *rtol=1e-05*, *atol=1e-08*, *equal_nan=False*)

Return a boolean tensor where two tensors are element-wise equal within a tolerance. Math function is defined as:

$$|input - other| atol + rtol » |other|$$

Two Infinite values are considered equal if they have the same sign, Two NaN values are considered equal if *equal_nan* is `True` .

Parameters

- **input** (`Tensor`) –The first input tensor.
- **other** (`Tensor`) –The second input tensor.
- **rtol** (*Union[float, int, bool], optional*) –Relative tolerance. Default `1e-05` .
- **atol** (*Union[float, int, bool], optional*) –Absolute tolerance. Default `1e-08` .
- **equal_nan** (*bool, optional*) –Whether two NaNs are considered equal. Default `False` .

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> mindspore.mint.isclose(mindspore.tensor([2e6, float("inf"), float("-inf"), float("inf"),␣
↪float("nan")]),
...                         mindspore.tensor([2e7, float("inf"), float("-inf"), float("-inf"),␣
↪float("nan")]))
Tensor(shape=[5], dtype=Bool, value= [False,  True,  True, False, False])
>>>
>>> mindspore.mint.isclose(mindspore.tensor([1e6, 2e6, 3e6]),
...                         mindspore.tensor([1.00008e6, 2.00008e7, 3.00008e8]), rtol=1e3)
Tensor(shape=[3], dtype=Bool, value= [ True,  True,  True])
>>>
>>> mindspore.mint.isclose(mindspore.tensor([1e6, 2e6, 3e6]),
...                         mindspore.tensor([1.00001e6, 2.00002e6, 3.00009e6]), atol=1e3)
Tensor(shape=[3], dtype=Bool, value= [ True,  True,  True])
>>> mindspore.mint.isclose(mindspore.tensor([float("nan"), 1, 2]),
...                         mindspore.tensor([float("nan"), 1, 2]), equal_nan=True)
Tensor(shape=[3], dtype=Bool, value= [ True,  True,  True])
```

mindspore.mint.isfinite

mindspore.mint.**isfinite**(*input*)

Determine which elements are finite for each position. If elements are not NaN , -INF , INF, they are finite.

$$out_i = \begin{cases} \text{if } input_i = \text{Finite}, & True \\ \text{if } input_i \neq \text{Finite}, & False \end{cases}$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor, has the same shape of input, and the dtype is bool.

Raises

TypeError – If input is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([np.log(-1), 1, np.log(0)]), mindspore.float32)
>>> output = mint.isfinite(x)
>>> print(output)
[False True False]
>>> x = Tensor(2.1, mindspore.float64)
>>> output = mint.isfinite(x)
>>> print(output)
True
```

mindspore.mint.isinf

mindspore.mint.**isinf**(*input*)

Return a boolean tensor indicating which elements are +/- inifnity.

Warning:

- This is an experimental API that is subject to change.
- For Ascend, it is only supported on platforms above Atlas A2.

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([-1, 3, float("inf"), float("-inf"), float("nan")])
>>> mindspore.mint.isinf(input)
Tensor(shape=[5], dtype=Bool, value= [False, False,  True,  True, False])
```

mindspore.mint.isneginf

mindspore.mint.**isneginf**(*input*)

Determines which elements are -inf for each position.

Warning:

- This API can be used only on the Atlas A2 training series.

Parameters

input (Tensor) – Input Tensor.

Returns

Tensor with the same shape as the input, where elements are *True* if the corresponding element in the *input* is negative infinity, and *False* otherwise.

Raises

TypeError – If the input is not a tensor.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import mint, Tensor
>>> from mindspore import dtype as mstype
>>> output = mint.isneginf(Tensor([[-float("inf"), float("inf")], [1, -float("inf")]],␣
↪mstype.float32))
>>> print(output)
[[ True False]
 [False  True]]
```

mindspore.mint.le

mindspore.mint.**le**(*input*, *other*)

Compute the value of $input <= other$ element-wise.

$$out_i = \begin{cases} \text{True, if } input_i <= other_i \\ \text{False, if } input_i > other_i \end{cases}$$

Note:

- Support implicit type conversion.
- The inputs must be two tensors or one tensor and one scalar.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.

Parameters

- **input** (*Union[Tensor, Number, bool]*) – The first input.
- **other** (*Union[Tensor, Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.mint.le(input, 2.0)
>>> print(output)
[True  True False]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.mint.le(input, other)
>>> print(output)
[ True  True  True]
```

mindspore.mint.less

mindspore.mint.**less**(*input*, *other*)

Compute the value of $input < other$ element-wise.

$$out_i = \begin{cases} \text{True, if } input_i < other_i \\ \text{False, if } input_i >= other_i \end{cases}$$

Note: Support implicit type conversion.

Parameters

- **input** (*Union[Tensor, Number, bool]*) – The first input.
- **other** (*Union[Tensor, Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.mint.less(input, 2.0)
>>> print(output)
[True  False False]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.mint.less(input, other)
>>> print(output)
[ False  False  True]
```

mindspore.mint.less_equal

mindspore.mint.**less_equal**(*input*, *other*)

Compute the value of $input <= other$ element-wise.

$$out_i = \begin{cases} \text{True, if } input_i <= other_i \\ \text{False, if } input_i > other_i \end{cases}$$

Note:

- Support implicit type conversion.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.

Parameters

- **input** (*Union[Tensor, Number, bool]*) – The first input.
- **other** (*Union[Tensor, Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.mint.less_equal(input, 2.0)
>>> print(output)
[True  True False]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.mint.less_equal(input, other)
>>> print(output)
[ True  True  True]
```

mindspore.mint.lt

mindspore.mint.**lt**(*input*, *other*)

Alias for *mindspore.mint.less()*.

Supported Platforms:

`Ascend`

mindspore.mint.maximum

mindspore.mint.**maximum**(*input*, *other*)

Compute the maximum of the two input tensors element-wise.

$$output_i = \max(input_i, other_i)$$

Note:

- Inputs of *input* and *other* comply with the implicit type conversion rules to make the data types consistent.
- When the inputs are two tensors, dtypes of them cannot be bool at the same time, and the shapes of them could be broadcast.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.
- Broadcasting is supported.
- If one of the elements being compared is a NaN, then that element is returned.

Warning: If all inputs are scalar of integers. In Graph mode, the output will be Tensor of int32, while in PyNative mode, the output will be Tensor of int64.

Parameters

- **input** (*Union[Tensor, Number, bool]*) – The first input.
- **other** (*Union[Tensor, Number, bool]*) – The second input.

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> # case 1 : same data type
>>> input = mindspore.tensor([1.0, 5.0, 3.0], mindspore.float32)
>>> other = mindspore.tensor([4.0, 2.0, 6.0], mindspore.float32)
>>> mindspore.mint.maximum(input, other)
Tensor(shape=[3], dtype=Float32, value= [ 4.00000000e+00,  5.00000000e+00,  6.00000000e+00])
>>>
>>> # case 2 : the data type is the one with higher precision or higher digits among the two␣
↪inputs.
>>> input = mindspore.tensor([1.0, 5.0, 3.0], mindspore.int64)
>>> other = mindspore.tensor([4.0, 2.0, 6.0], mindspore.float64)
>>> mindspore.mint.maximum(input, other)
Tensor(shape=[3], dtype=Float64, value= [ 4.00000000e+00,  5.00000000e+00,  6.00000000e+00])
```

mindspore.mint.minimum

`mindspore.mint.`**`minimum`**(*input*, *other*)

Compute the minimum of the two input tensors element-wise.

$$output_i = \min(input_i, other_i)$$

Note:

- Inputs of *input* and *other* comply with the implicit type conversion rules to make the data types consistent.
- When the inputs are two tensors, dtypes of them cannot be bool at the same time.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.
- Shapes of them are supposed to be broadcast.
- If one of the elements being compared is a NaN, then that element is returned.

Parameters

- **input** (*Union[Tensor, Number, bool]*) –The first input.
- **other** (*Union[Tensor, Number, bool]*) –The second input.

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> # case 1 : same data type
>>> input = mindspore.tensor([1.0, 5.0, 3.0], mindspore.float32)
>>> other = mindspore.tensor([4.0, 2.0, 6.0], mindspore.float32)
>>> mindspore.mint.minimum(input, other)
Tensor(shape=[3], dtype=Float32, value= [ 1.00000000e+00,  2.00000000e+00,  3.00000000e+00])
>>>
>>> # case 2 : the data type is the one with higher precision or higher digits among the two␣
 ↪inputs.
>>> input = mindspore.tensor([1.0, 5.0, 3.0], mindspore.int64)
>>> other = mindspore.tensor([4.0, 2.0, 6.0], mindspore.float64)
>>> mindspore.mint.minimum(input, other)
Tensor(shape=[3], dtype=Float64, value= [ 1.00000000e+00,  2.00000000e+00,  3.00000000e+00])
```

mindspore.mint.ne

`mindspore.mint.ne`(*input*, *other*)

Compute the non-equivalence of two inputs element-wise.

$$out_i = \begin{cases} \text{True, if } input_i \neq other_i \\ \text{False, if } input_i = other_i \end{cases}$$

Note:

- Support implicit type conversion.
- When the inputs are two tensors, the shapes of them could be broadcast.
- When the inputs are one tensor and one scalar, the scalar could only be a constant.
- Broadcasting is supported.

Parameters

- **input** (*Union[Tensor, Number, bool]*) –The first input.
- **other** (*Union[Tensor, Number, bool]*) –The second input.

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> # case 1: The shape of two inputs are different
>>> input = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.mint.ne(input, 2.0)
>>> print(output)
[True False  True]
>>> # case 2: The shape of two inputs are the same
>>> input = mindspore.tensor([1, 2, 3], mindspore.int32)
>>> other = mindspore.tensor([1, 2, 4], mindspore.int32)
>>> output = mindspore.mint.ne(input, other)
>>> print(output)
[ False False  True]
```

mindspore.mint.not_equal

mindspore.mint.**not_equal**(*input*, *other*)

Alias for *mindspore.mint.ne()* .

Supported Platforms:

`Ascend`

mindspore.mint.topk

mindspore.mint.**topk**(*input*, *k*, *dim=- 1*, *largest=True*, *sorted=True*)

Finds values and indices of the *k* largest or smallest entries along a given dimension.

Warning:

- If sorted is set to False, due to different memory layout and traversal methods on different platforms, the display order of calculation results may be inconsistent when *sorted* is False.

If the *input* is a one-dimensional Tensor, finds the *k* largest or smallest entries in the Tensor, and outputs its value and index as a Tensor. values[*k*] is the *k* largest item in *input*, and its index is indices [*k*].

For a multi-dimensional matrix, calculates the first or last *k* entries in a given dimension, therefore:

$$values.shape = indices.shape$$

If the two compared elements are the same, the one with the smaller index value is returned first.

Parameters

- **input** (`Tensor`) – Input to be computed.
- **k** (*int*) – The number of top or bottom elements to be computed along the last dimension.
- **dim** (*int, optional*) – The dimension to sort along. Default: `-1` .
- **largest** (*bool, optional*) – If largest is `False` then the k smallest elements are returned. Default: `True` .

- **sorted** (*bool, optional*) – If `True` , the obtained elements will be sorted by the values in descending order or ascending order according to *largest*. If `False` , the obtained elements will not be sorted. Default: `True` .

Returns

A tuple consisting of *values* and *indices*.

- values (Tensor) - The *k* largest or smallest elements in each slice of the given dimension.
- indices (Tensor) - The indices of values within the last dimension of input.

Raises

- **TypeError** – If *sorted* is not a bool.
- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If *k* is not an int.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint
>>> x = ms.Tensor([[0.5368, 0.2447, 0.4302, 0.9673],
...                [0.4388, 0.6525, 0.4685, 0.1868],
...                [0.3563, 0.5152, 0.9675, 0.8230]], dtype=ms.float32)
>>> output = mint.topk(x, 2, dim=1)
>>> print(output)
(Tensor(shape=[3, 2], dtype=Float32, value=
[[ 9.67299998e-01,  5.36800027e-01],
 [ 6.52499974e-01,  4.68499988e-01],
 [ 9.67499971e-01,  8.23000014e-01]]), Tensor(shape=[3, 2], dtype=Int64, value=
[[3, 0],
 [1, 2],
 [2, 3]]))
>>> output2 = mint.topk(x, 2, dim=1, largest=False)
>>> print(output2)
(Tensor(shape=[3, 2], dtype=Float32, value=
[[ 2.44700000e-01,  4.30200011e-01],
 [ 1.86800003e-01,  4.38800007e-01],
 [ 3.56299996e-01,  5.15200019e-01]]), Tensor(shape=[3, 2], dtype=Int64, value=
[[1, 2],
 [3, 0],
 [0, 1]]))
```

mindspore.mint.sort

mindspore.mint.**sort**(*input*, *, *dim=- 1*, *descending=False*, *stable=False*)

Sorts the elements of the input tensor along the given dimension in the specified order.

> **Warning:** Currently, the data types of float16, uint8, int8, int16, int32, int64 are well supported. If use float32, it may cause loss of accuracy.

Parameters

input (Tensor) – The input tensor to sort. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.

Keyword Arguments

- **dim** (int, *optional*) – The dimension to sort along. Default: -1, means the last dimension.
- **descending** (bool, *optional*) – Controls the sort order. If *descending* is True, the elements are sorted in descending order, or else sorted in ascending order. Default: False .
- **stable** (bool, *optional*) – Controls the sort order. If stable is True then the sorting routine becomes stable, preserving the order of equivalent elements. Default: False .

Returns

- y1, a tensor whose values are the sorted values, with the same shape and data type as input.
- y2, a tensor that consists of the indices of the elements in the original input tensor. Data type is int64.

Raises

- **TypeError** – If *dim* is not an int.
- **TypeError** – If *descending* is not a bool.
- **TypeError** – If *input* not in float16, float32, uint8, int8, int16, int32, int64, bfloat16
- **TypeError** – If *stable* is not a bool.
- **ValueError** – If *dim* is not in range of [-len(input.shape), len(input.shape)).

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[8, 2, 1], [5, 9, 3], [4, 6, 7]]), mindspore.float16)
>>> output = mint.sort(x)
>>> # The output below is based on the Ascend platform.
>>> print(output)
(Tensor(shape=[3, 3], dtype=Float16, value=
[[ 1.0000e+00,  2.0000e+00,  8.0000e+00],
[ 3.0000e+00,  5.0000e+00,  9.0000e+00],
[ 4.0000e+00,  6.0000e+00,  7.0000e+00]]), Tensor(shape=[3, 3], dtype=Int64, value=
[[2, 1, 0],
[2, 0, 1],
[0, 1, 2]]))
```

4.3.4 BLAS and LAPACK Operations

API Name	Description	Supported Platforms
mindspore.mint.addbmm	Applies batch matrix multiplication to *batch1* and *batch2*, with a reduced add step and add *input* to the result.	Ascend
mindspore.mint.addmm	Performs a matrix multiplication of the 2-D matrices mat1 and mat2.	Ascend
mindspore.mint.baddbmm	The result is the sum of the input and a batch matrix-matrix product of matrices in batch1 and batch2.	Ascend
mindspore.mint.bmm	Performs batch matrix-matrix multiplication of two three-dimensional tensors.	Ascend
mindspore.mint.dot	Computes the dot product of two 1D tensor.	Ascend
mindspore.mint.inverse	Compute the inverse of the input matrix.	Ascend
mindspore.mint.matmul	Return the matrix product of two tensors.	Ascend
mindspore.mint.meshgrid	Generates coordinate matrices from given coordinate tensors.	Ascend
mindspore.mint.mm	Returns the matrix product of two arrays.	Ascend
mindspore.mint.outer	Return outer product of *input* and *vec2*.	Ascend
mindspore.mint.trace	Returns a new tensor that is the sum of the *input* main trace.	Ascend

mindspore.mint.addbmm

mindspore.mint.**addbmm**(*input*, *batch1*, *batch2*, *, *beta=1*, *alpha=1*)

Applies batch matrix multiplication to *batch1* and *batch2*, with a reduced add step and add *input* to the result.

The optional value *alpha* is the matrix-matrix product between *batch1* and *batch2*, and *beta* is the scale factor for the added tensor *input*. If *beta* is 0, then *input* will be ignored.

$$output = \beta input + \alpha(\sum_{i=0}^{b-1} batch1_i @ batch2_i)$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –Tensor to be added.
- **batch1** (Tensor) –The first batch of tensor to be multiplied.
- **batch2** (Tensor) –The second batch of tensor to be multiplied.

Keyword Arguments

- **beta** (*Union[int, float], optional*) –Multiplier for *input*. Default: 1 .
- **alpha** (*Union[int, float], optional*) –Multiplier for *batch1* @ *batch2*. Default: 1 .

Returns

Tensor, has the same dtype as *input*.

Raises

- **TypeError** –If *alpha* or *beta* is not an int or float.
- **ValueError** –If *batch1*, *batch2* cannot apply batch matrix multiplication.
- **ValueError** –If *batch1* and *batch2* are not 3-D tensors.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> m = np.ones((3, 3)).astype(np.float32)
>>> arr1 = np.arange(24).astype(np.float32).reshape((2, 3, 4))
>>> arr2 = np.arange(24).astype(np.float32).reshape((2, 4, 3))
>>> a = Tensor(arr1)
>>> b = Tensor(arr2)
>>> c = Tensor(m)
>>> output = mint.addbmm(c, a, b)
>>> print(output)
[[ 949. 1009. 1069.]
 [1285. 1377. 1469.]
 [1621. 1745. 1869.]]
```

mindspore.mint.addmm

mindspore.mint.**addmm**(*input*, *mat1*, *mat2*, *, *beta=1*, *alpha=1*)

Performs a matrix multiplication of the 2-D matrices mat1 and mat2. The matrix input is added to the final result. The formula is defined as follows:

$$output = \beta input + \alpha(mat1@mat2)$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –matrix to be added, the shape must be broadcastable with $mat1@mat2$.
- **mat1** (Tensor) –the first matrix to be matrix multiplied, must be 2-D Tensor, with the same shape of the input.
- **mat2** (Tensor) –the second matrix to be matrix multiplied, must be 2-D Tensor, with the same shape of the input.

Keyword Arguments

- **beta** (*Union[float, int], optional*) –multiplier for input. Default: `1` .
- **alpha** (*Union[float, int], optional*) –multiplier for $mat1@mat2$. Default: `1` .

Returns

Tensor, with the same dtype as *input* and the same shape as $mat1@mat2$.

Raises

- **TypeError** –If the type of *input*, *mat1* or *mat2* is not Tensor.
- **TypeError** –If the types of *input*, *mat1*, *mat2* are different.
- **ValueError** –If *mat1* and *mat2* are not 2-D tensors.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.ones([3, 3]).astype(np.float32))
>>> mat1 = Tensor(np.ones([3, 4]).astype(np.float32))
>>> mat2 = Tensor(np.ones([4, 3]).astype(np.float32))
>>> output =  mint.addmm(input, mat1, mat2)
>>> print(output)
[[5. 5. 5.]
 [5. 5. 5.]
 [5. 5. 5.]]
```

mindspore.mint.baddbmm

mindspore.mint.**baddbmm**(*input*, *batch1*, *batch2*, *, *beta=1*, *alpha=1*)

The result is the sum of the input and a batch matrix-matrix product of matrices in batch1 and batch2. The formula is defined as follows:

$$\text{out}_i = \beta\text{input}_i + \alpha(\text{batch1}_i \mathbin{@} \text{batch2}_i)$$

Parameters

- **input** (Tensor) –The input Tensor. When batch1 is a (C, W, T) Tensor and batch2 is a (C, T, H) Tensor, input must be broadcastable with (C, W, H) Tensor.
- **batch1** (Tensor) –$batch1$ in the above formula. Must be 3-D Tensor, dtype is same as input.
- **batch2** (Tensor) –$batch2$ in the above formula. Must be 3-D Tensor, dtype is same as input.

Keyword Arguments

- **beta** (*Union[float, int], optional*) –multiplier for input. Default: `1` .
- **alpha** (*Union[float, int], optional*) –multiplier for $batch1@batch2$. Default: `1` .

Returns

Tensor, has the same dtype as input, shape will be (C, W, H).

Raises

- **TypeError** –If the type of *input*, *batch1*, *batch2* is not Tensor.
- **TypeError** –If the types of *input*, *batch1*, *batch2* are different.
- **ValueError** –If *batch1* and *batch2* are not 3-D tensors.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.ones([1, 3, 3]).astype(np.float32))
>>> batch1 = Tensor(np.ones([1, 3, 4]).astype(np.float32))
>>> batch2 = Tensor(np.ones([1, 4, 3]).astype(np.float32))
>>> output = mint.baddbmm(input, batch1, batch2)
>>> print(output)
[[[5. 5. 5.]
  [5. 5. 5.]
  [5. 5. 5.]]]
```

mindspore.mint.bmm

mindspore.mint.**bmm**(*input*, *mat2*)

Performs batch matrix-matrix multiplication of two three-dimensional tensors.

$$\text{output} = \text{input}@\text{mat2}$$

Parameters

- **input** (Tensor) – The first batch of matrices to be multiplied. Must be a three-dimensional tensor of shape *(b, n, m)*.
- **mat2** (Tensor) – The second batch of matrices to be multiplied. Must be a three-dimensional tensor of shape *(b, m, p)*.

Returns

Tensor, the output tensor of shape *(b, n, p)*, where each matrix is the product of the corresponding matrices in the input batches.

Raises

- **ValueError** – If *input* or *mat2* is not three-dimensional tensors.
- **ValueError** – If the length of the third dimension of *input* is not equal to the length of the second dimension of *mat2*.
- **ValueError** – If the batch size of the inputs is not equal to the batch size of the mat2.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> a = Tensor(np.ones(shape=[2, 3, 4]), mindspore.float32)
>>> b = Tensor(np.ones(shape=[2, 4, 5]), mindspore.float32)
>>> output = mint.bmm(a, b)
>>> print(output)
[[[4. 4. 4. 4. 4.]
  [4. 4. 4. 4. 4.]
  [4. 4. 4. 4. 4.]]
 [[4. 4. 4. 4. 4.]
```

(continues on next page)

(continued from previous page)

```
  [4. 4. 4. 4. 4.]
  [4. 4. 4. 4. 4.]]]
```

mindspore.mint.dot

mindspore.mint.**dot**(*input*, *other*)

Computes the dot product of two 1D tensor.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The first input in the dot product, must be 1D.
- **other** (Tensor) –The second input in the dot product, must be 1D.

Returns

Tensor, the shape is [] and the data type is same as *input*.

Raises

- **TypeError** –If dtype of *input*, *other* is not tensor.
- **TypeError** –If dtype of *input*, *other* are not in float16, float32 or bfloat16.
- **RuntimeError** –If dtypes of *input* and *other* are not same.
- **RuntimeError** –If shapes of *input* and *other* are not same.
- **RuntimeError** –If shapes of *input* and *other* are not 1D.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> x = Tensor([2.0, 3.0], mindspore.float32)
>>> y = Tensor([2.0, 1.0], mindspore.float32)
>>> output = mint.dot(x, y)
>>> print(output)
7.0
>>> print(output.dtype)
Float32
```

mindspore.mint.inverse

mindspore.mint.**inverse**(*input*)

Compute the inverse of the input matrix.

Parameters

input (Tensor) – A matrix to be calculated. Input *input* must be at least two dimensions, and the size of the last two dimensions must be the same size. And the matrix must be invertible.

Returns

Tensor, has the same type and shape as input *input*.

Raises

- **ValueError** – If the size of the last two dimensions of *input* is not the same.
- **ValueError** – If *input* is not empty and its dimensions are less than 2.
- **ValueError** – If the dimensions of *input* are larger than 6.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import Tensor, mint
>>> from mindspore import dtype as mstype
>>> x = Tensor([[1., 2.], [3., 4.]], mstype.float32)
>>> print(mint.inverse(x))
[[-2.   1. ]
 [ 1.5 -0.5]]
```

mindspore.mint.matmul

mindspore.mint.**matmul**(*input*, *other*)

Return the matrix product of two tensors.

Note:

- The dtype of *input* and *other* must be same.
- On Ascend, the rank of *input* or *other* must be between 1 and 6.

Parameters

- **input** (Tensor) – The first input tensor.
- **other** (Tensor) – The second input tensor.

Returns

Tensor or scalar

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> # case 1 : Reasonable application of broadcast mechanism.
>>> input = mindspore.ops.arange(24, dtype=mindspore.float32).reshape(2, 3, 4)
>>> other = mindspore.ops.arange(20, dtype=mindspore.float32).reshape(4, 5)
>>> output = mindspore.mint.matmul(input, other)
>>> print(output)
[[[  70,   76,   82,   88,   94],
  [ 190,  212,  234,  256,  278],
  [ 310,  348,  386,  424,  462]],
 [[ 430,  484,  538,  592,  646],
  [ 550,  620,  690,  760,  830],
  [ 670,  756,  842,  928, 1014]]]
>>>
>>> # case 2 : The rank of `input` is 1.
>>> input = mindspore.ops.ones(([1, 2]))
>>> other = mindspore.ops.ones(([2]))
>>> mindspore.mint.matmul(input, other)
Tensor(shape=[1], dtype=Float32, value= [ 2.00000000e+00])
```

mindspore.mint.meshgrid

mindspore.mint.**meshgrid**(**tensors*, *indexing='ij'*)

Generates coordinate matrices from given coordinate tensors.

Given N one-dimensional coordinate tensors, returns a tuple outputs of N N-D coordinate tensors for evaluating expressions on an N-D grid.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

tensors (*Union(tuple[Tensor], list[Tensor])*) – In GRAPH_MODE, a tuple of N 1-D Tensor objects and the length of input should be greater than 1. In PYNATIVE_MODE, a tuple of N 0-D or 1-D Tensor objects and the length of input should be greater than 0. The data type is Number.

Keyword Arguments

indexing (*str, optional*) – Cartesian ('xy', default) or matrix ('ij') indexing of output. Valid options: xy' or `'ij'`. In the 2-D case with inputs of length M and N, for `'xy'` indexing, the shape of outputs is (N, M) for `'ij'` indexing, the shape of outputs is (M, N). In the 3-D case with inputs of length M, N and P, for `'xy'` indexing, the shape of outputs is (N, M, P) and for `'ij'` indexing, the shape of outputs is (M, N, P). Default: `'ij'` .

Returns

Tensors, a Tuple of N N-D Tensor objects. The data type is the same with the Inputs.

Raises

- **TypeError** – If *indexing* is not a str or *tensors* is not a tuple.
- **ValueError** – If *indexing* is neither `'xy'` nor `'ij'`.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> x = Tensor(np.array([1, 2, 3, 4]).astype(np.int32))
>>> y = Tensor(np.array([5, 6, 7]).astype(np.int32))
>>> z = Tensor(np.array([8, 9, 0, 1, 2]).astype(np.int32))
>>> output = mint.meshgrid(x, y, z, indexing='xy')
>>> print(output)
(Tensor(shape=[3, 4, 5], dtype=Int32, value=
 [[[1, 1, 1, 1, 1],
   [2, 2, 2, 2, 2],
   [3, 3, 3, 3, 3],
   [4, 4, 4, 4, 4]],
  [[1, 1, 1, 1, 1],
   [2, 2, 2, 2, 2],
   [3, 3, 3, 3, 3],
   [4, 4, 4, 4, 4]],
  [[1, 1, 1, 1, 1],
   [2, 2, 2, 2, 2],
   [3, 3, 3, 3, 3],
   [4, 4, 4, 4, 4]]]),
 Tensor(shape=[3, 4, 5], dtype=Int32, value=
 [[[5, 5, 5, 5, 5],
   [5, 5, 5, 5, 5],
   [5, 5, 5, 5, 5],
   [5, 5, 5, 5, 5]],
  [[6, 6, 6, 6, 6],
   [6, 6, 6, 6, 6],
   [6, 6, 6, 6, 6],
   [6, 6, 6, 6, 6]],
  [[7, 7, 7, 7, 7],
   [7, 7, 7, 7, 7],
   [7, 7, 7, 7, 7],
   [7, 7, 7, 7, 7]]]),
 Tensor(shape=[3, 4, 5], dtype=Int32, value=
 [[[8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2]],
  [[8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2]],
  [[8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2],
   [8, 9, 0, 1, 2]]]))
```

mindspore.mint.mm

mindspore.mint.**mm**(*input*, *mat2*)

Returns the matrix product of two arrays. If *input* is a $(n \times m)$ Tensor, *mat2* is a $(m \times p)$ Tensor, *out* will be a $(n \times p)$ Tensor.

Note: This function cannot support broadcasting. Refer to *mindspore.ops.matmul()* instead if you need a broadcastable function.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The first matrix of matrix multiplication. The last dimension of *input* must be the same size as the first dimension of *mat2*.
- **mat2** (Tensor) –The second matrix of matrix multiplication. The last dimension of *input* must be the same size as the first dimension of *mat2*.

Returns

Tensor, the matrix product of the inputs.

Raises

- **ValueError** –If the last dimension of *input* is not the same size as the second-to-last dimension of *mat2*.
- **TypeError** –If *input* or *mat2* is not a Tensor.
- **TypeError** –If dtype of *input* or *mat2* is not float16, float32 or bfloat16.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint
>>> import numpy as np
>>> x1 = ms.Tensor(np.random.rand(2, 3), ms.float32)
>>> x2 = ms.Tensor(np.random.rand(3, 4), ms.float32)
>>> out = mint.mm(x1, x2)
>>> print(out.shape)
(2, 4)
```

mindspore.mint.outer

mindspore.mint.**outer**(*input*, *vec2*)

Return outer product of *input* and *vec2*. If *input* is a vector of size n and *vec2* is a vector of size m , then output must be a matrix of shape (n, m) .

> **Warning:** This is an experimental API that is subject to change or deletion.

Note: This function does not broadcast.

Parameters

- **input** (Tensor) – 1-D input vector.
- **vec2** (Tensor) – 1-D input vector.

Returns

out, 2-D matrix, the outer product of two vectors.

Raises

- **TypeError** – If *input* or *vec2* is not a Tensor.
- **TypeError** – The implicitly converted data types of *input* and *vec2* are not one of float16, float32, float64, bool, uint8, int8, int16, int32, int64, complex64, complex128, bfloat16
- **ValueError** – If the dimension of *input* or *vec2* is not equal to 1.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> input = Tensor(np.array([7, 8, 9]), mindspore.int32)
>>> vec2 = Tensor(np.array([7, 10, 11]), mindspore.int32)
>>> out = mint.outer(input, vec2)
>>> print(out)
[[49 70 77]
 [56 80 88]
 [63 90 99]]
```

mindspore.mint.trace

mindspore.mint.**trace**(*input*)

Returns a new tensor that is the sum of the *input* main trace.

Parameters

input (Tensor) –2-D Tensor.

Returns

Tensor, when the data type of *input* is integer or bool, its data type is int64, otherwise it is the same as *input*, and size equals to 1.

Raises

- **TypeError** –If *input* is not a Tensor.
- **ValueError** –If the dimension of *input* is not equal to 2.
- **TypeError** –If the dtype of *input* is not one of float16, float32, float64, bool, uint8, int8, int16, int32, int64, complex64, complex128, bfloat16.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[10, 11, 12], [13, 14, 15], [16, 17, 18]]), mindspore.float32)
>>> output = mint.trace(input)
>>> print(output)
42.0
>>> input = Tensor(np.arange(1, 13).reshape(3, 4), mindspore.float32)
>>> output = mint.trace(input)
>>> print(output)
18.0
>>> input = Tensor(np.arange(12, 0, -1).reshape(4, 3), mindspore.float32)
>>> output = mint.trace(input)
>>> print(output)
24.0
```

4.3.5 Other Operations

API Name	Description	Supported Platforms
mindspore.mint.broadcast_to	Broadcasts input tensor to a given shape.	Ascend
mindspore.mint.cdist	Computes p-norm distance between each pair of row vectors of two input Tensors.	Ascend
mindspore.mint.cummax	Returns a tuple (values, indices) where *values* is the cumulative maximum value of input Tensor *input* along the dimension *dim*, and *indices* is the index location of each maximum value.	Ascend

continues on next page

Table 8 – continued from previous page

mindspore.mint.cummin	Returns a tuple (values, indices) where *values* is the cumulative minimum value of input Tensor *input* along the dimension *dim*, and *indices* is the index location of each minimum value.	Ascend
mindspore.mint.cumsum	Computes the cumulative sum of input Tensor along *dim*.	Ascend
mindspore.mint.diag	If input is a vector (1-D tensor), then returns a 2-D square tensor with the elements of input as the diagonal.	Ascend
mindspore.mint.flatten	Flatten a tensor along dimensions from *start_dim* to *end_dim*.	Ascend
mindspore.mint.flip	Reverses elements in a tensor along the given dims.	Ascend
mindspore.mint.repeat_interleave	Repeat elements of a tensor along an axis, like mindspore.numpy.repeat().	Ascend
mindspore.mint.searchsorted	Return the position indices where the elements can be inserted into the input tensor to maintain the increasing order of the input tensor.	Ascend
mindspore.mint.tril	Zero the input tensor above the diagonal specified.	Ascend
mindspore.mint.triangular_solve	Solves a system of equations with a square upper or lower triangular invertible matrix *A* and multiple right-hand sides *b*.	Ascend

mindspore.mint.broadcast_to

mindspore.mint.**broadcast_to**(*input*, *shape*)

Broadcasts input tensor to a given shape. The dim of input must be smaller than or equal to that of target. Suppose input shape is $(x_1, x_2, ..., x_m)$, target shape is $(*, y_1, y_2, ..., y_m)$, where $*$ means any additional dimension. The broadcast rules are as follows:

Compare the value of x_m and y_m, x_{m-1} and y_{m-1}, $\cdots$, x_1 and y_1 consecutively and decide whether these shapes are broadcastable and what the broadcast result is.

If the value pairs at a specific dim are equal, then that value goes right into that dim of output shape. With an input shape $(2, 3)$, target shape $(2, 3)$, the inferred output shape is $(2, 3)$.

If the value pairs are unequal, there are three cases:

Case 1: If the value of the target shape in the dimension is -1, the value of the output shape in the dimension is the value of the corresponding input shape in the dimension. With an input shape $(3, 3)$, target shape $(-1, 3)$, the output shape is $(3, 3)$.

Case 2: If the value of target shape in the dimension is not -1, but the corresponding value in the input shape is 1, then the corresponding value of the output shape is that of the target shape. With an input shape $(1, 3)$, target shape $(8, 3)$, the output shape is $(8, 3)$.

Case 3: If the corresponding values of the two shapes do not satisfy the above cases, it means that broadcasting from the input shape to the target shape is not supported.

So far we got the last m dims of the outshape, now focus on the first $*$ dims, there are two cases:

If the first $*$ dims of output shape does not have -1 in it, then fill the input shape with ones until their length are the same, and then refer to Case 2 mentioned above to calculate the output shape. With target shape $(3, 1, 4, 1, 5, 9)$, input shape $(1, 5, 9)$, the filled input shape will be $(1, 1, 1, 1, 5, 9)$ and thus the output shape is $(3, 1, 4, 1, 5, 9)$.

If the first $*$ dims of output shape have -1 in it, it implies this -1 is corresponding to a non-existing dim so they're not broadcastable. With target shape $(3, -1, 4, 1, 5, 9)$, input shape $(1, 5, 9)$, instead of operating the dim-filling process first, it raises errors directly.

Parameters

- **input** (Tensor) –The input tensor.
- **shape** (*tuple*) –The target shape.

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> shape = (2, 3)
>>> x = mindspore.tensor([1, 2, 3], mindspore.float32)
>>> output = mindspore.mint.broadcast_to(x, shape)
>>> print(output)
[[1. 2. 3.]
 [1. 2. 3.]]
>>> shape = (-1, 2)
>>> x = mindspore.tensor([[1], [2]], mindspore.float32)
>>> output = mindspore.mint.broadcast_to(x, shape)
>>> print(output)
[[1. 1.]
 [2. 2.]]
```

mindspore.mint.cdist

mindspore.mint.**cdist**(*x1*, *x2*, *p=2.0*, *compute_mode='use_mm_for_euclid_dist_if_necessary'*)

Computes p-norm distance between each pair of row vectors of two input Tensors.

Warning: This is an experimental optimizer API that is subject to change.

Note: On Ascend, the supported dtypes are float16 and float32.

Parameters

- **x1** (Tensor) –Input tensor of shape (B, P, M). Letter B represents 0 or positive int number. When B is equal to 0, it means this dimension can be ignored, i.e. shape of the tensor is (P, M).
- **x2** (Tensor) –Input tensor of shape (B, R, M), has the same dtype as *x1*.
- **p** (*float, optional*) –P value for the p-norm distance to calculate between each vector pair, P >= 0. Default: `2.0`.
- **compute_mode** (*string, optional*) –Specify the cumpute mode. Setting this parameter currently has no effect. Default: `'use_mm_for_euclid_dist_if_necessary'`.

Returns

Tensor, p-norm distance, has the same dtype as *x1*, its shape is (B, P, R).

Raises

- **TypeError** –If *x1* or *x2* is not Tensor.
- **TypeError** –If dtype of *x1* or *x2* is not listed in the "Note" above.
- **TypeError** –If *p* is not float32.
- **ValueError** –If *p* is negative.
- **ValueError** –If dimension of *x1* is not the same as *x2*.
- **ValueError** –If dimension of *x1* or *x2* is neither 2 nor 3.
- **ValueError** –If the batch dim of *x1* and *x2* can not broadcast.
- **ValueError** –If the number of columns of *x1* is not the same as that of *x2*.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[[1.0, 1.0], [2.0, 2.0]]]).astype(np.float32))
>>> y = Tensor(np.array([[[3.0, 3.0], [3.0, 3.0]]]).astype(np.float32))
>>> output = mint.cdist(x, y, 2.0)
>>> print(output)
[[[2.8284273 2.8284273]
  [1.4142137 1.4142137]]]
```

mindspore.mint.cummax

mindspore.mint.**cummax**(*input*, *dim*)

Returns a tuple (values, indices) where *values* is the cumulative maximum value of input Tensor *input* along the dimension *dim*, and *indices* is the index location of each maximum value.

$$y_i = \max(x_1, x_2, ..., x_i)$$

Note: O2 mode is not supported in Ascend.

Parameters

- **input** (Tensor) –The input Tensor. Rank of *input* must be greater than 0.
- **dim** (*int*) –The dimension to do the operation over. The value of *dim* must be in the range *[-input.ndim, input.ndim - 1]*.

Returns

tuple [Tensor], tuple of 2 Tensors, containing the cumulative maximum of elements and the index. The shape of each output tensor is the same as that of input *input*.

Raises

- **TypeError** –If *input* is not a Tensor.

- **TypeError** –If *dim* is not an int.
- **ValueError** –If *dim* is out the range of *[-input.ndim, input.ndim - 1]*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> x = Tensor(np.array([[3, 4, 6, 10], [1, 6, 7, 9], [4, 3, 8, 7], [1, 3, 7, 9]]).astype(np.
↪float32))
>>> output = mint.cummax(x, dim=0)
>>> print(output[0])
[[ 3.  4.  6. 10.]
 [ 3.  6.  7. 10.]
 [ 4.  6.  8. 10.]
 [ 4.  6.  8. 10.]]
>>> print(output[1])
[[0 0 0 0]
 [0 1 1 0]
 [2 1 2 0]
 [2 1 2 0]]
```

mindspore.mint.cummin

`mindspore.mint.`**`cummin`**(*input*, *dim*)

Returns a tuple (values, indices) where *values* is the cumulative minimum value of input Tensor *input* along the dimension *dim*, and *indices* is the index location of each minimum value.

$$y_i = \min(x_1, x_2, ..., x_i)$$

Note: O2 mode is not supported in Ascend.

Parameters

- **input** (`Tensor`) –The input Tensor, The dimension must be greater than 0.
- **dim** (*int*) –Operation dimension. The value of *dim* must be in the range *[-input.ndim, input.ndim - 1]*.

Returns

tuple [Tensor], tuple of 2 Tensors, containing the cumulative minimum of elements and the index. The shape of each output tensor is the same as that of input *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *input* is a Tensor, but the type is complex or bool.
- **TypeError** –If *dim* is not an int.

- **ValueError** –If *dim* is out the range of *[-input.ndim, input.ndim - 1]*.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor, mint
>>> import mindspore
>>> a = Tensor([-0.2284, -0.6628,  0.0975,  0.2680, -1.3298, -0.4220], mindspore.float32)
>>> output = mint.cummin(a, dim=0)
>>> print(output[0])
[-0.2284 -0.6628 -0.6628 -0.6628 -1.3298 -1.3298]
>>> print(output[1])
[0 1 1 1 4 4]
```

mindspore.mint.cumsum

`mindspore.mint.`**`cumsum`**(*input*, *dim*, *dtype=None*)

Computes the cumulative sum of input Tensor along *dim*.

$$y_i = x_1 + x_2 + x_3 + ... + x_i$$

Parameters

- **input** (*Tensor*) –The input Tensor.
- **dim** (*int*) –Dim along which the cumulative sum is computed.
- **dtype** (*mindspore.dtype*, optional) –The desired dtype of returned Tensor. If specified, the input Tensor will be cast to *dtype* before the computation. This is useful for preventing overflows. If not specified, stay the same as original Tensor. Default: `None` .

Returns

Tensor, the shape of the output Tensor is consistent with the input Tensor's.

Raises

- **TypeError** –If *input* is not a Tensor.
- **ValueError** –If the *dim* is out of range.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> x = Tensor(np.array([[3, 4, 6, 10], [1, 6, 7, 9], [4, 3, 8, 7], [1, 3, 7, 9]]).astype(np.
↪float32))
>>> # case 1: along the dim 0
>>> y = mint.cumsum(x, 0)
>>> print(y)
[[ 3.  4.  6. 10.]
[ 4. 10. 13. 19.]
[ 8. 13. 21. 26.]
[ 9. 16. 28. 35.]]
>>> # case 2: along the dim 1
>>> y = mint.cumsum(x, 1)
>>> print(y)
[[ 3.  7. 13. 23.]
[ 1.  7. 14. 23.]
[ 4.  7. 15. 22.]
[ 1.  4. 11. 20.]]
```

mindspore.mint.diag

mindspore.mint.**diag**(*input*, *diagonal=0*)

If input is a vector (1-D tensor), then returns a 2-D square tensor with the elements of input as the diagonal.

If input is a matrix (2-D tensor), then returns a 1-D tensor with the diagonal elements of input.

The argument diagonal controls which diagonal to consider:

- If *diagonal* = 0, it is the main diagonal.
- If *diagonal* > 0, it is above the main diagonal.
- If *diagonal* < 0, it is below the main diagonal.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input tensor.
- **diagonal** (*int, optional*) –the diagonal to consider. Defaults: 0.

Returns

Tensor, has the same dtype as the *input*, its shape is up to *diagonal*.

- If *input* shape is (x_0) : then output shape is $(x_0 + |diagonal|, x_0 + |diagonal|)$ 2-D Tensor.
- If *input* shape is (x_0, x_1) : then output shape is main diagonal to move $(|diagonal|)$ elements remains elements' length 1-D Tensor.

Raises

- **TypeError** –If *input* is not a Tensor.

- **ValueError** –If shape of *input* is not 1-D and 2-D.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor, mint
>>> input = Tensor([1, 2, 3, 4]).astype('int32')
>>> output = mint.diag(input)
>>> print(output)
[[1 0 0 0]
 [0 2 0 0]
 [0 0 3 0]
 [0 0 0 4]]
```

mindspore.mint.flatten

`mindspore.mint.`**`flatten`**(*input*, *start_dim=0*, *end_dim=- 1*)

Flatten a tensor along dimensions from *start_dim* to *end_dim*.

Parameters

- **input** (`Tensor`) –The input Tensor.
- **start_dim** (*int, optional*) –The first dimension to flatten. Default: `0` .
- **end_dim** (*int, optional*) –The last dimension to flatten. Default: `-1` .

Returns

Tensor. If no dimensions are flattened, returns the original *input*, otherwise return the flattened Tensor. If *input* is a 0-dimensional Tensor, a 1-dimensional Tensor will be returned.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *start_dim* or *end_dim* is not int.
- **ValueError** –If *start_dim* is greater than *end_dim* after canonicalized.
- **ValueError** –If *start_dim* or *end_dim* is not in range of [-input.dim, input.dim-1].

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input_x = Tensor(np.ones(shape=[1, 2, 3, 4]), mindspore.float32)
>>> output = mint.flatten(input_x)
>>> print(output.shape)
(24,)
```

mindspore.mint.flip

mindspore.mint.**flip**(*input*, *dims*)

Reverses elements in a tensor along the given dims.

Parameters

- **input** (Tensor) –The input tensor.
- **dims** (*Union[list[int], tuple[int]]*) –The dimension to flip.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor(mindspore.ops.arange(1, 9).reshape((2, 2, 2)))
>>> output = mindspore.mint.flip(input, (0, 2))
>>> print(output)
[[[6 5]
  [8 7]]
 [[2 1]
  [4 3]]]
```

mindspore.mint.repeat_interleave

mindspore.mint.**repeat_interleave**(*input*, *repeats*, *dim=None*, ***, *output_size=None*) → *Tensor*

Repeat elements of a tensor along an axis, like *mindspore.numpy.repeat()*.

> **Warning:** Only support on Atlas A2 training series.

Parameters

- **input** (Tensor) –The tensor to repeat values for. Must be of types: float16, float32, int8, uint8, int16, int32, or int64.
- **repeats** (*Union[int, tuple, list, Tensor]*) –The number of times to repeat, must be positive.

- **dim** (*int, optional*) –The dim along which to repeat, Default: `None`. If dims is None, the input Tensor will be flattened and the output will alse be flattened.

Keyword Arguments

output_size (*int, optional*) –Total output size for the given axis (e.g. sum of repeats), Default: `None`.

Returns

One tensor with values repeated along the specified dim. If input has shape $(s1, s2, ..., sn)$ and dim is i, the output will have shape $(s1, s2, ..., si * repeats, ..., sn)$. The output type will be the same as the type of *input*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[0, 1, 2], [3, 4, 5]]), mindspore.int32)
>>> output = mint.repeat_interleave(input, repeats=2, dim=0)
>>> print(output)
[[0 1 2]
 [0 1 2]
 [3 4 5]
 [3 4 5]]
```

mindspore.mint.searchsorted

`mindspore.mint.`**searchsorted**(*sorted_sequence*, *values*, *, *out_int32=False*, *right=False*, *side=None*, *sorter=None*)

Return the position indices where the elements can be inserted into the input tensor to maintain the increasing order of the input tensor.

Parameters

- **sorted_sequence** (`Tensor`) –The input tensor. If *sorter* not provided, it must contain a increasing sequence on the innermost dimension.
- **values** (`Tensor`) –The value that need to be inserted.

Keyword Arguments

- **out_int32** (`bool, optional`) –Whether the output datatype will be mindspore.int32. if `False` , the output datatype will be mindspore.int64. Default `False` .
- **right** (`bool, optional`) –Search Strategy. If `True` , return the last suitable index found; if `False` , return the first such index. Default `False` .
- **side** (*str, optional*) –the same as right but preferred. `left` corresponds to `False` for *right* and `right` corresponds to `True` for *right*. An error will be reported if this parameter is set to `left` while *right* is `True`. Default `None` .
- **sorter** (`Tensor, optional`) –An index sequence sorted in ascending order along the innermost dimension of *sorted_sequence* , which is used together with the unsorted *sorted_sequence* . CPU and GPU only support `None`. Default `None` .

Returns

Tensor

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> sorted_sequence = mindspore.tensor([1, 2, 2, 3, 4, 5, 5])
>>> values = mindspore.tensor([2])
>>> mindspore.mint.searchsorted(sorted_sequence, values)
Tensor(shape=[1], dtype=Int64, value= [1])
```

mindspore.mint.triangular_solve

`mindspore.mint.`**`triangular_solve`**(*b*, *A*, *upper=True*, *transpose=False*, *unitriangular=False*)

Solves a system of equations with a square upper or lower triangular invertible matrix A and multiple right-hand sides b.

In symbols, it solves $AX = b$ and assumes A is square upper-triangular (or lower-triangular if `upper = False`) and does not have zeros on the diagonal.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **b** (*Tensor*) – A Tensor of shape $(*, M, K)$ where * is zero of more batch dimensions.
- **A** (*Tensor*) – A Tensor of shape $(*, M, M)$ where * is zero of more batch dimensions.
- **upper** (*bool, optional*) – Whether A is upper or lower triangular. Default: `True`.
- **transpose** (*bool, optional*) – Solves $op(A)X = b$ where $op(A) = A^T$ if this flag is True, and $op(A) = A$ if it is False, Default: `False`.
- **unitriangular** (*bool, optional*) – Whether A is unit triangular. If True, the diagonal elements of A are assumed to be 1 and not referenced from A. Default: `False`.

Returns

A tuple of X and A.

Raises

- **TypeError** – If argument b is not Tensor.
- **TypeError** – If argument A is not Tensor.
- **TypeError** – If *upper* is not bool.
- **TypeError** – If *transpose* is not bool.
- **TypeError** – If *unitriangular* is not bool.
- **ValueError** – If the rank of b or A is not in the range of $[2, 6]$.
- **ValueError** – If the shapes of b and A are not matched.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import mint
>>> from mindspore import Tensor
>>> b = Tensor(np.ones((2, 3, 4), dtype=np.float32))
>>> A = Tensor(np.ones((2, 3, 3), dtype=np.float32))
>>> output = mint.triangular_solve(b, A)
>>> print(output[0])
[[[ 0.  0.  0.  0.]
  [ 0.  0.  0.  0.]
  [ 1.  1.  1.  1.]]
 [[ 0.  0.  0.  0.]
  [ 0.  0.  0.  0.]
  [ 1.  1.  1.  1.]]]
```

4.4 mindspore.mint.nn

4.4.1 Convolution Layers

API Name	Description	Supported Platforms
mindspore.mint.nn.Conv2d	2D convolution layer.	Ascend
mindspore.mint.nn.Conv3d	3D convolution layer.	Ascend
mindspore.mint.nn.ConvTranspose2d	Applies a 2D transposed convolution operator over an input image composed of several input planes.	Ascend
mindspore.mint.nn.Fold	Combines an array of sliding local blocks into a large containing tensor.	Ascend
mindspore.mint.nn.Unfold	Extracts sliding local blocks from a batched input tensor.	Ascend

mindspore.mint.nn.Conv2d

class mindspore.mint.nn.**Conv2d**(*in_channels*, *out_channels*, *kernel_size*, *stride=1*, *padding=0*, *dilation=1*, *groups=1*, *bias=True*, *padding_mode='zeros'*, *dtype=None*)

2D convolution layer.

Applies a 2D convolution over an input tensor which is typically of shape $(N, C_{in}, H_{in}, W_{in})$, where N is batch size, C is channel number, H is feature height, W is feature width.

The output is calculated based on formula:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{in}-1} \text{ccor}(\text{weight}(C_{\text{out}_j}, k), \text{X}(N_i, k))$$

where *bias* is the output channel bias, *ccor* is the cross-correlation, *weight* is the convolution kernel value and X represents the input feature map.

- i corresponds to the batch number, the range is $[0, N-1]$, where N is the batch size of the input.

- j corresponds to the output channel, the range is $[0, C_{out} - 1]$, where C_{out} is the number of output channels, which is also equal to the number of kernels.
- k corresponds to the input channel, the range is $[0, C_{in} - 1]$, where C_{in} is the number of input channels, which is also equal to the number of channels in the convolutional kernels.

Therefore, in the above formula, $bias(C_{\text{out}_j})$ represents the bias of the j-th output channel, $weight(C_{\text{out}_j}, k)$ represents the slice of the j-th convolutional kernel in the k-th channel, and $X(N_i, k)$ represents the slice of the k-th input channel in the i-th batch of the input feature map.

The shape of the convolutional kernel is given by (kernel_size[0], kernel_size[1]), where kernel_size[0] and kernel_size[1] are the height and width of the kernel, respectively. If we consider the input and output channels as well as the *groups* parameter, the complete kernel shape will be (C_{out}, C_{in}/groups, kernel_size[0], kernel_size[1]), where *groups* is the number of groups dividing *x*'s input channel when applying groups convolution.

For more details about convolution layer, please refer to Gradient Based Learning Applied to Document Recognition.

Parameters

- **in_channels** (*int*) −The channel number of the input tensor of the Conv2d layer.
- **out_channels** (*int*) −The channel number of the output tensor of the Conv2d layer.
- **kernel_size** (*Union[int, tuple[int], list[int]]*) −Specifies the height and width of the 2D convolution kernel. The data type is an integer or a tuple of two integers. An integer represents the height and width of the convolution kernel. A tuple of two integers represents the height and width of the convolution kernel respectively.
- **stride** (*Union[int, tuple[int], list[int]], optional*) −The movement stride of the 2D convolution kernel. The data type is an integer or a tuple of two integers. An integer represents the movement step size in both height and width directions. A tuple of two integers represents the movement step size in the height and width directions respectively. Default: `1` .
- **padding** (*Union[int, tuple[int], list[int], str], optional*) −The number of padding on the height and width directions of the input. The data type is an integer or a tuple of two integers or string {`"valid"`, `"same"`}. If *padding* is an integer, then *padding_{H}* and *padding_{W}* are all equal to *padding*. If *padding* is a tuple of 2 integers, then *padding_{H}* and *padding_{W}* is equal to *padding[0]* and *padding[1]* respectively. The value should be greater than or equal to 0. Default: `0` .
  - `"same"`: Pad the input around its edges so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally, If the amount is even, it is uniformly distributed around the input, if it is odd, the excess amount goes to the right/bottom side. If this mode is set, *stride* must be 1.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible height and width. Extra pixels that could not complete a full stride will be discarded.
- **padding_mode** (*str, optional*) −Specifies the padding mode with a padding value of 0. It can be set to: `"zeros"` , `"reflect"` `"circular"` or `"replicate"` . Default: `"zeros"` .
- **dilation** (*Union[int, tuple[int], list[int]], optional*) −Specifies the dilation rate to use for dilated convolution. It can be a single int or a tuple of 2 or 4 integers. A single int means the dilation size is the same in both the height and width directions. A tuple of two ints represents the dilation size in the height and width directions, respectively. For a tuple of four ints, the two ints correspond to (N, C) dimension are treated as 1, and the two correspond to (H, W) dimensions is the dilation size in the height and width directions respectively. Assuming $dilation = (d0, d1)$, the convolutional kernel samples the input with a spacing of $d0 - 1$ elements in the height direction and $d1 - 1$ elements in the width direction. The values in the height and width dimensions are in the ranges [1, H] and [1, W], respectively. Default: `1` .
- **groups** (*int, optional*) −Splits filter into groups, *in_channels* and *out_channels* must be divisible by *groups*. If the groups is equal to *in_channels* and *out_channels*, this 2D convolution layer also can be called 2D depthwise convolution layer. Default: `1` . The following restraints must be met:
  - (C_{in}

– (C_{out}
– (C_{out} >= groups)
– (kernel_size[1] = C_{in}/groups)

- **bias** (*bool, optional*) –Whether the Conv2d layer has a bias parameter. Default: `True` .
- **dtype** (*mindspore.dtype*, optional) –Dtype of Parameters. Default: `None`, using `mstype.float32`.

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, H_{in}, W_{in})$ or (C_{in}, H_{in}, W_{in}).

Outputs:

Tensor of shape $(N, C_{out}, H_{out}, W_{out})$ or $(C_{out}, H_{out}, W_{out})$.

padding is `'same'`:

$$\begin{aligned} H_{out} &= \left\lceil \frac{H_{in}}{\text{stride}[0]} \right\rceil \\ W_{out} &= \left\lceil \frac{W_{in}}{\text{stride}[1]} \right\rceil \end{aligned}$$

padding is `'valid'`:

$$\begin{aligned} H_{out} &= \left\lfloor \frac{H_{in} - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) - 1}{\text{stride}[0]} \right\rfloor + 1 \\ W_{out} &= \left\lfloor \frac{W_{in} - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) - 1}{\text{stride}[1]} \right\rfloor + 1 \end{aligned}$$

padding is int or tuple/list:

$$\begin{aligned} H_{out} &= \left\lfloor \frac{H_{in} + padding[0] + padding[1] - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) - 1}{\text{stride}[0]} \right\rfloor + 1 \\ W_{out} &= \left\lfloor \frac{W_{in} + padding[2] + padding[3] - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) - 1}{\text{stride}[1]} \right\rfloor + 1 \end{aligned}$$

Raises

- **ValueError** –Args and size of the input feature map should satisfy the output formula to ensure that the size of the output feature map is positive; otherwise, an error will be reported.
- **RuntimeError** –On Ascend, due to the limitation of the L1 cache size of different NPU chip, if input size or kernel size is too large, it may trigger an error.
- **TypeError** –If *in_channels*, *out_channels* or *groups* is not an int.
- **TypeError** –If *kernel_size*, *stride* or *dilation* is neither an int nor a tuple.
- **ValueError** –If *in_channels*, *out_channels*, *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** –If *padding* is less than 0.
- **ValueError** –If *padding* is *same* , *stride* is not equal to 1.
- **ValueError** –The input parameters do not satisfy the convolution output formula.
- **ValueError** –The *kernel_size* cannot exceed the size of the input feature map.
- **ValueError** –The value of padding cannot cause the calculation area to exceed the input size.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> net = mint.nn.Conv2d(120, 240, 4, bias=False)
>>> x = Tensor(np.ones([1, 120, 1024, 640]), mindspore.float32)
>>> output = net(x).shape
>>> print(output)
(1, 240, 1021, 637)
```

mindspore.mint.nn.Conv3d

class mindspore.mint.nn.**Conv3d**(*in_channels*, *out_channels*, *kernel_size*, *stride=1*, *padding=0*, *dilation=1*, *groups=1*, *bias=True*, *padding_mode='zeros'*, *dtype=None*)

3D convolution layer.

Applies a 3D convolution over an input tensor. The input tensor is typically of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$, where N is batch size, C is channel number, D, H, W are the depth, height and width of the feature graph, respectively.

The output is calculated based on formula:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{in}-1} \text{ccor}(\text{weight}(C_{\text{out}_j}, k), \text{X}(N_i, k))$$

where $bias$ is the output channel bias, $ccor$ is the cross-correlation, $weight$ is the convolution kernel value and X represents the input feature map.

Here are the indices' meanings:

- i corresponds to the batch number, the range is $[0, N-1]$, where N is the batch size of the input.
- j corresponds to the output channel, the range is $[0, C_{out}-1]$, where C_{out} is the number of output channels, which is also equal to the number of kernels.
- k corresponds to the input channel, the range is $[0, C_{in}-1]$, where C_{in} is the number of input channels, which is also equal to the number of channels in the convolutional kernels.

Therefore, in the above formula, $bias(C_{\text{out}_j})$ represents the bias of the j-th output channel, $weight(C_{\text{out}_j}, k)$ represents the slice of the j-th convolutional kernel in the k-th channel, and $X(N_i, k)$ represents the slice of the k-th input channel in the i-th batch of the input feature map.

The shape of the convolutional kernel is given by (kernel_size[0], kernel_size[1], kernel_size[2]), where kernel_size[0], kernel_size[1] and kernel_size[2] are the depth, height and width of the kernel, respectively. If we consider the input and output channels as well as the *groups* parameter, the complete kernel shape will be $(C_{out}, C_{in}/\text{groups}, \text{kernel\_size}[0], \text{kernel\_size}[1], \text{kernel\_size}[2])$, where *groups* is the number of groups dividing x's input channel when applying groups convolution.

For more details about convolution layer, please refer to Gradient Based Learning Applied to Document Recognition.

For the detail of limitations of the parameters, please refer to `mindspore.mint.nn.functional.conv3d()`.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **in_channels** (*int*) –The channel number of the input tensor of the Conv3d layer.

- **out_channels** (*int*) −The channel number of the output tensor of the Conv3d layer.
- **kernel_size** (*Union[int, tuple[int], list[int]]*) −Specifies the height and width of the 3D convolution kernel. The data type is an integer or a tuple of two integers. An integer represents the height and width of the convolution kernel. A tuple of two integers represents the height and width of the convolution kernel respectively.
- **stride** (*Union[int, tuple[int], list[int]], optional*) −The movement stride of the 3D convolution kernel. The data type is an integer or a tuple of three integers. An integer represents the movement step size in both height and width directions. A tuple of three integers represents the movement step size in the depth, height and width directions respectively. Default: `1` .
- **padding** (*Union[int, tuple[int], list[int], str], optional*) −The number of padding on the depth, height and width directions of the input. The data type is an integer or string {`"valid"`, `"same"`} or a tuple of three integers. The value should be greater than or equal to 0. Default: `0` .
  - `"same"`: Pad the input around its edges so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally, If the amount is even, it is uniformly distributed around the input, if it is odd, the excess amount goes to the right/bottom side. If this mode is set, *padding* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *padding* must be 0.
- **padding_mode** (*str, optional*) −Specifies the padding mode with a padding value of 0. It can be set to: `"zeros"` , `"reflect"` `"circular"` or `"replicate"` . Default: `"zeros"` .
- **dilation** (*Union[int, tuple[int], list[int]], optional*) −Controlling the space between the kernel points. Default: `1` .
- **groups** (*int, optional*) −Splits filter into groups, *in_channels* and *out_channels* must be divisible by *groups*. If the groups is equal to *in_channels* and *out_channels*. Default: `1` .
- **bias** (*bool, optional*) −Whether the Conv3d layer has a bias parameter. Default: `True` .
- **dtype** (*mindspore.dtype*, optional) −Dtype of Parameters. Default: `None`, using `mstype.float32`.

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$ or $(C_{in}, D_{in}, H_{in}, W_{in})$.

Outputs:

Tensor of shape $(N, C_{out}, D_{out}, H_{out}, W_{out})$ or $(C_{out}, D_{out}, H_{out}, W_{out})$.

padding is `"same"`:

$$
\begin{aligned}
D_{out} &= \left\lceil \frac{D_{in}}{\text{stride}[0]} \right\rceil \\
H_{out} &= \left\lceil \frac{H_{in}}{\text{stride}[1]} \right\rceil \\
W_{out} &= \left\lceil \frac{W_{in}}{\text{stride}[2]} \right\rceil
\end{aligned}
$$

padding is `"valid"`:

$$
\begin{aligned}
D_{out} &= \left\lceil \frac{D_{in} - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1)}{\text{stride}[0]} \right\rceil \\
H_{out} &= \left\lceil \frac{H_{in} - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1)}{\text{stride}[1]} \right\rceil \\
W_{out} &= \left\lceil \frac{W_{in} - \text{dilation}[2] \times (\text{kernel\_size}[2] - 1)}{\text{stride}[2]} \right\rceil
\end{aligned}
$$

padding is int or tuple/list:

$$
\begin{aligned}
D_{out} &= \left\lfloor \frac{D_{in}+padding[0]+padding[1]-\text{dilation}[0]\times(\text{kernel\_size}[0]-1)-1}{\text{stride}[0]} + 1 \right\rfloor \\
H_{out} &= \left\lfloor \frac{H_{in}+padding[2]+padding[3]-\text{dilation}[1]\times(\text{kernel\_size}[1]-1)-1}{\text{stride}[1]} + 1 \right\rfloor \\
W_{out} &= \left\lfloor \frac{W_{in}+padding[4]+padding[5]-\text{dilation}[2]\times(\text{kernel\_size}[2]-1)-1}{\text{stride}[2]} + 1 \right\rfloor
\end{aligned}
$$

Raises

- **TypeError** – If *in_channels*, *out_channels* or *groups* is not an int.
- **TypeError** – If *kernel_size*, *stride*, *padding* or *dilation* is neither an int nor a tuple.
- **ValueError** – If *in_channels*, *out_channels*, *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** – If *padding* is less than 0.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> net = mint.nn.Conv3d(120, 10, 4)
>>> x = Tensor(np.ones([1, 120, 10, 23, 34]), mindspore.float32)
>>> output = net(x).shape
>>> print(output)
(1, 10, 7, 20, 31)
```

mindspore.mint.nn.ConvTranspose2d

class mindspore.mint.nn.**ConvTranspose2d**(*in_channels*, *out_channels*, *kernel_size*, *stride=1*, *padding=0*, *output_padding=0*, *groups=1*, *bias=True*, *dilation=1*, *padding_mode='zeros'*, *dtype=None*)

Applies a 2D transposed convolution operator over an input image composed of several input planes.

This module can be seen as the gradient of Conv2d with respect to its input. It is also known as a fractionally-strided convolution or a deconvolution (although it is not an actual deconvolution operation as it does not compute a true inverse of convolution).

The parameters *kernel_size*, *stride*, *padding*, *output_padding* can either be:

- a single `int` – in which case the same value is used for the height and width dimensions
- a `tuple` of two ints – in which case, the first *int* is used for the height dimension, and the second *int* for the width dimension

Warning:

- This is an experimental API that is subject to change or deletion.
- In the scenario where inputs are non-contiguous, *output_padding* must be less than *stride* .
- For Atlas training products, when the dtype of input is float32, the *groups* only supports 1.

Parameters

- **in_channels** (*int*) –Number of channels in the input image.
- **out_channels** (*int*) –Number of channels produced by the convolution.
- **kernel_size** (*Union[int, tuple(int)]*) –Size of the convolving kernel.
- **stride** (*Union[int, tuple(int)], optional*) –Stride of the convolution. Default: `1` .
- **padding** (*Union[int, tuple(int)], optional*) –$dilation * (kernel\_size - 1) - padding$ zero-padding will be added to both sides of each dimension in the input. Default: `0` .
- **output_padding** (*Union[int, tuple(int)], optional*) –Additional size added to one side of each dimension in the output shape. The value of *output_padding* must be less than *stride* or *dilation* . Default: `0` .
- **groups** (*int, optional*) –Number of blocked connections from input channels to output channels. Default: `1`
- **bias** (*bool, optional*) –If `True`, adds a learnable bias to the output. Default: `True` .
- **dilation** (*Union[int, tuple(int)], optional*) –Spacing between kernel elements. Default: `1` .
- **padding_mode** (*str, optional*) –Specifies the padding mode with a padding value. For now, it can only be set to: `"zeros"`. Default: `"zeros"` .
- **dtype** (*mindspore.dtype, optional*) –Dtype of Parameters. Default: `None` , when it's `None` , the dtype of Parameters would be mstype.float32.

Variables:

- **weigh** (Parameter) - the learnable weights of the module of shape (in_channels, $\frac{\text{out\_channels}}{\text{groups}}$, kernel_size[0], kernel_size[1]) . The values of these weights are sampled from $\mathcal{U}(-\sqrt{k}, \sqrt{k})$ where $k = \frac{groups}{C_{\text{out}} * \prod_{i=0}^{1} \text{kernel\_size}[i]}$
- **bias** (Parameter) - the learnable bias of the module of shape (out_channels,) . If `bias` is `True`, then the values of these weights are sampled from $\mathcal{U}(-\sqrt{k}, \sqrt{k})$ where $k = \frac{groups}{C_{\text{out}} * \prod_{i=0}^{1} \text{kernel\_size}[i]}$.

Inputs:

- **input** (Tensor) - Tensor of shape $(N, C_{in}, H_{in}, W_{in})$ or (C_{in}, H_{in}, W_{in}) .

Outputs:

Tensor of shape $(N, C_{out}, H_{out}, W_{out})$ or $(C_{out}, H_{out}, W_{out})$, where

$$H_{out} = (H_{in} - 1) \times \text{stride}[0] - 2 \times \text{padding}[0] + \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) + \text{output\_padding}[0] + 1$$

$$W_{out} = (W_{in} - 1) \times \text{stride}[1] - 2 \times \text{padding}[1] + \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) + \text{output\_padding}[1] + 1$$

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint
>>> # With square kernels and equal stride
>>> m = mint.nn.ConvTranspose2d(16, 33, 3, stride=2)
>>> # non-square kernels and unequal stride and with padding
>>> m = mint.nn.ConvTranspose2d(16, 33, (3, 5), stride=(2, 1), padding=(4, 2))
>>> input = mint.randn(20, 16, 50, 100)
```

(continues on next page)

(continued from previous page)

```
>>> output = m(input)
>>> # exact output size can be also specified as an argument
>>> input = mint.randn(1, 16, 12, 12)
>>> downsample = mint.nn.Conv2d(16, 16, 3, stride=2, padding=1)
>>> upsample = mint.nn.ConvTranspose2d(16, 16, 3, stride=2, padding=1)
>>> h = downsample(input)
>>> h.shape
(1, 16, 6, 6)
>>> output = upsample(h, output_size=input.shape)
>>> output.shape
(1, 16, 12, 12)
```

mindspore.mint.nn.Fold

class mindspore.mint.nn.**Fold**(*output_size*, *kernel_size*, *dilation=1*, *padding=0*, *stride=1*)

Combines an array of sliding local blocks into a large containing tensor.

For details, please refer to *mindspore.mint.nn.functional.fold()*.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> from mindspore import dtype as mstype
>>> fold = mint.nn.Fold([8, 8], [2, 2], [2, 2], [2, 2], [2, 2])
>>> input = Tensor(input_data=np.random.rand(16, 64, 25), dtype=mstype.float32)
>>> output = fold(input)
>>> print(output.shape)
(16, 16, 8, 8)
```

mindspore.mint.nn.Unfold

class mindspore.mint.nn.**Unfold**(*kernel_size*, *dilation=1*, *padding=0*, *stride=1*)

Extracts sliding local blocks from a batched input tensor.

For details, please refer to *mindspore.mint.nn.functional.unfold()*.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.random.rand(4, 4, 32, 32), mindspore.float64)
>>> unfold = mint.nn.Unfold(kernel_size=3, dilation=1, stride=1)
>>> output = unfold(input)
>>> print(output.shape)
(4, 36, 900)
```

4.4.2 Normalization Layers

API Name	Description	Supported Platforms
mindspore.mint.nn.BatchNorm1d	Applies Batch Normalization over a 2D or 3D input as described in the paper Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift .	Ascend
mindspore.mint.nn.BatchNorm2d	Applies Batch Normalization over a 4D input as described in the paper Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift .	Ascend
mindspore.mint.nn.BatchNorm3d	Applies Batch Normalization over a 5D input as described in the paper Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift .	Ascend
mindspore.mint.nn.GroupNorm	Group Normalization over a mini-batch of inputs.	Ascend
mindspore.mint.nn.LayerNorm	Applies Layer Normalization over a mini-batch of inputs.	Ascend
mindspore.mint.nn.SyncBatchNorm	Sync Batch Normalization layer over a N-dimension input.	Ascend

mindspore.mint.nn.BatchNorm1d

class mindspore.mint.nn.**BatchNorm1d**(*num_features: int*, *eps=1e-5*, *momentum=0.1*, *affine=True*, *track_running_stats=True*, *dtype=None*)

Applies Batch Normalization over a 2D or 3D input as described in the paper Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift .

$$y = \frac{x - mean}{\sqrt{variance + \epsilon}} * \gamma + \beta$$

The mean and standard-deviation are calculated per-dimension over the mini-batches and γ and β are learnable parameter vectors of size C (where C is the number of features or channels of the input). By default, the elements of γ are set to 1 and the elements of β are set to 0.

Warning: This API does not support Dynamic Rank. This is an experimental API that is subject to change or deletion.

Parameters

- **num_features** (*int*) –C from an expected input of shape (N, C, L).
- **eps** (*float, optional*) –a value added to the denominator for numerical stability. Default: `1e-5` .
- **momentum** (*float, optional*) –the value used for the running_mean and running_var computation. Can be set to `None` for cumulative moving average. Default: `0.1` .
- **affine** (*bool, optional*) –a boolean value that when set to `True`, this cell has learnable affine parameters. Default: `True` .
- **track_running_stats** (*bool, optional*) –a boolean value that when set to `True`, this cell tracks the running mean and variance, and when set to `False`, this cell does not track such statistics. And this cell always uses batch statistics in both training and eval modes. Default: `True` .
- **dtype** (*mindspore.dtype*, optional) –Dtype of Parameters. Default: `None` .

Inputs:

- **input** (Tensor) - The input with shape (N, C) or (N, C, L), where N means batch, C means the number of feature or the number of channel, and L is the length of sequence.

Outputs:

Tensor, has the same type and shape as *input*.

Raises

- **TypeError** –If *num_features* is not an int number.
- **TypeError** –If *eps* is not a float.
- **ValueError** –If *num_features* is less than 1.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input_x = mindspore.Tensor([[0.7, 0.5, 0.5, 0.6], [0.5, 0.4, 0.6, 0.9]])
>>> net = mint.nn.BatchNorm1d(4)
>>> output = net(input_x)
>>> print(output)
[[ 0.99950075 0.9980011 -0.9980068 -0.9997783]
 [-0.9995012 -0.99799967 0.9980068  0.9997778]]
```

mindspore.mint.nn.BatchNorm2d

class mindspore.mint.nn.**BatchNorm2d**(*num_features: int*, *eps=1e-5*, *momentum=0.1*, *affine=True*, *track_running_stats=True*, *dtype=None*)

Applies Batch Normalization over a 4D input as described in the paper Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift .

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

The mean and standard-deviation are calculated per-dimension over the mini-batches and γ and β are learnable parameter vectors of size C (where C is the number of features or channels of the input). By default, the elements of γ are set to 1 and the elements of β are set to 0.

Warning:

- This API does not support Dynamic Rank.
- This is an experimental API that is subject to change or deletion.

Parameters

- **num_features** (*int*) – C from an expected input of shape (N, C, H, W).
- **eps** (*float, optional*) – a value added to the denominator for numerical stability. Default: `1e-5` .
- **momentum** (*float, optional*) – the value used for the running_mean and running_var computation. Can be set to `None` for cumulative moving average. Default: `0.1` .
- **affine** (*bool, optional*) – a boolean value that when set to `True`, this cell has learnable affine parameters. Default: `True` .
- **track_running_stats** (*bool, optional*) – a boolean value that when set to `True`, this cell tracks the running mean and variance, and when set to `False`, this cell does not track such statistics. And this cell always uses batch statistics in both train and eval modes. Default: `True` .
- **dtype** (*mindspore.dtype*, optional) – Dtype of Parameters. Default: `None` .

Inputs:

- **input** (Tensor) - The input with shape (N, C, H, W).

Outputs:

Tensor, has the same type and shape as *input*.

Raises

- **TypeError** – If *num_features* is not an int number.
- **TypeError** – If *eps* is not a float.
- **ValueError** – If *num_features* is less than 1.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input_x = mindspore.Tensor([0.3, 0.4, 0.5, 0.3])
>>> input_x = input_x.reshape((2, 2, 1, 1))
>>> net = mint.nn.BatchNorm2d(2)
>>> output = net(input_x)
>>> print(output)
[[[[-0.99950075]]
  [[0.9980087]]]
  [[[0.999501]]
  [[-0.9980097]]]]
```

mindspore.mint.nn.BatchNorm3d

class mindspore.mint.nn.**BatchNorm3d**(*num_features: int*, *eps=1e-5*, *momentum=0.1*, *affine=True*, *track_running_stats=True*, *dtype=None*)

Applies Batch Normalization over a 5D input as described in the paper Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift .

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

The mean and standard-deviation are calculated per-dimension over the mini-batches and γ and β are learnable parameter vectors of size C (where C is the number of features or channels of the input). By default, the elements of γ are set to 1 and the elements of β are set to 0.

> **Warning:** This API does not support Dynamic Rank. This is an experimental API that is subject to change or deletion.

Parameters

- **num_features** (*int*) –C from an expected input of shape (N, C, D, H, W).
- **eps** (*float, optional*) –a value added to the denominator for numerical stability. Default: `1e-5` .
- **momentum** (*float, optional*) –the value used for the running_mean and running_var computation. Can be set to `None` for cumulative moving average. Default: `0.1` .
- **affine** (*bool, optional*) –a boolean value that when set to `True`, this cell has learnable affine parameters. Default: `True` .
- **track_running_stats** (*bool, optional*) –a boolean value that when set to `True`, this cell tracks the running mean and variance, and when set to `False`, this cell does not track such statistics. And this cell always uses batch statistics in both training and eval modes. Default: `True` .
- **dtype** (*mindspore.dtype*, optional) –Dtype of Parameters. Default: `None` .

Inputs:

- **input** (Tensor) - The input with shape (N, C, D, H, W).

Outputs:

Tensor, has the same type and shape as *input*.

Raises

- **TypeError** –If *num_features* is not an int number.
- **TypeError** –If *eps* is not a float.
- **ValueError** –If *num_features* is less than 1.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input_x = mindspore.Tensor([0.1, 0.9, 1.2, 2.3])
>>> input_x = input_x.reshape((1, 2, 1, 1, 2))
>>> net = mint.nn.BatchNorm3d(2)
>>> output = net(input_x)
>>> print(output)
[[[[[-0.9999688 0.99996865]]]
  [[[-0.9999833 06.9999831]]]]]
```

mindspore.mint.nn.GroupNorm

class mindspore.mint.nn.**GroupNorm**(*num_groups*, *num_channels*, *eps=1e-05*, *affine=True*, *dtype=None*)

Group Normalization over a mini-batch of inputs.

Group Normalization is widely used in recurrent neural networks. It applies normalization on a mini-batch of inputs for each single training case as described in the paper Group Normalization.

Group Normalization divides the channels into groups and computes within each group the mean and variance for normalization, and it performs very stable over a wide range of batch size. γ and β are trainable scale and shift. It can be described using the following formula:

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

where γ is *weight*, β is *bias*, and ϵ is *eps*.

Parameters

- **num_groups** (*int*) –The number of groups to be divided along the channel dimension.
- **num_channels** (*int*) –The number of input channels.
- **eps** (*float, optional*) –A value added to the denominator for numerical stability. Default: `1e-05` .
- **affine** (*bool, optional*) –The parameters, such as γ and β, are learnable when set to `true` . Default: `True` .
- **dtype** (*mindspore.dtype*, optional) –Dtype of Parameters. Default: `None` .

Inputs:

- **input** (Tensor) - The input feature with shape $(N, C, *)$, where $*$ means, any number of additional dimensions.

Outputs:

Tensor, the normalized and scaled offset tensor, has the same shape and data type as the *input*.

Raises

- **TypeError** – If *num_groups* or *num_channels* is not an int.
- **TypeError** – If *eps* is not a float.
- **TypeError** – If *affine* is not a bool.
- **ValueError** – If *num_groups* or *num_channels* is less than 1.
- **ValueError** – If *num_channels* is not divided by *num_groups*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> group_norm_op = ms.mint.nn.GroupNorm(2, 2)
>>> x = ms.Tensor(np.ones([1, 2, 4, 4], np.float32))
>>> output = group_norm_op(x)
>>> print(output)
[[[[0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]]
  [[0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]]]]
```

mindspore.mint.nn.LayerNorm

class mindspore.mint.nn.**LayerNorm**(*normalized_shape*, *eps=1e-5*, *elementwise_affine=True*, *bias=True*, *dtype=None*)

Applies Layer Normalization over a mini-batch of inputs.

Layer Normalization is widely used in recurrent neural networks. It applies normalization on a mini-batch of inputs for each single training case as described in the paper Layer Normalization.

Unlike Batch Normalization, Layer Normalization performs exactly the same computation at training and testing time. It is applied across all channels and pixel but only one batch size. γ is the scale value learned through training and β is the shift value. It can be described using the following formula:

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **normalized_shape** (*Union(tuple[int], list[int], int)*) – The normalized shape of x for LayerNorm.
- **eps** (*float, optional*) – A value added to the denominator for numerical stability(ϵ). Default: `1e-5` .

- **elementwise_affine** (*bool, optional*) –Whether affine transformation is required. When this parameter is set to `True`, the weight parameter is initialized to 1 and the offset is initialized to 0. Default: `True`.
- **bias** (*bool, optional*) –If set to `False`, the layer will not learn an additive bias (only relevant if *elementwise_affine* is `True`). Default: `True`.
- **dtype** (*mindspore.dtype*, optional) –Dtype of Parameters. Default: `None` .

Inputs:

- **x** (Tensor) - The shape is $(N, *)$, where $*$ is equal to normalized_shape.

Outputs:

Tensor, the normalized and scaled offset tensor, has the same shape and data type as the *x*.

Raises

TypeError –If *eps* is not a float.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> x = ms.Tensor(np.ones([20, 5, 10, 10]), ms.float32)
>>> shape1 = x.shape[1:]
>>> m = ms.mint.nn.LayerNorm(shape1)
>>> output = m(x).shape
>>> print(output)
(20, 5, 10, 10)
```

mindspore.mint.nn.SyncBatchNorm

class mindspore.mint.nn.**SyncBatchNorm**(*num_features: int*, *eps: float = 1e-5*, *momentum: float = 0.1*, *affine: bool = True*, *track_running_stats: bool = True*, *process_group: Optional[str] = None*, *dtype=None*)

Sync Batch Normalization layer over a N-dimension input.

Sync Batch Normalization is cross device synchronized Batch Normalization. The implementation of Batch Normalization only normalizes the data within each device. Sync Batch Normalization will normalize the input within the group. It has been described in the paper Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift. It rescales and recenters the feature using a mini-batch of data and the learned parameters which can be described in the following formula.

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **num_features** (*int*) –*C* from an expected input of size $(N, C, +)$.

- **eps** (*float, optional*) – ϵ, a value added to the denominator for numerical stability. Default: `1e-5` .
- **momentum** (*float, optional*) – A floating hyperparameter of the momentum for the running_mean and running_var computation. Default: `0.1` .
- **affine** (*bool, optional*) – A bool value. When set to `True` , γ and β are learnable parameters. When set to `False` , γ and β are unlearnable parameters. Default: `True` .
- **track_running_stats** (*bool, optional*) – a boolean value that when set to `True`, this cell tracks the running mean and variance, and when set to `False`, this cell does not track such statistics. And this cell always uses batch statistics in both training and eval modes. Default: `True` .
- **process_group** (*str, optional*) – synchronization of stats happen within each process group individually. Default behavior is synchronization across the whole world. Default: `None` .
- **dtype** (*mindspore.dtype*, optional) – Dtype of Parameters. Default: `None` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, +)$.

Outputs:

Tensor, the normalized, scaled, offset tensor, of shape $(N, C_{out}, +)$.

Raises

- **TypeError** – If *num_features* is not an int.
- **TypeError** – If *eps* is not a float.
- **ValueError** – If *num_features* is less than 1.
- **ValueError** – If *momentum* is not in range [0, 1].
- **ValueError** – If rank_id in *process_group* is not in range [0, rank_size).

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For the Ascend devices, users need to prepare the rank table, set rank_id and device_id. Here, examples use msrun to pull multi-process distributed tasks across nodes with a single command line instruction. Please see the Ascend tutorial for more details.

This example should be run with multiple devices.

```
>>> # Firstly, preparing test_syncbn.py:
>>> import numpy as np
>>> import mindspore
>>> import mindspore.context as context
>>> from mindspore.mint.nn.layer import SyncBatchNorm
>>> from mindspore import Tensor
>>> from mindspore.communication import init, create_group, get_local_rank
>>> init()
>>> context.set_context(mode=context.PYNATIVE_MODE, device_target="Ascend")
```

(continues on next page)

(continued from previous page)

```
>>> group = "0-1"
>>> rank_ids = [0, 1]
>>> create_group(group, rank_ids)
>>> sync_batch_norm = SyncBatchNorm(num_features=2, process_group=group, dtype=mindspore.
↪float32)
>>> sync_batch_norm.set_train(False)
>>> input_x = Tensor(np.linspace(0, 5, 2*2*2*2), mindspore.float32).reshape(2, 2, 2, 2)
>>> output_data = sync_batch_norm(input_x)
>>> # Then, executing the command such as the following:
>>> # msrun --worker_num=2 --local_worker_num=2 --master_port=8975 --log_dir=msrun_log --
↪join=True
>>> # --cluster_time_out=100 pytest -s -v test_syncbn.py
```

4.4.3 Non-linear Activations (weighted sum, nonlinearity)

API Name	Description	Supported Platforms
mindspore.mint.nn.ELU	Exponential Linear Unit activation function	Ascend
mindspore.mint.nn.GELU	Activation function GELU (Gaussian Error Linear Unit).	Ascend
mindspore.mint.nn.GLU	Computes GLU (Gated Linear Unit activation function) of the input tensor.	Ascend
mindspore.mint.nn.Hardshrink	Applies Hard Shrink activation function element-wise.	Ascend
mindspore.mint.nn.Hardsigmoid	Applies Hard Sigmoid activation function element-wise.	Ascend
mindspore.mint.nn.Hardswish	Applies Hard Swish activation function element-wise.	Ascend
mindspore.mint.nn.LogSigmoid	Applies logsigmoid activation element-wise.	Ascend
mindspore.mint.nn.LogSoftmax	Applies the Log Softmax function to the input tensor on the specified axis.	Ascend
mindspore.mint.nn.Mish	Computes MISH (A Self Regularized Non-Monotonic Neural Activation Function) of input tensors element-wise.	Ascend
mindspore.mint.nn.PReLU	Applies PReLU activation function element-wise.	Ascend
mindspore.mint.nn.ReLU	Applies ReLU (Rectified Linear Unit activation function) element-wise.	Ascend
mindspore.mint.nn.ReLU6	Activation function ReLU6.	Ascend
mindspore.mint.nn.SELU	Activation function SELU (Scaled exponential Linear Unit).	Ascend
mindspore.mint.nn.SiLU	Calculates the SiLU activation function element-wise.	Ascend
mindspore.mint.nn.Sigmoid	Applies sigmoid activation function element-wise.	Ascend
mindspore.mint.nn.Softmax	Applies the Softmax function to an n-dimensional input Tensor.	Ascend
mindspore.mint.nn.Softshrink	Applies the Softshrink function element-wise.	Ascend
mindspore.mint.nn.Tanh	Applies the Tanh function element-wise, returns a new tensor with the hyperbolic tangent of the elements of input.	Ascend

mindspore.mint.nn.ELU

class mindspore.mint.nn.**ELU**(*alpha=1.0*, *inplace=False*)

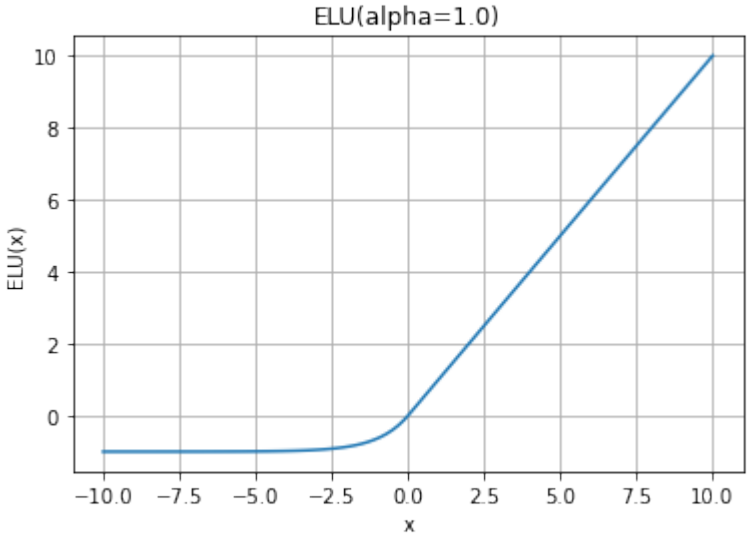
Exponential Linear Unit activation function

Applies the exponential linear unit function element-wise.The activation function is defined as:

$$ELU_i = \begin{cases} x_i, & \text{if } x_i \geq 0; \\ \alpha * (\exp(x_i) - 1), & \text{otherwise.} \end{cases}$$

where x_i represents the element of the input and α represents the *alpha* parameter, and *alpha* represents the smoothness of the ELU.

ELU Activation Function Graph:



Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **alpha** (*float, optional*) – The alpha value of ELU, the data type is float. Default: `1.0`.
- **inplace** (*bool, optional*) – Whether to use inplace mode, the data type is bool. Default: `False`.

Inputs:

- **input** (Tensor) - The input of ELU is a Tensor of any dimension.

Outputs:

Tensor, with the same shape and type as the *input*.

Raises

- **RuntimeError** – If the dtype of *input* is not float16, float32 or bfloat16.
- **TypeError** – If the dtype of *alpha* is not float.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float32)
>>> elu = mint.nn.ELU()
>>> result = elu(input)
>>> print(result)
[-0.63212055  -0.86466473  0.  2.  1.]
```

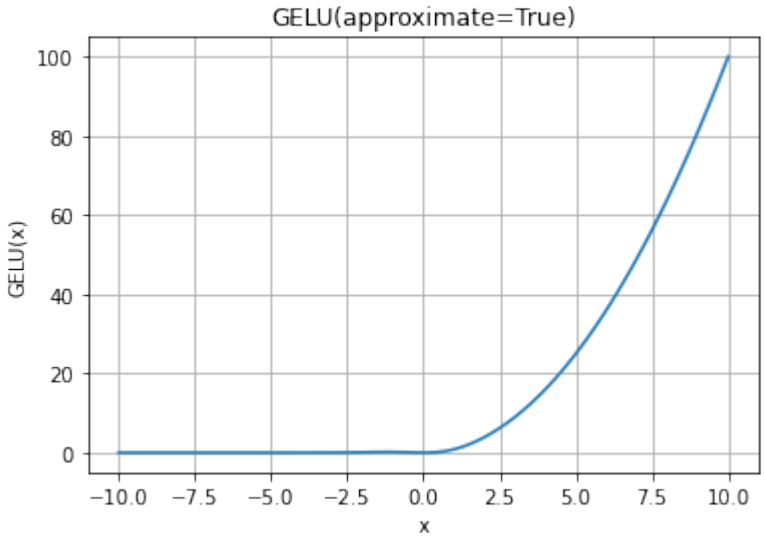
mindspore.mint.nn.GELU

class mindspore.mint.nn.**GELU**(*approximate='none'*)

Activation function GELU (Gaussian Error Linear Unit).

Refer to *mindspore.mint.nn.functional.gelu()* for more details.

GELU Activation Function Graph:



Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> gelu = mint.nn.GELU()
>>> output = gelu(input)
>>> print(output)
[[-1.58655241e-01  3.99987316e+00 -0.00000000e+00]
 [ 1.95449972e+00 -1.41860323e-06  9.0000000e+00]]
>>> gelu = mint.nn.GELU(approximate="tanh")
```

(continues on next page)

(continued from previous page)

```
>>> output = gelu(input)
>>> print(output)
[[-1.58808023e-01  3.99992990e+00 -3.10779147e-21]
 [ 1.95459759e+00 -2.29180174e-07  9.0000000e+00]]
```

mindspore.mint.nn.GLU

class mindspore.mint.nn.**GLU**(*dim=-1*)

Computes GLU (Gated Linear Unit activation function) of the input tensor.

$$GLU(a, b) = a \otimes \sigma(b)$$

where a is the first half of the *input* Tensor after *input* is split and b is the second half.

Here σ is the sigmoid function, and $\otimes$ is the Hadamard product. See Language Modeling with Gated Convluational Networks .

Parameters

dim (*int, optional*) – The dimension to split the input *input*. The value range is *[-r, r)* where *r* is the number of dimensions of *input*. Default: `-1` , the last dimension in *input*.

Inputs:

- **input** (Tensor) - Tensor to be calculated. Dtype is floating point and the shape is $(*_1, N, *_2)$ where * means, any number of additional dimensions. N is required to be an even number, where N is the size of *input* on the dimension selected by *dim*.

Outputs:

Tensor, the same dtype as the *input*, with the shape $(*_1, M, *_2)$ where $M = N/2$.

Raises

- **TypeError** – If *input* is not a Tensor or *dim* is not an int.
- **IndexError** – If the value of *dim* is out of the range of *[-r, r)*, where *r* is the number of dimensions of *input*.
- **RuntimeError** – If dtype of *input* is not supported.
- **RuntimeError** – If the length of *input* in the dimension selected by *dim* is not even.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import mint, Tensor
>>> glu = mint.nn.GLU()
>>> input = Tensor([[0.1, 0.2, 0.3, 0.4], [0.5, 0.6, 0.7, 0.8]])
>>> output = glu(input)
>>> print(output)
[[0.05744425 0.11973753]
 [0.33409387 0.41398472]]
```

mindspore.mint.nn.Hardshrink

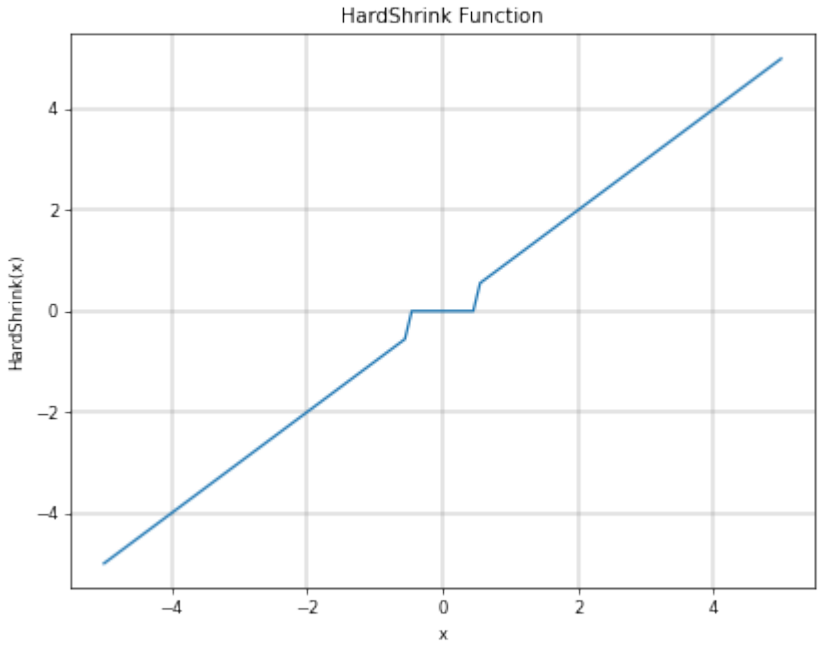
class mindspore.mint.nn.**Hardshrink**(*lambd=0.5*)

Applies Hard Shrink activation function element-wise.

The formula is defined as follows:

$$\text{Hardshrink}(x) = \begin{cases} x, & \text{if } x > \lambda \\ x, & \text{if } x < -\lambda \\ 0, & \text{otherwise} \end{cases}$$

Hardshrink Activation Function Graph:



Parameters

lambd (*number, optional*) – The threshold λ defined by the Hard Shrink formula. Default: `0.5`.

Inputs:

- **input** (Tensor) - The input of Hard Shrink. Supported dtypes:
  - Ascend: float16, float32, bfloat16.

Outputs:

Tensor, the same shape and data type as the input.

Raises

- **TypeError** – If *lambd* is not a float, int or bool.
- **TypeError** – If *input* is not a tensor.
- **TypeError** – If dtype of *input* is not float16, float32 or bfloat16.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([[0.5, 1, 2.0], [0.0533, 0.0776, -2.1233]]), mindspore.float32)
>>> hshrink = mint.nn.Hardshrink()
>>> output = hshrink(input)
>>> print(output)
[[ 0.      1.      2.    ]
 [ 0.      0.     -2.1233]]
```

mindspore.mint.nn.Hardsigmoid

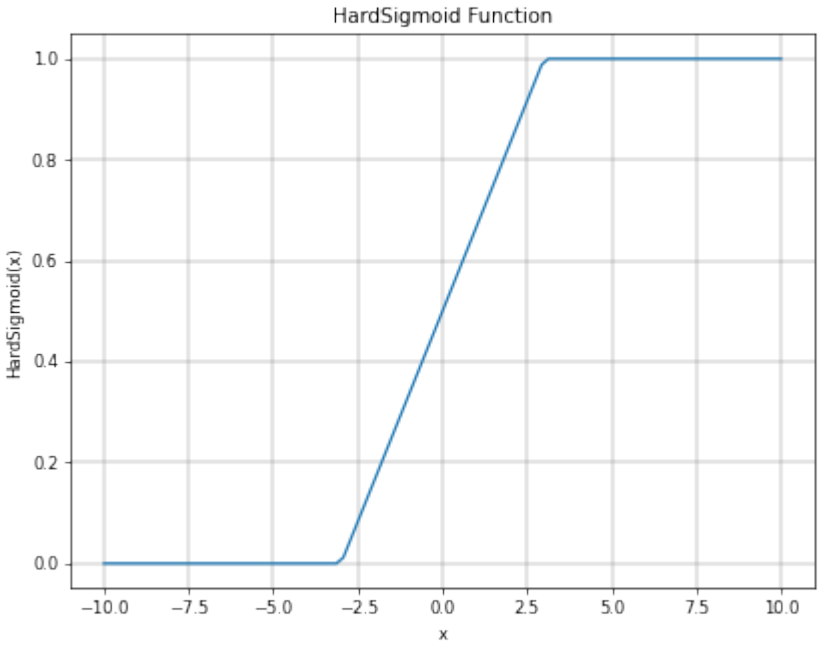
class mindspore.mint.nn.**Hardsigmoid**

Applies Hard Sigmoid activation function element-wise.

Hard Sigmoid is defined as:

$$\text{Hardsigmoid}(input) = \begin{cases} 0, & \text{if } input \leq -3, \\ 1, & \text{if } input \geq +3, \\ input/6 + 1/2, & \text{otherwise} \end{cases}$$

Hardsigmoid Activation Function Graph:



Inputs:

- **input** (Tensor) - The input of Hardsigmoid.

Outputs:

Tensor, with the same type and shape as the *input*.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If *input* is neither int nor float.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> hsigmoid = mint.nn.Hardsigmoid()
>>> result = hsigmoid(input)
>>> print(result)
[0.3333 0.1666 0.5    0.8335 0.6665]
```

mindspore.mint.nn.Hardswish

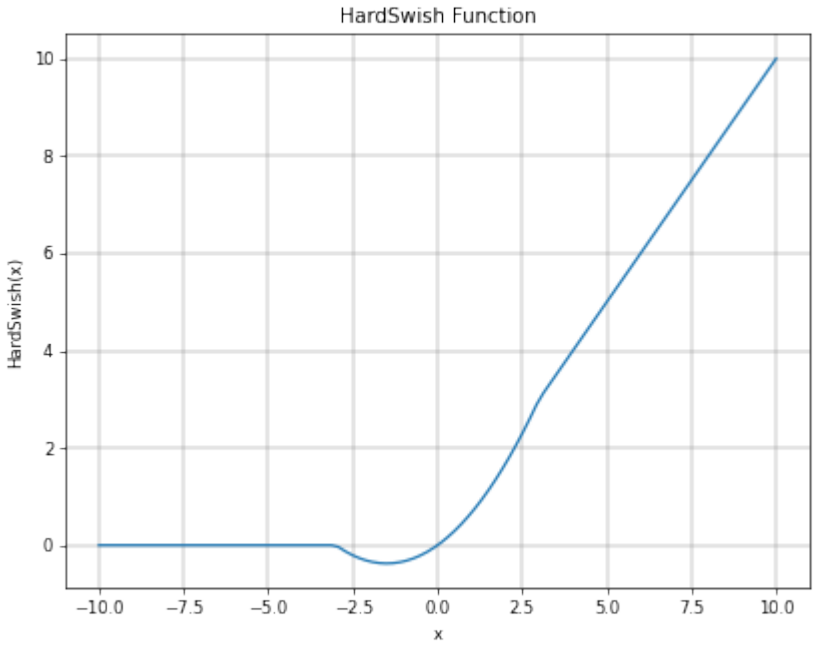
class mindspore.mint.nn.**Hardswish**

Applies Hard Swish activation function element-wise.

Hard swish is defined as:

$$\text{Hardswish}(input) = \begin{cases} 0, & \text{if } input \leq -3, \\ input, & \text{if } input \geq +3, \\ input * (input + 3)/6, & \text{otherwise} \end{cases}$$

Hardswish Activation Function Graph:



Inputs:

- **input** (Tensor) - The input of Hardswish.

Outputs:

Tensor, with the same type and shape as the *input*.

Raises

- **TypeError** – If *input* is not a tensor.
- **TypeError** – If *input* is neither int nor float.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> hswish = mint.nn.Hardswish()
>>> result = hswish(input)
>>> print(result)
[-0.3333 -0.3333  0.      1.667   0.6665]
```

mindspore.mint.nn.LogSigmoid

class mindspore.mint.nn.**LogSigmoid**

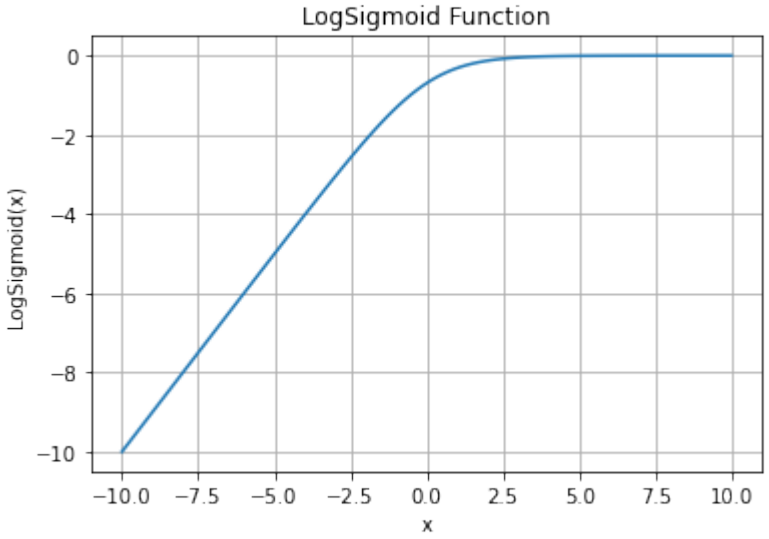
Applies logsigmoid activation element-wise. The input is a Tensor with any valid shape.

Logsigmoid is defined as:

$$\text{LogSigmoid}(x_i) = \log(\frac{1}{1 + \exp(-x_i)}),$$

where x_i is the element of the input.

LogSigmoid Activation Function Graph:



Warning: This is an experimental API that is subject to change or deletion.

Inputs:

- **input** (Tensor) - The input of LogSigmoid with data type of bfloat16, float16 or float32. The shape is $(*)$ where $*$ means, any number of additional dimensions.

Outputs:

Tensor, with the same type and shape as the *input*.

Raises

- **TypeError** – If dtype of *input* is not bfloat16, float16 and float32.
- **TypeError** – If *input* is not a Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> net = mint.nn.LogSigmoid()
>>> input = Tensor([1.0, 2.0, 3.0], mindspore.float32)
>>> output = net(input)
>>> print(output)
[-0.31326166 -0.12692806 -0.04858734]
```

mindspore.mint.nn.LogSoftmax

class mindspore.mint.nn.**LogSoftmax**(*dim=None*)

Applies the Log Softmax function to the input tensor on the specified axis. Supposes a slice in the given axis, x for each element x_i, the Log Softmax function is shown as follows:

$$\text{output}(x_i) = \log\left(\frac{\exp(x_i)}{\sum_{j=0}^{N-1}\exp(x_j)}\right),$$

where N is the length of the Tensor.

Parameters

dim (*int, optional*) – The axis to perform the Log softmax operation. Default: `None` .

Returns

Tensor, with the same shape as the input.

Raises

ValueError – If *dim* is not in range [-len(input.shape), len(input.shape)).

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> log_softmax = mint.nn.LogSoftmax(dim=-1)
>>> output = log_softmax(x)
>>> print(output)
[[-5.00672150e+00 -6.72150636e-03 -1.20067215e+01]
 [-7.00091219e+00 -1.40009127e+01 -9.12250078e-04]]
```

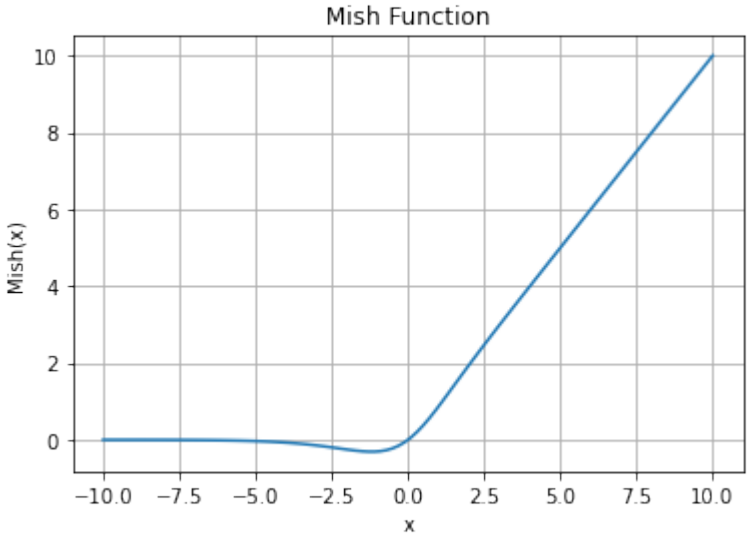
mindspore.mint.nn.Mish

class mindspore.mint.nn.**Mish**

Computes MISH (A Self Regularized Non-Monotonic Neural Activation Function) of input tensors element-wise.

Refer to *mindspore.mint.nn.functional.mish()* for more details.

Mish Activation Function Graph:



Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> x = Tensor(np.array([[-1.1, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> mish = mint.nn.Mish()
>>> output = mish(x)
>>> print(output)
[[-3.0764845e-01 3.9974124e+00 -2.6832507e-03]
 [ 1.9439589e+00 -3.3576239e-02 8.9999990e+00]]
```

mindspore.mint.nn.PReLU

class mindspore.mint.nn.**PReLU**(*num_parameters=1*, *init=0.25*, *dtype=None*)

Applies PReLU activation function element-wise.

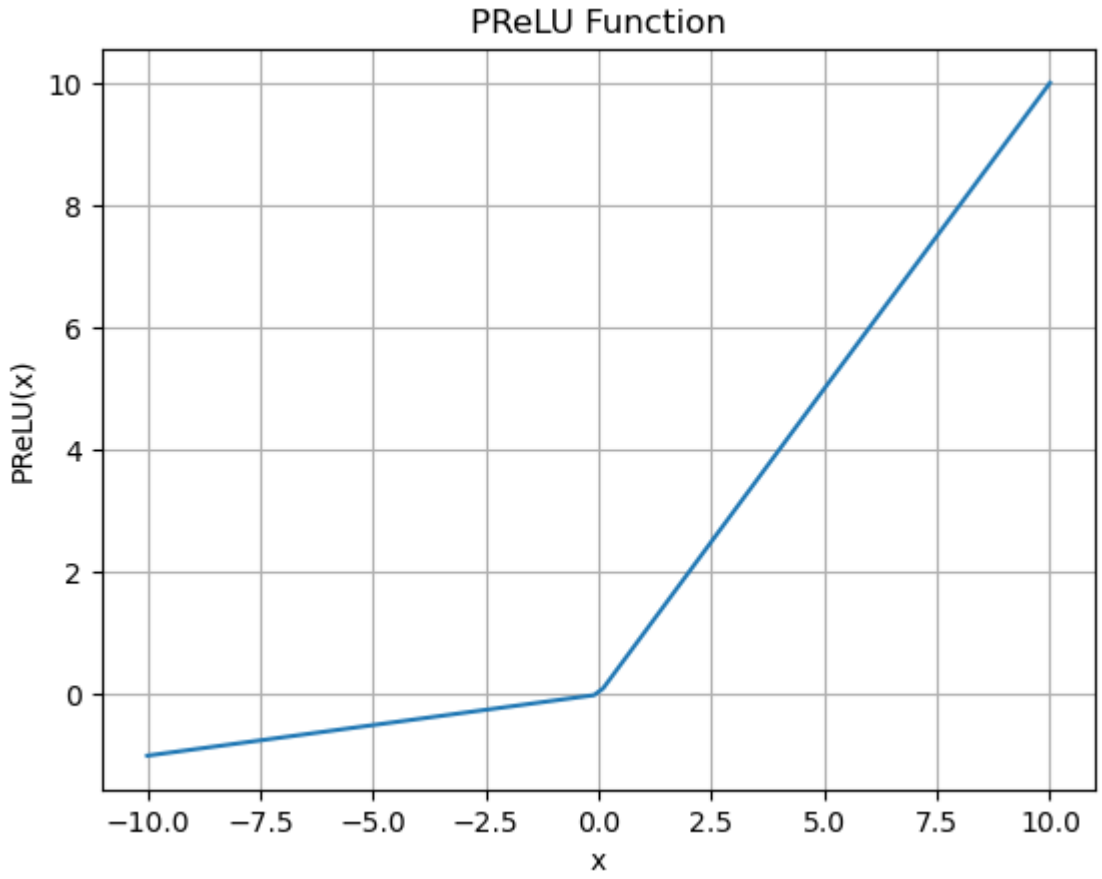
PReLU is defined as:

$$PReLU(x_i) = \max(0, x_i) + w * \min(0, x_i),$$

where x_i is an element of an channel of the input.

Here w is a learnable parameter with a default initial value 0.25. Parameter w has dimensionality of the argument channel. If called without argument channel, a single parameter w will be shared across all channels.

PReLU Activation Function Graph:



Note: Channel dim is the 2nd dim of input. When input has dims < 2, then there is no channel dim and the number of channels = 1.

Parameters

- **num_parameters** (*int, optional*) – number of *w* to learn. Although it takes an int as input, there is only two legitimate values: 1, or the number of channels at Tensor *input*. Default: `1` .
- **init** (*float, optional*) – the initial value of *w*. Default: `0.25` .
- **dtype** (`mindspore.dtype`, *optional*) – the type of *w*. Default: `None` . Supported data type is {float16, float32, bfloat16}.

Inputs:

- **input** (Tensor) - The input of PReLU.

Outputs:

Tensor, with the same dtype and shape as the *input*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> x = Tensor(np.array([[[[0.1, 0.6], [0.9, 0.9]]]]), mindspore.float32)
>>> prelu = mint.nn.PReLU()
>>> output = prelu(x)
>>> print(output)
[[[[0.1 0.6]
   [0.9 0.9]]]]
```

mindspore.mint.nn.ReLU

class mindspore.mint.nn.**ReLU**

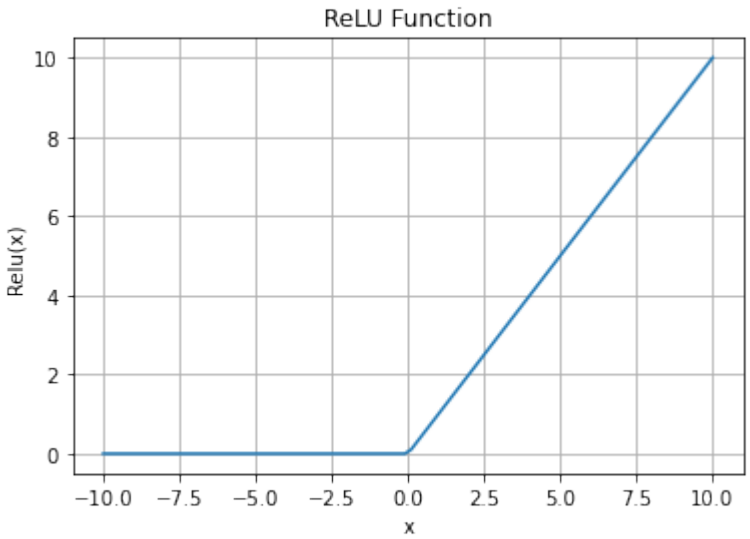
Applies ReLU (Rectified Linear Unit activation function) element-wise.

$$\text{ReLU}(input) = (input)^+ = \max(0, input),$$

It returns element-wise $\max(0, input)$.

Note: The neurons with the negative output will be suppressed and the active neurons will stay the same.

ReLU Activation Function Graph:



Inputs:

- **input** (Tensor) - The input of ReLU is a Tensor of any dimension.

Outputs:

Tensor, with the same type and shape as the *input*.

Raises

TypeError – If dtype of *input* is not supported.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([-1, 2, -3, 2, -1]), mindspore.float16)
>>> relu = mint.nn.ReLU()
>>> output = relu(input)
>>> print(output)
[0. 2. 0. 2. 0.]
```

mindspore.mint.nn.ReLU6

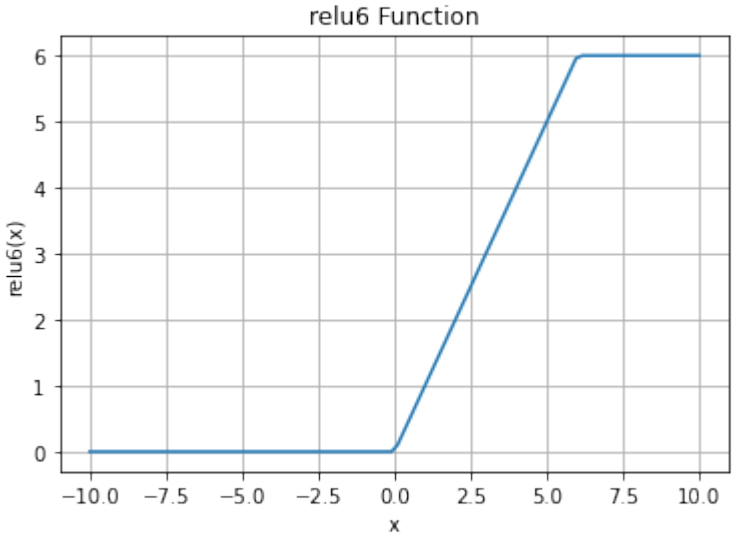
class mindspore.mint.nn.**ReLU6**(*inplace=False*)

Activation function ReLU6.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.mint.nn.functional.relu6()* for more details.

ReLU6 Activation Function Graph:



Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> relu6 = mint.nn.ReLU6()
>>> output = relu6(input)
>>> print(output)
[[0. 4. 0.]
[2. 0. 6.]]
```

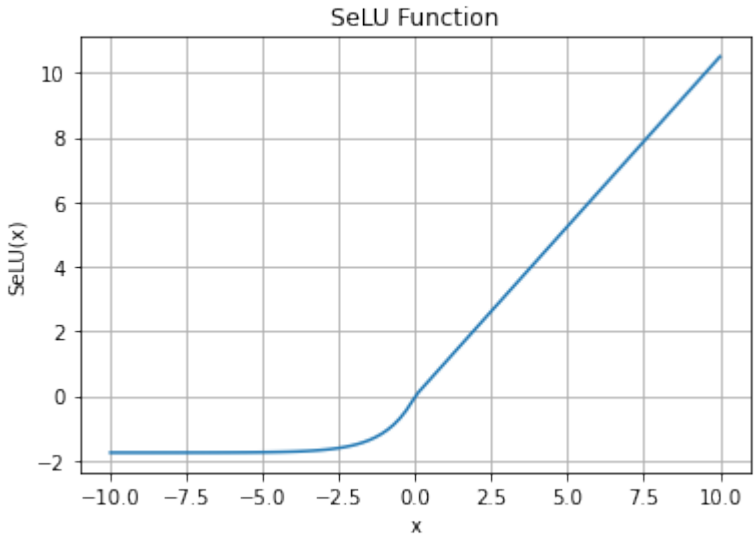
mindspore.mint.nn.SELU

class mindspore.mint.nn.**SELU**

Activation function SELU (Scaled exponential Linear Unit).

Refer to *mindspore.mint.nn.functional.selu()* for more details.

SELU Activation Function Graph:



Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> selu = mint.nn.SELU()
>>> output = selu(input)
>>> print(output)
[[-1.1113307 4.202804 -1.7575096]
[ 2.101402 -1.7462534 9.456309 ]]
```

mindspore.mint.nn.SiLU

class mindspore.mint.nn.**SiLU**

Calculates the SiLU activation function element-wise. It is also sometimes referred to as Swish function.

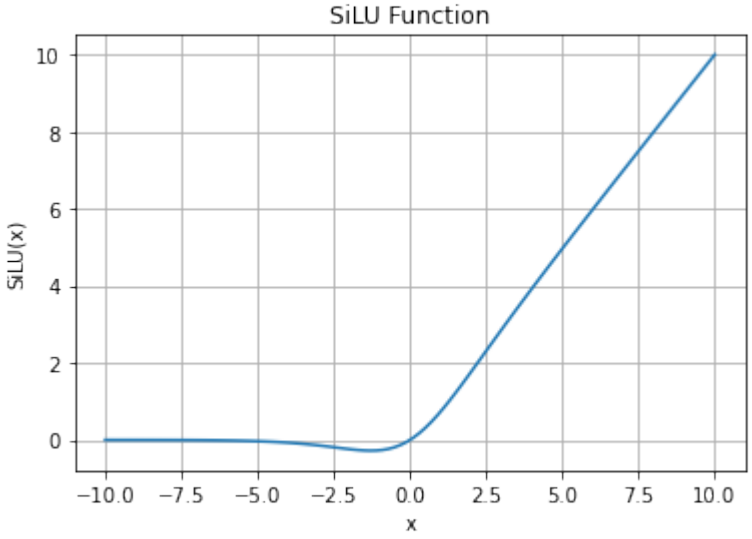
The SiLU function is defined as follows:

$$\text{SiLU}(x) = x * \sigma(x),$$

where x_i is an element of the input, $\sigma(x)$ is Sigmoid function.

$$\text{sigmoid}(x_i) = \frac{1}{1 + \exp(-x_i)},$$

SiLU Activation Function Graph:



Warning: This is an experimental API that is subject to change or deletion.

Inputs:

- **input** (Tensor) - *input* is x in the preceding formula. Input with the data type float16 or float32. Tensor of any dimension.

Outputs:

Tensor, with the same type and shape as the *input*.

Raises

TypeError – If dtype of *input* is neither float16 nor float32.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([-1, 2, -3, 2, -1]), mindspore.float16)
>>> silu = mint.nn.SiLU()
>>> output = silu(input)
>>> print(output)
[-0.269  1.762  -0.1423  1.762  -0.269]
```

mindspore.mint.nn.Sigmoid

class mindspore.mint.nn.**Sigmoid**

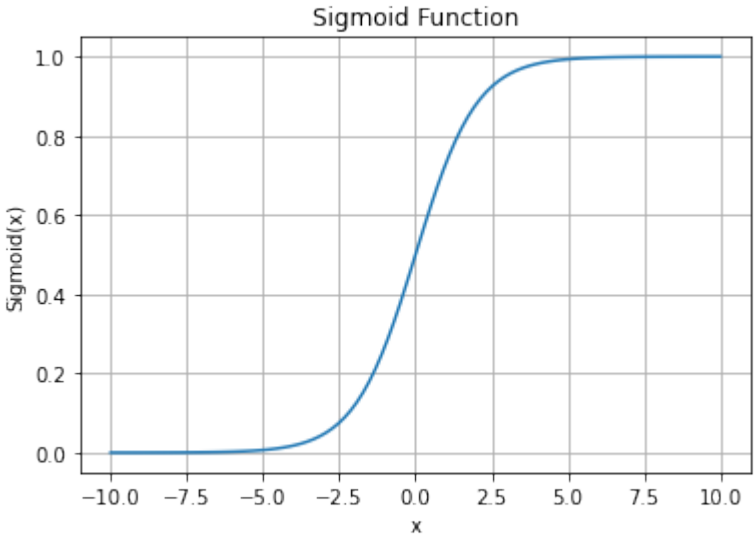
Applies sigmoid activation function element-wise.

Sigmoid function is defined as:

$$\text{sigmoid}(x_i) = \frac{1}{1 + \exp(-x_i)},$$

where x_i is the element of x.

Sigmoid Activation Function Graph:



Inputs:

- **input** (Tensor) - *input* is x in the preceding formula. Tensor of any dimension, the data type is float16, float32, float64, complex64 or complex128.

Outputs:

Tensor, with the same type and shape as the *input*.

Raises

- **TypeError** – If dtype of *input* is not float16, float32, float64, complex64 or complex128.
- **TypeError** – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> sigmoid = mint.nn.Sigmoid()
>>> output = sigmoid(input)
>>> print(output)
[0.2688  0.11914 0.5     0.881   0.7305 ]
```

mindspore.mint.nn.Softmax

class mindspore.mint.nn.**Softmax**(*dim=None*)

Applies the Softmax function to an n-dimensional input Tensor.

For details, please refer to *mindspore.mint.nn.functional.softmax()*.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> softmax = mint.nn.Softmax()
>>> output = softmax(input)
>>> print(output)
[0.03168 0.01166 0.0861  0.636   0.2341 ]
```

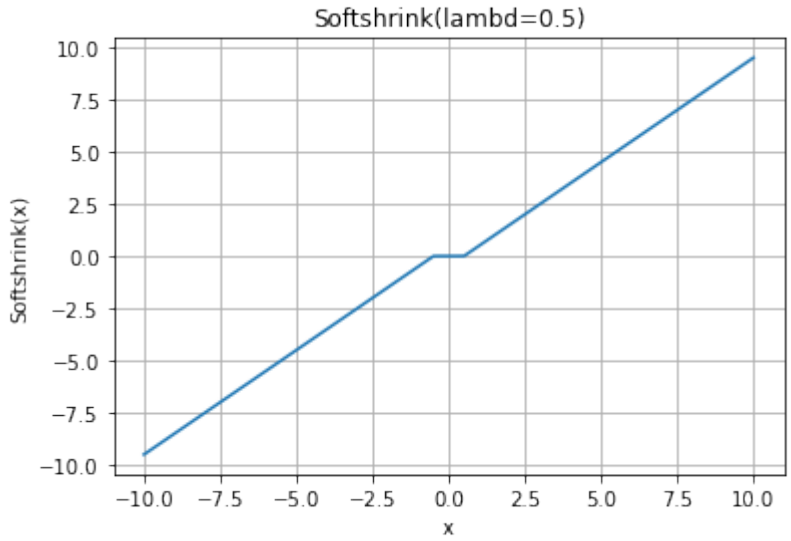
mindspore.mint.nn.Softshrink

class mindspore.mint.nn.**Softshrink**(*lambd=0.5*)

Applies the Softshrink function element-wise.

$$\text{Softshrink}(x) = \begin{cases} x - \lambda, & \text{if } x > \lambda \\ x + \lambda, & \text{if } x < -\lambda \\ 0, & \text{otherwise} \end{cases}$$

Softshrink Activation Function Graph:



Parameters

lambd (*number, optional*) – The threshold λ defined by the Soft Shrink formula. It should be greater than or equal to 0, default: `0.5`.

Inputs:

- **input** (Tensor) - The input of Soft Shrink. Supported dtypes:
  - Ascend: float16, float32, bfloat16.

Outputs:

Tensor, the same shape and data type as the input.

Raises

- **TypeError** – If *lambd* is not a float, int or bool.
- **TypeError** – If *input* is not a tensor.
- **TypeError** – If dtype of *input* is not float16, float32 or bfloat16.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([[ 0.5297,  0.7871,  1.1754], [ 0.7836,  0.6218, -1.1542]]),␣
↪mindspore.float16)
>>> softshrink = mint.nn.Softshrink()
>>> output = softshrink(input)
>>> print(output)
[[ 0.02979  0.287    0.676  ]
 [ 0.2837   0.1216  -0.6543 ]]
```

mindspore.mint.nn.Tanh

class mindspore.mint.nn.**Tanh**

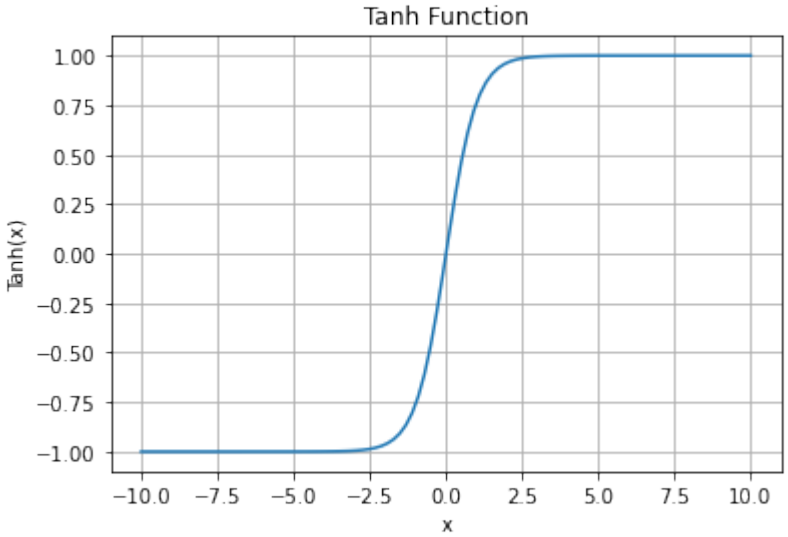
Applies the Tanh function element-wise, returns a new tensor with the hyperbolic tangent of the elements of input.

Tanh function is defined as:

$$tanh(x_i) = \frac{\exp(x_i) - \exp(-x_i)}{\exp(x_i) + \exp(-x_i)} = \frac{\exp(2x_i) - 1}{\exp(2x_i) + 1},$$

where x_i is an element of the input Tensor.

Tanh Activation Function Graph:



Warning: This is an experimental API that is subject to change or deletion.

Inputs:

- **input** (Tensor) - Tensor of any dimension, input with data type of float16 or float32.

Outputs:

Tensor, with the same type and shape as the *input*.

Raises

TypeError – If dtype of *input* is neither float16 nor float32.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([1, 2, 3, 2, 1]), mindspore.float16)
>>> tanh = mint.nn.Tanh()
>>> output = tanh(input)
>>> print(output)
[0.7617 0.964  0.995  0.964  0.7617]
```

4.4.4 Embedding Layers

API Name	Description	Supported Platforms
mindspore.mint.nn.Embedding	The value in *input* is used as the index, and the corresponding embedding vector is queried from *weight* .	Ascend

mindspore.mint.nn.Embedding

class mindspore.mint.nn.**Embedding**(*num_embeddings*, *embedding_dim*, *padding_idx=None*, *max_norm=None*, *norm_type=2.0*, *scale_grad_by_freq=False*, *sparse=False*, *_weight=None*, *_freeze=False*, *dtype=None*)

The value in *input* is used as the index, and the corresponding embedding vector is queried from *weight* .

Warning:

- This is an experimental API that is subject to change or deletion.
- On Ascend, the behavior is unpredictable when the value of *input* is invalid.

Parameters

- **num_embeddings** (*int*) –Size of the dictionary of embeddings.
- **embedding_dim** (*int*) –The size of each embedding vector.
- **padding_idx** (*int, optional*) –If the value is not None, the corresponding row of embedding vector will not be updated in training. The value of embedding vector at *padding_idx* will default to zeros when the Embedding layer is newly constructed. The value should be in range *[-num_embeddings, num_embeddings)* if it's not `None`. Default `None`.
- **max_norm** (*float, optional*) –If the value is not None, firstly get the p-norm result of the embedding vector specified by *input* where p is specified by *norm_type*; if the result is larger then *max_norm*, update the embedding vector with $\frac{max\_norm}{result+1e^{-7}}$. Default `None`.
- **norm_type** (*float, optional*) –Indicated the value of p in p-norm. Default `2.0`.
- **scale_grad_by_freq** (*bool, optional*) –If `True` the gradients will be scaled by the inverse of frequency of the index in *input*. Default `False`.
- **sparse** (*bool, optional*) –If `True`, gradient w.r.t. *weight* matrix will be a sparse tensor which has not been supported. Default: `False`.

- **_weight** (Tensor, *optional*) –Used to initialize the *weight* of Embedding. If None, the weight will be initialized from normal distribution $N(\text{sigma}=1.0, \text{mean}=0.0)$. Default None.
- **_freeze** (*bool*, *optional*) –If *weight* , the learnable weights of this module, should be freezed. Default: False.
- **dtype** (mindspore.dtype, *optional*) –Dtype of Embedding's *weight* . It is meaningless when *_weight* is not None. Default: None.

Variables:

- **weight** (Parameter) - The learnable weights of this module of shape (num_embeddings, embedding_dim), which initialized from $N(\text{sigma}=1.0, \text{mean}=0.0)$ or *_weight* .

Inputs:

- **input** (Tensor) - The indices used to lookup in the embedding vector. The data type must be int32 or int64, and the value should be in range *[0, num_embeddings)*.

Outputs:

Tensor, has the same data type as weight, the shape is $(*input.shape, embedding\_dim)$.

Raises

- **TypeError** –If *num_embeddings* is not an int.
- **TypeError** –If *embedding_dim* is not an int.
- **ValueError** –If *padding_idx* is out of valid range.
- **TypeError** –If *max_norm* is not a float.
- **TypeError** –If *norm_type* is not a float.
- **TypeError** –If *scale_grad_by_freq* is not a bool.
- **ValueError** –If *weight.shape* is invalid.
- **TypeError** –If *dtype* is not one of mindspore.dtype.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> mindspore.set_seed(0)
>>> input = Tensor([[1, 0, 1, 1], [0, 0, 1, 0]])
>>> embedding = mint.nn.Embedding(num_embeddings=10, embedding_dim=3)
>>> output = embedding(input)
>>> print(output)
[[[ 0.6712398   0.5407775   1.0317237]
  [-0.49091062 -0.42302188 -1.4807187]
  [ 0.6712398   0.5407775   1.0317237]
  [ 0.0024154   0.5407775   1.0317237]]
 [[-0.49091062 -0.42302188 -1.4807187]
  [-0.49091062 -0.42302188 -1.4807187]
  [ 0.6712398   0.5407775   1.0317237]
  [-0.49091062 -0.42302188 -1.4807187]]]
```

4.4.5 Linear Layers

API Name	Description	Supported Platforms
mindspore.mint.nn.Linear	The linear connected layer.	Ascend

mindspore.mint.nn.Linear

class mindspore.mint.nn.**Linear**(*in_features*, *out_features*, *bias=True*, *weight_init=None*, *bias_init=None*, *dtype=None*)
The linear connected layer.

Applies linear connected layer for the input. This layer implements the operation as:

$$\text{outputs} = X * kernel + bias$$

Warning: On the Ascend platform, if *bias* is `False` , the *x* cannot be greater than 6D in PYNATIVE or KBK mode.

where X is the input tensors, kernel is a weight matrix with the same data type as the X created by the layer, and bias is a bias vector with the same data type as the X created by the layer (only if the parameter *bias* is True).

Warning: In PyNative mode, if *bias* is `False` , the *x* cannot be greater than 6D.

Parameters

- **in_features** (*int*) –The number of features in the input space.
- **out_features** (*int*) –The number of features in the output space.
- **bias** (*bool, optional*) –Specifies whether the layer uses a bias vector bias. Default: `True`.
- **weight_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –The trainable weight_init parameter. The dtype is same as *x*. The values of str refer to the function *initializer*. Default: `None` , weight will be initialized using HeUniform.
- **bias_init** (*Union[Tensor, str, Initializer, numbers.Number], optional*) –The trainable bias_init parameter. The dtype is same as *x*. The values of str refer to the function *initializer*. Default: `None` , bias will be initialized using Uniform.
- **dtype** (*mindspore.dtype*, optional) –Data type of Parameter. Default: `None` . If *dtype* is `None` , *dtype* is set to `mstype.float32` when initializing the method. When *weight_init* is Tensor, Parameter has the same data type as *weight_init* , in other cases, Parameter has the same data type as *dtype*, the same goes for *bias_init*.

Inputs:

- **x** (Tensor) - Tensor of shape $(*, in\_features)$. The *in_features* in *Args* should be equal to $in\_features$ in *Inputs*.

Outputs:

Tensor of shape $(*, out\_features)$.

Raises

- **TypeError** –If *in_features* or *out_features* is not an int.
- **TypeError** –If *bias* is not a bool.

- **ValueError** –If length of shape of *weight_init* is not equal to 2 or shape[0] of *weight_init* is not equal to *out_features* or shape[1] of *weight_init* is not equal to *in_features*.
- **ValueError** –If length of shape of *bias_init* is not equal to 1 or shape[0] of *bias_init* is not equal to *out_features*.
- **RuntimeError** –On the Ascend platform, if *bias* is `False` and *x* is greater than 6D in PYNATIVE or KBK mode.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> import numpy as np
>>> x = Tensor(np.array([[180, 234, 154], [244, 48, 247]]), mindspore.float32)
>>> net = mint.nn.Linear(3, 4)
>>> output = net(x)
>>> print(output.shape)
(2, 4)
```

4.4.6 Dropout Layers

API Name	Description	Supported Platforms
mindspore.mint.nn.Dropout	Dropout layer for the input.	`Ascend`
mindspore.mint.nn.Dropout2d	During training, randomly zeroes some channels of the input tensor with probability *p* from a Bernoulli distribution (For a 4-dimensional tensor with a shape of *NCHW*, the channel feature map refers to a 2-dimensional feature map with the shape of *HW*).	`Ascend`

mindspore.mint.nn.Dropout

class mindspore.mint.nn.**Dropout**(*p=0.5*, *inplace=False*)

Dropout layer for the input.

Dropout is a means of regularization that reduces overfitting by preventing correlations between neuronal nodes. The operator randomly sets some neurons output to 0 according to *p*, which means the probability of discarding during training. And the return will be multiplied by $\frac{1}{1-p}$ during training. During the reasoning, this layer returns the same Tensor as the *x*.

This technique is proposed in paper Dropout: A Simple Way to Prevent Neural Networks from Overfitting and proved to be effective to reduce over-fitting and prevents neurons from co-adaptation. See more details in Improving neural networks by preventing co-adaptation of feature detectors.

Note:

- Each channel will be zeroed out independently on every construct call.
- Parameter *p* means the probability of the element of the input tensor to be zeroed.

Parameters

- **p** (*float, optional*) –The dropout rate of input neurons, E.g. *p* =0.9, dropping out 90% of input neurons. Default: `0.5` .
- **inplace** (*bool, optional*) –Whether to enable the operation in-place. If set to `True` , will do this operation in-place. Default: `False` .

Inputs:

- **x** (Tensor) - The input of Dropout.

Outputs:

Tensor, output tensor with the same shape as the *x*.

Raises

- **TypeError** –If the dtype of *p* is not float.
- **ValueError** –If length of shape of *x* is less than 1.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> x = Tensor(np.ones([2, 2, 3]), mindspore.float32)
>>> net = mint.nn.Dropout(p=0.2)
>>> net.set_train()
>>> output = net(x)
>>> print(output.shape)
(2, 2, 3)
```

mindspore.mint.nn.Dropout2d

class mindspore.mint.nn.**Dropout2d**(*p=0.5*)

During training, randomly zeroes some channels of the input tensor with probability *p* from a Bernoulli distribution (For a 4-dimensional tensor with a shape of *NCHW*, the channel feature map refers to a 2-dimensional feature map with the shape of *HW*).

For example, the *j_th* channel of the *i_th* sample in the batched input is a to-be-processed *2D* tensor input[i,j]. Each channel will be zeroed out independently on every forward call with probability *p* using samples from a Bernoulli distribution.

Dropout2d can improve the independence between channel feature maps.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.mint.nn.functional.dropout2d()* for more details.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> dropout = mint.nn.Dropout2d(p=0.5)
>>> x = Tensor(np.ones([2, 1, 2, 3]), mindspore.float32)
>>> output = dropout(x)
>>> print(output.shape)
(2, 1, 2, 3)
```

4.4.7 Pooling Layers

API Name	Description	Supported Platforms
mindspore.mint.nn.AdaptiveAvgPool1d	Applies a 1D adaptive average pooling over an input signal composed of several input planes.	Ascend
mindspore.mint.nn.AdaptiveAvgPool2d	Applies a 2D adaptive average pooling over an input signal composed of several input planes.	Ascend
mindspore.mint.nn.AdaptiveAvgPool3d	This operator applies a 3D adaptive average pooling to an input signal composed of multiple input planes.	Ascend
mindspore.mint.nn.AdaptiveMaxPool1d	Applies a 1D adaptive max pooling over an input signal composed of several input planes.	Ascend
mindspore.mint.nn.AvgPool2d	Applies a 2D average pooling over an input Tensor which can be regarded as a composition of 2D input planes.	Ascend
mindspore.mint.nn.AvgPool3d	Applies a 3D average pooling over an input Tensor which can be regarded as a composition of 3D input planes.	Ascend
mindspore.mint.nn.MaxUnpool2d	Computes the inverse of *Maxpool2d*.	Ascend

mindspore.mint.nn.AdaptiveAvgPool1d

class mindspore.mint.nn.**AdaptiveAvgPool1d**(*output_size*)

Applies a 1D adaptive average pooling over an input signal composed of several input planes.

The output is of size L_{out} , for any input size. The number of output features is equal to the number of input planes.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

output_size (*int*) – the target output size L_{out} .

Inputs:

- **input** (Tensor) - The input with shape (N, C, L_{in}) or (C, L_{in}) .

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([[[2, 1, 2], [2, 3, 5]]]), mindspore.float16)
>>> net = mint.nn.AdaptiveAvgPool1d(3)
>>> output = net(input)
>>> print(output)
[[[2. 1. 2.]
  [2. 3. 5.]]]
```

mindspore.mint.nn.AdaptiveAvgPool2d

class mindspore.mint.nn.**AdaptiveAvgPool2d**(*output_size*)

Applies a 2D adaptive average pooling over an input signal composed of several input planes.

The output is of size HxW , for any input size. The number of output features is equal to the number of input planes.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

output_size (*Union(int, tuple[int])*) – the target output size of the image of the form HxW . Can be a tuple (H, W) or a single H for square image HxH . H and W can be either a `int` , or `None` which means the size will be the same as that of the input.

Inputs:

- **input** (Tensor) - The input with shape (N, C, H, W) or (C, H, W) .

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([[[2, 1, 2], [2, 3, 5]]]), mindspore.float16)
>>> net = mint.nn.AdaptiveAvgPool2d((2, 2))
>>> output = net(input)
>>> print(output)
[[[1.5 1.5]
  [2.5 4. ]]]
```

mindspore.mint.nn.AdaptiveAvgPool3d

class mindspore.mint.nn.**AdaptiveAvgPool3d**(*output_size*)

This operator applies a 3D adaptive average pooling to an input signal composed of multiple input planes. That is, for any input size, the size of the specified output is (D, H, W). The number of output features is equal to the number of input planes.

Suppose the last 3 dimension size of input is (inD, inH, inW), then the last 3 dimension size of output is $(outD, outH, outW)$.

$$
\begin{aligned}
&\forall \quad od \in [0, outD-1], oh \in [0, outH-1], ow \in [0, outW-1] \\
&output[od, oh, ow] = \\
&\qquad mean(input[istartD : iendD+1, istartH : iendH+1, istartW : iendW+1]) \\
&where, \\
&\qquad istartD = \left\lceil \frac{od * inD}{outD} \right\rceil \\
&\qquad iendD = \left\lfloor \frac{(od+1) * inD}{outD} \right\rfloor \\
&\qquad istartH = \left\lceil \frac{oh * inH}{outH} \right\rceil \\
&\qquad iendH = \left\lfloor \frac{(oh+1) * inH}{outH} \right\rfloor \\
&\qquad istartW = \left\lceil \frac{ow * inW}{outW} \right\rceil \\
&\qquad iendW = \left\lfloor \frac{(ow+1) * inW}{outW} \right\rfloor
\end{aligned}
$$

> **Warning:** For Ascend, it is only supported on Atlas A2 Training Series Products. This is an experimental optimizer API that is subject to change or deletion.

Parameters

output_size (*Union[int, tuple]*) – The target output size. *output_size* can be a tuple (D, H, W), or an int D for (D, D, D). D, H and W can be int or None which means the output size is the same as that of the input.

Inputs:

- **input** (Tensor) - The input of AdaptiveAvgPool3d, which is a 5D or 4D Tensor.

Outputs:

Tensor, with the same type as the *input*.

Raises

- **TypeError** – If *input* is not a Tensor.
- **ValueError** – If the dimension of *input* is not 4D or 5D.
- **ValueError** – If *output_size* value is not positive.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint
>>> import numpy as np
>>> # case 1: output_size=(3, 3, 4)
>>> output_size=(3, 3, 4)
>>> input_x_val = np.random.randn(4, 3, 5, 6, 7)
>>> input_x = ms.Tensor(input_x_val, ms.float32)
>>> net = mint.nn.AdaptiveAvgPool3d(output_size)
>>> output = net(input_x)
>>> print(output.shape)
(4, 3, 3, 3, 4)
>>> # case 2: output_size=4
>>> output_size=5
>>> input_x_val = np.random.randn(2, 3, 8, 6, 12)
>>> input_x = ms.Tensor(input_x_val, ms.float32)
>>> net = mint.nn.AdaptiveAvgPool3d(output_size)
>>> output = net(input_x)
>>> print(output.shape)
(2, 3, 5, 5, 5)
>>> # case 3: output_size=(None, 4, 5)
>>> output_size=(None, 4, 5)
>>> input_x_val = np.random.randn(4, 1, 9, 10, 8)
>>> input_x = ms.Tensor(input_x_val, ms.float32)
>>> net = mint.nn.AdaptiveAvgPool3d(output_size)
>>> output = net(input_x)
>>> print(output.shape)
(4, 1, 9, 4, 5)
```

mindspore.mint.nn.AdaptiveMaxPool1d

class mindspore.mint.nn.**AdaptiveMaxPool1d**(*output_size*, *return_indices=False*)

Applies a 1D adaptive max pooling over an input signal composed of several input planes.

The output is of size L_{out} , for any input size. The number of output features is equal to the number of input planes.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **output_size** (*Union[int, tuple]*) –the target output size L_{out} .
- **return_indices** (*bool, optional*) –Whether to return the index of the maximum value. Default: `False` .

Inputs:

- **input** (Tensor) - The input with shape (N, C, L_{in}) or (C, L_{in}) .

Outputs:

Union(Tensor, tuple(Tensor, Tensor)).

- If *return_indices* is False, output is a Tensor, with shape (N, C, L_{out}). It has the same data type as x.
- If *return_indices* is True, output is a Tuple of 2 Tensors, representing the result and where the max values are generated.

Raises

- **TypeError** – If *input* is not a tensor.
- **TypeError** – If dtype of *input* is not float16, float32 or float64.
- **TypeError** – If *output_size* is not int or tuple.
- **TypeError** – If *return_indices* is not a bool.
- **ValueError** – If *output_size* is a tuple and the length of *output_size* is not 1.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([[[2, 1, 2], [2, 3, 5]]]), mindspore.float16)
>>> net = mint.nn.AdaptiveMaxPool1d(3)
>>> output = net(input)
>>> print(output)
[[[2. 1. 2.]
  [2. 3. 5.]]]
```

mindspore.mint.nn.AvgPool2d

class mindspore.mint.nn.**AvgPool2d**(*kernel_size*, *stride=None*, *padding=0*, *ceil_mode=False*, *count_include_pad=True*, *divisor_override=None*)

Applies a 2D average pooling over an input Tensor which can be regarded as a composition of 2D input planes.

For details, please refer to *mindspore.mint.nn.functional.avg_pool2d()*.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> from mindspore import dtype as mstype
>>> input = Tensor(np.arange(1 * 3 * 3 * 4).reshape(1, 3, 3, 4), mstype.float32)
>>> net = mint.nn.AvgPool2d(kernel_size=2, stride=1)
>>> output = net(input)
>>> print(output.shape)
(1, 3, 2, 3)
```

mindspore.mint.nn.AvgPool3d

class mindspore.mint.nn.**AvgPool3d**(*kernel_size*, *stride=None*, *padding=0*, *ceil_mode=False*, *count_include_pad=True*, *divisor_override=None*)

Applies a 3D average pooling over an input Tensor which can be regarded as a composition of 3D input planes.

> **Warning:** This is an experimental API that is subject to change or deletion.

For details, please refer to *mindspore.mint.nn.functional.avg_pool3d()*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> pool = ms.mint.nn.AvgPool3d(kernel_size=3, stride=1)
>>> x = ms.ops.randn(1, 2, 4, 4, 5).astype(ms.float32)
>>> output = pool(x)
>>> print(output.shape)
(1, 2, 2, 2, 3)
>>> x1 = ms.ops.randn(6, 5, 7, 7, 5).astype(ms.float32)
>>> pool2 = ms.mint.nn.AvgPool3d(4, stride=2, padding=(2, 2, 1), divisor_override=10)
>>> output2 = pool2(x1)
>>> print(output2.shape)
(6, 5, 4, 4, 2)
```

mindspore.mint.nn.MaxUnpool2d

class mindspore.mint.nn.**MaxUnpool2d**(*kernel_size*, *stride=None*, *padding=0*)

Computes the inverse of *Maxpool2d*.

MaxUnpool2d keeps the maximal value and set all position of non-maximal values to zero. Typically the input is of shape (N, C, H_{in}, W_{in}) or (C, H_{in}, W_{in}), and the output is of shape (N, C, H_{out}, W_{out}) or (C, H_{out}, W_{out}). The operation is as follows.

$$H_{out} = (H_{in} - 1) \times stride[0] - 2 \times padding[0] + kernel\_size[0]$$
$$W_{out} = (W_{in} - 1) \times stride[1] - 2 \times padding[1] + kernel\_size[1]$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **kernel_size** (*Union[int, tuple[int]]*) – The size of kernel used to take the maximum value, an int number that represents height and width of the kernel, or a tuple of two int numbers that represent height and width respectively.
- **stride** (*Union[int, tuple[int]], optional*) – The distance of kernel moving, an int number that represents the height and width of movement are both stride, or a tuple of two int numbers that represent height and width of movement respectively. Default: `None` , which indicates the moving step is *kernel_size* .

- **padding** (*Union[int, tuple[int]], optional*) –The pad value to be filled. Default: `0` . If *padding* is an integer, the paddings of height and width are the same, equal to padding. If *padding* is a tuple of two integers, the padding of height and width equal to padding[0] and padding[1] correspondingly.

Inputs:

- **input** (Tensor) - The input Tensor to invert. Tensor of shape (N, C, H_{in}, W_{in}) or (C, H_{in}, W_{in}).
- **indices** (Tensor) - Max values' index represented by the indices. Tensor of shape must be same with input 'input'. Values of indices must belong to $[0, H_{in} \times W_{in} - 1]$. Data type must be in int32 or int64.
- **output_size** (tuple[int], optional) - The target output size. Default: `None` . If output_size == (), then the shape of output computed by *kernel_size*, *stride* and *padding*. If output_size != (), then output_size must be (N, C, H, W) , (C, H, W) or (H, W) and output_size must belong to $[(N, C, H_{out} - stride[0], W_{out} - stride[1]), (N, C, H_{out} + stride[0], W_{out} + stride[1])]$.

Outputs:

Tensor, with shape (N, C, H_{out}, W_{out}) or (C, H_{out}, W_{out}), with the same data type with *input*.

Raises

- **TypeError** –If data type of *input* or *indices* is not supported.
- **TypeError** –If *kernel_size*, *stride* or *padding* is neither an int nor a tuple.
- **ValueError** –If numbers in *stride*, *padding* or *kernel_size* is not positive.
- **ValueError** –If the shapes of *input* and *indices* are not equal.
- **ValueError** –If *input* whose length is not 3 or 4.
- **ValueError** –If *output_size* whose type is not tuple.
- **ValueError** –If *output_size* is not close to output size computed by attr *kernel_size*, *stride*, *padding*.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[[[0, 1], [8, 9]]]]).astype(np.float32))
>>> indices = Tensor(np.array([[[[0, 1], [2, 3]]]]).astype(np.int64))
>>> net =  mint.nn.MaxUnpool2d(1, stride=1, padding=0)
>>> output = net(input, indices)
>>> print(output.asnumpy())

4.4.8 Padding Layers

API Name	Description	Supported Platforms
mindspore.mint.nn.ConstantPad1d	Pad the last dimension of *input* tensor using *padding* and *value*.	Ascend
mindspore.mint.nn.ConstantPad2d	Pad the last 2 dimensions of *input* tensor using *padding* and *value*.	Ascend
mindspore.mint.nn.ConstantPad3d	Pad the last 3 dimension of *input* tensor using *padding* and *value*.	Ascend
mindspore.mint.nn.ReflectionPad1d	Pad the last dimension of *input* tensor using the reflection of the input boundary.	Ascend
mindspore.mint.nn.ReflectionPad2d	Pad the last 2 dimension of *input* tensor using the reflection of the input boundary.	Ascend
mindspore.mint.nn.ReflectionPad3d	Pad the last 3 dimension of *input* tensor using the reflection of the input boundary.	Ascend
mindspore.mint.nn.ReplicationPad1d	Pad the last dimension of *input* tensor using the replication of the input boundary.	Ascend
mindspore.mint.nn.ReplicationPad2d	Pad the last 2 dimension of *input* tensor using the replication of the input boundary.	Ascend
mindspore.mint.nn.ReplicationPad3d	Pad the last 3 dimension of *input* tensor using the replication of the input boundary.	Ascend
mindspore.mint.nn.ZeroPad1d	Pad the last dimension of *input* tensor with 0 using *padding*.	Ascend
mindspore.mint.nn.ZeroPad2d	Pad the last 2 dimension of *input* tensor with 0 using *padding*.	Ascend
mindspore.mint.nn.ZeroPad3d	Pad the last 3 dimension of *input* tensor with 0 using *padding*.	Ascend

mindspore.mint.nn.ConstantPad1d

class mindspore.mint.nn.**ConstantPad1d**(*padding*, *value*)

Pad the last dimension of *input* tensor using *padding* and *value*.

For more information, please refer to *mindspore.mint.nn.functional.pad()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **padding** (*Union[int, tuple, list]*) –Specifies padding size.
- **value** (*Union[int, float]*) –Specifies padding value.

Inputs:

- **input** (Tensor) - shape is $(N, *)$, where $*$ means, any number of additional dimensions.

Outputs:

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not an integer of a list or tuple of 2 integers.
- **TypeError** – If *input* is not Tensor.
- **TypeError** – If *value* is not int or float.
- **ValueError** – If *padding* contains negative value.
- **ValueError** – If *padding* is a tuple or list, and the length does not match the tensor dimension.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = np.ones(shape=(1, 2, 3, 4)).astype(np.float32)
>>> x = ms.Tensor(x)
>>> # padding is tuple
>>> padding = (0, 1)
>>> value = 0.5
>>> pad1d = ms.mint.nn.ConstantPad1d(padding, value)
>>> out = pad1d(x)
>>> print(out)
[[[[1.  1.  1.  1.  0.5]
   [1.  1.  1.  1.  0.5]
   [1.  1.  1.  1.  0.5]]
  [[1.  1.  1.  1.  0.5]
   [1.  1.  1.  1.  0.5]
   [1.  1.  1.  1.  0.5]]]]
>>> print(out.shape)
(1, 2, 3, 5)
>>> # padding is int
>>> padding = 1
>>> value = 0.5
>>> pad1d = ms.mint.nn.ConstantPad1d(padding, value)
>>> out = pad1d(x)
>>> print(out)
[[[[0.5 1.  1.  1.  1.  0.5]
   [0.5 1.  1.  1.  1.  0.5]
   [0.5 1.  1.  1.  1.  0.5]]
  [[0.5 1.  1.  1.  1.  0.5]
   [0.5 1.  1.  1.  1.  0.5]
   [0.5 1.  1.  1.  1.  0.5]]]]
>>> print(out.shape)
(1, 2, 3, 6)
```

mindspore.mint.nn.ConstantPad2d

class mindspore.mint.nn.**ConstantPad2d**(*padding*, *value*)

Pad the last 2 dimensions of *input* tensor using *padding* and *value*.

For more information, please refer to *mindspore.mint.nn.functional.pad()*.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **padding** (*Union[int, tuple, list]*) –Specifies padding size.
- **value** (*Union[int, float]*) –Specifies padding value.

Inputs:

- **input** (Tensor) - shape is $(N, *)$, where $*$ means, any number of additional dimensions.

Outputs:

Tensor, the tensor after padding.

Raises

- **TypeError** –If *padding* is not an integer of a list or tuple of 4 integers.
- **TypeError** –If *input* is not Tensor.
- **TypeError** –If *value* is not int or float.
- **ValueError** –If *padding* contains negative value.
- **ValueError** –If *padding* is a tuple or list, and the length does not match the tensor dimension.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = np.ones(shape=(1, 2, 3, 4)).astype(np.float32)
>>> x = ms.Tensor(x)
>>> padding = (1, 1, 0, 1)
>>> value = 0.5
>>> pad2d = ms.mint.nn.ConstantPad2d(padding, value)
>>> out = pad2d(x)
>>> print(out)
[[[[0.5  1.  1.  1.  1.  0.5]
   [0.5  1.  1.  1.  1.  0.5]
   [0.5  1.  1.  1.  1.  0.5]
   [0.5  0.5 0.5 0.5 0.5 0.5]]
  [[0.5  1.  1.  1.  1.  0.5]
   [0.5  1.  1.  1.  1.  0.5]
   [0.5  1.  1.  1.  1.  0.5]
   [0.5  0.5 0.5 0.5 0.5 0.5]]]]
```

(continues on next page)

(continued from previous page)

```
>>> print(out.shape)
(1, 2, 4, 6)
```

mindspore.mint.nn.ConstantPad3d

class mindspore.mint.nn.**ConstantPad3d**(*padding*, *value*)

Pad the last 3 dimension of *input* tensor using *padding* and *value*.

For more information, please refer to *mindspore.mint.nn.functional.pad()*.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **padding** (*Union[int, tuple, list]*) –Specifies padding size.
- **value** (*Union[int, float]*) –Specifies padding value.

Inputs:

- **input** (Tensor) - shape is $(N, *)$, where $*$ means, any number of additional dimensions.

Outputs:

Tensor, the tensor after padding.

Raises

- **TypeError** –If *padding* is not an integer of a list or tuple of 6 integers.
- **TypeError** –If *input* is not Tensor.
- **TypeError** –If *value* is not int or float.
- **ValueError** –If *padding* contains negative value.
- **ValueError** –If *padding* is a tuple or list, and the length does not match the tensor dimension.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = np.ones(shape=(1, 2, 3, 4)).astype(np.float32)
>>> x = ms.Tensor(x)
>>> padding = (1, 1, 0, 1, 1, 0)
>>> value = 0.5
>>> pad3d = ms.mint.nn.ConstantPad3d(padding, value)
>>> out = pad3d(x)
>>> print(out)
[[[[0.5 0.5 0.5 0.5 0.5 0.5]
   [0.5 0.5 0.5 0.5 0.5 0.5]
```

(continues on next page)

(continued from previous page)

```
    [0.5 0.5 0.5 0.5 0.5 0.5]

   [[0.5 1.  1.  1.  1.  0.5]
    [0.5 1.  1.  1.  1.  0.5]
    [0.5 1.  1.  1.  1.  0.5]
    [0.5 0.5 0.5 0.5 0.5 0.5]]
   [[0.5 1.  1.  1.  1.  0.5]
    [0.5 1.  1.  1.  1.  0.5]
    [0.5 1.  1.  1.  1.  0.5]
    [0.5 0.5 0.5 0.5 0.5 0.5]]]]
>>> print(out.shape)
(1, 3, 4, 6)
```

mindspore.mint.nn.ReflectionPad1d

class mindspore.mint.nn.**ReflectionPad1d**(*padding*)

Pad the last dimension of *input* tensor using the reflection of the input boundary.

For more information, please refer to *mindspore.mint.nn.functional.pad()*.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

padding (*Union[int, tuple, list]*) – Specifies padding size.

Inputs:

- **input** (Tensor) - 2D or 3D input Tensor with shape: (C, W_{in}) or (N, C, W_{in}).

Outputs:

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not an integer of a list or tuple of 2 integers.
- **TypeError** – If *input* is not Tensor.
- **ValueError** – If *padding* contains negative value.
- **ValueError** – If *padding* is a tuple or list, and the length does not match the tensor dimension.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = ms.Tensor(np.array([[[0, 1, 2, 3], [4, 5, 6, 7]]]).astype(np.float32))
>>> # x has shape (1, 2, 4)
>>> padding = (3, 1)
>>> # The first and the second dimension of x remain the same.
>>> # The third dimension of x: W_out = W_in + pad_left + pad_right = 4 + 3 + 1 = 8
>>> pad1d = ms.mint.nn.ReflectionPad1d(padding)
>>> out = pad1d(x)
>>> # The shape of out is (1, 2, 8)
>>> print(out)
[[[3. 2. 1. 0. 1. 2. 3. 2.]
  [7. 6. 5. 4. 5. 6. 7. 6.]]]
```

mindspore.mint.nn.ReflectionPad2d

class mindspore.mint.nn.**ReflectionPad2d**(*padding*)

Pad the last 2 dimension of *input* tensor using the reflection of the input boundary.

For more information, please refer to *mindspore.mint.nn.functional.pad()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

padding (*Union[int, tuple, list]*) – Specifies padding size.

Inputs:

- **input** (Tensor) - 3D or 4D input Tensor with shape: (C, H_{in}, W_{in}) or (N, C, H_{in}, W_{in}).

Outputs:

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not an integer of a list or tuple of 4 integers.
- **TypeError** – If *input* is not Tensor.
- **ValueError** – If *padding* contains negative value.
- **ValueError** – If *padding* is a tuple or list, and the length does not match the tensor dimension.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = ms.Tensor(np.array([[[0, 1, 2], [3, 4, 5], [6, 7, 8]]]).astype(np.float32))
>>> # x has shape (1, 3, 3)
>>> padding = (1, 1, 2, 0)
>>> pad2d = ms.mint.nn.ReflectionPad2d(padding)
>>> # The first dimension of x remains the same.
>>> # The second dimension of x: H_out = H_in + pad_up + pad_down = 3 + 1 + 1 = 5
>>> # The third dimension of x: W_out = W_in + pad_left + pad_right = 3 + 2 + 0 = 5
>>> out = pad2d(x)
>>> # The shape of out is (1, 5, 5)
>>> print(out)
[[[7. 6. 7. 8. 7.]
  [4. 3. 4. 5. 4.]
  [1. 0. 1. 2. 1.]
  [4. 3. 4. 5. 4.]
  [7. 6. 7. 8. 7.]]]
```

mindspore.mint.nn.ReflectionPad3d

class mindspore.mint.nn.**ReflectionPad3d**(*padding*)

Pad the last 3 dimension of *input* tensor using the reflection of the input boundary.

For more information, please refer to *mindspore.mint.nn.functional.pad()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

padding (*Union[int, tuple, list]*) – Specifies padding size.

Inputs:

- **input** (Tensor) - 4D or 5D input Tensor with shape: $(N, D_{in}, H_{in}, W_{in})$ or $(N, C, D_{in}, H_{in}, W_{in})$.

Outputs:

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not an integer of a list or tuple of 6 integers.
- **TypeError** – If *input* is not Tensor.
- **ValueError** – If *padding* contains negative value.
- **ValueError** – If *padding* is a tuple or list, and the length does not match the tensor dimension.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> arr = np.arange(8).astype(np.float32).reshape((1, 2, 2, 2))
>>> x = ms.Tensor(arr)
>>> # x has shape (1, 2, 2, 2)
>>> padding = (1, 1, 1, 0, 0, 1)
>>> pad3d = ms.mint.nn.ReflectionPad3d(padding)
>>> out = pad3d(x)
>>> # The first dimension of x remains the same.
>>> # The second dimension of x: D_out = D_in + pad_front + pad_back = 2 + 0 + 1 = 3
>>> # The third dimension of x: H_out = H_in + pad_up + pad_down = 2 + 1 + 0 = 3
>>> # The last dimension of x: W_out = W_in + pad_left + pad_right = 2 + 1 + 1 = 4
>>> # The shape of out is (1, 3, 3, 4)
>>> print(out)
[[[[3. 2. 3. 2.]
   [1. 0. 1. 0.]
   [3. 2. 3. 2.]]
  [[7. 6. 7. 6.]
   [5. 4. 5. 4.]
   [7. 6. 7. 6.]]
  [[3. 2. 3. 2.]
   [1. 0. 1. 0.]
   [3. 2. 3. 2.]]]]
```

mindspore.mint.nn.ReplicationPad1d

class mindspore.mint.nn.**ReplicationPad1d**(*padding*)

Pad the last dimension of *input* tensor using the replication of the input boundary.

For more information, please refer to *mindspore.mint.nn.functional.pad()*.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

padding (*Union[int, tuple, list]*) – Specifies padding size.

Inputs:

- **input** (Tensor) - 2D or 3D input Tensor with shape: (C, W_{in}) or (N, C, W_{in}).

Outputs:

The tensor after padding.

Raises

- **TypeError** – If *padding* is not an integer of a list or tuple of 2 integers.
- **TypeError** – If *input* is not Tensor.
- **ValueError** – If *padding* is a tuple or list, and the length does not match the tensor dimension.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> pad1d = ms.mint.nn.ReplicationPad1d(2)
>>> input = ms.Tensor(np.arange(0, 8).reshape(1, 2, 4), ms.float32)
>>> print(input)
[[[0. 1. 2. 3.]
  [4. 5. 6. 7.]]]
>>> out = pad1d(input)
>>> print(out)
[[[0. 0. 0. 1. 2. 3. 3. 3.]
  [4. 4. 4. 5. 6. 7. 7. 7.]]]
>>> pad1d = ms.mint.nn.ReplicationPad1d((3, 1))
>>> out = pad1d(input)
>>> print(out)
[[[0. 0. 0. 0. 1. 2. 3. 3.]
  [4. 4. 4. 4. 5. 6. 7. 7.]]]
```

mindspore.mint.nn.ReplicationPad2d

class mindspore.mint.nn.**ReplicationPad2d**(*padding*)

Pad the last 2 dimension of *input* tensor using the replication of the input boundary.

For more information, please refer to *mindspore.mint.nn.functional.pad()*.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

padding (*Union[int, tuple, list]*) – Specifies padding size.

Inputs:

- **input** (Tensor) - 3D or 4D input Tensor with shape: (C, H_{in}, W_{in}) or (N, C, H_{in}, W_{in}).

Outputs:

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not an integer of a list or tuple of 4 integers.
- **TypeError** – If *input* is not Tensor.
- **ValueError** – If *padding* is a tuple or list, and the length does not match the tensor dimension.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> pad2d = ms.mint.nn.ReplicationPad2d(2)
>>> input = ms.Tensor(np.arange(0, 9).reshape(1, 1, 3, 3), ms.float32)
>>> print(input)
[[[[0. 1. 2.]
   [3. 4. 5.]
   [6. 7. 8.]]]]
>>> out = pad2d(input)
>>> print(out)
[[[[0. 0. 0. 1. 2. 2. 2.]
   [0. 0. 0. 1. 2. 2. 2.]
   [0. 0. 0. 1. 2. 2. 2.]
   [3. 3. 3. 4. 5. 5. 5.]
   [6. 6. 6. 7. 8. 8. 8.]
   [6. 6. 6. 7. 8. 8. 8.]
   [6. 6. 6. 7. 8. 8. 8.]]]]
>>> pad2d = ms.mint.nn.ReplicationPad2d((1, 1, 2, 0))
>>> out = pad2d(input)
>>> print(out)
[[[[0. 0. 1. 2. 2.]
   [0. 0. 1. 2. 2.]
   [0. 0. 1. 2. 2.]
   [3. 3. 4. 5. 5.]
   [6. 6. 7. 8. 8.]]]]
```

mindspore.mint.nn.ReplicationPad3d

class mindspore.mint.nn.**ReplicationPad3d**(*padding*)

Pad the last 3 dimension of *input* tensor using the replication of the input boundary.

For more information, please refer to *mindspore.mint.nn.functional.pad()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

padding (*Union[int, tuple, list]*) – Specifies padding size.

Inputs:

- **input** (Tensor) - 4D or 5D input Tensor with shape: $(N, D_{in}, H_{in}, W_{in})$ or $(N, C, D_{in}, H_{in}, W_{in})$.

Outputs:

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not an integer of a list or tuple of 6 integers.
- **TypeError** – If *input* is not Tensor.
- **ValueError** – If *padding* is a tuple or list, and the length does not match the tensor dimension.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> pad3d = ms.mint.nn.ReplicationPad3d(1)
>>> input = ms.Tensor(np.arange(0, 9).reshape(1, 1, 1, 3, 3), ms.float32)
>>> out = pad3d(input)
>>> print(out)
[[[[[0. 0. 1. 2. 2.]
    [0. 0. 1. 2. 2.]
    [3. 3. 4. 5. 5.]
    [6. 6. 7. 8. 8.]
    [6. 6. 7. 8. 8.]]
   [[0. 0. 1. 2. 2.]
    [0. 0. 1. 2. 2.]

    [6. 6. 7. 8. 8.]]
   [[0. 0. 1. 2. 2.]
    [0. 0. 1. 2. 2.]
    [3. 3. 4. 5. 5.]
    [6. 6. 7. 8. 8.]
    [6. 6. 7. 8. 8.]]]]]
```

mindspore.mint.nn.ZeroPad1d

class mindspore.mint.nn.**ZeroPad1d**(*padding*)

Pad the last dimension of *input* tensor with 0 using *padding*.

For more information, please refer to *mindspore.mint.nn.functional.pad()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

padding (*Union[int, tuple, list]*) – Specifies padding size.

Inputs:

- **input** (Tensor) - shape is $(N, *)$, where $*$ means, any number of additional dimensions.

Outputs:

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not an integer of a list or tuple of 2 integers.
- **TypeError** – If *input* is not Tensor.
- **ValueError** – If *padding* contains negative value.

- **ValueError** – If *padding* is a tuple or list, and the length does not match the tensor dimension.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = np.ones(shape=(1, 2, 3, 4)).astype(np.float32)
>>> x = ms.Tensor(x)
>>> # padding is tuple
>>> padding = (0, 1)
>>> pad1d = ms.mint.nn.ZeroPad1d(padding)
>>> out = pad1d(x)
>>> print(out)
[[[[1.  1.  1.  1.  0.]

>>> print(out.shape)
(1, 2, 3, 6)
```

mindspore.mint.nn.ZeroPad2d

class mindspore.mint.nn.**ZeroPad2d**(*padding*)

Pad the last 2 dimension of *input* tensor with 0 using *padding*.

For more information, please refer to *mindspore.mint.nn.functional.pad()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

padding (*Union[int, tuple, list]*) – Specifies padding size.

Inputs:

- **input** (Tensor) - shape is $(N, *)$, where $*$ means, any number of additional dimensions.

Outputs:

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not an integer of a list or tuple of 4 integers.
- **TypeError** – If *input* is not Tensor.
- **ValueError** – If *padding* contains negative value.
- **ValueError** – If *padding* is a tuple or list, and the length does not match the tensor dimension.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = np.ones(shape=(1, 2, 3, 4)).astype(np.float32)
>>> x = ms.Tensor(x)
>>> padding = (1, 1, 0, 1)
>>> pad = ms.mint.nn.ZeroPad2d(padding)
>>> out = pad(x)
>>> print(out)
[[[[0. 1. 1. 1. 1. 0.]
   [0. 1. 1. 1. 1. 0.]
   [0. 1. 1. 1. 1. 0.]
   [0. 0. 0. 0. 0. 0.]]
  [[0. 1. 1. 1. 1. 0.]
   [0. 1. 1. 1. 1. 0.]
   [0. 1. 1. 1. 1. 0.]
   [0. 0. 0. 0. 0. 0.]]]]
>>> print(out.shape)
(1, 2, 4, 6)
```

mindspore.mint.nn.ZeroPad3d

class mindspore.mint.nn.**ZeroPad3d**(*padding*)

Pad the last 3 dimension of *input* tensor with 0 using *padding*.

For more information, please refer to *mindspore.mint.nn.functional.pad()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

padding (*Union[int, tuple, list]*) – Specifies padding size.

Inputs:

- **input** (Tensor) - shape is $(N, *)$, where $*$ means, any number of additional dimensions.

Outputs:

Tensor, the tensor after padding.

Raises

- **TypeError** – If *padding* is not an integer of a list or tuple of 6 integers.
- **TypeError** – If *input* is not Tensor.
- **ValueError** – If *padding* contains negative value.
- **ValueError** – If *padding* is a tuple or list, and the length does not match the tensor dimension.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> x = np.ones(shape=(1, 2, 3, 4)).astype(np.float32)
>>> x = ms.Tensor(x)
>>> padding = (1, 1, 0, 1, 1, 0)
>>> pad3d = ms.mint.nn.ZeroPad3d(padding)
>>> out = pad3d(x)
>>> print(out)
[[[[0. 0. 0. 0. 0. 0.]
   [0. 0. 0. 0. 0. 0.]
   [0. 0. 0. 0. 0. 0.]
   [0. 0. 0. 0. 0. 0.]]
  [[0. 1.  1.  1.  1.  0.]
   [0. 1.  1.  1.  1.  0.]
   [0. 1.  1.  1.  1.  0.]
   [0. 0. 0. 0. 0. 0.]]
  [[0. 1.  1.  1.  1.  0.]
   [0. 1.  1.  1.  1.  0.]
   [0. 1.  1.  1.  1.  0.]
   [0. 0. 0. 0. 0. 0.]]]]
>>> print(out.shape)
(1, 3, 4, 6)
```

4.4.9 Loss Functions

API Name	Description	Supported Platforms
mindspore.mint.nn.BCELoss	Compute the binary cross entropy between the true labels and predicted labels.	`Ascend`
mindspore.mint.nn.BCEWithLogitsLoss	Adds sigmoid activation function to *input* as logits, and uses this logits to compute binary cross entropy between the logits and the target.	`Ascend`
mindspore.mint.nn.CrossEntropyLoss	The cross entropy loss between input and target.	`Ascend`
mindspore.mint.nn.KLDivLoss	Computes the Kullback-Leibler divergence between the *input* and the *target*.	`Ascend`

continues on next page

Table 17 – continued from previous page

mindspore.mint.nn.L1Loss	L1Loss is used to calculate the mean absolute error between the predicted value and the target value.	Ascend
mindspore.mint.nn.MSELoss	Calculates the mean squared error between the predicted value and the label value.	Ascend
mindspore.mint.nn.NLLLoss	Gets the negative log likelihood loss between inputs and target.	Ascend
mindspore.mint.nn.SmoothL1Loss	Computes smooth L1 loss, a robust L1 loss.	Ascend

mindspore.mint.nn.BCELoss

class mindspore.mint.nn.**BCELoss**(*weight=None*, *reduction='mean'*)

Compute the binary cross entropy between the true labels and predicted labels.

Set the predicted labels as x, true labels as y, the output loss as $\ell(x, y)$. The formula is as follow:

$$L = \{l_1, \ldots, l_n, \ldots, l_N\}^\top, \quad l_n = -w_n \left[y_n \cdot \log x_n + (1 - y_n) \cdot \log(1 - x_n) \right]$$

where N is the batch size. Then,

$$\ell(x, y) = \begin{cases} L, & \text{if reduction = 'none';} \\ \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Note: Note that the predicted labels should always be the output of sigmoid. Because it is a two-class classification, the true labels should be numbers between 0 and 1. And if x_n is either 0 or 1, one of the log terms would be mathematically undefined in the above loss equation.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **weight** (Tensor, *optional*) – A rescaling weight applied to the loss of each batch element. And it must have the same shape and data type as *inputs*. Default: None .
- **reduction** (*str*, *optional*) – Apply specific reduction method to the output: 'none' , 'mean' , 'sum' . Default: 'mean' .
  - 'none': no reduction will be applied.
  - 'mean': compute and return the weighted mean of elements in the output.
  - 'sum': the output elements will be summed.

Inputs:

- **input** (Tensor) - The input tensor with shape $(N, *)$ where $*$ means, any number of additional dimensions. The data type must be float16 or float32 or bfloat16(only supported by Atlas A2 training series products).
- **target** (Tensor) - The label tensor with shape $(N, *)$ where $*$ means, any number of additional dimensions. The same shape and data type as *input*.

Outputs:

Tensor, has the same dtype as *input*. if *reduction* is 'none', then it has the same shape as *input*. Otherwise, it is a scalar Tensor.

Raises

- **TypeError** –If dtype of *input*, *target* or *weight* (if given) is not float16, float32 or bfloat16.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.
- **ValueError** –If shape of *input* is not the same as *target* or *weight* (if given).

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint
>>> import numpy as np
>>> weight = ms.Tensor(np.array([[1.0, 2.0, 3.0], [4.0, 3.3, 2.2]]), ms.float32)
>>> loss = mint.nn.BCELoss(weight=weight, reduction='mean')
>>> input = ms.Tensor(np.array([[0.1, 0.2, 0.3], [0.5, 0.7, 0.9]]), ms.float32)
>>> target = ms.Tensor(np.array([[0, 1, 0], [0, 0, 1]]), ms.float32)
>>> output = loss(input, target)
>>> print(output)
1.8952923
```

mindspore.mint.nn.BCEWithLogitsLoss

class mindspore.mint.nn.**BCEWithLogitsLoss**(*weight=None*, *reduction='mean'*, *pos_weight=None*)

Adds sigmoid activation function to *input* as logits, and uses this logits to compute binary cross entropy between the logits and the target.

Sets input *input* as X, input *target* as Y, output as L. Then,

$$p_{ij} = sigmoid(X_{ij}) = \frac{1}{1 + e^{-X_{ij}}}$$

$$L_{ij} = -[Y_{ij} \cdot \log(p_{ij}) + (1 - Y_{ij}) \cdot \log(1 - p_{ij})]$$

Then,

$$\ell(x, y) = \begin{cases} L, & \text{if reduction = 'none';} \\ \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Parameters

- **weight** (*Tensor, optional*) –A rescaling weight applied to the loss of each batch element. If not None, it can be broadcast to a tensor with shape of *target*, data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported). Default: `None` .
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.

- **pos_weight** (Tensor, *optional*) –A weight of positive examples. Must be a vector with length equal to the number of classes. If not None, it must be broadcast to a tensor with shape of *input*, data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported). Default: `None` .

Inputs:

- **input** (Tensor) - Input *input* with shape $(N, *)$ where $*$ means, any number of additional dimensions. The data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported).
- **target** (Tensor) - Ground truth label with shape $(N, *)$ where $*$ means, any number of additional dimensions. The same shape and data type as *input*.

Outputs:

Tensor or Scalar, if *reduction* is `'none'`, its shape is the same as *input*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** –If input *input* or *target* is not Tensor.
- **TypeError** –If *weight* or *pos_weight* is a parameter.
- **TypeError** –If data type of *reduction* is not string.
- **ValueError** –If *weight* or *pos_weight* can not be broadcast to a tensor with shape of *input*.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint
>>> import numpy as np
>>> input = ms.Tensor(np.array([[-0.8, 1.2, 0.7], [-0.1, -0.4, 0.7]]).astype(np.float32))
>>> target = ms.Tensor(np.array([[0.3, 0.8, 1.2], [-0.6, 0.1, 2.2]]).astype(np.float32))
>>> loss = mint.nn.BCEWithLogitsLoss()
>>> output = loss(input, target)
>>> print(output)
0.3463612
```

mindspore.mint.nn.CrossEntropyLoss

class mindspore.mint.nn.**CrossEntropyLoss**(*weight=None*, *ignore_index=- 100*, *reduction='mean'*, *label_smoothing=0.0*)

The cross entropy loss between input and target.

The cross entropy supports two kind of targets:

- Class indices (int) in the range $[0, C)$ where C is the number of classes, the loss with reduction=none can be described as:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -w_{y_n} \log \frac{\exp(x_{n,y_n})}{\sum_{c=1}^{C} \exp(x_{n,c})} \cdot \mathbb{1}\{y_n \neq \text{ignore\_index}\}$$

where x is the inputs, y is the target, w is the weight, N is the batch size, c belonging to $[0, C-1]$ is class index, where C is the number of classes.

If *reduction* is not `None` (default `'mean'`), then

$$\ell(x, y) = \begin{cases} \sum_{n=1}^{N} \frac{1}{\sum_{n=1}^{N} w_{y_n} \cdot \mathbb{1}\{y_n \neq \text{ignore\_index}\}} l_n, & \text{if reduction = 'mean',} \\ \sum_{n=1}^{N} l_n, & \text{if reduction = 'sum'.} \end{cases}$$

- Probabilities (float) for each class, useful when labels beyond a single class per minibatch item are required, the loss with reduction=none can be described as:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -\sum_{c=1}^{C} w_c \log \frac{\exp(x_{n,c})}{\sum_{i=1}^{C} \exp(x_{n,i})} y_{n,c}$$

where x is the inputs, y is the target, w is the weight, N is the batch size, c belonging to $[0, C-1]$ is class index, where C is the number of classes.

If *reduction* is not `None` (default `'mean'`), then

$$\ell(x, y) = \begin{cases} \frac{\sum_{n=1}^{N} l_n}{N}, & \text{if reduction = 'mean',} \\ \sum_{n=1}^{N} l_n, & \text{if reduction = 'sum'.} \end{cases}$$

Warning: This is an experimental API that is subject to change or deletion.

Note: Dynamic shape, dynamic rank and variable constant input are not supported in strict graph mode (jit_syntax_level=mindspore.STRICT).

Parameters

- **weight** (*Tensor, optional*) –A rescaling weight applied to the loss of each batch element. If not None, the shape is $(C,)$, data type must be float16 or float32 or bfloat16(only supported by Atlas A2 training series products). Default: `None` .
- **ignore_index** (*int, optional*) –Specifies a target value that is ignored and does not contribute to the input gradient. Only valid in class indices, please set it to a negative number in probabilities. Default: `-100` .
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **label_smoothing** (*float, optional*) –Label smoothing values, a regularization tool used to prevent the model from overfitting when calculating Loss. The value range is [0.0, 1.0]. Default: `0.0` .

Inputs:

- **input** (Tensor) - (N) or (N, C) where C = *number of classes* or (N, C, H, W) in case of 2D Loss, or $(N, C, d_1, d_2, ..., d_K)$. *input* is expected to be log-probabilities, data type must be float16 or float32 or bfloat16(only supported by Atlas A2 training series products).
- **target** (Tensor) - For class indices, tensor of shape (), (N) or $(N, d_1, d_2, ..., d_K)$, data type must be int32 or int64. For probabilities, tensor of shape $(N,)$, (N, C) or $(N, C, d_1, d_2, ..., d_K)$, data type must be float16 or float32 or bfloat16(only supported by Atlas A2 training series products).

Outputs:

Tensor, the data type is the same as *input* .

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> # Case 1: Indices labels
>>> inputs = ms.Tensor(np.random.randn(3, 5), ms.float32)
>>> target = ms.Tensor(np.array([1, 0, 4]), ms.int32)
>>> op = ms.mint.nn.CrossEntropyLoss()
>>> output = op(inputs, target)
>>> # Case 2: Probability labels
>>> inputs = ms.Tensor(np.random.randn(3, 5), ms.float32)
>>> target = ms.Tensor(np.random.randn(3, 5), ms.float32)
>>> op = ms.mint.nn.CrossEntropyLoss()
>>> output = op(inputs, target)
```

mindspore.mint.nn.KLDivLoss

class mindspore.mint.nn.**KLDivLoss**(*reduction='mean'*, *log_target=False*)

Computes the Kullback-Leibler divergence between the *input* and the *target*.

For tensors of the same shape x and y, the updating formulas of KLDivLoss algorithm are as follows,

$$L(x, y) = y \cdot (\log y - x)$$

Then,

$$\ell(x, y) = \begin{cases} L(x, y), & \text{if reduction = 'none';} \\ \text{mean}(L(x, y)), & \text{if reduction = 'mean';} \\ \text{sum}(L(x, y))/x.\text{shape}[0], & \text{if reduction = 'batchmean';} \\ \text{sum}(L(x, y)), & \text{if reduction = 'sum'.} \end{cases}$$

where x represents *input*, y represents *target*, and $\ell(x, y)$ represents the output.

Note: The output aligns with the mathematical definition of Kullback-Leibler divergence only when *reduction* is set to `'batchmean'`.

Parameters

- **reduction** (*str, optional*) –Specifies the reduction to be applied to the output. Default: `'mean'`.
- **log_target** (*bool, optional*) –Specifies whether *target* is passed in the log space. Default: `False`.

Inputs:

- **input** (Tensor) - The input Tensor. The data type must be float16, float32 or bfloat16(only supported by Atlas A2 training series products).

- **target** (Tensor) - The target Tensor which has the same type as *input*. The shapes of *target* and *input* should be broadcastable.

Outputs:

Tensor, has the same dtype as *input*. If *reduction* is `'none'`, then output has the shape as broadcast result of the *input* and *target*. Otherwise, it is a scalar Tensor.

Raises

- **TypeError** – If neither *input* nor *target* is a Tensor.
- **TypeError** – If dtype of *input* or *target* is not float16, float32 or bfloat16.
- **TypeError** – If dtype of *target* is not the same as *input*.
- **ValueError** – If *reduction* is not one of `'none'`, `'mean'`, `'sum'`, `'batchmean'`.
- **ValueError** – If shapes of *target* and *input* can not be broadcastable.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint
>>> import numpy as np
>>> input = ms.Tensor(np.array([[0.5, 0.5], [0.4, 0.6]]), ms.float32)
>>> target = ms.Tensor(np.array([[0., 1.], [1., 0.]]), ms.float32)
>>> loss = mint.nn.KLDivLoss(reduction='mean', log_target=False)
>>> output = loss(input, target)
>>> print(output)
-0.225
```

mindspore.mint.nn.L1Loss

class mindspore.mint.nn.**L1Loss**(*reduction='mean'*)

L1Loss is used to calculate the mean absolute error between the predicted value and the target value.

Assuming that the x and y are 1-D Tensor, length N, then calculate the loss of x and y without dimensionality reduction (the reduction parameter is set to `'none'`). The formula is as follows:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad \text{with } l_n = |x_n - y_n|,$$

where N is the batch size. If *reduction* is not `'none'`, then:

$$\ell(x, y) = \begin{cases} \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Parameters

reduction (*str, optional*) – Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'mean'`.

- `'none'`: no reduction will be applied.
- `'mean'`: compute and return the mean of elements in the output.

- `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - Predicted value, Tensor of any dimension.
- **labels** (Tensor) - Target value, same shape as the *logits* in common cases. However, it supports the shape of *logits* is different from the shape of *labels* and they should be broadcasted to each other.

Outputs:

Tensor, data type is float.

Raises

- **ValueError** – If *reduction* is not one of `'none'`, `'mean'` or `'sum'`.
- **ValueError** – If *logits* and *labels* have different shapes and cannot be broadcasted to each other.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> # Case 1: logits.shape = labels.shape = (3,)
>>> loss = mint.nn.L1Loss()
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([1, 2, 2]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
0.33333334
>>> # Case 2: logits.shape = (3,), labels.shape = (2, 3)
>>> loss = mint.nn.L1Loss(reduction='none')
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([[1, 1, 1], [1, 2, 2]]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
[[0. 1. 2.]
 [0. 0. 1.]]
```

mindspore.mint.nn.MSELoss

class mindspore.mint.nn.**MSELoss**(*reduction='mean'*)

Calculates the mean squared error between the predicted value and the label value.

For simplicity, let x and y be 1-dimensional Tensor with length N, the unreduced loss (i.e. with argument reduction set to 'none') of x and y is given as:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad \text{with} \quad l_n = (x_n - y_n)^2.$$

where N is the batch size. If *reduction* is not `'none'`, then:

$$\ell(x, y) = \begin{cases} \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Parameters

reduction (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .

- `'none'`: no reduction will be applied.
- `'mean'`: compute and return the mean of elements in the output.
- `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - The predicted value of the input. Tensor of any dimension. The data type needs to be consistent with the *labels*. It should also be broadcastable with the *labels*.
- **labels** (Tensor) - The input label. Tensor of any dimension. The data type needs to be consistent with the *logits*. It should also be broadcastable with the *logits*.

Outputs:

- Tensor. If *reduction* is `'mean'` or `'sum'`, the shape of output is *Tensor Scalar*.
- If reduction is `'none'`, the shape of output is the broadcasted shape of *logits* and *labels* .

Raises

- **ValueError** –If *reduction* is not one of `'mean'`, `'sum'` or `'none'`.
- **ValueError** –If *logits* and *labels* are not broadcastable.
- **TypeError** –If *logits* and *labels* are in different data type.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> # Case 1: logits.shape = labels.shape = (3,)
>>> loss = mint.nn.MSELoss()
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([1, 1, 1]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
1.6666667
>>> # Case 2: logits.shape = (3,), labels.shape = (2, 3)
>>> loss = mint.nn.MSELoss(reduction='none')
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([[1, 1, 1], [1, 2, 2]]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
[[0. 1. 4.]
 [0. 0. 1.]]
```

mindspore.mint.nn.NLLLoss

class mindspore.mint.nn.**NLLLoss**(*weight=None*, *ignore_index=- 100*, *reduction='mean'*)

Gets the negative log likelihood loss between inputs and target.

The nll loss with reduction=none can be described as:

$$\ell(x,t) = L = \{l_1,\dots,l_N\}^\top, \quad l_n = -w_{t_n} x_{n,t_n}, \quad w_c = \text{weight}\,[c] \cdot \mathbb{1}\{c \neq \text{ignore\_index}\},$$

where x is the inputs, t is the target, w is the weight, N is the batch size, c belonging to $[0, C-1]$ is class index, where C is the number of classes.

If *reduction* is not `'None'` (default `'mean'`), then

$$\ell(x,t) = \begin{cases} \sum_{n=1}^{N} \frac{1}{\sum_{n=1}^{N} w_{tn}} l_n, & \text{if reduction} = \text{'mean'}, \\ \sum_{n=1}^{N} l_n, & \text{if reduction} = \text{'sum'} \end{cases}$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **weight** (*Tensor, optional*) – A rescaling weight applied to the loss of each batch element. If not None, the shape is $(C,)$, data type must be float16 or float32 or bfloat16(only supported by Atlas A2 training series products). It should have the same data type as *input* . Default: `None` .
- **ignore_index** (*int, optional*) – Specifies a target value that is ignored and does not contribute to the input gradient. Only valid in class indices, please set it to a negative number in probabilities. Default: `-100` .
- **reduction** (*str, optional*) – Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **input** (Tensor) - (N) or (N, C) where C = *number of classes* , N = *batch size* , or $(N, C, d_1, d_2, ..., d_K)$ (for high-dimensional data). *input* is expected to be log-probabilities, data type must be float16 or float32 or bfloat16(only supported by Atlas A2 training series products).
- **target** (Tensor) - () or (N) , where the value range is $[0, C-1]$, or $(N, d_1, d_2, ..., d_K)$ for high-dimensional loss, data type must be int32 or int64 or uint8.

Outputs:

Tensor, the data type is the same as *input* .

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> inputs = mindspore.Tensor(np.random.randn(3, 5), mindspore.float32)
>>> target = mindspore.Tensor(np.array([1, 0, 4]), mindspore.int32)
>>> op = mindspore.mint.nn.NLLLoss()
>>> output = op(inputs, target)
```

mindspore.mint.nn.SmoothL1Loss

class mindspore.mint.nn.**SmoothL1Loss**(*reduction='mean'*, *beta=1.0*)

Computes smooth L1 loss, a robust L1 loss.

Refer to *mindspore.mint.nn.functional.smooth_l1_loss()* for more details.

> **Warning:** This is an experimental API that is subject to change or deletion.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([2, 2, 3]), mindspore.float32)
>>> target = Tensor(np.array([2, 2, 2]), mindspore.float32)
>>> beta = 1.0
>>> reduction_1 = 'none'
>>> loss1 = mint.nn.SmoothL1Loss(reduction=reduction_1, beta=beta)
>>> output = loss1(input, target)
>>> print(output)
[0.  0.  0.5]
>>> reduction_2 = 'mean'
>>> loss2 = mint.nn.SmoothL1Loss(reduction=reduction_2, beta=beta)
>>> output = loss2(input, target)
>>> print(output)
0.16666667
>>> reduction_3 = 'sum'
>>> loss3 = mint.nn.SmoothL1Loss(reduction=reduction_3, beta=beta)
>>> output = loss3(input, target)
>>> print(output)
0.5
```

4.4.10 Vision Layer

API Name	Description	Supported Platforms
mindspore.mint.nn.PixelShuffle	Rearrange elements in a tensor according to an upscaling factor.	Ascend
mindspore.mint.nn.Upsample	For details, please refer to *mindspore.mint.nn.functional.interpolate()*.	Ascend

mindspore.mint.nn.PixelShuffle

class mindspore.mint.nn.**PixelShuffle**(*upscale_factor*)

Rearrange elements in a tensor according to an upscaling factor.

For details, please refer to *mindspore.mint.nn.functional.pixel_shuffle()*.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import mint
>>> pixel_shuffle = mint.nn.PixelShuffle(3)
>>> input = mint.randn(1, 9, 4, 4)
>>> output = pixel_shuffle(input)
>>> print(output.shape())
    [1, 1, 12, 12]
```

mindspore.mint.nn.Upsample

class mindspore.mint.nn.**Upsample**(*size=None*, *scale_factor=None*, *mode='nearest'*, *align_corners=None*, *recompute_scale_factor=None*)

For details, please refer to *mindspore.mint.nn.functional.interpolate()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint
>>> x = ms.Tensor([[[[1.0, 2.0, 3.0, 4.0], [5.0, 6.0, 7.0, 8.0]]]])
>>> upsample = mint.nn.Upsample(size=(5, 5))
>>> out = upsample(x)
>>> print(x.asnumpy())
[[[[1. 2. 3. 4.]
```

(continues on next page)

(continued from previous page)

```
   [5. 6. 7. 8.]]]]
>>> print(out.asnumpy())
[[[[1. 1. 2. 3. 4.]
   [1. 1. 2. 3. 4.]
   [1. 1. 2. 3. 4.]
   [5. 5. 6. 7. 8.]
   [5. 5. 6. 7. 8.]]]]
>>> print(out.shape)
(1, 1, 5, 5)

4.4.11 Tools

API Name	Description	Supported Platforms
mindspore.mint.nn.Identity	A placeholder identity operator that returns the same as input.	Ascend

mindspore.mint.nn.Identity

class mindspore.mint.nn.**Identity**(**args*, ***kwargs*)

A placeholder identity operator that returns the same as input.

Parameters

- **args** (*Any*) – Any argument.
- **kwargs** (*Any*) – Any keyword argument.

Inputs:

- **input** (Any) - The input of Identity.

Outputs:

The same as *input*.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([1, 2, 3, 4]), mindspore.int64)
>>> net = mint.nn.Identity()
>>> output = net(input)
>>> print(output)
[1 2 3 4]
```

4.5 mindspore.mint.nn.functional

4.5.1 Convolution functions

API Name	Description	Supported Platforms
mindspore.mint.nn.functional.conv2d	Applies a 2D convolution over an input tensor.	Ascend
mindspore.mint.nn.functional.conv3d	Applies a 3D convolution over an input tensor.	Ascend
mindspore.mint.nn.functional.conv_transpose2d	Applies a 2D transposed convolution operator over an input image composed of several input planes, sometimes also called deconvolution (although it is not an actual deconvolution).	Ascend
mindspore.mint.nn.functional.fold	Combines an array of sliding local blocks into a large containing tensor.	Ascend
mindspore.mint.nn.functional.unfold	Extracts sliding local blocks from a batched input tensor.	Ascend

mindspore.mint.nn.functional.conv2d

mindspore.mint.nn.functional.**conv2d**(*input*, *weight*, *bias=None*, *stride=1*, *padding=0*, *dilation=1*, *groups=1*)

Applies a 2D convolution over an input tensor. The input tensor is typically of shape $(N, C_{in}, H_{in}, W_{in})$ or (C_{in}, H_{in}, W_{in}), where N is batch size, C is channel number, H is feature height, W is feature width.

The output is calculated based on formula:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{in}-1} \text{ccor}(\text{weight}(C_{\text{out}_j}, k), \text{X}(N_i, k))$$

where $bias$ is the output channel bias, $ccor$ is the cross-correlation, , $weight$ is the convolution kernel value and X represents the input feature map.

- i corresponds to the batch number, the range is $[0, N-1]$, where N is the batch size of the input.
- j corresponds to the output channel, the range is $[0, C_{out}-1]$, where C_{out} is the number of output channels, which is also equal to the number of kernels.
- k corresponds to the input channel, the range is $[0, C_{in}-1]$, where C_{in} is the number of input channels, which is also equal to the number of channels in the convolutional kernels.

Therefore, in the above formula, $bias(C_{out_j})$ represents the bias of the j-th output channel, $weight(C_{out_j}, k)$ represents the slice of the j-th convolutional kernel in the k-th channel, and $X(N_i, k)$ represents the slice of the k-th input channel in the i-th batch of the input feature map.

The shape of the convolutional kernel is given by (kernel_size[0], kernel_size[1]), where kernel_size[0] and kernel_size[1] are the height and width of the kernel, respectively. If we consider the input and output channels as well as the *group* parameter, the complete kernel shape will be $(C_{out}, C_{in}/\text{group}, \text{kernel\_size}[0], \text{kernel\_size}[1])$, where *group* is the number of groups dividing *x*'s input channel when applying group convolution.

For more details about convolution layer, please refer to Gradient Based Learning Applied to Document Recognition and ConvNets.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –Tensor of shape $(N, C_{in}, H_{in}, W_{in})$ or (C_{in}, H_{in}, W_{in}).
- **weight** (Tensor) –Tensor of shape $(N, C_{in}/\text{groups}, \text{kernel\_size}[0], \text{kernel\_size}[1])$, then the size of kernel is (kernel_size[0], kernel_size[1]).
- **bias** (Tensor, *optional*) –Bias Tensor with shape (C_{out}). When bias is None , zeros will be used. Default: None .
- **stride** (*Union(int, tuple[int], list[int])*, *optional*) –The distance of kernel moving, an int number that represents the height and width of movement are both strides, or a tuple of two int numbers that represent height and width of movement respectively. Default: 1 .
- **padding** (*Union[int, tuple[int], list[int], str]*, *optional*) –The number of padding on the height and width directions of the input. The data type is an integer or a tuple of two integers or string {*valid*, *same*}. If *padding* is an integer, then *padding_{H}* and *padding_{W}* are all equal to *padding*. If *padding* is a tuple of 2 integers, then *padding_{H}* and *padding_{W}* is equal to *padding[0]* and *padding[1]* respectively. The value should be greater than or equal to 0. Default: 0 .
  - "same": Pad the input around its edges so that the shape of input and output are the same when *stride* is set to 1. The amount of padding to is calculated by the operator internally, If the amount is even, it is uniformly distributed around the input, if it is odd, the excess amount goes to the right/bottom side. If this mode is set, *stride* must be 1.
  - "valid": No padding is applied to the input, and the output returns the maximum possible height and width. Extra pixels that could not complete a full stride will be discarded.
- **dilation** (*Union(int, tuple[int], list[int])*, *optional*) –Gaps between kernel elements.The data type is int or a tuple of 2 integers. Specifies the dilation rate to use for dilated convolution. If set to be $k > 1$, there will be $k - 1$ pixels skipped for each sampling location. Its value must be greater than or equal to 1 and bounded by the height and width of the input *x*. Default: 1 .
- **groups** (*int*, *optional*) –Splits *input* into groups. Default: 1 .
  - (C_{in}

Returns

Tensor, the value that applied 2D convolution. The shape is $(N, C_{out}, H_{out}, W_{out})$. To see how different pad modes affect the output shape, please refer to *mindspore.mint.nn.Conv2d* for more details.

Raises

- **ValueError** –Args and size of the input feature map should satisfy the output formula to ensure that the size of the output feature map is positive; otherwise, an error will be reported. For more details on the output formula, please refer to *mindspore.mint.nn.Conv2d*.
- **RuntimeError** –On Ascend, due to the limitation of the L1 cache size of different NPU chip, if input size or kernel size is too large, it may trigger an error.
- **TypeError** –If *in_channels* , *out_channels* or *groups* is not an int.
- **TypeError** –If *kernel_size* , *stride* or *dilation* is neither an int nor a tuple.
- **TypeError** –If *bias* is not a Tensor.
- **ValueError** –If the shape of *bias* is not (C_{out}) .
- **ValueError** –If *stride* or *dilation* is less than 1.
- **ValueError** –If *padding* is *same* , *stride* is not equal to 1.
- **ValueError** –The input parameters do not satisfy the convolution output formula.
- **ValueError** –The KernelSize cannot exceed the size of the input feature map.

- **ValueError** –The value of padding cannot cause the calculation area to exceed the input size.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint, mint
>>> x = Tensor(np.ones([10, 32, 32, 32]), mindspore.float32)
>>> weight = Tensor(np.ones([32, 32, 3, 3]), mindspore.float32)
>>> output = mint.nn.functional.conv2d(x, weight)
>>> print(output.shape)
(10, 32, 30, 30)
```

mindspore.mint.nn.functional.conv3d

mindspore.mint.nn.functional.**conv3d**(*input*, *weight*, *bias=None*, *stride=1*, *padding=0*, *dilation=1*, *groups=1*)

Applies a 3D convolution over an input tensor. The input tensor is typically of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$ or $(C_{in}, D_{in}, H_{in}, W_{in})$, where N is batch size, C is channel number, D, H, W are the depth, height and width of the feature graph, respectively.

The output is calculated based on formula:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{in}-1} \text{ccor}(\text{weight}(C_{\text{out}_j}, k), \text{X}(N_i, k))$$

where $bias$ is the output channel bias, $ccor$ is the cross-correlation , $weight$ is the convolution kernel value and X represents the input feature map.

Here are the indices' meanings:

- i corresponds to the batch number, the range is $[0, N-1]$, where N is the batch size of the input.
- j corresponds to the output channel, the range is $[0, C_{out}-1]$, where C_{out} is the number of output channels, which is also equal to the number of kernels.
- k corresponds to the input channel, the range is $[0, C_{in}-1]$, where C_{in} is the number of input channels, which is also equal to the number of channels in the convolutional kernels.

Therefore, in the above formula, $bias(C_{\text{out}_j})$ represents the bias of the j-th output channel, $weight(C_{\text{out}_j}, k)$ represents the slice of the j-th convolutional kernel in the k-th channel, and $X(N_i, k)$ represents the slice of the k-th input channel in the i-th batch of the input feature map.

The shape of the convolutional kernel is given by (kd, kh, kw) where kd , kd andkw are the depth, height and width of the kernel, respectively. If we consider the input and output channels as well as the *group* parameter, the complete kernel shape will be $(C_{out}, C_{in}/\text{group}, kd, kh, kw)$, where *group* is the number of groups dividing x's input channel when applying group convolution.

For more details about convolution layer, please refer to Gradient Based Learning Applied to Document Recognition.

The following lists some of the limitations of the parameters.

- input –The input to the conv3d. The input must have each dimension size within the range [1, int32_max].
- weight –Filters of shape $(C_{out}, C_{in}/groups, kd, kh, kw)$. The value of kh and kw is in the range [1, 511]. The remaining values are in the range [1, int32_max]. And $kh * kw * k0$ is less 65536 (k0 is 16. If data type is float32, k0 is 8).

- bias −Bias Tensor with shape (C_{out}). The shape must equal the first dimension of the weight.
- stride −The distance of kernel moving. It can be an int number or tuple (noted by $(stride_d, stride_h, stride_w)$). stride_h and stride_w are in the range [1, 63]. stride_d is in the range [1, 255].
- padding −If padding is an int number, it is in the range [0, 255].
- dilation −The value is in the range [1, 255].
- groups −The value is in the range [1, 65535].
- C_{in}%groups == 0 and C_{out}%groups == 0 .
- $weight[1] == C_{in}/groups$.
- $H_{in} + PadUp + PadDown >= (kh - 1) * DilationH + 1$.
- $W_{in} + PadLeft + PadRight >= (kw - 1) * DilationW + 1$.
- $D_{in} + PadFront + PadBack >= (kd - 1) * DilationD + 1$.
- $H_{out} = (H_{in} + PadUp + PadDown - ((kh - 1) * DilationH + 1))/StrideH + 1$.
- $W_{out} = (W_{in} + PadLeft + PadRight - ((kw - 1) * DilationW + 1))/StrideW + 1$.
- $D_{out} = (D_{in} + PadFront + PadBack - ((kd - 1) * DilationD + 1))/StrideD + 1$.
- $(D_{in} + PadFront + PadBack - ((kd - 1) * DilationD + 1))/$
- $(H_{in} + PadUp + PadDown - ((kh - 1) * Dilationh + 1))/$
- $stride_d <= kernel_d$.
- $PadUp < kh$ and $PadDown < kh$. When *padding* = `'valid'`, both PadUp and PadDown are zeros. When *padding* = `'same'`, pad can be calculated by $floor(((H_{out} - 1) * strideH + (kh - 1) * DilationH + 1 - H_{in})/2)$ for high dimension. It is similar way to calculate the padding for depth and width dimension. And the depth and width dimensions also have the same constraints.
- $((kh - 1) * DilationH - PadUp)$ should be in [0, 255]. It is the same constraint for depth and width dimension.
- If *padding* is `'same'`, *stride* must be 1.

> **Warning:** This API does not support Atlas series products. This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) −Tensor of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$.
- **weight** (Tensor) −Set size of kernel is (kd, kh, kw), then the shape is $(C_{out}, C_{in}/groups, kd, kh, kw)$.
- **bias** (Tensor, *optional*) −Bias Tensor with shape (C_{out}). When bias is `None` , zeros will be used. Default: `None` .
- **stride** (*Union(int, tuple[int], list[int]), optional*) −The distance of kernel moving, an int number that represents the depth, the height and width of movement are both strides, or a tuple of triple int numbers that represent the depth, height and width of movement respectively. Default: `1` .
- **padding** (*Union(int, tuple[int], list[int], str), optional*) −Implicit paddings on both sides of the input *x*. Can be a string, one integer or a tuple/list with 3 integers. If *padding* is a string, the optional values are `"same"` , `"valid"`.
  - same: Adopts the way of completion. The height and width of the output will be equal to the input *x* divided by stride. The padding will be evenly calculated in top and bottom, left and right possiblily. Otherwise, the last extra padding will be calculated from the bottom and the right side. If this mode is set, *stride* must be 1.

– valid: Adopts the way of discarding. The possible largest height and width of output will be returned without padding. Extra pixels will be discarded.

If *padding* is one integer, the paddings of top, bottom, left and right are the same, equal to padding. If *padding* is a tuple/list with 3 integers, the padding of head, tail, top, bottom, left and right equal to pad[0], pad[0], pad[1], pad[1], pad[2] and pad[2] correspondingly. Default: `0` .

- **dilation** (*Union[int, tuple[int], list[int]], optional*) – Controlling the space between the kernel points. Default: `1` .
- **groups** (*int, optional*) – Splits *input* into groups. Default: `1` .

Returns

Tensor, the same dtype as the *input*, with the shape $(N, C_{out}, D_{out}, H_{out}, W_{out})$ or $(C_{out}, D_{out}, H_{out}, W_{out})$.

Raises

- **TypeError** – If *stride*, *padding* or *dilation* is neither an int nor a tuple.
- **TypeError** – *groups* is not an int.
- **TypeError** – If *bias* is not a Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import mint
>>> x = mindspore.Tensor(np.random.randn(12, 1, 60, 50, 8), mindspore.float16)
>>> w = mindspore.Tensor(np.random.randn(26, 1, 2, 4, 4), mindspore.float16)
>>> out = mint.nn.functional.conv3d(x, w)
>>> print(out.shape)
(12, 26, 59, 47, 5)
```

mindspore.mint.nn.functional.conv_transpose2d

mindspore.mint.nn.functional.**conv_transpose2d**(*input*, *weight*, *bias=None*, *stride=1*, *padding=0*, *output_padding=0*, *groups=1*, *dilation=1*)

Applies a 2D transposed convolution operator over an input image composed of several input planes, sometimes also called deconvolution (although it is not an actual deconvolution).

Refer to *mindspore.mint.nn.ConvTranspose2d* for more details.

Warning:

- This is an experimental API that is subject to change or deletion.
- In the scenario where inputs are non-contiguous, *output_padding* must be less than *stride* .
- For Atlas training products, when the dtype of input is float32, the *groups* only supports 1.

Parameters

- **input** (Tensor) –input tensor of shape $(minibatch, in\_channels, iH, iW)$ or $(in\_channels, iH, iW)$.
- **weight** (Tensor) –filters of shape $(in\_channels, \frac{out\_channels}{\text{groups}}, kH, kW)$.
- **bias** (Tensor, *optional*) –bias of shape $(out\_channels)$. Default: None .
- **stride** (*Union[int, tuple(int), list[int]], optional*) –the stride of the convolving kernel. Can be a single number or a tuple (sH, sW) . Default: 1 .
- **padding** (*Union[int, tuple(int), list[int]], optional*) –$dilation * (kernel\_size - 1) - padding$ zero-padding will be added to both sides of each dimension in the input. Can be a single number or a tuple $(padH, padW)$. Default: 0 .
- **output_padding** (*Union[int, tuple(int), list[int]], optional*) –additional size added to one side of each dimension in the output shape. Can be a single number or a tuple (out_padH, out_padW) . The value of *output_padding* must be less than *stride* or *dilation* . Default: 0 .
- **groups** (*int, optional*) –split input into groups, $in\_channels$ should be divisible by the number of groups. Default: 1 .
- **dilation** (*Union[int, tuple(int), list[int]], optional*) –the spacing between kernel elements. Can be a single number or a tuple (dH, dW) . Default: 1 .

Returns

Tensor of shape $(minibatch, out\_channels, oH, oW)$ or $(out\_channels, oH, oW)$, where

$$oH = (iH - 1) \times sH - 2 \times padH + dH \times (kH - 1) + out\_padH + 1$$

$$oW = (iW - 1) \times sW - 2 \times padW + dW \times (kW - 1) + out\_padW + 1$$

Raises

- **TypeError** –If *stride*, *padding*, *output_padding* or *dilation* is neither an int nor a tuple or a list.
- **TypeError** –If *groups* is not an int.
- **ValueError** –If the shape of *bias* is not $(out\_channels)$.
- **ValueError** –If *stride* or *dilation* is less than 1.
- **ValueError** –If *padding* or *output_padding* is less than 0.
- **ValueError** –If *stride*, *padding*, *output_padding* or *dilation* is a tuple whose length is not equal to 2.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.ones([1, 4, 5, 5]), mindspore.float32)
>>> weight = Tensor(np.ones([4, 8, 3, 3]), mindspore.float32)
>>> output = mint.nn.functional.conv_transpose2d(x, weight)
>>> print(output.shape)
(1, 8, 7, 7)
```

mindspore.mint.nn.functional.fold

mindspore.mint.nn.functional.**fold**(*input*, *output_size*, *kernel_size*, *dilation=1*, *padding=0*, *stride=1*)

Combines an array of sliding local blocks into a large containing tensor.

Consider a batched input tensor of shape $(N, C \times \prod(\text{kernel\_size}), L)$, where N is the batch dimension, $C \times \prod(\text{kernel\_size})$ is the total number of values within each block (a block has $\prod(\text{kernel\_size})$ spatial locations each containing a C-channeled vector), and L is the total number of such blocks:

$$L = \prod_{d} \left\lfloor \frac{\text{output\_size}[d] + 2 \times \text{padding}[d] - \text{dilation}[d] \times (\text{kernel\_size}[d] - 1) - 1}{\text{stride}[d]} + 1 \right\rfloor,$$

where d is over all spatial dimensions.

Therefore, *output_size* is the spatial shape of the large containing tensor of the sliding local blocks.

The *dilation*, *padding* and *stride* arguments specify how the sliding blocks are retrieved.

> **Warning:** Currently, only unbatched(3D) or batched(4D) image-like output tensors are supported.

Parameters

- **input** (Tensor) −2-D or 3-D Tensor.
- **output_size** (*Union[int, tuple[int], list[int]]*) −The shape of the spatial dimensions of the output(i.e., output.shape[2:]).
- **kernel_size** (*Union[int, tuple[int], list[int]]*) −The size of the kernel, should be two int for height and width. If type is int, it means that height equal with width. Must be specified.
- **dilation** (*Union[int, tuple[int], list[int]], optional*) −The size of the dilation, should be two int for height and width. If type is int, it means that height equal with width. Default: `1` .
- **padding** (*Union[int, tuple[int], list[int]], optional*) −The size of the padding, should be two int for height and width. If type is int, it means that height equal with width. Default: `0` .
- **stride** (*Union[int, tuple[int], list[int]], optional*) −The size of the stride, should be two int for height and width. If type is int, it means that height equal with width. Default: `1` .

Returns

A Tensor, with same type as *input* .

Shape:

- Input: $(N, C \times \prod(\text{kernel\_size}), L)$ or $(C \times \prod(\text{kernel\_size}), L)$
- Output: $(N, C, output\_size[0], output\_size[1], ...)$ or $(C, output\_size[0], output\_size[1], ...)$

Raises

- **TypeError** −If *output_size*, *kernel_size*, *stride*, *dilation*, *padding* data type is not int, tuple or list.
- **ValueError** −If *output_size*, *kernel_size*, *dilation*, *stride* value is not greater than zero or elements number invalid.
- **ValueError** −If *padding* value is less than zero or elements number invalid.
- **ValueError** −If input.shape[-2] can't be divisible by the product of kernel_size.
- **ValueError** −If *input.shape[-1]* is not equal to the calculated number of sliding blocks *L*.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.random.rand(16, 64, 25).astype(np.float32))
>>> output = mint.nn.functional.fold(x, (8, 8), [2, 2], [2, 2], [2, 2], [2, 2])
>>> print(output.shape)
(16, 16, 8, 8)
```

mindspore.mint.nn.functional.unfold

mindspore.mint.nn.functional.**unfold**(*input*, *kernel_size*, *dilation=1*, *padding=0*, *stride=1*)

Extracts sliding local blocks from a batched input tensor.

Consider a batched input tensor of shape $(N, C, *)$, where N is the batch dimension, C is the channel dimension, and $*$ represent arbitrary spatial dimensions. This operation flattens each sliding *Kernel_size*- sized block within the spatial dimensions of *input* into a column (i.e., last dimension) of a 3-D output tensor of shape $(N, C \times \prod(\text{kernel\_size}), L)$, where $C \times \prod(\text{kernel\_size})$ is the total number of values within each block (a block has $\prod(\text{kernel\_size})$ spatial locations each containing a C-channeled vector), and L is the total number of such blocks:

$$L = \prod_{d} \left\lfloor \frac{\text{spatial\_size}[d] + 2 \times \text{padding}[d] - \text{dilation}[d] \times (\text{kernel\_size}[d] - 1) - 1}{\text{stride}[d]} + 1 \right\rfloor,$$

where spatial_size is formed by the spatial dimensions of *input* ($*$ above), and d is over all spatial dimensions.

Therefore, indexing *output* at the last dimension (column dimension) gives all values within a certain block.

The *dilation*, *padding* and *stride* arguments specify how the sliding blocks are retrieved.

Warning:

- Currently, batched(4D) image-like tensors are supported.
- For Ascend, it is only supported on platforms above Atlas A2.

Parameters

- **input** (Tensor) – 4-D Tensor.
- **kernel_size** (*Union[int, tuple[int], list[int]]*) – The size of the kernel, should be two int for height and width. If type is int, it means that height equal with width. Must be specified.
- **dilation** (*Union[int, tuple[int], list[int]], optional*) – The dilation of the window, should be two int for height and width. If type is int, it means that height equal with width. Default: `1` .
- **padding** (*Union[int, tuple[int], list[int]], optional*) – The pad of the window, should be two int for height and width. If type is int, it means that height equal with width. Default: `0` .
- **stride** (*Union[int, tuple[int], list[int]], optional*) – The stride of the window, should be two int for height and width. If type is int, it means that height equal with width. Default: `1` .

Returns

A Tensor, with same type as *input* .

Shape:

- Input: $(N, C, *)$
- Output: $(N, C \times \prod(\text{kernel\_size}), L)$

Raises

- **TypeError** – If any data type of *kernel_size*, *stride*, *dilation*, *padding* is not int, tuple or list.
- **ValueError** – If *kernel_size*, *dilation*, *stride* value is not greater than zero or elements number more than *2*.
- **ValueError** – If *padding* value is less than zero.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.random.rand(4, 4, 32, 32), mindspore.float32)
>>> output = mint.nn.functional.unfold(x, kernel_size=3, dilation=1, stride=1)
>>> print(output.shape)
(4, 36, 900)
```

4.5.2 Pooling functions

API Name	Description	Supported Platforms
mindspore.mint.nn.functional.adaptive_avg_pool1d	Performs 1D adaptive average pooling on a multi-plane input signal.	`Ascend`
mindspore.mint.nn.functional.adaptive_avg_pool2d	Performs 2D adaptive average pooling on a multi-plane input signal.	`Ascend`
mindspore.mint.nn.functional.adaptive_avg_pool3d	Performs 3D adaptive average pooling on a multi-plane input signal.	`Ascend`
mindspore.mint.nn.functional.adaptive_max_pool1d	Performs 1D adaptive max pooling on a multi-plane input signal.	`Ascend`
mindspore.mint.nn.functional.avg_pool1d	Applies a 1D average pooling over an input Tensor which can be regarded as a composition of 1D input planes.	`Ascend`
mindspore.mint.nn.functional.avg_pool2d	Applies a 2D average pooling over an input Tensor which can be regarded as a composition of 2D input planes.	`Ascend`
mindspore.mint.nn.functional.avg_pool3d	Applies a 3D average pooling over an input Tensor which can be regarded as a composition of 3D input planes.	`Ascend`
mindspore.mint.nn.functional.max_pool2d	Performs a 2D max pooling on the input Tensor.	`Ascend`
mindspore.mint.nn.functional.max_unpool2d	Computes the inverse of *max_pool2d*.	`Ascend`

mindspore.mint.nn.functional.adaptive_avg_pool1d

mindspore.mint.nn.functional.**adaptive_avg_pool1d**(*input*, *output_size*)

Performs 1D adaptive average pooling on a multi-plane input signal. That is, for any input size, the size of the specified output is L. The number of output features is equal to the number of input features.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input of adaptive_avg_pool1d, which is a 2D or 3D tensor, with float16 or float32 data type.
- **output_size** (*int*) –The target output feature size. *output_size* is an integer.

Returns

Tensor, with the same type as the *input*.

Shape of the output is *input_shape[:len(input_shape) - 1] + [output_size]*.

Raises

- **ValueError** –If *output_size* is not integer.
- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If dtype of *input* is not float16, float32.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input = Tensor([[2,3],[3,4]],dtype=mindspore.float16)
>>> output = mint.nn.functional.adaptive_avg_pool1d(input, 3)
>>> print(output)
[[2.  2.5 3. ]
 [3.  3.5 4. ]]
```

mindspore.mint.nn.functional.adaptive_avg_pool2d

mindspore.mint.nn.functional.**adaptive_avg_pool2d**(*input*, *output_size*)

Performs 2D adaptive average pooling on a multi-plane input signal. That is, for any input size, the size of the specified output is H x W. The number of output features is equal to the number of input features.

The input and output data format can be "NCHW" and "CHW". N is the batch size, C is the number of channels, H is the feature height, and W is the feature width.

For adaptive average pooling for 2D:

$$
\begin{aligned}
h_{start} &= floor(i * H_{in}/H_{out}) \\
h_{end} &= ceil((i+1) * H_{in}/H_{out}) \\
w_{start} &= floor(j * W_{in}/W_{out}) \\
w_{end} &= ceil((j+1) * W_{in}/W_{out}) \\
Output(i,j) &= \frac{\sum Input[h_{start}:h_{end}, w_{start}:w_{end}]}{(h_{end}-h_{start})*(w_{end}-w_{start})}
\end{aligned}
$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input of adaptive_avg_pool2d, which is a 3D or 4D tensor, with float16 or float32 data type.
- **output_size** (*Union[int, tuple]*) –The target output size. *output_size* can be a tuple (H, W), or an int H for (H, H). H and W can be int or None. If it is None, it means the output size is the same as the input size.

Returns

Tensor, with the same type as the *input*.

Shape of the output is *input_shape[:len(input_shape) - len(out_shape)] + out_shape*.

$$
out\_shape = \begin{cases}
input\_shape[-2] + output\_size[1], & \text{if } output\_size \text{ is (None, w);} \\
output\_size[0] + input\_shape[-1], & \text{if } output\_size \text{ is (h, None);} \\
input\_shape[-2:], & \text{if } output\_size \text{ is (None, None);} \\
(h, h), & \text{if } output\_size \text{ is h;} \\
(h, w), & \text{if } output\_size \text{ is (h, w)}
\end{cases}
$$

Raises

- **ValueError** –If *output_size* is a tuple and the length of *output_size* is not 2.
- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If dtype of *input* is not float16, float32 or float64.
- **ValueError** –If the dimension of *input* is less than or equal to the dimension of *output_size*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> # case 1: output_size=(3, 2)
>>> input = Tensor(np.array([[[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]],
...                          [[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]],
...                          [[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]]]),␣
↪mindspore.float32)
>>> output = mint.nn.functional.adaptive_avg_pool2d(input, (3, 2))
```

(continues on next page)

(continued from previous page)

```
>>> print(output)
[[[1.5 2.5]
  [4.5 5.5]
  [7.5 8.5]]
 [[1.5 2.5]
  [4.5 5.5]
  [7.5 8.5]]
 [[1.5 2.5]
  [4.5 5.5]
  [7.5 8.5]]]
```

mindspore.mint.nn.functional.adaptive_avg_pool3d

mindspore.mint.nn.functional.**adaptive_avg_pool3d**(*input*, *output_size*)

Performs 3D adaptive average pooling on a multi-plane input signal. That is, for any input size, the size of the specified output is (D, H, W). The number of output features is equal to the number of input planes.

Suppose the last 3 dimension size of x is (D_{in}, H_{in}, W_{in}), the last 3 dimension size of output is $(D_{out}, H_{out}, W_{out})$.

$$
\begin{aligned}
&\forall \quad od \in [0, D_{out} - 1], oh \in [0, H_{out} - 1], ow \in [0, W_{out} - 1] \\
&output[od, oh, ow] = \\
&\qquad mean(x[D_{istart} : D_{iend} + 1, H_{istart} : H_{iend} + 1, W_{istart} : W_{iend} + 1]) \\
&where, \\
&\qquad D_{istart} = \left\lceil \frac{od * D_{in}}{D_{out}} \right\rceil \\
&\qquad D_{iend} = \left\lfloor \frac{(od+1) * D_{in}}{D_{out}} \right\rfloor \\
&\qquad H_{istart} = \left\lceil \frac{oh * H_{in}}{H_{out}} \right\rceil \\
&\qquad H_{iend} = \left\lfloor \frac{(oh+1) * H_{in}}{H_{out}} \right\rfloor \\
&\qquad W_{istart} = \left\lceil \frac{ow * W_{in}}{W_{out}} \right\rceil \\
&\qquad W_{iend} = \left\lfloor \frac{(ow+1) * W_{in}}{W_{out}} \right\rfloor
\end{aligned}
$$

Warning: For Ascend, it is only supported on Atlas A2 Training Series Products. This is an experimental optimizer API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input of adaptive_avg_pool3d, which is a 4D or 5D Tensor.
- **output_size** (*Union[int, tuple]*) –The target output size. *output_size* can be a tuple (D, H, W), or an int D for (D, D, D). D, H and W can be int or None which means the output size is the same as that of the input.

Returns

Tensor, with the same type as the *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **ValueError** –If the dimension of *input* is not 4D or 5D.
- **ValueError** –If *output_size* value is not positive.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> # case 1: output_size=(3, 3, 4)
>>> output_size=(3, 3, 4)
>>> input_val = np.random.randn(4, 3, 5, 6, 7)
>>> input = Tensor(input_val, mindspore.float32)
>>> output = mint.nn.functional.adaptive_avg_pool3d(input, output_size)
>>> print(output.shape)
(4, 3, 3, 3, 4)
>>> # case 2: output_size=4
>>> output_size=5
>>> input_val = np.random.randn(2, 3, 8, 6, 12)
>>> input = Tensor(input_val, mindspore.float32)
>>> output = mint.nn.functional.adaptive_avg_pool3d(input, output_size)
>>> print(output.shape)
(2, 3, 5, 5, 5)
>>> # case 3: output_size=(None, 4, 5)
>>> output_size=(None, 4, 5)
>>> input_val = np.random.randn(4, 1, 9, 10, 8)
>>> input = Tensor(input_val, mindspore.float32)
>>> output = mint.nn.functional.adaptive_avg_pool3d(input, output_size)
>>> print(output.shape)
(4, 1, 9, 4, 5)
```

mindspore.mint.nn.functional.adaptive_max_pool1d

mindspore.mint.nn.functional.**adaptive_max_pool1d**(*input*, *output_size*, *return_indices=False*)

Performs 1D adaptive max pooling on a multi-plane input signal. That is, for any input size, the size of the specified output is L. The number of output features is equal to the number of input features.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (`Tensor`) −The input of adaptive_max_pool1d, which is a 2D or 3D tensor, with float16, float32 or float64 data type.
- **output_size** (*int*) −The target output feature size. *output_size* is an integer.
- **return_indices** (*bool, optional*) −Whether to return the index of the maximum value. Default: `False`.

Returns

Union(Tensor, tuple(Tensor, Tensor)).

- If *return_indices* is False, output is a Tensor, with shape (N, C, L_{out}). It has the same data type as *input*.
- If *return_indices* is True, output is a Tuple of 2 Tensors, representing the result and where the max values are generated.

Raises

- **TypeError** – If *input* is not a tensor.
- **TypeError** – If dtype of *input* is not float16, float32 or float64.
- **TypeError** – If *output_size* is not int or tuple.
- **TypeError** – If *return_indices* is not a bool.
- **ValueError** – If *output_size* is a tuple and the length of *output_size* is not 1.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input = Tensor([[2,3],[3,4]],dtype=mindspore.float16)
>>> output = mint.nn.functional.adaptive_max_pool1d(input, 3)
>>> print(output)
[[2.  3.  3. ]
 [3.  4.  4. ]]
```

mindspore.mint.nn.functional.avg_pool1d

mindspore.mint.nn.functional.**avg_pool1d**(*input*, *kernel_size*, *stride=None*, *padding=0*, *ceil_mode=False*, *count_include_pad=True*)

Applies a 1D average pooling over an input Tensor which can be regarded as a composition of 1D input planes.

Typically the input is of shape (N_{in}, C_{in}, L_{in}), avg_pool1d outputs regional average in the (L_{in})-dimension. Given kernel size as $ks = l_{ker}$ and *stride* as $s = s_0$, the operation is as follows.

$$\text{output}(N_i, C_j, l) = \frac{1}{l_{ker}} \sum_{n=0}^{l_{ker}-1} \text{input}(N_i, C_j, s_0 \times l + n)$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) – Tensor of shape (N, C_{in}, L_{in}).
- **kernel_size** (*Union(int, tuple[int])*) – The size of kernel window used to take the average value.
- **stride** (*Union(int, tuple[int]), optional*) – The distance of kernel moving. *stride* can either be an int number or a tuple of one int number. Default: `None`, the same value as *kernel_size*.
- **padding** (*Union(int, tuple[int]), optional*) – The pad length to be filled. *padding* can either be an integer or a tuple of one integer. Default: `0` .
- **ceil_mode** (*bool, optional*) – If True, apply ceil instead of floor to compute the output shape. Default: `False`.
- **count_include_pad** (*bool, optional*) – If True, include the zero-padding in the averaging calculation. Default: `True` .

Returns

Tensor of shape (N, C_{in}, L_{out}).

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *kernel_size* or *stride* is not an int.
- **TypeError** –If *ceil_mode* or *count_include_pad* is not a bool.
- **ValueError** –If *kernel_size* or *stride* is less than *1*.
- **ValueError** –If *kernel_size* or *stride* or *padding* is not int nor a tuple whose length is greater than *1*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input_x = Tensor(np.random.randint(0, 10, [1, 3, 6]), mindspore.float32)
>>> output = mint.nn.functional.avg_pool1d(input_x, kernel_size=6, stride=1)
>>> print(output.shape)
(1, 3, 1)
```

mindspore.mint.nn.functional.avg_pool2d

mindspore.mint.nn.functional.**avg_pool2d**(*input*, *kernel_size*, *stride=None*, *padding=0*, *ceil_mode=False*, *count_include_pad=True*, *divisor_override=None*)

Applies a 2D average pooling over an input Tensor which can be regarded as a composition of 2D input planes. Typically the input is of shape (N, C, H_{in}, W_{in}) , outputs regional average in the (H_{in}, W_{in}) -dimension. Given kernel size (kH, kW) and *stride* , the operation is as follows.

$$\text{output}(N_i, C_j, h, w) = \frac{1}{kH * kW} \sum_{m=0}^{kH-1} \sum_{n=0}^{kW-1} \text{input}(N_i, C_j, stride[0] \times h + m, stride[1] \times w + n)$$

Note: On the Atlas platform, when calculating the input, the precision is degraded from float32 to float16.

Parameters

- **input** (`Tensor`) –Tensor of shape (N, C, H_{in}, W_{in}) or (C, H_{in}, W_{in}).
- **kernel_size** (*Union[int, tuple[int], list[int]]*) –The size of kernel used to take the average value. Can be a single number or a tuple (kH, kW) .
- **stride** (*Union[int, tuple[int], list[int]], optional*) –The distance of kernel moving. Can be a single number or a tuple (sH, sW) . Default: `None`, where its value is equal to *kernel_size*.
- **padding** (*Union[int, tuple[int], list[int]], optional*) –Implicit zero padding to be added on both sides. Can be a single number or a tuple $(padH, padW)$. Default: `0`.
- **ceil_mode** (*bool, optional*) –If True, apply ceil instead of floor to compute the output shape. Default: `False`.

- **count_include_pad** (*bool, optional*) –If True, include the zero-padding in the averaging calculation. Default: `True` .
- **divisor_override** (*int, optional*) –If specified, it will be used as divisor in the averaging calculation, otherwise size of pooling region will be used. Default: `None`.

Returns

Tensor, with shape (N, C, H_{out}, W_{out}) or (C, H_{out}, W_{out}).

$$H_{out} = \frac{H_{in}+2\times padding[0]-kernel\_size[0]}{stride[0]} + 1$$
$$W_{out} = \frac{W_{in}+2\times padding[1]-kernel\_size[1]}{stride[1]} + 1$$

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *kernel_size* or *stride* is neither int nor tuple.
- **TypeError** –If *ceil_mode* or *count_include_pad* is not a bool.
- **TypeError** –If *divisor_override* is not an int or None.
- **ValueError** –If the dimension of *input* is not equal to *3* or *4*.
- **ValueError** –If *kernel_size* or *stride* is less than 1.
- **ValueError** –If value of *padding* is less than *0*.
- **ValueError** –If *kernel_size*, *padding* or *stride* is a tuple whose length is not equal to *1* or *2*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.arange(1 * 3 * 3 * 4).reshape(1, 3, 3, 4), mindspore.float32)
>>> output = mint.nn.functional.avg_pool2d(x, kernel_size=2, stride=1)
>>> print(output)
[[[[ 2.5   3.5   4.5]
   [ 6.5   7.5   8.5]]
  [[14.5  15.5  16.5]
   [18.5  19.5  20.5]]
  [[26.5  27.5  28.5]
   [30.5  31.5  32.5]]]]
```

mindspore.mint.nn.functional.avg_pool3d

mindspore.mint.nn.functional.**avg_pool3d**(*input*, *kernel_size*, *stride=None*, *padding=0*, *ceil_mode=False*, *count_include_pad=True*, *divisor_override=None*)

Applies a 3D average pooling over an input Tensor which can be regarded as a composition of 3D input planes. Typically the input is of shape $(N, C, D_{in}, H_{in}, W_{in})$, outputs regional average in the (D_{in}, H_{in}, W_{in}) -dimension. Given kernel size (kD, kH, kW) and *stride* , the operation is as follows.

$$\text{output}(N_i, C_j, d, h, w) = \frac{1}{kD * kH * kW} \sum_{l=0}^{kD-1} \sum_{m=0}^{kH-1} \sum_{n=0}^{kW-1}$$
$$\text{input}(N_i, C_j, stride[0] \times d + l, stride[1] \times h + m, stride[2] \times w + n)$$

Warning: This is an experimental API that is subject to change or deletion.

Note: This interface currently does not support Atlas A2 training series products.

Parameters

- **input** (Tensor) –Tensor of shape $(N, C, D_{in}, H_{in}, W_{in})$ or $(C, D_{in}, H_{in}, W_{in})$.
- **kernel_size** (*Union[int, tuple[int], list[int]]*) –The size of kernel used to take the average value. Can be a single number or a tuple (kD, kH, kW) .
- **stride** (*Union[int, tuple[int], list[int]], optional*) –The distance of kernel moving. Can be a single number or a tuple (sD, sH, sW) . Default: None, where its value is equal to *kernel_size*.
- **padding** (*Union[int, tuple[int], list[int]], optional*) –Implicit zero padding to be added on both sides. Can be a single number or a tuple $(padD, padH, padW)$. Default: 0.
- **ceil_mode** (*bool, optional*) –If True, apply ceil instead of floor to compute the output shape. Default: False.
- **count_include_pad** (*bool, optional*) –If True, include the zero-padding in the averaging calculation. Default: True .
- **divisor_override** (*int, optional*) –If specified, it will be used as divisor in the averaging calculation, otherwise size of pooling region will be used. Default: None.

Returns

Tensor, with shape $(N, C, D_{out}, H_{out}, W_{out})$ or $(C, D_{out}, H_{out}, W_{out})$.

$$D_{out} = \frac{D_{in}+2\times padding[0]-kernel\_size[0]}{stride[0]} + 1$$
$$H_{out} = \frac{H_{in}+2\times padding[1]-kernel\_size[0]}{stride[1]} + 1$$
$$W_{out} = \frac{W_{in}+2\times padding[2]-kernel\_size[1]}{stride[2]} + 1$$

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *kernel_size* or *stride* is neither int nor tuple.
- **TypeError** –If *ceil_mode* or *count_include_pad* is not a bool.

- **TypeError** –If *divisor_override* is not an int or None.
- **ValueError** –If the dimension of *input* is not equal to *4* or *5*.
- **ValueError** –If *kernel_size* or *stride* is less than 1.
- **ValueError** –If value of *padding* is less than *0*.
- **ValueError** –If *kernel_size*, *padding* or *stride* is a tuple whose length is not equal to *1* or *3*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input_x = Tensor(np.arange(1 * 2 * 2 * 2 * 3).reshape((1, 2, 2, 2, 3)), mindspore.
↪float16)
>>> output = mint.nn.functional.avg_pool3d(input_x, kernel_size=2, stride=1)
>>> print(output)
[[[[[ 5.  6.]]]
  [[[17. 18.]]]]]
```

mindspore.mint.nn.functional.max_pool2d

mindspore.mint.nn.functional.**max_pool2d**(*input*, *kernel_size*, *stride=None*, *padding=0*, *dilation=1*, *ceil_mode=False*, *return_indices=False*)

Performs a 2D max pooling on the input Tensor.

Typically, the input is a Tensor with shape $(N_{in}, C_{in}, H_{in}, W_{in})$, outputs regional maximum in the (H_{in}, W_{in})-dimension. Given *kernel_size* $ks = (h_{ker}, w_{ker})$ and *stride* $s = (s_0, s_1)$, the operation is as follows:

$$\text{output}(N_i, C_j, h, w) = \max_{m=0,\ldots,h_{ker}-1} \max_{n=0,\ldots,w_{ker}-1} \text{input}(N_i, C_j, s_0 \times h + m, s_1 \times w + n)$$

Warning: Only support on Atlas A2 training series.

Parameters

- **input** (Tensor) –Tensor of shape $(N_{in}, C_{in}, H_{in}, W_{in})$ with data type of float32 in Ascend.
- **kernel_size** (*Union[int, tuple[int]]*) –The size of kernel used to take the maximum value and arg value, is an int number that represents height and width of the kernel, or a tuple of two int numbers that represent height and width respectively.
- **stride** (*Union[int, tuple[int], None], optional*) –The distance of kernel moving, an int number that represents the height and width of movement are both stride, or a tuple of two int numbers that represent height and width of movement respectively. Default: `None` , which indicates the moving step is *kernel_size* .
- **padding** (*Union[int, tuple[int]], optional*) –An int number that represents the height and width of movement are both strides, or a tuple of two int numbers that represent height and width of movement respectively. Default: `0` .

- **dilation** (*Union[int, tuple[int]], optional*) – Control the stride of elements in the kernel. Default: `1` .
- **ceil_mode** (*bool, optional*) – Whether to use ceil instead of floor to calculate output shape. Default: `False` .
- **return_indices** (*bool, optional*) – Whether to output the indices of max value. Default: `False` .

Returns

If *return_indices* is `False` , return a Tensor *output*, else return a tuple (*output*, *argmax*).

- **output** (Tensor) - Maxpooling result, with shape $(N_{out}, C_{out}, H_{out}, W_{out})$. It has the same data type as *input*.

$$H_{out} = \left\lfloor \frac{H_{in} + 2 * \text{padding}[0] - \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) - 1}{\text{stride}[0]} + 1 \right\rfloor$$

$$W_{out} = \left\lfloor \frac{W_{in} + 2 * \text{padding}[1] - \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) - 1}{\text{stride}[1]} + 1 \right\rfloor$$

- **argmax** (Tensor) - Index corresponding to the maximum value. In Ascend, data type is int32. It will be return only when *return_indices* is True.

Raises

- **TypeError** – If *input* is not a Tensor.
- **ValueError** – If length of shape of *input* is not equal to 4.
- **TypeError** – If *kernel_size* , *stride* , *padding* or *dilation* is not int or tuple.
- **ValueError** – If *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** – If *dilation* is not all 1.
- **ValueError** – If *padding* is less than 0.
- **ValueError** – If *padding* is more than half of *kernel_size*.
- **TypeError** – If *ceil_mode* is not bool.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.arange(20 * 16 * 50 * 32).reshape((20, 16, 50, 32)), mindspore.float32)
>>> output_tensor, argmax = mint.nn.functional.max_pool2d(input, kernel_size=(3, 2),␣
↪stride=(2, 1),
...                                                                    ceil_mode=False, return_
↪indices=True)
>>> print(output_tensor.shape)
(20, 16, 24, 31)
>>> print(argmax.shape)
(20, 16, 24, 31)
```

mindspore.mint.nn.functional.max_unpool2d

mindspore.mint.nn.functional.**max_unpool2d**(*input*, *indices*, *kernel_size*, *stride=None*, *padding=0*, *output_size=None*)

Computes the inverse of *max_pool2d*.

max_unpool2d keeps the maximal value and set all position of non-maximal values to zero. Typically the input is of shape (N, C, H_{in}, W_{in}) or (C, H_{in}, W_{in}), and the output is of shape (N, C, H_{out}, W_{out}) or (C, H_{out}, W_{out}). The operation is as follows.

$$H_{out} = (H_{in} - 1) \times stride[0] - 2 \times padding[0] + kernel\_size[0]$$
$$W_{out} = (W_{in} - 1) \times stride[1] - 2 \times padding[1] + kernel\_size[1]$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –The input Tensor to invert. Tensor of shape (N, C, H_{in}, W_{in}) or (C, H_{in}, W_{in}).
- **indices** (Tensor) –Max values' index represented by the indices. Tensor of shape must be same with input 'input'. Values of indices must belong to $[0, H_{in} \times W_{in} - 1]$. Data type must be in int32 or int64.
- **kernel_size** (*Union[int, tuple[int]]*) –The size of kernel used to take the maximum value, an int number that represents height and width of the kernel, or a tuple of two int numbers that represent height and width respectively.
- **stride** (*Union[int, tuple[int]], optional*) –The distance of kernel moving, an int number that represents the height and width of movement are both stride, or a tuple of two int numbers that represent height and width of movement respectively. Default: None , which indicates the moving step is *kernel_size* .
- **padding** (*Union[int, tuple[int]], optional*) –The pad value to be filled. Default: 0 . If *padding* is an integer, the paddings of height and width are the same, equal to padding. If *padding* is a tuple of two integers, the padding of height and width equal to padding[0] and padding[1] correspondingly.
- **output_size** (*tuple[int], optional*) –The target output size. Default: None . If output_size == (), then the shape of output computed by *kernel_size*, *stride* and *padding*. If output_size != (), then output_size must be (N, C, H, W) , (C, H, W) or (H, W) and output_size must belong to $[(N, C, H_{out} - stride[0], W_{out} - stride[1]), (N, C, H_{out} + stride[0], W_{out} + stride[1])]$.

Returns

Tensor, with shape (N, C, H_{out}, W_{out}) or (C, H_{out}, W_{out}), with the same data type with *input*.

Raises

- **TypeError** –If data type of *input* or *indices* is not supported.
- **TypeError** –If *kernel_size*, *stride* or *padding* is neither an int nor a tuple.
- **ValueError** –If numbers in *stride*, *padding* or *kernel_size* are not positive.
- **ValueError** –If the shapes of *input* and *indices* are different.
- **ValueError** –If the length of *input* is not 3 or 4.
- **ValueError** –If the type of *output_size* is not tuple.
- **ValueError** –If *output_size* is not close to output size computed by attr *kernel_size*, *stride*, *padding*.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[[[0, 1], [8, 9]]]]).astype(np.float32))
>>> indices = Tensor(np.array([[[[0, 1], [2, 3]]]]).astype(np.int64))
>>> output = mint.nn.functional.max_unpool2d(input, indices, 1, stride=1, padding=0)
>>> print(output.asnumpy())
[[[[0. 1.]
   [8. 9.]]]]
```

4.5.3 Non-linear activation functions

API Name	Description	Supported Platforms
mindspore.mint.nn.functional.batch_norm	Batch Normalization for input data and updated parameters.	Ascend
mindspore.mint.nn.functional.elu	Exponential Linear Unit activation function	Ascend
*mindspore.mint.nn.functional.elu_*	Exponential Linear Unit activation function	Ascend
mindspore.mint.nn.functional.gelu	Gaussian Error Linear Units activation function.	Ascend
mindspore.mint.nn.functional.glu	Computes GLU (Gated Linear Unit activation function) of the input tensor.	Ascend
mindspore.mint.nn.functional.group_norm	Group Normalization over a mini-batch of inputs.	Ascend
mindspore.mint.nn.functional.hardshrink	Hard Shrink activation function.	Ascend
mindspore.mint.nn.functional.hardsigmoid	Hard Sigmoid activation function.	Ascend
mindspore.mint.nn.functional.hardswish	Hard Swish activation function.	Ascend
mindspore.mint.nn.functional.layer_norm	Applies the Layer Normalization on the mini-batch input.	Ascend
mindspore.mint.nn.functional.leaky_relu	leaky_relu activation function.	Ascend
mindspore.mint.nn.functional.log_softmax	Applies the Log Softmax function to the input tensor on the specified axis.	Ascend
mindspore.mint.nn.functional.logsigmoid	Applies logsigmoid activation element-wise.	Ascend
mindspore.mint.nn.functional.mish	Computes MISH (A Self Regularized Non-Monotonic Neural Activation Function) of input tensors element-wise.	Ascend
mindspore.mint.nn.functional.prelu	Parametric Rectified Linear Unit activation function.	Ascend
mindspore.mint.nn.functional.relu	Computes ReLU (Rectified Linear Unit activation function) of input tensors element-wise.	Ascend
mindspore.mint.nn.functional.relu6	Computes ReLU (Rectified Linear Unit) upper bounded by 6 of input tensors element-wise.	Ascend
*mindspore.mint.nn.functional.relu_*	ReLuComputes ReLU (Rectified Linear Unit activation function) inplace of input tensors element-wise.	Ascend

continues on next page

Table 22 – continued from previous page

mindspore.mint.nn.functional.selu	Activation function SELU (Scaled exponential Linear Unit).	Ascend
mindspore.mint.nn.functional.sigmoid	Computes Sigmoid of input element-wise.	Ascend
mindspore.mint.nn.functional.silu	Computes Sigmoid Linear Unit of input element-wise, also known as Swish function.	Ascend
mindspore.mint.nn.functional.softmax	Applies the Softmax operation to the input tensor on the specified axis.	Ascend
mindspore.mint.nn.functional.softplus	Applies softplus function to *input* element-wise.	Ascend
mindspore.mint.nn.functional.softshrink	Soft Shrink activation function.	Ascend
mindspore.mint.nn.functional.tanh	Computes hyperbolic tangent of input element-wise.	Ascend

mindspore.mint.nn.functional.batch_norm

mindspore.mint.nn.functional.**batch_norm**(*input*, *running_mean*, *running_var*, *weight=None*, *bias=None*, *training=False*, *momentum=0.1*, *eps=1e-5*)

Batch Normalization for input data and updated parameters.

Batch Normalization is widely used in convolutional neural networks. This operation applies Batch Normalization over inputs to avoid internal covariate shift as described in the paper Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift. It rescales and recenters the features using a mini-batch of data and the learned parameters can be described in the following formula,

$$y = \frac{x - mean}{\sqrt{variance + \epsilon}} * \gamma + \beta$$

where γ is *weight*, β is *bias*, ϵ is *eps*, $mean$ is the mean of x, $variance$ is the variance of x.

Parameters

- **input** (Tensor) –Tensor of shape $(N, C, *)$, with bfloat16, float16 or float32 data type. For Atlas training products, the shape must be 2-4 dimensions currently.
- **running_mean** (Tensor) –The shape $(C,)$, with bfloat, float16 or float32 data type.
- **running_var** (Tensor) –The shape $(C,)$, with bfloat, float16 or float32 data type.
- **weight** (Tensor, *optional*) –The shape $(C,)$, with bfloat, float16 or float32 data type, Default: None. Initialized to 1 when *weight* is None.
- **bias** (Tensor, *optional*) –The shape $(C,)$, with bfloat, float16 or float32 data type. Default: None. Initialized to 0 when *weight* is None.
- **training** (*bool*, *optional*) –If *training* is *True*, *mean* and *variance* are computed during training. If *training* is *False*, they're loaded from checkpoint during inference. Default: False .
- **momentum** (*float*, *optional*) –The hyper parameter to compute moving average for *running_mean* and *running_var* (e.g. $new\_running\_mean = (1 - momentum) * running\_mean + momentum * current\_mean$). Default: 0.1 .
- **eps** (*float*, *optional*) –A small value added for numerical stability. Default: 1e-5.

Returns

Tensor, has the same type and shape as *input*. The shape is $(N, C, *)$.

Raises

- **TypeError** – If *training* is not a bool.
- **TypeError** – If dtype of *eps* or *momentum* is not float.
- **TypeError** – If *input*, *weight*, *bias*, *running_mean* or *running_var* is not a Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input_x = Tensor([[1.0, 2.0], [3.0, 4.0]], mindspore.float32)
>>> running_mean = Tensor([0.5, 1.5], mindspore.float32)
>>> running_var = Tensor([0.1, 0.2], mindspore.float32)
>>> weight = Tensor([2.0, 2.0], mindspore.float32)
>>> bias = Tensor([-1.0, -1.0], mindspore.float32)
>>> output = mint.nn.functional.batch_norm(input_x, running_mean, running_var, weight, bias)
>>> print(output)
[[ 2.1621194  1.2360122]
 [14.810596  10.180061 ]]
```

mindspore.mint.nn.functional.elu

`mindspore.mint.nn.functional.`**`elu`**(*input*, *alpha=1.0*, *inplace=False*)

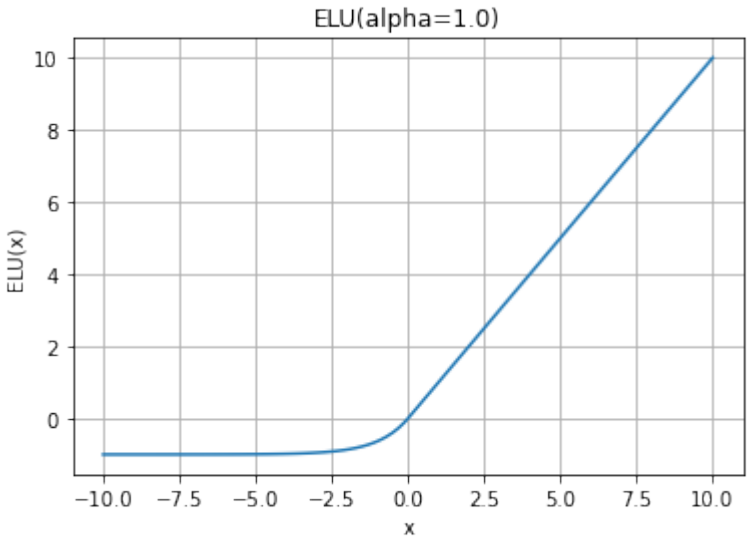
Exponential Linear Unit activation function

Applies the exponential linear unit function element-wise. The activation function is defined as:

$$ELU_i = \begin{cases} x_i, & \text{if } x_i \geq 0; \\ \alpha * (\exp(x_i) - 1), & \text{otherwise.} \end{cases}$$

where x_i represents the element of the input and α represents the *alpha* parameter, and *alpha* represents the smoothness of the ELU.

ELU Activation Function Graph:



Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (*Tensor*) – The input of ELU is a Tensor of any dimension.
- **alpha** (*float, optional*) – The alpha value of ELU, the data type is float. Default: `1.0`.
- **inplace** (*bool, optional*) – Whether to use inplace mode, the data type is bool. Default: `False`.

Returns

Tensor, with the same shape and type as the *input*.

Raises

- **RuntimeError** – If the dtype of *input* is not float16, float32 or bfloat16.
- **TypeError** – If the dtype of *alpha* is not float.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float32)
>>> output = mint.nn.functional.elu(input)
>>> print(output)
[-0.63212055  -0.86466473  0.  2.  1.]
```

mindspore.mint.nn.functional.elu_

mindspore.mint.nn.functional.**elu_**(*input*, *alpha=1.0*)

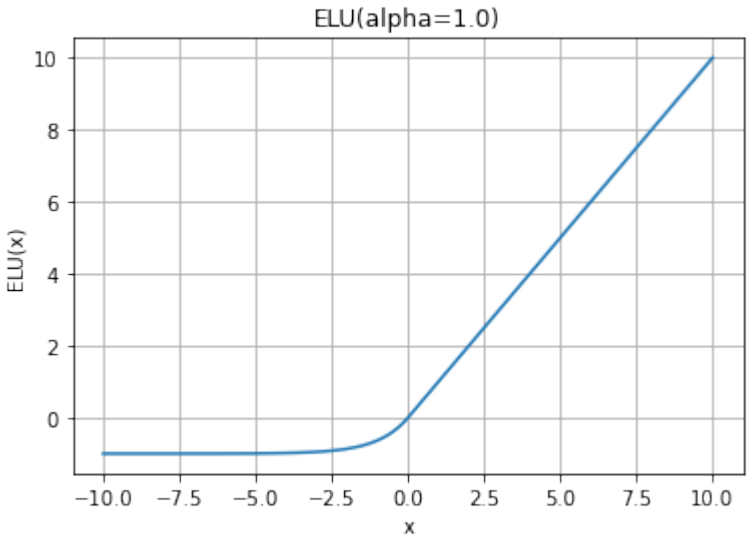
Exponential Linear Unit activation function

Applies the exponential linear unit function inplace element-wise. The activation function is defined as:

$$ELU_i = \begin{cases} x_i, & \text{if } x_i \geq 0; \\ \alpha * (\exp(x_i) - 1), & \text{otherwise.} \end{cases}$$

where x_i represents the element of the input and α represents the *alpha* parameter, and *alpha* represents the smoothness of the ELU.

ELU Activation Function Graph:



Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) −The input of ELU is a Tensor of any dimension.
- **alpha** (*float, optional*) −The alpha value of ELU, the data type is float and *alpha* should be greater than 0. Default: 1.0.

Returns

Tensor, with the same shape and type as the *input*.

Raises

- **RuntimeError** −If the dtype of *input* is not float16, float32 or bfloat16.
- **TypeError** −If the dtype of *alpha* is not float.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float32)
>>> mint.nn.functional.elu_(input)
>>> print(input)
[-0.63212055  -0.86466473  0.  2.  1.]
```

mindspore.mint.nn.functional.gelu

mindspore.mint.nn.functional.**gelu**(*input*, *, *approximate='none'*) → *Tensor*

Gaussian Error Linear Units activation function.

GeLU is described in the paper Gaussian Error Linear Units (GELUs). And also please refer to BERT: Pre-training of Deep Bidirectional Transformers for Language Understanding.

When *approximate* argument is *none*, GELU is defined as follows:

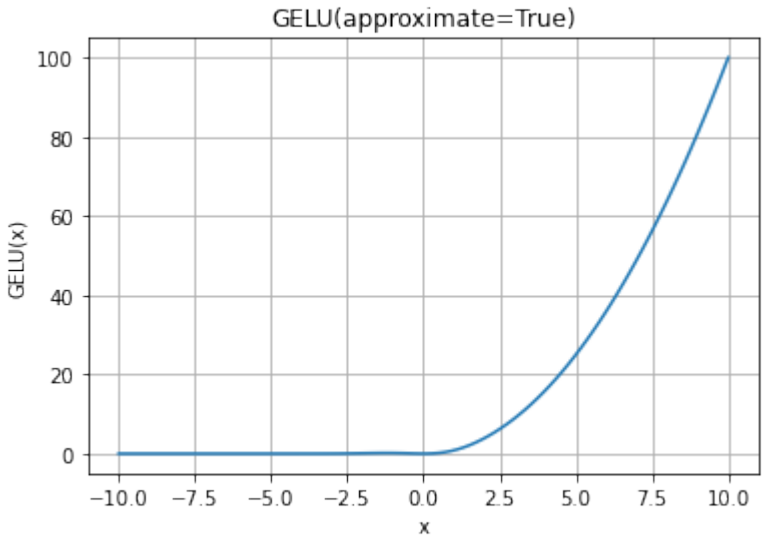
$$GELU(x_i) = x_i * P(X < x_i),$$

where P is the cumulative distribution function of the standard Gaussian distribution, x_i is the input element.

When *approximate* argument is *tanh*, GELU is estimated with:

$$GELU(x_i) = 0.5 * x_i * (1 + \tanh(\sqrt{(2/\pi)} * (x_i + 0.044715 * x_i^3)))$$

GELU Activation Function Graph:



Note: On the Ascend platform, when *input* is -inf, its gradient is 0, and when *input* is inf, its gradient is *dout*.

Parameters

input (Tensor) −The input of the activation function GeLU, the data type is float16, float32 or float64.

Keyword Arguments

approximate (*str, optional*) –the gelu approximation algorithm to use. Acceptable vaslues are `'none'` and `'tanh'`. Default: `'none'`.

Returns

Tensor, with the same type and shape as *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If dtype of *input* is not bfloat16, float16, float32 or float64.
- **ValueError** –If *approximate* value is neither *none* nor *tanh*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> result = mint.nn.functional.gelu(input)
>>> print(result)
[[-1.58655241e-01  3.99987316e+00 -0.00000000e+00]
 [ 1.95449972e+00 -1.41860323e-06  9.0000000e+00]]
>>> result = mint.nn.functional.gelu(input, approximate="tanh")
>>> print(result)
[[-1.58808023e-01  3.99992990e+00 -3.10779147e-21]
 [ 1.95459759e+00 -2.29180174e-07  9.0000000e+00]]
```

mindspore.mint.nn.functional.glu

`mindspore.mint.nn.functional.`**glu**(*input*, *dim=- 1*)

Computes GLU (Gated Linear Unit activation function) of the input tensor.

$$GLU(a, b) = a \otimes \sigma(b)$$

where a is the first half of the *input* Tensor after *input* is split and b is the second half.

Here σ is the sigmoid function, and $\otimes$ is the Hadamard product. See Language Modeling with Gated Convluational Networks.

Parameters

- **input** (`Tensor`) –Tensor to be calculated. Dtype is floating point and the shape is $(*_1, N, *_2)$ where * means, any number of additional dimensions. N is required to be an even number, where N is the size of *input* on the dimension selected by *dim*.
- **dim** (*int, optional*) –The dimension to split the input *input*. The value range is *[-r, r)* where *r* is the number of dimensions of *input*. Default: `-1` , the last dimension in *input*.

Returns

Tensor, the same dtype as the input *input*. The shape is $(*_1, M, *_2)$ where $M = N/2$.

Raises

- **TypeError** –If *input* is not a Tensor or *dim* is not an int.
- **IndexError** –If the value of *dim* is out of the range of *[-r, r)*, where *r* is the number of dimensions of *input*.
- **RuntimeError** –If dtype of *input* is not supported.
- **RuntimeError** –If the length of *input* in the dimension selected by *dim* is not even.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor, mint
>>> input = Tensor([[0.1, 0.2, 0.3, 0.4], [0.5, 0.6, 0.7, 0.8]])
>>> output = mint.nn.functional.glu(input)
>>> print(output)
[[0.05744425 0.11973753]
 [0.33409387 0.41398472]]
```

mindspore.mint.nn.functional.group_norm

mindspore.mint.nn.functional.**group_norm**(*input*, *num_groups*, *weight=None*, *bias=None*, *eps=1e-5*)

Group Normalization over a mini-batch of inputs.

Group Normalization is widely used in recurrent neural networks. It applies normalization on a mini-batch of inputs for each single training case as described in the paper Group Normalization. Group Normalization divides the channels into groups and computes within each group the mean and variance for normalization, and it performs very stable over a wide range of batch size. γ and β are trainable scale and shift. It can be described using the following formula:

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

where γ is *weight*, β is *bias*, ϵ is *eps*.

Parameters

- **input** (Tensor) –The input feature with shape $(N, C, *)$ where $*$ means, any number of additional dimensions.
- **num_groups** (*int*) –The number of groups to be divided along the channel dimension.
- **weight** (Tensor, *optional*) –The shape $(C,)$, Default: `None`, has the same data type with *input*.
- **bias** (Tensor, *optional*) –The shape $(C,)$, Default: `None`, has the same data type with *input*.
- **eps** (*float*, *optional*) –A value added to the denominator for numerical stability. Default: `1e-5` .

Returns

Tensor, the normalized and scaled offset tensor, has the same shape and data type as the *input*.

Raises

- **TypeError** –If *num_groups* is not an int.
- **TypeError** –If *eps* is not a float.
- **ValueError** –If *num_groups* is less than 1.

- **ValueError** – If *C* (the second parameter of dimensions of *input*) is not divided by *num_groups*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import mint
>>> x = ms.Tensor(np.ones([1, 2, 4, 4], np.float32))
>>> output = mint.nn.functional.group_norm(x, 2)
>>> print(output)
[[[[0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]]
  [[0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]
   [0. 0. 0. 0.]]]]
```

mindspore.mint.nn.functional.hardshrink

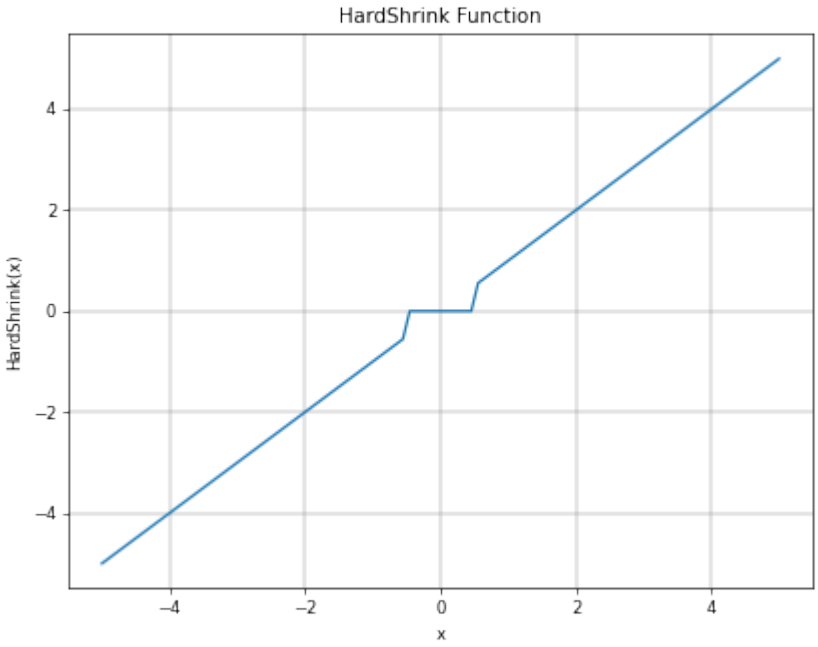
`mindspore.mint.nn.functional.`**`hardshrink`**(*input*, *lambd=0.5*)

Hard Shrink activation function. Calculates the output according to the input elements.

The formula is defined as follows:

$$\text{HardShrink}(x) = \begin{cases} x, & \text{if } x > \lambda \\ x, & \text{if } x < -\lambda \\ 0, & \text{otherwise} \end{cases}$$

HardShrink Activation Function Graph:



Parameters

- **input** (Tensor) – The input of Hard Shrink. Supported dtypes:
  - Ascend: float16, float32, bfloat16.
- **lambd** (*number, optional*) – The threshold λ defined by the Hard Shrink formula. Default: `0.5`.

Returns

Tensor, has the same data type and shape as the input *input*.

Raises

- **TypeError** – If *lambd* is not a float, int or bool.
- **TypeError** – If *input* is not a tensor.
- **TypeError** – If dtype of *input* is not float16, float32 or bfloat16.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[0.5, 1, 2.0], [0.0533, 0.0776, -2.1233]]), mindspore.float32)
>>> output = mint.nn.functional.hardshrink(input)
>>> print(output)
[[ 0.      1.      2.    ]
 [ 0.      0.     -2.1233]]
```

mindspore.mint.nn.functional.hardsigmoid

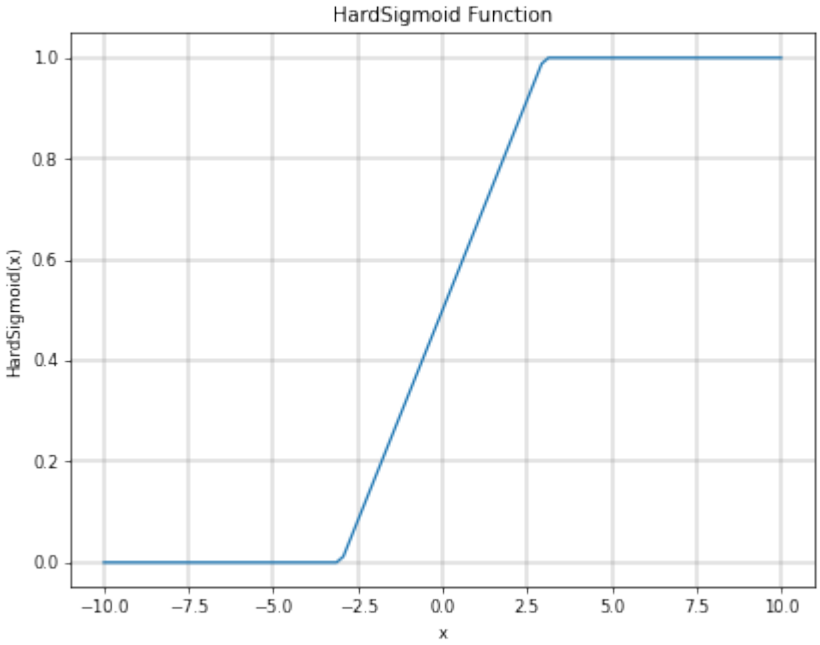
mindspore.mint.nn.functional.**hardsigmoid**(*input*)

Hard Sigmoid activation function. Calculates the output according to the input elements.

Hard Sigmoid is defined as:

$$\text{HardSigmoid}(input) = \begin{cases} 0, & \text{if } input \leq -3, \\ 1, & \text{if } input \geq +3, \\ input/6 + 1/2, & \text{otherwise} \end{cases}$$

HardSigmoid Activation Function Graph:



Parameters

input (Tensor) – The input Tensor.

Returns

Tensor, with the same type and shape as the *input*.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If *input* is neither int nor float.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> output = mint.nn.functional.hardsigmoid(input)
>>> print(output)
[0.3333 0.1666 0.5    0.8335 0.6665]
```

mindspore.mint.nn.functional.hardswish

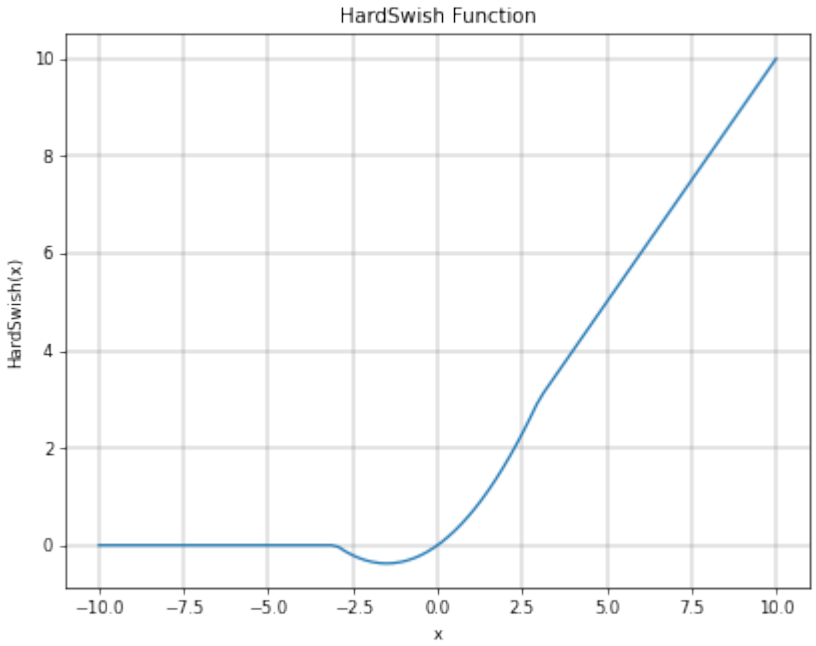
mindspore.mint.nn.functional.**hardswish**(*input*)

Hard Swish activation function. The input is a Tensor with any valid shape.

Hard swish is defined as:

$$\text{HardSwish}(input) = \begin{cases} 0, & \text{if } input \leq -3, \\ input, & \text{if } input \geq +3, \\ input * (input + 3)/6, & \text{otherwise} \end{cases}$$

HardSwish Activation Function Graph:



Parameters

input (Tensor) – The input Tensor.

Returns

Tensor, with the same type and shape as the *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *input* is neither int nor float.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([-1, -2, 0, 2, 1]), mindspore.float16)
>>> output = mint.nn.functional.hardswish(input)
>>> print(output)
[-0.3333  -0.3333  0  1.667  0.6665]
```

mindspore.mint.nn.functional.layer_norm

`mindspore.mint.nn.functional.`**`layer_norm`**(*input*, *normalized_shape*, *weight=None*, *bias=None*, *eps=1e-5*)

Applies the Layer Normalization on the mini-batch input.

Layer normalization is widely used in recurrent neural networks. Apply normalization to the mini-batch input of a single training case. LayerNorm is described in the paper Layer Normalization.

Unlike batch normalization, layer normalization performs the exact same calculations at training and test time. Applies to all channels and pixels, even batch_size=1. The formula is as follows:

$$y = \frac{x - \mathrm{E}[x]}{\sqrt{\mathrm{Var}[x] + \epsilon}} * \gamma + \beta$$

where γ is the weight value learned through training, β is the bias value learned through training.

Parameters

- **input** (`Tensor`) –The shape of input is *(N, *)*, where * represents any additional dimension.
- **normalized_shape** (*`Union(int, tuple[int], list[int])`*) –The normalized shape of *input* for LayerNorm. *normalized_shape* equal to *input_shape[begin_norm_axis:]*, where *begin_norm_axis* represents the axis where normalization begins.
- **weight** (`Tensor, optional`) –Learnable parameter γ . Tensor of shape *normalized_shape*. Default: `None`, has the same data type with *input*. Initialized to `1` when *weight* is None.
- **bias** (`Tensor, optional`) –Learnable parameter β . Tensor of shape *normalized_shape*. Default: `None`, has the same data type with *input*. Initialized to `0` when *bias* is None.
- **eps** (*`float, optional`*) –A value added to the denominator for numerical stability(ϵ). Default: `1e-5` .

Returns

Tensor. The normalized tensor, has the same type and shape as the *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *normalized_shape* is not an integer, a list or a tuple.
- **TypeError** –If *eps* is not a float.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input_x = Tensor(np.array([[1, 2, 3], [1, 2, 3]]), mindspore.float32)
>>> normalized_shape = (3,)
>>> gamma = Tensor(np.ones(normalized_shape), mindspore.float32)
>>> beta = Tensor(np.zeros(normalized_shape), mindspore.float32)
>>> eps = 1e-7
>>> output = mint.nn.functional.layer_norm(input_x, normalized_shape, gamma, beta, eps)
>>> print(output)
[[-1.2247448 0. 1.2247448]
 [-1.2247448 0. 1.2247448]]
```

mindspore.mint.nn.functional.leaky_relu

`mindspore.mint.nn.functional.`**`leaky_relu`**(*input*, *negative_slope=0.01*)

leaky_relu activation function. The element of *input* less than 0 times *negative_slope* .

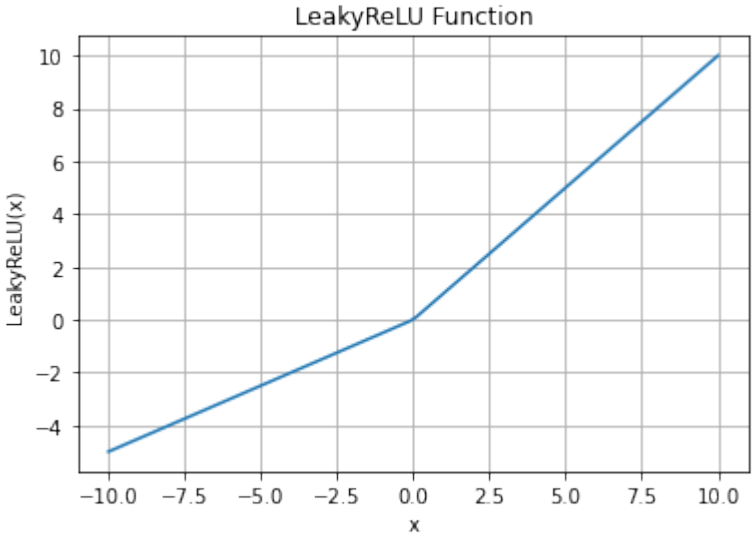
The activation function is defined as:

$$\text{leaky\_relu}(input) = \begin{cases} input, & \text{if } input \geq 0; \\ \text{negative\_slope} * input, & \text{otherwise.} \end{cases}$$

where $negative\_slope$ represents the *negative_slope* parameter.

For more details, see Rectifier Nonlinearities Improve Neural Network Acoustic Models.

LeakyReLU Activation Function Graph:



Parameters

- **`input`** (`Tensor`) –The input of leaky_relu is a Tensor of any dimension.

- **negative_slope** (*Union[int, float], optional*) –Slope of the activation function when the element of *input* is less than 0. Default: `0.01` .

Returns

Tensor, has the same type and shape as the *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *negative_slope* is not a float or an int.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> print(mint.nn.functional.leaky_relu(input, negative_slope=0.2))
[[-0.2  4.  -1.6]
 [ 2.  -1.   9. ]]
```

mindspore.mint.nn.functional.log_softmax

`mindspore.mint.nn.functional.`**log_softmax**(*input*, *dim=None*, *, *dtype=None*)

Applies the Log Softmax function to the input tensor on the specified axis. Supposes a slice in the given axis, x for each element x_i, the Log Softmax function is shown as follows:

$$\text{output}(x_i) = \log\left(\frac{\exp(x_i)}{\sum_{j=0}^{N-1}\exp(x_j)}\right),$$

where N is the length of the Tensor.

Parameters

- **input** (`Tensor`) –The input Tensor.
- **dim** (*int, optional*) –The axis to perform the Log softmax operation. Default: `None` .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –The desired dtype of returned Tensor. If not set to None, the input Tensor will be cast to *dtype* before the operation is performed. This is useful for preventing overflows. If set to None, stay the same as original Tensor. Default: `None` .

Returns

Tensor, with the same shape as the input.

Raises

- **TypeError** –If *dim* is not an int.
- **ValueError** –If *dim* is not in range [-len(input.shape), len(input.shape)).

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> logits = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> output = mint.nn.functional.log_softmax(logits, dim=-1)
>>> print(output)
[-4.4519143 -3.4519143 -2.4519143 -1.4519144 -0.4519144]
```

mindspore.mint.nn.functional.logsigmoid

`mindspore.mint.nn.functional.`**`logsigmoid`**(*input*)

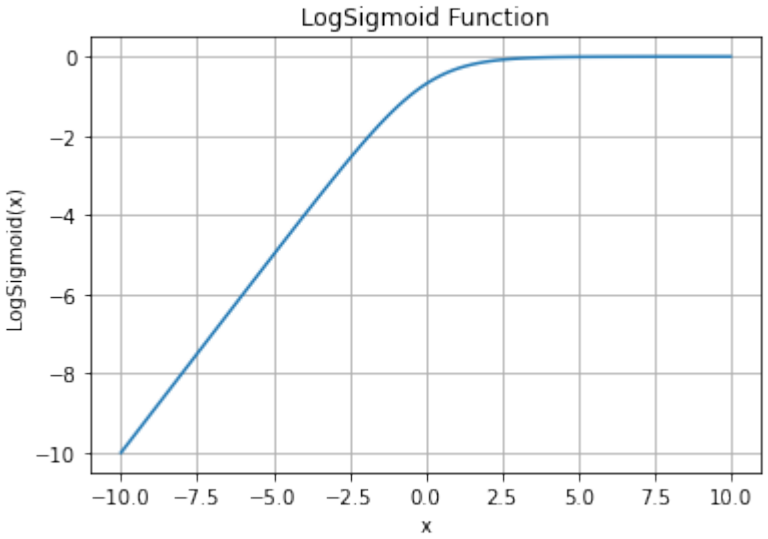
Applies logsigmoid activation element-wise. The input is a Tensor with any valid shape.

Logsigmoid is defined as:

$$\text{logsigmoid}(x_i) = \log(\frac{1}{1 + \exp(-x_i)}),$$

where x_i is the element of the input.

LogSigmoid Activation Function Graph:



Warning: This is an experimental API that is subject to change or deletion.

Parameters

`input` (`Tensor`) −The input of LogSigmoid with data type of bfloat16, float16 or float32. The shape is $(*)$ where $*$ means, any number of additional dimensions.

Returns

Tensor, with the same type and shape as the *input*.

Raises

- **TypeError** – If dtype of *input* is not bfloat16, float16 and float32.
- **TypeError** – If *input* is not a Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input = Tensor([1.0, 2.0, 3.0], mindspore.float32)
>>> output = mint.nn.functional.logsigmoid(input)
>>> print(output)
[-0.31326166 -0.12692806 -0.04858734]
```

mindspore.mint.nn.functional.mish

mindspore.mint.nn.functional.**mish**(*input*)

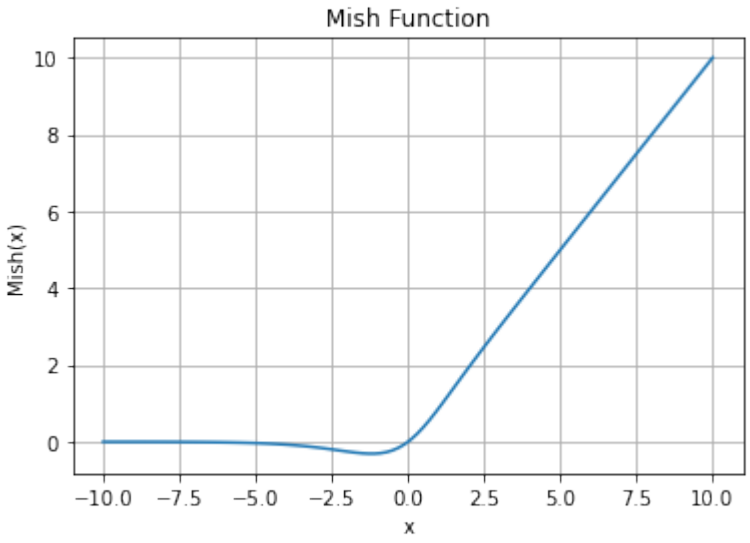
Computes MISH (A Self Regularized Non-Monotonic Neural Activation Function) of input tensors element-wise.

The formula is defined as follows:

$$\text{mish}(input) = input * \tanh(softplus(\text{input}))$$

See more details in A Self Regularized Non-Monotonic Neural Activation Function.

Mish Activation Function Graph:



Parameters

input (Tensor) – The input of MISH. Supported dtypes:

- Ascend: float16, float32.

Returns

Tensor, has the same type and shape as the *input*.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If dtype of *input* is not float16 or float32.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> x = Tensor(np.array([[-1.1, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> output = mint.nn.functional.mish(x)
>>> print(output)
[[-3.0764845e-01 3.9974124e+00 -2.6832507e-03]
 [ 1.9439589e+00 -3.3576239e-02 8.9999990e+00]]
```

mindspore.mint.nn.functional.prelu

mindspore.mint.nn.functional.**prelu**(*input*, *weight*)

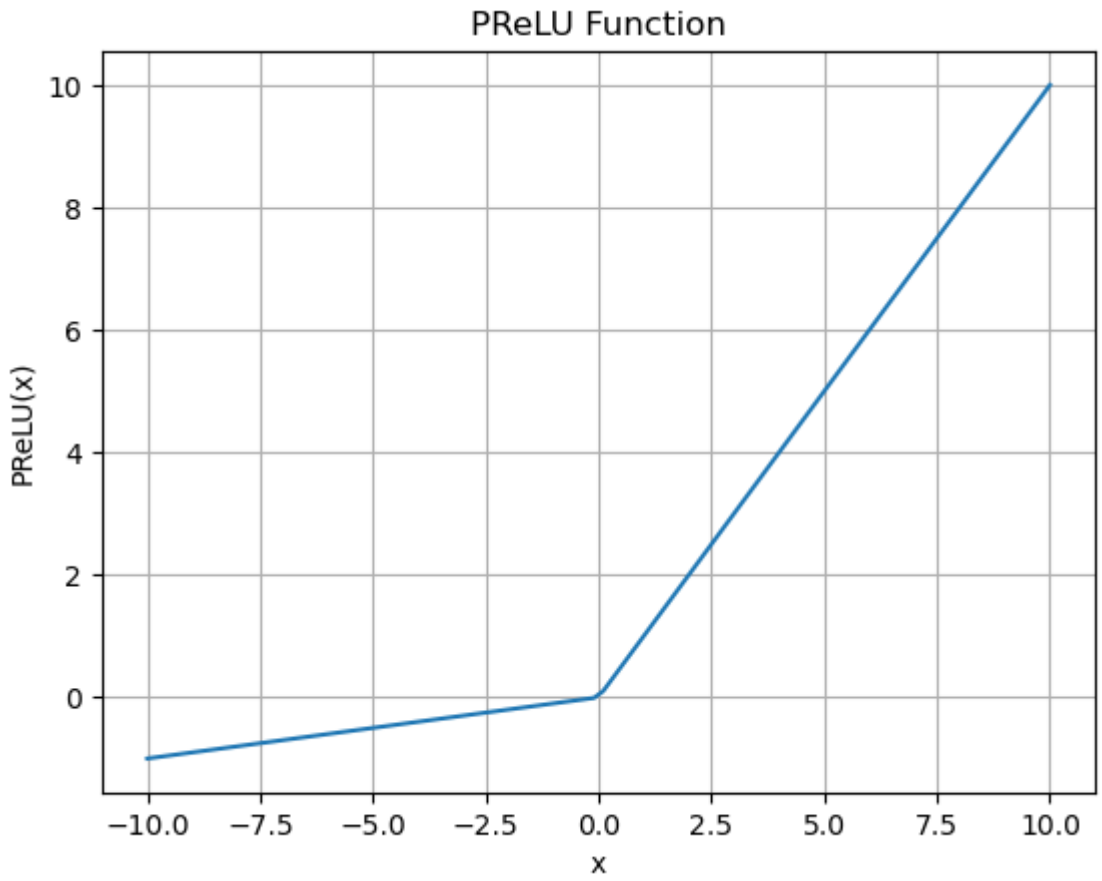
Parametric Rectified Linear Unit activation function.

PReLU is described in the paper Delving Deep into Rectifiers: Surpassing Human-Level Performance on ImageNet Classification. Defined as follows:

$$prelu(x_i) = \max(0, x_i) + \min(0, w * x_i),$$

where x_i is an element of a channel of the input, w is the weight of the channel.

PReLU Activation Function Graph:



Note: Channel dim is the 2nd dim of input. When input has dims < 2, then there is no channel dim and the number of channels = 1.

Parameters

- **input** (Tensor) −The input Tensor of the activation function.
- **weight** (Tensor) −Weight Tensor. The size of the weight should be 1 or the number of channels at Tensor *input*.

Returns

Tensor, with the same shape and dtype as *input*. For detailed information, please refer to *mindspore.mint.nn.PReLU*.

Raises

- **TypeError** −If the *input* or the *weight* is not a Tensor.
- **ValueError** −If the *weight* is not a 0-D or 1-D Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.arange(-6, 6).reshape((2, 3, 2)), mindspore.float32)
>>> weight = Tensor(np.array([0.1, 0.6, -0.3]), mindspore.float32)
>>> output = mint.nn.functional.prelu(x, weight)
>>> print(output)
[[[-0.60 -0.50]
  [-2.40 -1.80]
  [ 0.60  0.30]]
 [[ 0.00  1.00]
  [ 2.00  3.00]
  [ 4.0   5.00]]]
```

mindspore.mint.nn.functional.relu

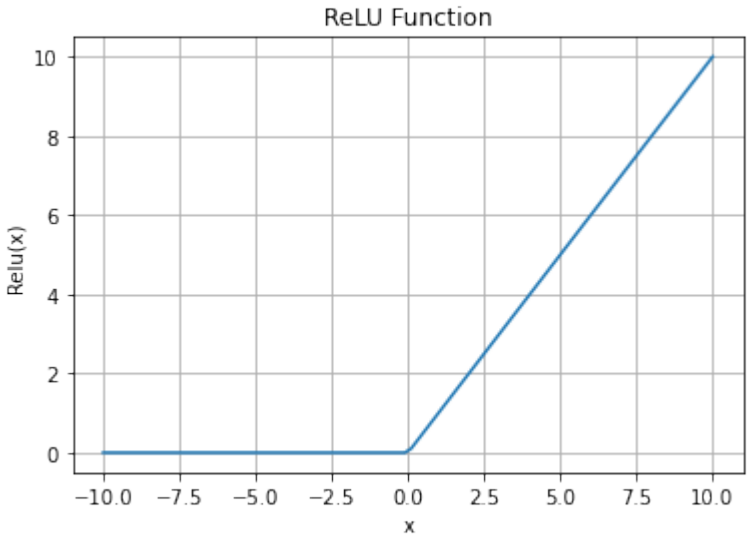
mindspore.mint.nn.functional.**relu**(*input*, *inplace=False*)

Computes ReLU (Rectified Linear Unit activation function) of input tensors element-wise.

It returns $\max(input,\ 0)$ element-wise. Specially, the neurons with the negative output will be suppressed and the active neurons will stay the same.

$$ReLU(input) = (input)^+ = \max(0, input)$$

ReLU Activation Function Graph:



Parameters

- **input** (Tensor) –The input Tensor.
- **inplace** (*bool, optional*) –Whether to use inplace mode, Defaults to False.

Returns

Tensor, with the same dtype and shape as the *input*.

Raises

- **TypeError** – If dtype of *input* is not Number type.
- **TypeError** – If *input* is not a Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> output = mint.nn.functional.relu(input)
>>> print(output)
[[0. 4. 0.]
 [2. 0. 9.]]
```

mindspore.mint.nn.functional.relu6

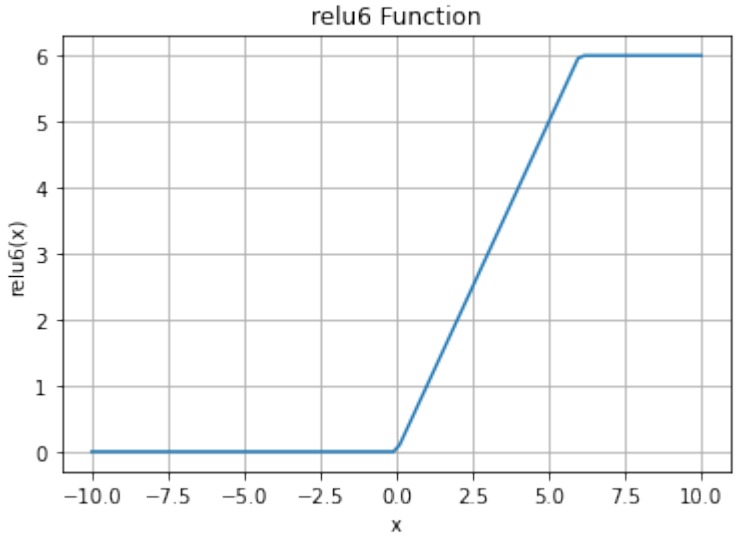
`mindspore.mint.nn.functional.`**`relu6`**(*input*, *inplace=False*)

Computes ReLU (Rectified Linear Unit) upper bounded by 6 of input tensors element-wise.

$$\text{ReLU6}(input) = \min(\max(0, input), 6)$$

It returns $\min(\max(0, input), 6)$ element-wise.

ReLU6 Activation Function Graph:



Warning: This is an experimental optimizer API that is subject to change.

Parameters

- **input** (`Tensor`) – input Tensor. Dtype is in int8, int16, int32, int64, uint8, float16, float32, bfloat16.

- **inplace** (*bool, optional*) −Whether to apply erasing inplace. Default: `False`.

Returns

Tensor, with the same dtype and shape as the *input*.

Raises

- **TypeError** −If *input* is not a Tensor.
- **TypeError** −If dtype of *input* is not one of: int8, int16, int32, int64, uint8, float16, float32, bfloat16.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> result = mint.nn.functional.relu6(x)
>>> print(result)
[[0. 4. 0.]
 [2. 0. 6.]]
```

mindspore.mint.nn.functional.relu_

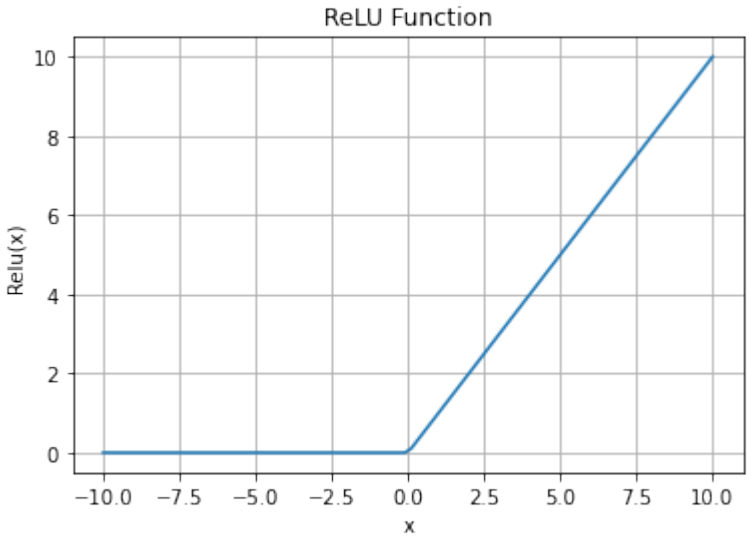
mindspore.mint.nn.functional.**relu_**(*input*)

ReLuComputes ReLU (Rectified Linear Unit activation function) inplace of input tensors element-wise.

It returns $\max(input,\ 0)$ element-wise. Specially, the neurons with the negative output will be suppressed and the active neurons will stay the same.

$$ReLU(input) = (input)^+ = \max(0, input)$$

ReLU Activation Function Graph:



Warning: This is an experimental API that is subject to change or deletion.

Parameters

input (Tensor) –The input Tensor.

Returns

Tensor, with the same dtype and shape as the *input*.

Raises

- **TypeError** –If dtype of *input* is not Number type.
- **TypeError** –If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> mint.nn.functional.relu_(input)
>>> print(input)
[[0. 4. 0.]
 [2. 0. 9.]]
```

mindspore.mint.nn.functional.selu

mindspore.mint.nn.functional.**selu**(*input*)

Activation function SELU (Scaled exponential Linear Unit).

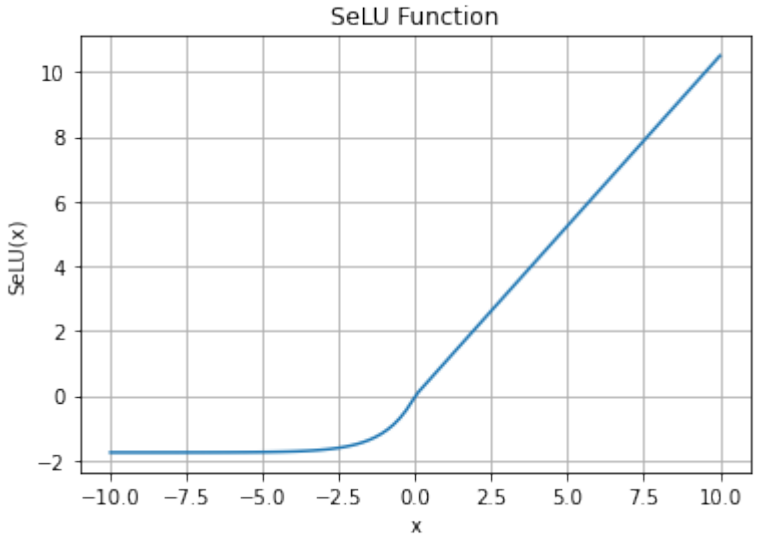
The activation function is defined as:

$$E_i = scale * \begin{cases} x_i, & \text{if } x_i \geq 0; \\ \text{alpha} * (\exp(x_i) - 1), & \text{otherwise.} \end{cases}$$

where $alpha$ and $scale$ are pre-defined constants($alpha = 1.67326324$ and $scale = 1.05070098$).

See more details in Self-Normalizing Neural Networks.

SELU Activation Function Graph:



Parameters

input (Tensor) – Tensor of any dimension. The data type is float16, float32, bfloat16.

Returns

Tensor, with the same type and shape as the *input*.

Raises

TypeError – If dtype of *input* is not float16, float32, bfloat16.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> output = mint.nn.functional.selu(input)
>>> print(output)
[[-1.1113307 4.202804 -1.7575096]
 [ 2.101402 -1.7462534 9.456309 ]]
```

mindspore.mint.nn.functional.sigmoid

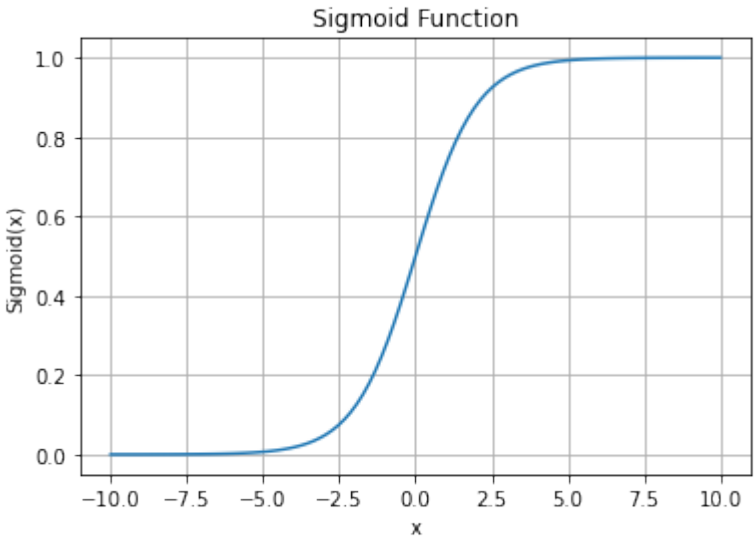
mindspore.mint.nn.functional.**sigmoid**(*input*)

Computes Sigmoid of input element-wise. The Sigmoid function is defined as:

$$\text{sigmoid}(x_i) = \frac{1}{1 + \exp(-x_i)}$$

where x_i is an element of x.

Sigmoid Function Graph:



Parameters

input (Tensor) – *input* is *x* in the preceding formula. Tensor of any dimension, the data type is float16, float32, float64, complex64 or complex128.

Returns

Tensor, with the same type and shape as the input.

Raises

- **TypeError** – If dtype of *input* is not float16, float32, float64, complex64 or complex128.
- **TypeError** – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> output = mint.nn.functional.sigmoid(input)
>>> print(output)
[0.7310586  0.880797   0.95257413 0.98201376 0.9933072 ]
```

mindspore.mint.nn.functional.silu

mindspore.mint.nn.functional.**silu**(*input*)

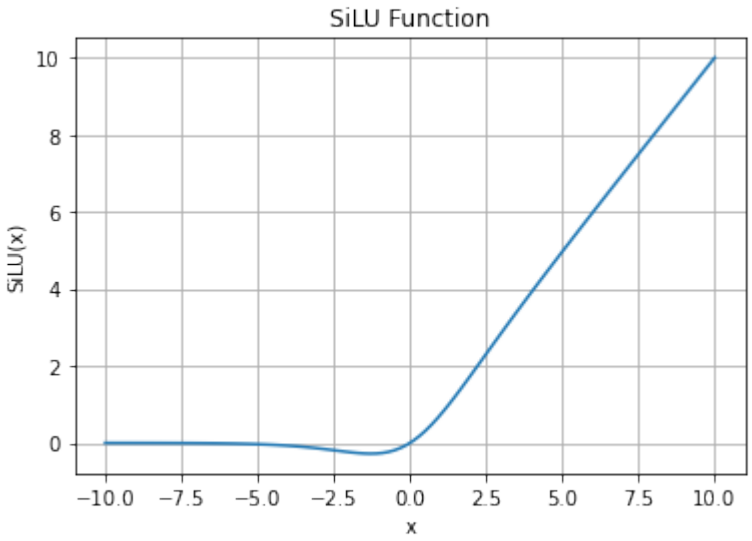
Computes Sigmoid Linear Unit of input element-wise, also known as Swish function. The SiLU function is defined as:

$$\text{SiLU}(x) = x * \sigma(x),$$

where x is an element of the input, $\sigma(x)$ is Sigmoid function.

$$\text{sigma}(x_i) = \frac{1}{1 + \exp(-x_i)},$$

SiLU Function Graph:



Parameters

input (Tensor) – *input* is x in the preceding formula. Input with the data type float16 or float32.

Returns

Tensor, with the same type and shape as the *input*.

Raises

TypeError – If dtype of *input* is neither float16 nor float32.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> import numpy as np
>>> input = Tensor(np.array([-1, 2, -3, 2, -1]), mindspore.float16)
>>> output = mint.nn.functional.silu(input)
>>> print(output)
[-0.269  1.762  -0.1423  1.762  -0.269]
```

mindspore.mint.nn.functional.softmax

mindspore.mint.nn.functional.**softmax**(*input*, *dim=None*, *dtype=None*)

Applies the Softmax operation to the input tensor on the specified axis. Suppose a slice in the given axis dim, then for each element $input_i$, the Softmax function is shown as follows:

$$\text{output}(input_i) = \frac{\exp(input_i)}{\sum_{j=0}^{N-1}\exp(input_j)},$$

where N is the length of the tensor.

Parameters

- **input** (Tensor) –Tensor of shape $(N, *)$, where $*$ means, any number of additional dimensions.
- **dim** (*int, optional*) –The dim to perform the Softmax operation. Default: None .
- **dtype** (*mindspore.dtype*, optional) –When set, *input* will be converted to the specified type, *dtype*, before execution, and dtype of returned Tensor will also be *dtype*. Default: None .

Returns

Tensor, with the same type and shape as the *input*.

Raises

TypeError –If *dim* is not an int.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> output = mint.nn.functional.softmax(input)
>>> print(output)
[0.01165623 0.03168492 0.08612854 0.23412167 0.6364086 ]
```

mindspore.mint.nn.functional.softplus

mindspore.mint.nn.functional.**softplus**(*input*, *beta=1*, *threshold=20*)

Applies softplus function to *input* element-wise.

The softplus function is shown as follows, x is the element of *input* :

$$\text{output} = \frac{1}{beta}\log(1 + \exp(\text{beta} * \text{x}))$$

where $input * beta > threshold$, the implementation converts to the linear function to ensure numerical stability.

Parameters

- **input** (Tensor) –Tensor of any dimension. Supported dtypes:
  - Ascend: float16, float32, bfloat16.

- **beta** (*number.Number, optional*) –Scaling parameters in the softplus function. Default: `1` .
- **threshold** (*number.Number, optional*) –For numerical stability, the softplus function is converted to a threshold parameter of a linear function. Default: `20` .

Returns

Tensor, with the same type and shape as the input.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If dtype of *input* is not float16, float32, bfloat16.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([0.1, 0.2, 30, 25]), mindspore.float32)
>>> output = mint.nn.functional.softplus(input)
>>> print(output)
[0.74439657 0.7981388 30. 25.]
```

mindspore.mint.nn.functional.softshrink

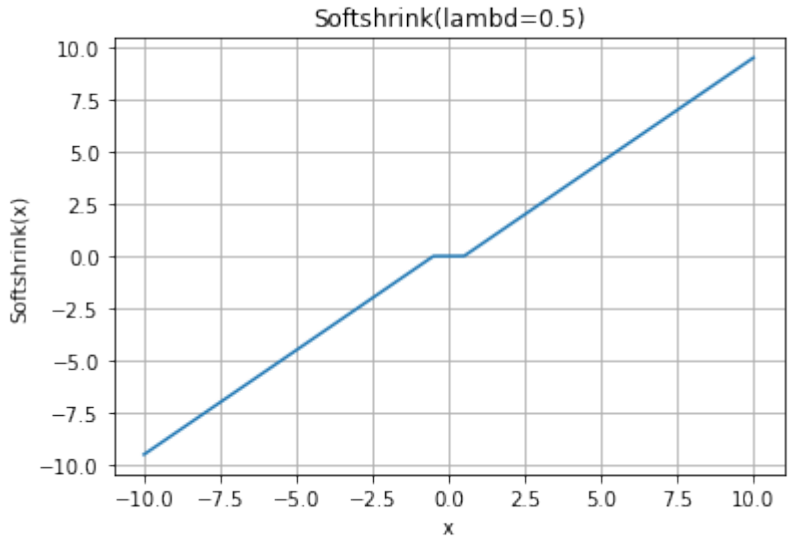
mindspore.mint.nn.functional.**softshrink**(*input*, *lambd=0.5*)

Soft Shrink activation function. Calculates the output according to the input elements.

The formula is defined as follows:

$$\text{SoftShrink}(x) = \begin{cases} x - \lambda, & \text{if } x > \lambda \\ x + \lambda, & \text{if } x < -\lambda \\ 0, & \text{otherwise} \end{cases}$$

SoftShrink Activation Function Graph:



Parameters

- **input** (Tensor) – The input of Soft Shrink. Supported dtypes:
  - Ascend: float16, float32, bfloat16.
- **lambd** (*number, optional*) – The threshold λ defined by the Soft Shrink formula. It should be greater than or equal to 0, default: `0.5`.

Returns

Tensor, has the same data type and shape as the input *input*.

Raises

- **TypeError** – If *lambd* is not a float, int or bool.
- **TypeError** – If *input* is not a tensor.
- **TypeError** – If dtype of *input* is not float16, float32 or bfloat16.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore import mint
>>> import numpy as np
>>> x = Tensor(np.array([[ 0.5297,  0.7871,  1.1754], [ 0.7836,  0.6218, -1.1542]]),␣
↪mindspore.float32)
>>> output = mint.nn.functional.softshrink(x)
>>> print(output)
[[ 0.02979  0.287    0.676  ]
[ 0.2837   0.1216  -0.6543 ]]
```

mindspore.mint.nn.functional.tanh

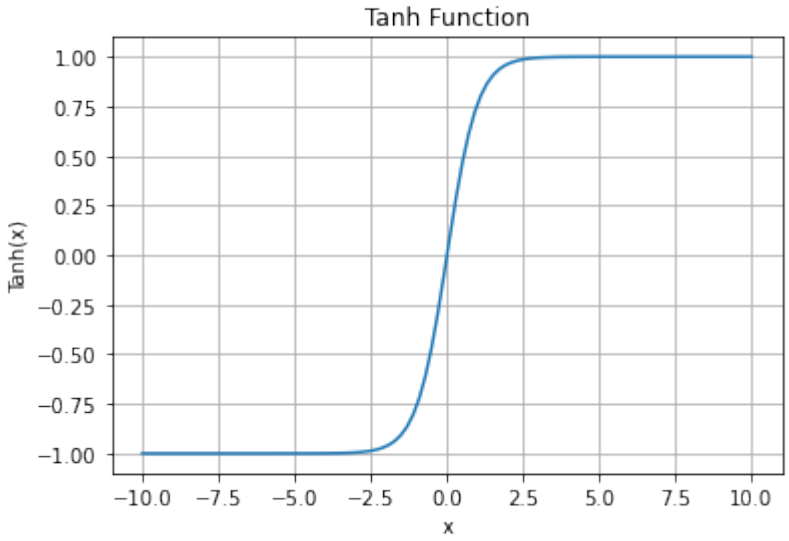
mindspore.mint.nn.functional.**tanh**(*input*)

Computes hyperbolic tangent of input element-wise. The Tanh function is defined as:

$$tanh(x_i) = \frac{\exp(x_i) - \exp(-x_i)}{\exp(x_i) + \exp(-x_i)} = \frac{\exp(2x_i) - 1}{\exp(2x_i) + 1},$$

where x_i is an element of the input Tensor.

Tanh Activation Function Graph:



Parameters

input (Tensor) – Input of Tanh.

Returns

Tensor, with the same type and shape as the *input*.

Raises

TypeError – If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> output = mint.nn.functional.tanh(input)
>>> print(output)
[0.7615941 0.9640276 0.9950547 0.9993293 0.9999092]
```

4.5.4 Normalization functions

API Name	Description	Supported Platforms
mindspore.mint.nn.functional.normalize	Perform normalization of inputs over specified dimension	Ascend

mindspore.mint.nn.functional.normalize

mindspore.mint.nn.functional.**normalize**(*input*, *p=2.0*, *dim=1*, *eps=1e-12*)

Perform normalization of inputs over specified dimension

For a tensor input of sizes $(n_0, ..., n_{dim}, ..., n_k)$, each n_{dim} -element vector v along dimension *dim* is transformed as

$$v = \frac{v}{\max(\|v\|_p, \epsilon)}$$

With the default arguments it uses the Euclidean norm over vectors along dimension 1 for normalization.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) – input tensor of any shape.
- **p** (*float*) – the exponent value in the norm formulation. default: 2.
- **dim** (*int*) – the dimension to reduce. default: 1.
- **eps** (*float*) – small value to avoid division by zero. default: 1e-12.

Returns

Tensor, shape and data type are the same as input.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> tensor = Tensor(np.array([[0, 1, 2], [3, 4, 5], [6, 7, 8]]), mindspore.float32)
>>> output = mint.nn.functional.normalize(tensor)
>>> print(output)
[[0.0000 0.4472 0.8944]
 [0.4243 0.5657 0.7071]
 [0.4915 0.5735 0.6554]]
```

4.5.5 Linear functions

API Name	Description	Supported Platforms
mindspore.mint.nn.functional.linear	Applies the dense connected operation to the *input*.	Ascend

mindspore.mint.nn.functional.linear

mindspore.mint.nn.functional.**linear**(*input*, *weight*, *bias=None*)

Applies the dense connected operation to the *input*. The dense function is defined as:

$$output = input * weight^T + bias$$

Warning:

- This is an experimental API that is subject to change or deletion.
- On the Ascend platform, if *bias* is not 1D, the *input* cannot be greater than 6D in PYNATIVE or KBK mode.

Parameters

- **input** (Tensor) –Input Tensor of shape $(*, in\_channels)$, where $*$ means any number of additional dimensions.
- **weight** (Tensor) –The weight applied to the input. The shape is $(out\_channels, in\_channels)$ or $(in\_channels)$.
- **bias** (Tensor, *optional*) –Additive biases to the output. The shape is $(out\_channels)$ or (). Defaults: None, the *bias* is 0.

Returns

Output whose shape is determined by the shape of the input and the weight.

Raises

- **TypeError** –If *input* is not Tensor.
- **TypeError** –If *weight* is not Tensor.
- **TypeError** –If *bias* is not Tensor.
- **RuntimeError** –On the Ascend platform, if *bias* is not 1D and *input* is greater than 6D in PYNATIVE or KBK mode.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input = Tensor([[-1., 1., 2.], [-3., -3., 1.]], mindspore.float32)
>>> weight = Tensor([[-2., -2., -2.], [0., -1., 0.]], mindspore.float32)
>>> bias = Tensor([0., 1.], mindspore.float32)
>>> output = mint.nn.functional.linear(input, weight, bias)
>>> print(output)
[[-4.  0.]
 [10.  4.]]
```

4.5.6 Dropout functions

API Name	Description	Supported Platforms
mindspore.mint.nn.functional.dropout	During training, randomly zeroes some of the elements of the input tensor with probability *p* from a Bernoulli distribution.	Ascend
mindspore.mint.nn.functional.dropout2d	During training, randomly zeroes some channels of the input tensor with probability *p* from a Bernoulli distribution (For a 4-dimensional tensor with a shape of (N, C, H, W), the channel feature map refers to a 2-dimensional feature map with the shape of (H, W)).	Ascend

mindspore.mint.nn.functional.dropout

mindspore.mint.nn.functional.**dropout**(*input*, *p=0.5*, *training=True*, *inplace=False*)

During training, randomly zeroes some of the elements of the input tensor with probability *p* from a Bernoulli distribution. It plays the role of reducing neuron correlation and avoid overfitting. And the return will be multiplied by $\frac{1}{1-p}$ during training. During the reasoning, this operation returns the same Tensor as the *input*.

Parameters

- **input** (Tensor) –The input Tensor of shape $(*, N)$.
- **p** (*float, optional*) –The dropping rate of input neurons, between 0 and 1, e.g. $p = 0.1$, means dropping out 10% of input neurons. Default: `0.5` .
- **training** (*bool, optional*) –Apply dropout if it is `True` , if it is `False` , the input is returned directly, and *p* is invalid. Default: `True` .
- **inplace** (*bool, optional*) –If set to `True` , will do this operation in-place. Default: `False` .

Returns

- **output** (Tensor) - Zeroed tensor, with the same shape and data type as *input*.

Raises

- **TypeError** –If *p* is not a float.
- **TypeError** –If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input = Tensor(((20, 16), (50, 50)), mindspore.float32)
>>> output = mint.nn.functional.dropout(input, p=0.5)
>>> print(output.shape)
(2, 2)
```

mindspore.mint.nn.functional.dropout2d

mindspore.mint.nn.functional.**dropout2d**(*input*, *p=0.5*, *training=True*)

During training, randomly zeroes some channels of the input tensor with probability *p* from a Bernoulli distribution (For a 4-dimensional tensor with a shape of (N, C, H, W), the channel feature map refers to a 2-dimensional feature map with the shape of (H, W)).

For example, the *j_th* channel of the *i_th* sample in the batched input is a to-be-processed *2D* tensor input[i,j]. Each channel will be zeroed out independently on every forward call which based on Bernoulli distribution probability *p*. The parper Dropout: A Simple Way to Prevent Neural Networks from Overfitting mentioned this technology, and it is proved that it can effectively reduce over fitting and prevent neuronal coadaptation. For more details, refer to Improving neural networks by preventing co-adaptation of feature detectors .

dropout2d can improve the independence between channel feature maps.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –A *4D* tensor with shape (N, C, H, W), where N is the batch size, C is the number of channels, H is the feature height, and W is the feature width.
- **p** (*float, optional*) –The dropping probability of a channel, between 0 and 1, e.g. $p = 0.8$, which means dropping out 80% of channels. Default: 0.5 .
- **training** (*bool, optional*) –If *training* is True, applying dropout, otherwise, not applying. Default: True .

Returns

Tensor, output, with the same shape and data type as *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If the data type of *p* is not float.
- **ValueError** –If *p* is out of the range *[0.0, 1.0]*.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.ones([2, 1, 2, 3]), mindspore.float32)
>>> output = mint.nn.functional.dropout2d(input, 0.5)
>>> print(output.shape)
(2, 1, 2, 3)
```

4.5.7 Sparse functions

API Name	Description	Supported Platforms
mindspore.mint.nn.functional.embedding	Retrieve the word embeddings in *weight* using indices specified in *input*.	Ascend
mindspore.mint.nn.functional.one_hot	Computes a one-hot tensor.	Ascend

mindspore.mint.nn.functional.embedding

mindspore.mint.nn.functional.**embedding**(*input*, *weight*, *padding_idx=None*, *max_norm=None*, *norm_type=2.0*, *scale_grad_by_freq=False*)

Retrieve the word embeddings in *weight* using indices specified in *input*.

> **Warning:** On Ascend, the behavior is unpredictable when the value of input is invalid.

Parameters

- **input** (*Tensor*) – The indices used to lookup in the *weight*. The data type must be mindspore.int32 or mindspore.int64, and the value should be in range *[0, weight.shape[0])*.
- **weight** (*Union[Parameter, Tensor]*) – The matrix where to lookup from. The shape must be 2D.
- **padding_idx** (*int, optional*) – If the value is not None, the corresponding row of *weight* will not be updated in training. The value should be in range *[-weight.shape[0], weight.shape[0])* if it's not None. Default None.
- **max_norm** (*float, optional*) – If not None, firstly get the p-norm result of the *weight* specified by *input* where p is specified by *norm_type*; if the result is larger then *max_norm*, update the *weight* with $\frac{max\_norm}{result+1e^{-7}}$ in-place. Default None.
- **norm_type** (*float, optional*) – Indicates the value of p in p-norm. Default 2.0.
- **scale_grad_by_freq** (*bool, optional*) – If True the gradients will be scaled by the inverse of frequency of the index in *input*. Default False.

Returns

Tensor, has the same data type as *weight*, the shape is $(*input.shape, weight.shape[1])$.

Raises

- **ValueError** – If *padding_idx* is out of valid range.
- **ValueError** – If the shape of *weight* is invalid.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, Parameter, mint
>>> input = Tensor([[1, 0, 1, 1], [0, 0, 1, 0]])
>>> weight = Parameter(np.random.randn(3, 3).astype(np.float32))
>>> output = mint.nn.functional.embedding(input, weight, max_norm=0.4)
>>> print(output)
[[[ 5.49015924e-02,  3.47811311e-01, -1.89771220e-01],
  [ 2.09307984e-01, -2.24846993e-02,  3.40124398e-01],
  [ 5.49015924e-02,  3.47811311e-01, -1.89771220e-01],
  [ 5.49015924e-02,  3.47811311e-01, -1.89771220e-01]],
 [[ 2.09307984e-01, -2.24846993e-02,  3.40124398e-01],
  [ 2.09307984e-01, -2.24846993e-02,  3.40124398e-01],
  [ 5.49015924e-02,  3.47811311e-01, -1.89771220e-01],
  [ 2.09307984e-01, -2.24846993e-02,  3.40124398e-01]]]
```

mindspore.mint.nn.functional.one_hot

mindspore.mint.nn.functional.**one_hot**(*tensor*, *num_classes=- 1*)

Computes a one-hot tensor.

The locations represented by tensor in *tensor* take value *1*, while all other locations take value *0*.

Parameters

- **tensor** (Tensor) – A tensor of indices. Tensor of shape $(X_0, \ldots, X_n)$. Data type must be int32 or int64. Dimension cannot be greater than 7.
- **num_classes** (*int, optional*) – A scalar defining the depth of the one-hot dimension, default: -1.

Returns

Tensor, one-hot tensor.

Raises

- **TypeError** – If *num_classes* is not an int.
- **TypeError** – If dtype of *tensor* is not int32 or int64.
- **ValueError** – If *num_classes* is less than -1.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> tensor = Tensor(np.array([0, 1, 2]), mindspore.int32)
>>> num_classes = 3
>>> output = mint.nn.functional.one_hot(tensor, num_classes)
>>> print(output)
[[1 0 0]
 [0 1 0]
 [0 0 1]]
```

4.5.8 Loss Functions

API Name	Description	Supported Platforms
mindspore.mint.nn.functional.cross_entropy	The cross entropy loss between input and target.	Ascend
mindspore.mint.nn.functional.binary_cross_entropy	Computes the binary cross entropy(Measure the difference information between two probability distributions) between predictive value *input* and target value *target*.	Ascend
mindspore.mint.nn.functional.binary _cross_entropy_with_logits	Adds sigmoid activation function to *input* as logits, and uses this logits to compute binary cross entropy between the logits and the target.	Ascend
mindspore.mint.nn.functional.kl_div	Computes the Kullback-Leibler divergence between the *input* and the *target*.	Ascend
mindspore.mint.nn.functional.l1_loss	Calculate the mean absolute error between the *input* value and the *target* value.	Ascend
mindspore.mint.nn.functional.mse_loss	Calculates the mean squared error between the predicted value and the label value.	Ascend
mindspore.mint.nn.functional.nll_loss	Gets the negative log likelihood loss between input and target.	Ascend
mindspore.mint.nn.functional.smooth_l1_loss	Computes smooth L1 loss, a robust L1 loss.	Ascend

mindspore.mint.nn.functional.cross_entropy

mindspore.mint.nn.functional.**cross_entropy**(*input*, *target*, *weight=None*, *ignore_index=- 100*, *reduction='mean'*, *label_smoothing=0.0*)

The cross entropy loss between input and target.

The cross entropy supports two kind of targets:

- Class indices (int) in the range $[0, C)$ where C is the number of classes, the loss with reduction=none can be described as:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -w_{y_n} \log \frac{\exp(x_{n,y_n})}{\sum_{c=1}^{C} \exp(x_{n,c})} \cdot \mathbb{1}\{y_n \neq \text{ignore\_index}\}$$

where x is the inputs, y is the target, w is the weight, N is the batch size, c belonging to $[0, C-1]$ is class index, where C is the number of classes.

If *reduction* is not `None` (default `'mean'`), then

$$\ell(x, y) = \begin{cases} \sum_{n=1}^{N} \frac{1}{\sum_{n=1}^{N} w_{y_n} \cdot \mathbb{1}\{y_n \neq \text{ignore\_index}\}} l_n, & \text{if reduction = 'mean',} \\ \sum_{n=1}^{N} l_n, & \text{if reduction = 'sum'.} \end{cases}$$

- Probabilities (float) for each class, useful when labels beyond a single class per minibatch item are required, the loss with reduction=none can be described as:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -\sum_{c=1}^{C} w_c \log \frac{\exp(x_{n,c})}{\sum_{i=1}^{C} \exp(x_{n,i})} y_{n,c}$$

where x is the inputs, y is the target, w is the weight, N is the batch size, c belonging to $[0, C-1]$ is class index, where C is the number of classes.

If *reduction* is not `None` (default `'mean'`), then

$$\ell(x, y) = \begin{cases} \frac{\sum_{n=1}^{N} l_n}{N}, & \text{if reduction = 'mean',} \\ \sum_{n=1}^{N} l_n, & \text{if reduction = 'sum'.} \end{cases}$$

Warning: This is an experimental API that is subject to change or deletion.

Note: Dynamic shape, dynamic rank and variable constant input are not supported in strict graph mode (jit_syntax_level=mindspore.STRICT).

Parameters

- **input** (Tensor) –(N) or (N, C) where C = *number of classes* or (N, C, H, W) in case of 2D Loss, or $(N, C, d_1, d_2, ..., d_K)$. *input* is expected to be log-probabilities, data type must be float16 or float32 or bfloat16 (only supported by Atlas A2 training series products).
- **target** (Tensor) –For class indices, tensor of shape (), (N) or $(N, d_1, d_2, ..., d_K)$, data type must be int32 or int64. For probabilities, tensor of shape $(N,)$, (N, C) or $(N, C, d_1, d_2, ..., d_K)$, data type must be float16 or float32 or bfloat16(only supported by Atlas A2 training series products).
- **weight** (Tensor, *optional*) –A rescaling weight applied to the loss of each batch element. If not None, the shape is $(C,)$, data type must be float16 or float32 or bfloat16(only supported by Atlas A2 training series products). Default: `None` .
- **ignore_index** (*int*, *optional*) –Specifies a target value that is ignored and does not contribute to the input gradient. Only valid in class indices, please set it to a negative number in probabilities. Default: `-100` .
- **reduction** (*str*, *optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **label_smoothing** (*float*, *optional*) –Label smoothing values, a regularization tool used to prevent the model from overfitting when calculating Loss. The value range is [0.0, 1.0]. Default: `0.0` .

Returns

Tensor, the data type is the same as *input* .

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint, Tensor
>>> import numpy as np
>>> # Case 1: Indices labels
>>> inputs = Tensor(np.random.randn(3, 5), ms.float32)
>>> target = Tensor(np.array([1, 0, 4]), ms.int32)
>>> output = mint.nn.functional.cross_entropy(inputs, target)
>>> # Case 2: Probability labels
>>> inputs = Tensor(np.random.randn(3, 5), ms.float32)
>>> target = Tensor(np.random.randn(3, 5), ms.float32)
>>> output = mint.nn.functional.cross_entropy(inputs, target)
```

mindspore.mint.nn.functional.binary_cross_entropy

`mindspore.mint.nn.functional.`**`binary_cross_entropy`**(*input*, *target*, *weight=None*, *reduction='mean'*)

Computes the binary cross entropy(Measure the difference information between two probability distributions) between predictive value *input* and target value *target*.

Set *input* as x, *target* as y, output as $\ell(x, y)$, the weight of nth batch of binary cross entropy is w_n. Let,

$$L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -w_n \left[y_n \cdot \log x_n + (1 - y_n) \cdot \log(1 - x_n) \right]$$

In which, L indicates the loss of all *batch_size*, l indicates the loss of one *batch_size*, and n indicates one *batch_size* in the $1 - N$ range. Then,

$$\ell(x, y) = \begin{cases} L, & \text{if reduction = 'none';} \\ \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Warning:

- The value of *input* must range from *0* to *1*.

Parameters

- **`input`** (`Tensor`) −The predictive value whose data type must be float16 or float32.
- **`target`** (`Tensor`) −The target value which has the same shape and data type as *input*. And the data type is float16 or float32.
- **`weight`** (`Tensor, optional`) −A rescaling weight applied to the loss of each batch element. Its shape must be able to broadcast to that of *input* and *target*. And it must have the same shape and data type as *input*. Default: `None` . If set to `None` , the loss function will not consider any sample weights, and each sample will be treated as having equal importance when calculating the loss.

- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Returns

Tensor or Scalar. Returns Tensor that has the same dtype and shape as *input* if *reduction* is `'none'`. Otherwise, returns a scalar Tensor.

Raises

- **TypeError** –If *input*, *target* or *weight* is not a Tensor.
- **TypeError** –If dtype of *input*, *target* or *weight* (if given) is neither float16 nor float32.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'` or `'sum'`.
- **ValueError** –If shape of *target* is not the same as *input* or *weight* (if given).

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([0.2, 0.7, 0.1]), mindspore.float32)
>>> target = Tensor(np.array([0., 1., 0.]), mindspore.float32)
>>> weight = Tensor(np.array([1, 2, 2]), mindspore.float32)
>>> output = mint.nn.functional.binary_cross_entropy(input, target, weight)
>>> print(output)
0.38240486
```

mindspore.mint.nn.functional.binary_cross_entropy_with_logits

mindspore.mint.nn.functional.**binary_cross_entropy_with_logits**(*input*, *target*, *weight=None*, *reduction='mean'*, *pos_weight=None*)

Adds sigmoid activation function to *input* as logits, and uses this logits to compute binary cross entropy between the logits and the target. Consistent with the function of *mindspore.ops.binary _cross_entropy_with_logits()* .

Sets input *input* as X, input *target* as Y, input *weight* as W, output as L. Then,

$$
\begin{aligned}
p_{ij} &= sigmoid(X_{ij}) = \frac{1}{1+e^{-X_{ij}}} \\
L_{ij} &= -[Y_{ij}log(p_{ij}) + (1 - Y_{ij})log(1 - p_{ij})]
\end{aligned}
$$

i indicates the i^{th} sample, j indicates the category. Then,

$$
\ell(x, y) = \begin{cases} L, & \text{if reduction = 'none';} \\ \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}
$$

ℓ indicates the method of calculating the loss. There are three methods: the first method is to provide the loss value directly, the second method is to calculate the average value of all losses, and the third method is to calculate the sum of all losses.

This operator will multiply the output by the corresponding weight. The tensor $weight$ assigns different weights to each piece of data in the batch, and the tensor pos_weight adds corresponding weights to the positive examples of each category.

In addition, it can trade off recall and precision by adding weights to positive examples. In the case of multi-label classification the loss can be described as:

$$p_{ij,c} = sigmoid(X_{ij,c}) = \frac{1}{1+e^{-X_{ij,c}}}$$
$$L_{ij,c} = -[P_c Y_{ij,c} * log(p_{ij,c}) + (1 - Y_{ij,c}) log(1 - p_{ij,c})]$$

where c is the class number (c>1 for multi-label binary classification, c=1 for single-label binary classification), n is the number of the sample in the batch and P_c is the weight of the positive answer for the class c. $P_c > 1$ increases the recall, $P_c < 1$ increases the precision.

Parameters

- **input** (Tensor) −Input *input* with shape $(N, *)$ where $*$ means, any number of additional dimensions. The data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported).
- **target** (Tensor) −Ground truth label, has the same shape as *input*. The data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported).
- **weight** (Tensor, *optional*) −A rescaling weight applied to the loss of each batch element. It can be broadcast to a tensor with shape of *input*. Data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported). Default: `None`, *weight* is a Tensor whose value is `1`.
- **reduction** (*str, optional*) −Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **pos_weight** (Tensor, *optional*) −A weight of positive examples. Must be a vector with length equal to the number of classes. It can be broadcast to a tensor with shape of *input*. Data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported). Default: `None`, it equals to *pos_weight* is a Tensor whose value is `1`.

Returns

Tensor or Scalar, if *reduction* is `'none'`, it's a tensor with the same shape and type as input *input*. Otherwise, the output is a Scalar.

Raises

- **TypeError** −If input *input*, *target*, *weight*, *pos_weight* is not Tensor.
- **TypeError** −If data type of input *reduction* is not string.
- **ValueError** −If *weight* or *pos_weight* can not be broadcast to a tensor with shape of *input*.
- **ValueError** −If *reduction* is not one of `'none'`, `'mean'` or `'sum'`.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([[-0.8, 1.2, 0.7], [-0.1, -0.4, 0.7]]), mindspore.float32)
>>> target = Tensor(np.array([[0.3, 0.8, 1.2], [-0.6, 0.1, 2.2]]), mindspore.float32)
>>> weight = Tensor(np.array([1.0, 1.0, 1.0]), mindspore.float32)
>>> pos_weight = Tensor(np.array([1.0, 1.0, 1.0]), mindspore.float32)
>>> output = mint.nn.functional.binary_cross_entropy_with_logits(input, target, weight, 'mean
↪', pos_weight)
>>> print(output)
0.3463612
```

mindspore.mint.nn.functional.kl_div

mindspore.mint.nn.functional.**kl_div**(*input*, *target*, *reduction='mean'*, *log_target=False*)

Computes the Kullback-Leibler divergence between the *input* and the *target*.

For tensors of the same shape x and y, the updating formulas of KLDivLoss algorithm are as follows,

$$L(x, y) = y \cdot (\log y - x)$$

Then,

$$\ell(x, y) = \begin{cases} L(x, y), & \text{if reduction = 'none';} \\ \text{mean}(L(x, y)), & \text{if reduction = 'mean';} \\ \text{sum}(L(x, y))/x.\text{shape}[0], & \text{if reduction = 'batchmean';} \\ \text{sum}(L(x, y)), & \text{if reduction = 'sum'.} \end{cases}$$

where x represents *input*, y represents *target*, and $\ell(x, y)$ represents the output.

Note: The output aligns with the mathematical definition of Kullback-Leibler divergence only when *reduction* is set to `'batchmean'`.

Parameters

- **input** (Tensor) –The input Tensor. The data type must be float16, float32 or bfloat16(only supported by Atlas A2 training series products).
- **target** (Tensor) –The target Tensor which has the same type as *input*. The shapes of *target* and *input* should be broadcastable.
- **reduction** (*str, optional*) –Specifies the reduction to be applied to the output. Default: `'mean'`.
- **log_target** (*bool, optional*) –Specifies whether *target* is passed in the log space. Default: `False`.

Returns

Tensor, has the same dtype as *input*. If *reduction* is `'none'`, then output has the shape as broadcast result of the *input* and *target*. Otherwise, it is a scalar Tensor.

Raises

- **TypeError** –If neither *input* nor *target* is a Tensor.
- **TypeError** –If dtype of *input* or *target* is not float16, float32 or bfloat16.

- **TypeError** –If dtype of *target* is not the same as *input*.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`, `'batchmean'`.
- **ValueError** –If shapes of *target* and *input* can not be broadcastable.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint
>>> import numpy as np
>>> input = ms.Tensor(np.array([[0.5, 0.5], [0.4, 0.6]]), ms.float32)
>>> target = ms.Tensor(np.array([[0., 1.], [1., 0.]]), ms.float32)
>>> output = mint.nn.functional.kl_div(input, target, reduction='mean', log_target=False)
>>> print(output)
-0.225
```

mindspore.mint.nn.functional.l1_loss

`mindspore.mint.nn.functional.l1_loss`(*input*, *target*, *reduction='mean'*)

Calculate the mean absolute error between the *input* value and the *target* value.

Assuming that the x and y are the predicted value and target value, both are one-dimensional tensors of length N, length N, *reduction* is set to `'none'` , then calculate the loss of x and y without dimensionality reduction.

The formula is as follows:

$$\ell(x, y) = L = \{l_1, \ldots, l_N\}^\top, \quad \text{with } l_n = |x_n - y_n|,$$

where N is the batch size.

If *reduction* is `'mean'` or `'sum'` , then:

$$\ell(x, y) = \begin{cases} \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Parameters

- **input** (Tensor) –Predicted value, Tensor of any dimension.
- **target** (Tensor) –Target value, usually has the same shape as the *input*. If *input* and *target* have different shapes, make sure they can broadcast to each other.
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output. Notice: At least one of the input and target is float type when the reduction is `'mean'` .
  - `'sum'`: the output elements will be summed.

Returns

Tensor or Scalar, if *reduction* is `'none'` , return a Tensor with same shape and dtype as *input*. Otherwise, a scalar value will be returned.

Raises

- **TypeError** –If *input* is not a Tensor.
- **TypeError** –If *target* is not a Tensor.
- **ValueError** –If *reduction* is not one of `'none'` , `'mean'` or `'sum'` .

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore import Tensor, mint
>>> from mindspore import dtype as mstype
>>> x = Tensor([[1, 2, 3], [4, 5, 6]], mstype.float32)
>>> target = Tensor([[6, 5, 4], [3, 2, 1]], mstype.float32)
>>> output = mint.nn.functional.l1_loss(x, target, reduction="mean")
>>> print(output)
3.0
```

mindspore.mint.nn.functional.mse_loss

mindspore.mint.nn.functional.**mse_loss**(*input*, *target*, *reduction='mean'*)

Calculates the mean squared error between the predicted value and the label value.

For detailed information, please refer to *mindspore.nn.MSELoss*.

Parameters

- **input** (Tensor) –Tensor of any dimension. The data type needs to be consistent with the *target*. It should also be broadcastable with the *target*.
- **target** (Tensor) –The input label. Tensor of any dimension. The data type needs to be consistent with the *input*. It should also be broadcastable with the *input*.
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'mean'` , `'none'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Returns

- Tensor. If *reduction* is `'mean'` or `'sum'`, the shape of output is *Tensor Scalar*.
- If reduction is `'none'`, the shape of output is the broadcasted shape of **input** and **target** .

Raises

- **ValueError** –If *reduction* is not one of `'mean'` , `'sum'` or `'none'`.
- **ValueError** –If *input* and *target* are not broadcastable.
- **TypeError** –If *input* and *target* are in different data type.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([[1, 1, 1], [1, 2, 2]]), mindspore.float32)
>>> output = mint.nn.functional.mse_loss(logits, labels, reduction='none')
>>> print(output)
[[0. 1. 4.]
 [0. 0. 1.]]
```

mindspore.mint.nn.functional.nll_loss

`mindspore.mint.nn.functional.`**`nll_loss`**(*input*, *target*, *weight=None*, *ignore_index=- 100*, *reduction='mean'*)

Gets the negative log likelihood loss between input and target.

The nll loss with reduction=none can be described as:

$$\ell(x,t) = L = \{l_1,\dots,l_N\}^\top, \quad l_n = -w_{t_n} x_{n,t_n}, \quad w_c = \text{weight}\,[c] \cdot \mathbb{1}\{c \neq \text{ignore\_index}\},$$

where x is the input, t is the target, w is the weight, N is the batch size, c belonging to $[0, C-1]$ is class index, where C is the number of classes.

If *reduction* is not `'None'` (default `'mean'`), then

$$\ell(x,t) = \begin{cases} \sum_{n=1}^{N} \frac{1}{\sum_{n=1}^{N} w_{tn}} l_n, & \text{if reduction} = \text{'mean'}, \\ \sum_{n=1}^{N} l_n, & \text{if reduction} = \text{'sum'} \end{cases}$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **`input`** (`Tensor`) – (N) or (N, C) where C = *number of classes* , N = *batch size* , or $(N, C, d_1, d_2, ..., d_K)$ (for high-dimensional data). *input* is expected to be log-probabilities. Data type only supports float32 or float16 or bfloat16(only supported by Atlas A2 training series products).
- **`target`** (`Tensor`) – $()$ or (N) , where the value range is $[0, C-1]$, or $(N, d_1, d_2, ..., d_K)$ for high-dimensional loss, data type must be int32 or int64 or uint8.
- **`weight`** (`Tensor, optional`) – A rescaling weight applied to the loss of each batch element. If not None, the shape is $(C,)$. The data type must be float16 or float32 or bfloat16(only supported by Atlas A2 training series products). It should have the same data type as *input* . Default: `'None'` .
- **`ignore_index`** (`int, optional`) – Specifies a target value that is ignored and does not contribute to the input gradient. Default: `-100` .
- **`reduction`** (`str, optional`) – Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.

- `'mean'`: compute and return the weighted mean of elements in the output.
- `'sum'`: the output elements will be summed.

Returns

Tensor. The data type is the same as that of *input*.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = mindspore.Tensor(np.random.randn(3, 5), mindspore.float32)
>>> target = mindspore.Tensor(np.array([1, 0, 4]), mindspore.int32)
>>> output = mint.nn.functional.nll_loss(input, target)
```

mindspore.mint.nn.functional.smooth_l1_loss

`mindspore.mint.nn.functional.`**`smooth_l1_loss`**(*input*, *target*, *reduction='mean'*, *beta=1.0*)

Computes smooth L1 loss, a robust L1 loss.

SmoothL1Loss is a Loss similar to MSELoss but less sensitive to outliers as described in the Fast R-CNN by Ross Girshick.

Given two inputs x, y of length N, the SmoothL1Loss can be described as follows:

$$L_i = \begin{cases} \frac{0.5(x_i - y_i)^2}{\text{beta}}, & \text{if } |x_i - y_i| < \text{beta} \\ |x_i - y_i| - 0.5 * \text{beta}, & \text{otherwise.} \end{cases}$$

If *reduction* is not *none*, then:

$$L = \begin{cases} \text{mean}(L_i), & \text{if reduction = 'mean';} \\ \text{sum}(L_i), & \text{if reduction = 'sum'.} \end{cases}$$

Here beta controls the point where the loss function changes from quadratic to linear. beta ≥ 0 , its default value is `1.0` . N is the batch size.

Warning: This is an experimental optimizer API that is subject to change.

Note:

- Arg *input* and *target* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower precision data type will be converted to relatively the highest precision data type.

Parameters

- **`input`** (`Tensor`) –Tensor of shape $(N, *)$ where $*$ means, any number of additional dimensions. Supported dtypes:
  - Ascend: float16, float32, bfloat16.

- **target** (Tensor) –Ground truth data, tensor of shape $(N, *)$, same shape as the *input*. Supported dtypes:
  - Ascend: float16, float32, bfloat16.
- **reduction** (*str, optional*) –Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute the mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **beta** (*number, optional*) –A parameter used to control the point where the function will change between L1 to L2 loss. The value should be greater than or equal to zero. Default: `1.0` .

Returns

Tensor, the data type is the same as *input*. If *reduction* is `'none'`, then output is a tensor with the same shape as *input*. Otherwise, the shape of output tensor is ().

Raises

- **TypeError** –If *input* or *target* is not a Tensor.
- **RuntimeError** –If dtype of *input* or *target* is not one of float16, float32, bfloat16.
- **ValueError** –If shape of *input* is not the same as *target*.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.
- **TypeError** –If *beta* is not a float, int or bool.
- **RuntimeError** –If *beta* is less than 0.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([2, 2, 3]), mindspore.float32)
>>> target = Tensor(np.array([2, 2, 2]), mindspore.float32)
>>> beta = 1.0
>>> reduction_1 = 'none'
>>> output = mint.nn.functional.smooth_l1_loss(input, target, reduction_1, beta)
>>> print(output)
[0.  0.  0.5]
>>> reduction_2 = 'mean'
>>> output = mint.nn.functional.smooth_l1_loss(input, target, reduction_2, beta)
>>> print(output)
0.16666667
>>> reduction_3 = 'sum'
>>> output = mint.nn.functional.smooth_l1_loss(input, target, reduction_3, beta)
>>> print(output)
0.5
```

4.5.9 Vision functions

API Name	Description	Supported Platforms
mindspore.mint.nn.functional.interpolate	Samples the input Tensor to the given size or scale_factor by using one of the interpolate algorithms.	Ascend
mindspore.mint.nn.functional.grid_sample	Given an *input* and a flow-field *grid*, computes the *output* using *input* values and pixel locations from *grid*.	Ascend
mindspore.mint.nn.functional.pad	Pads the input tensor according to the pad.	Ascend
mindspore.mint.nn.functional.pixel_shuffle	Rearrange elements in a tensor according to an upscaling factor.	Ascend

mindspore.mint.nn.functional.interpolate

mindspore.mint.nn.functional.**interpolate**(*input*, *size=None*, *scale_factor=None*, *mode='nearest'*, *align_corners=None*, *recompute_scale_factor=None*)

Samples the input Tensor to the given size or scale_factor by using one of the interpolate algorithms.

Warning: This is an experimental API that is subject to change or deletion.

Note:

- In 'linear' mode, the scenarios, where *scale_factor* is not None and *align_corners* is False, is not supported.
- In 'nearest' mode, there may exist precision problem in the scenarios, where input is 3-D/4-D Tensor and the image is scaled by scale_factor.
- *mode* and *recompute_scale_factor* should be constants.

Parameters

- **input** (Tensor) −Tensor to be resized. Input tensor must be a 3-D, 4-D, or 5-D tensor with shape $(N, C, [optionalD], [optionalH], W)$, with data type of float.
- **size** (*Union[int, tuple[int], list[int]], optional*) −The target size. If size is a tuple or list, its length should be the same as the number of dimensions in input after removing the first two dimensions N, C. One and only one of size and scale_factor can be set to None. Default: None .
- **scale_factor** (*Union[float, tuple[float], list[float]], optional*) −The scale factor of new size of the tensor. If scale_factor is a tuple or list, its length should be the same as the number of dimensions in input after removing the first two dimensions N, C. One and only one of size and scale_factor can be set to None. Default: None .
- **mode** (*str*) −The sampling algorithm. One of 'nearest', 'linear' (3D only), 'bilinear' (4D only), 'trilinear' (5D only), and 'bicubic' (4D only). Default: "nearest" .
- **align_corners** (*bool, optional*) −Whether to use corner alignment for coordinate mapping. Assuming a transformation is applied to the input Tensor along the x-axis, the specific calculation formula is as follows:

```
ori_i = new_length != 1 ? new_i * (ori_length - 1) / (new_length - 1) : 0   # 'align_
↪corners' = True

ori_i = new_length > 1 ? (new_i + 0.5) * ori_length / new_length - 0.5 : 0  # 'align_
↪corners' = False
```

Among them, *ori_length* and *new_length* represent the length of the Tensor before and after transformation along the x-axis respectively; *new_i* represents the coordinate of the i-th element along the x-axis after transformation; *ori_i* represents the corresponding coordinate of the original data along the x-axis.

This is only valid for `'linear'`, `'bilinear'`, or `'bicubic'` modes. Default: `None` .

- **recompute_scale_factor** (*bool, optional*) – Recalculate *scale_factor*. If True, the parameter *size* will be calculated using the value of the *scale_factor*, and finally scaled using the value of *size*. If False, the value of *size* or *scale_factor* will be used for direct interpolation. Default: `None` .

Args Support List and Supported Platforms:

mode	input.dim	align_corners	scale_factor	device
nearest	3	-	√	Ascend
	4	-	√	Ascend
	5	-	√	Ascend
linear	3	√	√	Ascend
bilinear	4	√	×	Ascend
bicubic	4	√	×	Ascend
trilinear	5	√	√	Ascend

- - indicates that there is no such parameter.
- × indicates that this parameter is not currently supported.
- √ indicates that this parameter is supported.

Returns

Tensor, sampled, whose dimensions and dtype are the same as *input*.

Raises

- **TypeError** – *input* is not a Tensor.
- **ValueError** – Both *size* and *scale_factor* are not empty.
- **ValueError** – Both *size* and *scale_factor* are empty.
- **ValueError** – When *size* is a tuple or list, its length is not equal to *input.ndim - 2*.
- **ValueError** – When *scale_factor* is a tuple or list, its length is not equal to *input.ndim - 2*.
- **ValueError** – *mode* is not in the list of supported modes.
- **ValueError** – *input.ndim* is not in the list of supported dimensions for the corresponding mode.
- **ValueError** – *size* is not empty, *recompute_scale_factor* is not empty.
- **ValueError** – *scale_factor* is not in the corresponding list of supported values.
- **ValueError** – *align_corners* is not in the corresponding list of supported values.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, mint
>>> input = Tensor([[[1, 2, 3], [4, 5, 6]]], mindspore.float32)
>>> output = mint.nn.functional.interpolate(input, size=(6,), mode='nearest')
>>> print(output)
[[[1. 1. 2. 2. 3. 3.]
  [4. 4. 5. 5. 6. 6.]]]
```

mindspore.mint.nn.functional.grid_sample

mindspore.mint.nn.functional.**grid_sample**(*input*, *grid*, *mode='bilinear'*, *padding_mode='zeros'*, *align_corners=False*)

Given an *input* and a flow-field *grid*, computes the *output* using *input* values and pixel locations from *grid*. Only spatial (4-D) and volumetric (5-D) *input* is supported.

In the spatial (4-D) case, for *input* with shape (N, C, H_{in}, W_{in}) and *grid* with shape $(N, H_{out}, W_{out}, 2)$, the *output* will have shape (N, C, H_{out}, W_{out}).

For each output location *output[n, :, h, w]*, the size-2 vector *grid[n, h, w]* specifies *input* pixel locations *x* and *y*, which are used to interpolate the output value *output[n, :, h, w]*. In the case of 5D inputs, *grid[n, d, h, w]*, specifies the *x*, *y*, *z* pixel locations for interpolating *output[n, :, d, h, w]*. And *mode* argument specifies "nearest" or "bilinear" ("bicubic" is not supported yet) interpolation method to sample the input pixels.

grid specifies the sampling pixel locations normalized by the *input* spatial dimensions. Therefore, it should have most values in the range of $[-1, 1]$.

If *grid* has values outside the range of $[-1, 1]$, the corresponding outputs are handled as defined by *padding_mode*. If *padding_mode* is set to be "zeros", use 0 for out-of-bound grid locations. If *padding_mode* is set to be "border", use border values for out-of-bound grid locations. If *padding_mode* is set to be "reflection", use values at locations reflected by the border for out-of-bound grid locations. For location far away from the border, it will keep being reflected until becoming in bound.

Parameters

- **input** (Tensor) –input with shape of (N, C, H_{in}, W_{in}) (4-D case) or $(N, C, D_{in}, H_{in}, W_{in})$ (5-D case) and dtype of float32 or float64.
- **grid** (Tensor) –flow-field with shape of $(N, H_{out}, W_{out}, 2)$ (4-D case) or $(N, D_{out}, H_{out}, W_{out}, 3)$ (5-D case) and same dtype as *input*.
- **mode** (*str, optional*) –An optional string specifying the interpolation method. The optional values are `'bilinear'`, `'nearest'`. Default: `'bilinear'` . Note: *bicubic* is not supported yet. When *mode="bilinear"* and the input is 5-D, the interpolation mode used internally will actually be trilinear. However, when the input is 4-D, the interpolation mode will legistimately be bilinear. Default: `'bilinear'` .
  - `'nearest'`: Nearest neighbor interpolation. Each output pixel is assigned the value of the nearest input pixel. This method is simple and fast but can result in blocky or pixelated outputs.
  - `'bilinear'`: Bilinear interpolation. Each output pixel is a weighted average of the four nearest input pixels, computed using bilinear interpolation. This method produces smoother results compared to nearest neighbor interpolation.
  - `'trilinear'`: Trilinear interpolation. This is an extension of bilinear interpolation to 3D data. It performs bilinear interpolation in the two spatial dimensions and linear interpolation along the third dimension. It is commonly used for volume or 3D image interpolation.

- **padding_mode** (*str, optional*) – An optional string specifying the pad method. The optional values are "zeros", "border" or "reflection". Default: `'zeros'` .
- **align_corners** (*bool, optional*) – If set to *True*, the extrema (-1 and 1) are considered as referring to the center points of the input's corner pixels. If set to *False*, they are instead considered as referring to the corner points of the input's corner pixels, making the sampling more resolution agnostic. Default: `False` .

Returns

Tensor, dtype is the same as *input* and whose shape is (N, C, H_{out}, W_{out}) (4-D) and $(N, C, D_{out}, H_{out}, W_{out})$ (5-D).

Raises

- **TypeError** – If *input* or *grid* is not a Tensor.
- **TypeError** – If the dtypes of *input* and *grid* are inconsistent.
- **TypeError** – If the dtype of *input* or *grid* is not a valid type.
- **TypeError** – If *align_corners* is not a boolean value.
- **ValueError** – If the rank of *input* or *grid* is not equal to 4(4-D case) or 5(5-D case).
- **ValueError** – If the first dimension of *input* is not equal to that of *grid*.
- **ValueError** – If the last dimension of *grid* is not equal to 2(4-D case) or 3(5-D case).
- **ValueError** – If *mode* is not "bilinear", "nearest" or a string value.
- **ValueError** – If *padding_mode* is not "zeros", "border", "reflection" or a string value.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input_x = Tensor(np.arange(16).reshape((2, 2, 2, 2)).astype(np.float32))
>>> grid = Tensor(np.arange(0.2, 1, 0.1).reshape((2, 2, 1, 2)).astype(np.float32))
>>> output = mint.nn.functional.grid_sample(input_x, grid, mode='bilinear', padding_mode=
↪'zeros',
...                                         align_corners=True)
>>> print(output)
[[[[ 1.9       ]
   [ 2.1999998]]
  [[ 5.9       ]
   [ 6.2       ]]]
 [[[10.5       ]
   [10.8       ]]
  [[14.5       ]
   [14.8       ]]]]
```

mindspore.mint.nn.functional.pad

mindspore.mint.nn.functional.**pad**(*input*, *pad*, *mode='constant'*, *value=None*)

Pads the input tensor according to the pad.

> **Warning:** *circular* mode has poor performance and is not recommended.

Parameters

- **input** (Tensor) –Tensor of shape $(N, *)$, where $*$ means, any number of additional dimensions.
- **pad** (*Union[tuple[int], list[int], Tensor]*) –Filling position of pad. $\left\lfloor \frac{\text{len(pad)}}{2} \right\rfloor$ dimensions of *input* will be padded.

  Example: to pad only the last dimension of the input tensor, then *pad* has the form (padding_left, padding_right);

  Example: to pad the last 2 dimensions of the input tensor, then use (padding_left, padding_right, padding_top, padding_bottom);

  Example: to pad the last 3 dimensions, use (padding_left, padding_right, padding_top, padding_bottom, padding_front, padding_ba
  and so on.
- **mode** (*str, optional*) –Pad filling mode, `'constant'`, `'reflect'`, `'replicate'` or `'circular'`. Default: `'constant'`.

  For `'constant'` mode, please refer to *mindspore.nn.ConstantPad1d* as an example to understand this filling pattern and extend the padding pattern to n dimensions.

  For `'reflect'` mode, please refer to *mindspore.nn.ReflectionPad1d* as an example to understand this filling pattern. The reflect mode is used to pad the last three dimensions of 4D or 5D input, the last two dimensions of 3D or 4D input, or the last dimension of 2D or 3D input.

  For `'replicate'` mode, please refer to *mindspore.nn.ReplicationPad1d* as an example to understand this filling pattern. The replicate mode is used to pad the last three dimensions of 4D or 5D input, the last two dimensions of 3D or 4D input, or the last dimension of 2D or 3D input.

  For `'circular'` mode, the pixels from one edge of the image are wrapped around to the opposite edge, such that the pixel on the right edge of the image is replaced with the pixel on the left edge, and the pixel on the bottom edge is replaced with the pixel on the top edge. The circular mode is used to pad the last three dimensions of 4D or 5D input, the last two dimensions of 3D or 4D input, or the last dimension of 2D or 3D input.
- **value** (*Union[int, float, None], optional*) –Valid only in `'constant'` mode. Set the padding value in `'constant'` mode. If the value is None, 0 is used as the default padding value. Default: `None`.

Returns

Tensor, the tensor after padding.

Raises

- **TypeError** –If *pad* is not an int of tuple or int of list.
- **TypeError** –If *input* is not a Tensor.
- **ValueError** –If length of *pad* is not even.
- **ValueError** –If length of *pad* is greater than 6.
- **ValueError** –If *mode* is not `'constant'` and *value* is neither `None` nor 0.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint
>>> import numpy as np
>>> x = ms.Tensor(np.arange(1 * 2 * 2 * 2).reshape((1, 2, 2, 2)), dtype=ms.float64)
>>> output = mint.nn.functional.pad(x, [1, 0, 0, 1], mode='constant', value=6.0)
>>> print(output)
[[[[6. 0. 1.]
   [6. 2. 3.]
   [6. 6. 6.]]
  [[6. 4. 5.]
   [6. 6. 7.]
   [6. 6. 6.]]]]
```

mindspore.mint.nn.functional.pixel_shuffle

mindspore.mint.nn.functional.**pixel_shuffle**(*input*, *upscale_factor*) → *Tensor*

Rearrange elements in a tensor according to an upscaling factor.

Rearranges elements in a tensor of shape $(*, C \times r^2, H, W)$ to a tensor of shape $(*, C, H \times r, W \times r)$, where r is an upscale factor.

This is useful for implementing efficient sub-pixel convolution with a stride of $1/r$.

For detailed introduction to the pixel_shuffle algorithm, refer to Real-Time Single Image and Video Super-Resolution Using an Efficient Sub-Pixel Convolutional Neural Network .

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **input** (Tensor) –Tensor of shape $(*, C \times r^2, H, W)$. The dimension of *input* is larger than 2, and the length of third to last dimension can be divisible by the square of *upscale_factor*.
- **upscale_factor** (*int*) –factor to shuffle the input Tensor, and is a positive integer. *upscale_factor* is the above-mentioned r.

Returns

- **output** (Tensor) - Tensor of shape $(*, C, H \times r, W \times r)$.

Raises

- **ValueError** –If *upscale_factor* is not a positive integer.
- **ValueError** –If the length of third to last dimension is not divisible by the square of *upscale_factor*.
- **ValueError** –If the dimension of *input* is less than 3.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import mint
>>> input = mint.randn(1, 9, 4, 4)
>>> output = mint.nn.functional.pixel_shuffle(input, 3)
>>> print(output.shape)
    (1, 1, 12, 12)
```

4.6 mindspore.mint.optim

API Name	Description	Supported Platforms
mindspore.mint.optim.Adam	Implements Adaptive Moment Estimation (Adam) algorithm.	Ascend
mindspore.mint.optim.AdamW	Implements Adam Weight Decay algorithm.	Ascend
mindspore.mint.optim.SGD	Stochastic Gradient Descent optimizer.	Ascend

4.6.1 mindspore.mint.optim.Adam

class mindspore.mint.optim.**Adam**(*params*, *lr=1e-3*, *betas=(0.9, 0.999)*, *eps=1e-8*, *weight_decay=0.0*, *amsgrad=False*, ***, *maximize=False*)

Implements Adaptive Moment Estimation (Adam) algorithm.

The updating formulas are as follows:

input : γ (lr), β_1, β_2 (betas), θ_0 (params), $f(\theta)$ (objective)
λ (weight decay), *amsgrad*, *maximize*
initialize : $m_0 \leftarrow 0$ (first moment), $v_0 \leftarrow 0$ (second moment), $\widehat{v_0}^{max} \leftarrow 0$
for $t = 1$ **to** ... **do**
  if *maximize* :
    $g_t \leftarrow -\nabla_\theta f_t(\theta_{t-1})$
  else
    $g_t \leftarrow \nabla_\theta f_t(\theta_{t-1})$
  if $\lambda \neq 0$
    $g_t \leftarrow g_t + \lambda\theta_{t-1}$
  $m_t \leftarrow \beta_1 m_{t-1} + (1-\beta_1) g_t$
  $v_t \leftarrow \beta_2 v_{t-1} + (1-\beta_2) g_t^2$
  $\widehat{m_t} \leftarrow m_t / \left(1-\beta_1^t\right)$
  $\widehat{v_t} \leftarrow v_t / \left(1-\beta_2^t\right)$
  if *amsgrad*
    $\widehat{v_t}^{max} \leftarrow \max(\widehat{v_t}^{max}, \widehat{v_t})$
    $\theta_t \leftarrow \theta_{t-1} - \gamma \widehat{m_t} / \left(\sqrt{\widehat{v_t}^{max}} + \epsilon\right)$
  else
    $\theta_t \leftarrow \theta_{t-1} - \gamma \widehat{m_t} / \left(\sqrt{\widehat{v_t}} + \epsilon\right)$
return θ_t

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) –list of parameters to optimize or dicts defining parameter groups
- **lr** (*Union[int, float, Tensor], optional*) –learning rate. Default: `1e-3`.
- **betas** (*Tuple[float, float], optional*) –The exponential decay rate for the moment estimations. Should be in range (0.0, 1.0). Default: `(0.9, 0.999)`.
- **eps** (*float, optional*) –term added to the denominator to improve numerical stability. Should be greater than 0. Default: `1e-8`.
- **weight_decay** (*float, optional*) –weight decay (L2 penalty). Default: `0.`.
- **amsgrad** (*bool, optional*) –whether to use the AMSGrad algorithm. Default: `False`.

Keyword Arguments

maximize (`bool, optional`) –maximize the params based on the objective, instead of minimizing. Default: `False`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** –If the *lr* is not int, float or Tensor.
- **ValueError** –If the *lr* is less than 0.
- **ValueError** –If the *eps* is less than 0.0.
- **ValueError** –If the *betas* is not in the range of [0, 1).
- **ValueError** –If the *weight_decay* is less than 0.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import mint
>>> from mindspore import mint
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = mint.optim.Adam(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

4.6.2 mindspore.mint.optim.AdamW

class mindspore.mint.optim.**AdamW**(*params*, *lr=1e-3*, *betas=(0.9, 0.999)*, *eps=1e-8*, *weight_decay=1e-2*, *amsgrad=False*, ***, *maximize=False*)

Implements Adam Weight Decay algorithm.

---

input : γ(lr), β_1, β_2(betas), θ_0(params), $f(\theta)$(objective), ϵ (epsilon)

λ(weight decay), *amsgrad*, *maximize*

initialize : $m_0 \leftarrow 0$ (first moment), $v_0 \leftarrow 0$ (second moment), $\widehat{v_0}^{max} \leftarrow 0$

---

for $t = 1$ **to** ... **do**

if *maximize* :

$g_t \leftarrow -\nabla_\theta f_t(\theta_{t-1})$

else

$g_t \leftarrow \nabla_\theta f_t(\theta_{t-1})$

$\theta_t \leftarrow \theta_{t-1} - \gamma\lambda\theta_{t-1}$

$m_t \leftarrow \beta_1 m_{t-1} + (1-\beta_1) g_t$

$v_t \leftarrow \beta_2 v_{t-1} + (1-\beta_2) g_t^2$

$\widehat{m_t} \leftarrow m_t / \left(1-\beta_1^t\right)$

$\widehat{v_t} \leftarrow v_t / \left(1-\beta_2^t\right)$

if $amsgrad$

$\widehat{v_t}^{max} \leftarrow \max(\widehat{v_t}^{max}, \widehat{v_t})$

$\theta_t \leftarrow \theta_t - \gamma\widehat{m_t} / \left(\sqrt{\widehat{v_t}^{max}} + \epsilon\right)$

else

$\theta_t \leftarrow \theta_t - \gamma\widehat{m_t} / \left(\sqrt{\widehat{v_t}} + \epsilon\right)$

---

return θ_t

Warning:

- This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .
- For Ascend, it is only supported on platforms above Atlas A2.

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) –list of parameters to optimize or dicts defining parameter groups.
- **lr** (*float, optional*) –learning rate. Default: `1e-3`.
- **betas** (*Tuple[float, float], optional*) –The exponential decay rate for the moment estimations. Default: `(0.9, 0.999)`.
- **eps** (*float, optional*) –term added to the denominator to improve numerical stability. Must be greater than 0. Default: `1e-8`.
- **weight_decay** (*float, optional*) –weight decay (L2 penalty). Default: `1e-2`..
- **amsgrad** (*bool, optional*) –whether to use the AMSGrad algorithm. Default: `False`.

Keyword Arguments

maximize (`bool, optional`) –maximize the params based on the objective, instead of minimizing. Default: `False`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** –If the learning rate is not float.
- **ValueError** –If the learning rate is less than 0.
- **ValueError** –If the *eps* is less than 0.
- **ValueError** –If the *betas* not in the range of [0, 1).
- **ValueError** –If the *weight_decay* is less than 0.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import mint
>>> from mindspore.mint import optim

...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

4.6.3 mindspore.mint.optim.SGD

class mindspore.mint.optim.**SGD**(*params*, *lr*, *momentum=0*, *dampening=0*, *weight_decay=0*, *nesterov=False*, ***, *maximize=False*)

Stochastic Gradient Descent optimizer.

$$v_{t+1} = u * v_t + gradient * (1 - dampening)$$

If nesterov is True:

$$p_{t+1} = p_t - lr * (gradient + u * v_{t+1})$$

If nesterov is False:

$$p_{t+1} = p_t - lr * v_{t+1}$$

To be noticed, for the first step, $v_{t+1} = gradient$.

Here : p, v and u denote the parameters, accum, and momentum respectively.

Warning: This is an experimental optimizer API, which may be modified or removed in the future. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) –list of parameters to optimize or dicts defining parameter groups.
- **lr** (*Union[bool, int, float, Tensor]*) –learning rate.
- **momentum** (*Union[bool, int, float], optional*) –momentum factor. Default: `0`.
- **weight_decay** (*Union[bool, int, float], optional*) –weight decay (L2 penalty). Must be greater than or equal to 0. Default: `0`..
- **dampening** (*Union[bool, int, float], optional*) –dampening for momentum. Default: `0`.
- **nesterov** (*bool, optional*) –enable Nesterov momentum. If Nesterov is utilized, the momentum must be positive, and the damping must be equal to 0. Default: `False`.

Keyword Arguments

maximize (*bool, optional*) –maximize the params based on the objective, instead of minimizing. Default: `False`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** – If the learning rate is not bool, int, float or Tensor.
- **ValueError** – If the learning rate is less than 0.
- **ValueError** – If the *momentum* or *weight_decay* value is less than 0.0.
- **ValueError** – If the *momentum*, *dampening* or *weight_decay* value is not bool, int or float.
- **ValueError** – If the *nesterov* and *maximize* are not bool.
- **ValueError** – If the *nesterov* is true, *momentum* is not positive or *dampening* is not 0.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> from mindspore import mint
>>> from mindspore.mint import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.SGD(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

4.7 mindspore.mint.linalg

4.7.1 Inverses

API Name	Description	Supported Platforms
mindspore.mint.linalg.inv	Compute the inverse of the input matrix.	`Ascend`
mindspore.mint.linalg.matrix_norm	Returns the matrix norm of a given tensor on the specified dimensions.	`Ascend`
mindspore.mint.linalg.norm	Returns the matrix norm or vector norm of a given tensor.	`Ascend`
mindspore.mint.linalg.vector_norm	Returns the vector norm of the given tensor on the specified dimensions.	`Ascend`
mindspore.mint.linalg.qr	Orthogonal decomposition of the input $A = QR$.	`Ascend`

mindspore.mint.linalg.inv

mindspore.mint.linalg.**inv**(*input*)

Compute the inverse of the input matrix.

Parameters

input (Tensor) – A matrix to be calculated. Input *input* must be at least two dimensions, and the size of the last two dimensions must be the same size. And the matrix must be invertible.

Returns

Tensor, has the same type and shape as input *input*.

Raises

- **ValueError** – If the size of the last two dimensions of *input* is not the same.
- **ValueError** – If *input* is not empty and its dimensions are less than 2.
- **ValueError** – If the dimensions of *input* are larger than 6.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import Tensor, mint
>>> from mindspore import dtype as mstype
>>> x = Tensor([[1., 2.], [3., 4.]], mstype.float32)
>>> print(mint.linalg.inv(x))
[[-2.   1. ]
 [ 1.5 -0.5]]
```

mindspore.mint.linalg.matrix_norm

mindspore.mint.linalg.**matrix_norm**(*A*, *ord='fro'*, *dim=(- 2, - 1)*, *keepdim=False*, ***, *dtype=None*)

Returns the matrix norm of a given tensor on the specified dimensions.

ord is the calculation mode of norm. The following norm modes are supported.

ord	norm for matrix
'fro' (Default)	Frobenius norm
'nuc'	nuclear norm
inf	$max(sum(abs(x), dim = 1))$
-inf	$min(sum(abs(x), dim = 1))$
1	$max(sum(abs(x), dim = 0))$
-1	$min(sum(abs(x), dim = 0))$
2	largest singular value
-2	smallest singular value

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **A** (Tensor) –Tensor of shape $(*, m, n)$ where * is zero or more batch dimensions.
- **ord** (*Union[int, inf, -inf, 'fro', 'nuc'], optional*) –norm's mode. refer to the table above for behavior. Default: `'fro'` .
- **dim** (*Tuple(int, int), optional*) –calculate the dimension of the matrix norm. Default: `(-2, -1)` .
- **keepdim** (*bool*) –whether the output Tensor retains the original dimension. Default: `False` .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –When set, *A* will be converted to the specified type, *dtype*, before execution, and dtype of returned Tensor will also be *dtype*. When *dtype* is `None` , the dtype of *A* is preserved. Default: `None` .

Returns

Tensor, the result of norm calculation on the specified dimension, *dim*.

Raises

- **TypeError** –If *dim* is not a tuple of int.
- **ValueError** –If the length of *dim* is not equal to 2.
- **ValueError** –If *ord* is not in [2, -2, 1, -1, float('inf'), float('-inf'), 'fro', 'nuc'].
- **ValueError** –If two elements of *dim* is same after normalize.
- **ValueError** –If any elements of *dim* is out of range.

Note: Dynamic shape, Dynamic rank and mutable input is not supported in graph mode (mode=mindspore.GRAPH_MODE).

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> A = ms.ops.arange(0, 12, dtype=ms.float32).reshape(3, 4)
>>> print(ms.mint.linalg.matrix_norm(A, ord='fro'))
22.494444
>>> print(ms.mint.linalg.matrix_norm(A, ord='nuc'))
24.364643
>>> print(ms.mint.linalg.matrix_norm(A, ord=float('inf')))
38.0
>>> print(ms.mint.linalg.matrix_norm(A, ord=float('-inf')))
6.0
```

mindspore.mint.linalg.norm

mindspore.mint.linalg.**norm**(*A*, *ord=None*, *dim=None*, *keepdim=False*, *, *dtype=None*)

Returns the matrix norm or vector norm of a given tensor.

ord is the calculation mode of norm. The following norm modes are supported.

ord	norm for matrices	norm for vectors
None (default)	Frobenius norm	*2*-norm (see below)
'fro'	Frobenius norm	–not supported –
'nuc'	nuclear norm	–not supported –
inf	$max(sum(abs(x), dim = 1))$	$max(abs(x))$
-inf	$min(sum(abs(x), dim = 1))$	$min(abs(x))$
0	–not supported –	$sum(x! = 0)$
1	$max(sum(abs(x), dim = 0))$	as below
-1	$min(sum(abs(x), dim = 0))$	as below
2	largest singular value	as below
-2	smallest singular value	as below
other *int* or *float*	–not supported –	$sum(abs(x)^{ord})^{(1/ord)}$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **A** (Tensor) –Tensor of shape $(*, n)$ or $(*, m, n)$ where * is zero or more batch dimensions.
- **ord** (*Union[int, float, inf, -inf, 'fro', 'nuc'], optional*) –norm's mode. Refer to the table above for behavior. Default: None .
- **dim** (*Union[int, Tuple(int)], optional*) –calculate the dimension of vector norm or matrix norm. Default: None .
  - When *dim* is int, it will be calculated by vector norm.
  - When *dim* is a 2-tuple, it will be calculated by matrix norm.
  - If *dim* is None and *ord* is None, *A* will be flattened to 1D and the 2-norm of the vector will be calculated.
  - If *dim* is None and *ord* is not None, *A* must be 1D or 2D.
- **keepdim** (*bool*) –whether the output Tensor retains the original dimension. Default: False .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –When set, *A* will be converted to the specified type, *dtype*, before execution, and dtype of returned Tensor will also be *dtype*. Default: None .

Returns

Tensor, the result of norm calculation on the specified dimension, *dim*, has the same dtype as *A*.

Raises

- **ValueError** –If *dim* is out of range.
- **TypeError** –If *dim* is neither an int nor a tuple of int.
- **TypeError** –If *A* is a vector and *ord* is a str.
- **ValueError** –If *A* is a matrices and *ord* is not in valid mode.

- **ValueError** –If two elements of *dim* is same after normalize.
- **ValueError** –If any elements of *dim* is out of range.

Note: Dynamic shape, Dynamic rank and mutable input is not supported in graph mode (mode=mindspore.GRAPH_MODE).

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore import mint, ops
>>> data_range = ops.arange(-13, 13, dtype=ms.float32)
>>> x = data_range[data_range != 0]
>>> print(mint.linalg.norm(x))
38.327538
>>> print(mint.linalg.norm(x, 1))
169.0
>>> n = ops.arange(27, dtype=ms.float32).reshape(3, 3, 3)
>>> print(mint.linalg.norm(n, dim=(1, 2)))
[14.282857 39.76179  66.45299 ]
>>> print(mint.linalg.norm(n[0, :, :]))
14.282857
>>> print(mint.linalg.norm(n[1, :, :]))
39.76179
```

mindspore.mint.linalg.vector_norm

mindspore.mint.linalg.**vector_norm**(*x*, *ord=2*, *dim=None*, *keepdim=False*, *, *dtype=None*)

Returns the vector norm of the given tensor on the specified dimensions.

ord is the calculation mode of norm. The following norm modes are supported.

ord	norm for vectors
2 (Default)	2-norm (see below)
inf	$max(abs(x))$
-inf	$min(abs(x))$
0	$sum(x! = 0)$
other int or float	$sum(abs(x)^{ord})^{(1/ord)}$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **x** (Tensor) –Tensor of shape $(*)$ where * is zero s more batch dimensions.
- **ord** (*Union[bool, int, float, inf, -inf], optional*) –norm's mode. refer to the table above for behavior. Default: 2 .

- **dim** (*Union[int, List(int), Tuple(int)], optional*) –The dimensions along which to perform the vector norm calculation. Default: `None` .
  - When *dim* is an integer, a list or a tuple, the norm calculation will be performed across these specified dimensions, while the remaining dimensions will be considered as batch dimensions.
  - When *dim* is None, the norm will be calculated after flattening the Tensor *x* .
- **keepdim** (*bool*) –whether the output Tensor retains the original dimension. Default: `False` .

Keyword Arguments

dtype (*mindspore.dtype*, optional) –When set, *x* will be converted to the specified type, *dtype* before execution, and dtype of returned Tensor will also be *dtype*. When *dtype* is `None` , the dtype of *x* is preserved. Default: `None` .

Returns

Tensor, the result of norm calculation on the specified dimension, *dim*.

Raises

- **TypeError** –If *x* is not a Tensor.
- **TypeError** –If *dim* is neither an int nor a list or tuple.
- **ValueError** –If *ord* is not in [bool, int, float, inf, -inf].
- **ValueError** –The elements of *dim* are duplicate.
- **ValueError** –If any elements of *dim* is out of range.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> x = ms.ops.arange(0, 12, dtype=ms.float32) - 6
>>> print(ms.mint.linalg.vector_norm(x, ord=2))
12.083046
>>> print(ms.mint.linalg.vector_norm(x, ord=float('inf')))
6.0
>>> print(ms.mint.linalg.vector_norm(x, ord=float('-inf')))
0.0
>>> print(ms.mint.linalg.vector_norm(x, ord=0))
11.0
>>> print(ms.mint.linalg.vector_norm(x, ord=4.5))
7.2243643
```

mindspore.mint.linalg.qr

mindspore.mint.linalg.**qr**(*A*, *mode='reduced'*)

Orthogonal decomposition of the input $A = QR$.

Where A is an input tensor, a dimension is at least 2, and A may be represented as a product form of an orthogonal matrix Q and an upper triangular matrix R.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **A** (Tensor) −The calculated matrix, A is at least two-dimensional.
- **mode** (*str, optional*) −Matrix decomposition mode. The options are `reduced`, `complete`, and `r`. The default value is `reduced`.
  - `"reduced"`: For input $A(*, m, n)$ output simplified size $Q(*, m, k)$, $R(*, k, n)$, where k is the minimum value of m and n.
  - `"complete"`: For input $A(*, m, n)$ output full-size $Q(*, m, m)$, $R(*, m, n)$.
  - `"r"`: Only $R(*, k, n)$ in the reduced scenario is calculated, where k is the minimum value of m and n, and Q is returned as an empty tensor.

Returns

- **Q** (Tensor) - The shape is $Q(*, m, k)$ or $(*, m, n)$, has the same dtype as A.
- **R** (Tensor) - The shape is $Q(*, k, n)$ or $(*, m, n)$, has the same dtype as A.

Raises

- **TypeError** −If A is not a Tensor.
- **TypeError** −If the dtype of A is not the float32.
- **ValueError** −If A is not empty and its dimension is less than 2 dimensions.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([[1.0, 1.0, 2.0, 4.0], [1.0, 1.0, 2.0, 4.0]]), mindspore.float32)
>>> output = mindspore.mint.linalg.qr(x)
>>> print(output)
(Tensor(shape=[2, 2], dtype=Float32, value=
[[-7.07106829e-01, -7.07106769e-01],
[-7.07106769e-01,  7.07106829e-01]]),
Tensor(shape=[2, 4], dtype=Float32, value=
[[-1.41421354e+00, -1.41421354e+00, -2.82842731e+00, -5.65685463e+00],
[ 0.00000000e+00,  3.42285418e-08,  0.00000000e+00,  0.00000000e+00]]))
```

4.8 mindspore.mint.special

4.8.1 Pointwise Operations

API Name	Description	Supported Platforms
mindspore.mint.special.erfc	Compute the complementary error function of input tensor element-wise.	Ascend
mindspore.mint.special.exp2	Calculates the base-2 exponent of the Tensor *input* element by element.	Ascend
mindspore.mint.special.expm1	Compute exponential of the input tensor, then minus 1, element-wise.	Ascend
mindspore.mint.special.log1p	Compute the natural logarithm of (tensor + 1) element-wise.	Ascend
mindspore.mint.special.log_softmax	Applies the Log Softmax function to the input tensor on the specified axis.	Ascend
mindspore.mint.special.round	Returns half to even of a tensor element-wise.	Ascend
mindspore.mint.special.sinc	Compute the normalized sinc of input.	Ascend

mindspore.mint.special.erfc

mindspore.mint.special.**erfc**(*input*)

Compute the complementary error function of input tensor element-wise.

$$\operatorname{erfc}(x) = 1 - \frac{2}{\sqrt{\pi}} \int_0^x e^{-t^2} dt$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> # The datatype of output will be float32 when datatype of input is in [int64,␣
↪bool](Datatype only supported on Ascend).
>>> input = mindspore.tensor([-1, 0, 1, 2, 3], mindspore.int64)
>>> mindspore.mint.special.erfc(input)
Tensor(shape=[5], dtype=Float32, value= [ 1.84270079e+00,  1.00000000e+00,  1.57299207e-01, ␣
↪4.67773498e-03,  2.20904970e-05])
>>>
>>> # Otherwise output has the same dtype as the input.
>>> input = mindspore.tensor([-1, 0, 1, 2, 3], mindspore.float64)
>>> mindspore.mint.special.erfc(input)
Tensor(shape=[5], dtype=Float64, value= [ 1.84270079e+00,  1.00000000e+00,  1.57299207e-01, ␣
↪4.67773498e-03,  2.20904970e-05])
```

mindspore.mint.special.exp2

mindspore.mint.special.**exp2**(*input*)

Calculates the base-2 exponent of the Tensor *input* element by element.

$$out_i = 2^{input_i}$$

Parameters

input (Tensor) –The input Tensor.

Returns

Tensor, which has the same shape as the *input*.

Raises

TypeError –If *input* is not a Tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> x = Tensor(np.array([0.0, 1.0, 2.0, 4.0]), mindspore.float32)
>>> output = mint.special.exp2(x)
>>> print(output)
[ 1. 2. 4. 16.]
```

mindspore.mint.special.expm1

mindspore.mint.special.**expm1**(*input*)

Compute exponential of the input tensor, then minus 1, element-wise.

$$out_i = e^{x_i} - 1$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.0, 1.0, 3.0], mindspore.float32)
>>> output = mindspore.mint.special.expm1(input)
>>> print(output)
[ 0.         1.7182817 19.085537 ]
```

mindspore.mint.special.log1p

mindspore.mint.special.**log1p**(*input*)

Compute the natural logarithm of (tensor + 1) element-wise.

$$out_i = \log_e(input_i + 1)$$

Parameters

input (Tensor) –The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> x = mindspore.tensor([1.0, 2.0, 4.0], mindspore.float32)
>>> output = mindspore.mint.special.log1p(x)
>>> print(output)
[0.6931472 1.0986123 1.609438 ]
```

mindspore.mint.special.log_softmax

mindspore.mint.special.**log_softmax**(*input*, *dim=None*, ***, *dtype=None*)

Applies the Log Softmax function to the input tensor on the specified axis. Supposes a slice in the given axis, x for each element x_i, the Log Softmax function is shown as follows:

$$\text{output}(x_i) = \log\left(\frac{\exp(x_i)}{\sum_{j=0}^{N-1}\exp(x_j)}\right),$$

where N is the length of the Tensor.

Parameters

- **input** (Tensor) –The input Tensor.
- **dim** (*int, optional*) –The axis to perform the Log softmax operation. Default: None .

Keyword Arguments

dtype (*mindspore.dtype*, optional) −The desired dtype of returned Tensor. If not set to None, the input Tensor will be cast to *dtype* before the operation is performed. This is useful for preventing overflows. If set to None, stay the same as original Tensor. Default: `None` .

Returns

Tensor, with the same shape as the input.

Raises

- **TypeError** −If *dim* is not an int.
- **ValueError** −If *dim* is not in range [-len(input.shape), len(input.shape)).

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> logits = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> output = mint.special.log_softmax(logits, dim=-1)
>>> print(output)
[-4.4519143 -3.4519143 -2.4519143 -1.4519144 -0.4519144]
```

mindspore.mint.special.round

mindspore.mint.special.**round**(*input*)

Returns half to even of a tensor element-wise.

$$out_i \approx input_i$$

Note: The input data types supported by the Ascend platform include bfloat16 (Atlas training series products are not supported), float16, float32, float64, int32, and int64.

Parameters

input (Tensor) −The input tensor.

Returns

Tensor, has the same shape and type as the *input*.

Raises

TypeError −If *input* is not a Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, mint
>>> input = Tensor(np.array([0.8, 1.5, 2.3, 2.5, -4.5]), mindspore.float32)
>>> output = mint.special.round(input)
>>> print(output)
[ 1.  2.  2.  2. -4.]
```

mindspore.mint.special.sinc

mindspore.mint.special.**sinc**(*input*)

Compute the normalized sinc of input.

$$out_i = \begin{cases} \frac{sin(\pi input_i)}{\pi input_i} & input_i \neq 0 \\ 1 & input_i = 0 \end{cases}$$

Parameters

input (Tensor) – The input tensor.

Returns

Tensor

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([0.62, 0.28, 0.43, 0.62], mindspore.float32)
>>> output = mindspore.mint.special.sinc(input)
>>> print(output)
[0.47735003 0.8759357  0.7224278  0.47735003]
```

4.9 mindspore.mint.distributed

API Name	Description	Supported Platforms
mindspore.mint.distributed.all_gather	Gathers tensors from the specified communication group and returns the tensor list which is all gathered.	Ascend
mindspore.mint.distributed.all_gather_into_tensor	Gathers tensors from the specified communication group and returns the tensor which is all gathered.	Ascend
mindspore.mint.distributed.all_gather_object	Aggregates Python objects in a specified communication group.	Ascend
mindspore.mint.distributed.all_reduce	Reduce tensors across all devices in such a way that all deviceswill get the same final result, returns the tensor which is all reduced.	Ascend

continues on next page

Table 32 – continued from previous page

mindspore.mint.distributed.all_to_all	scatter and gather list of tensor to/from all rank according to input/output tensor list.	Ascend
mindspore.mint.distributed.all_to_all_single	scatter and gather input with split size to/from all rank, and return result in a single tensor.	Ascend
mindspore.mint.distributed.barrier	Synchronizes all processes in the specified group.	Ascend
mindspore.mint.distributed.batch_isend_irecv	Batch send and recv tensors asynchronously.	Ascend
mindspore.mint.distributed.broadcast	Broadcasts the tensor to the whole group.	Ascend
mindspore.mint.distributed.broadcast_object_list	Broadcasts the entire group of input Python objects.	Ascend
mindspore.mint.distributed.destroy_process_group	Destroy the user collective communication group.	Ascend
mindspore.mint.distributed.gather	Gathers tensors from the specified communication group.	Ascend
mindspore.mint.distributed.gather_object	Gathers python objects from the whole group in a single process.	Ascend
mindspore.mint.distributed.get_backend	Get the backend of communication process groups.	Ascend
mindspore.mint.distributed.get_global_rank	A function that returns the rank id in the world group corresponding to the rank which id is 'group_rank' in the user group.	Ascend
mindspore.mint.distributed.get_group_rank	Get the rank ID in the specified user communication group corresponding to the rank ID in the world communication group.	Ascend
mindspore.mint.distributed.get_process_group_ranks	Gets the ranks of the specific group and returns the process ranks in the communication group as a list.	Ascend
mindspore.mint.distributed.get_rank	Get the rank ID for the current device in the specified collective communication group.	Ascend
mindspore.mint.distributed.get_world_size	Get the rank size of the specified collective communication group.	Ascend
mindspore.mint.distributed.init_process_group	Init collective communication lib.	Ascend
mindspore.mint.distributed.irecv	Receive tensors from src asynchronously.	Ascend
mindspore.mint.distributed.isend	Send tensors to the specified dest_rank asynchronously.	Ascend
mindspore.mint.distributed.is_available	Checks if distributed module is available.	Ascend
mindspore.mint.distributed.is_initialized	Checks if default process group has been initialized.	Ascend
mindspore.mint.distributed.new_group	Create a new distributed group.	Ascend
mindspore.mint.distributed.P2POp	Object for *batch_isend_irecv* input, to store information of "isend" and "irecv".	Ascend
mindspore.mint.distributed.recv	Receive tensors from src.	Ascend
mindspore.mint.distributed.reduce	Reduces tensors across the processes in the specified communication group, sends the result to the target dst(global rank), and returns the tensor which is sent to the target process.	Ascend

continues on next page

Table 32 – continued from previous page

mindspore.mint.distributed.reduce_scatter	Reduces and scatters tensors from the specified communication group and returns the tensor which is reduced and scattered.	Ascend
mindspore.mint.distributed.reduce_scatter_tensor	Reduces and scatters tensors from the specified communication group and returns the tensor which is reduced and scattered.	Ascend
mindspore.mint.distributed.scatter	Scatter tensor evently across the processes in the specified communication group.	Ascend
mindspore.mint.distributed.scatter_object_list	Scatters picklable objects in scatter_object_input_list to the whole group.	Ascend
mindspore.mint.distributed.send	Send tensors to the specified dest_rank.	Ascend

4.9.1 mindspore.mint.distributed.all_gather

mindspore.mint.distributed.**all_gather**(*tensor_list*, *tensor*, *group=None*, *async_op=False*)

Gathers tensors from the specified communication group and returns the tensor list which is all gathered.

Note: The tensors must have the same shape and format in all processes of the collection.

Parameters

- **tensor_list** (*list[Tensor]*) –Output list.
- **tensor** (Tensor) –The input tensor to be all gathered into tensor.
- **group** (*str, optional*) –The communication group to work on. If None, which means "hccl_world_group" in Ascend. Default: None.
- **async_op** (*bool, optional*) –Whether this operator should be an async operator. Default: False .

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** –If the type of input *tensor* is not Tensor, *tensor_list* is not Tensor List, *group* is not a str or async_op is not bool.
- **TypeError** –If size of *tensor_list* is not equal to group size。
- **TypeError** –If the type or shape of *tensor* not equal to the member of *tensor_list*。
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group
>>> from mindspore.mint.distributed import all_gather
>>> from mindspore import Tensor
>>>
>>> init_process_group()
>>> input_tensor = Tensor(np.ones([2, 8]).astype(np.float32))
>>> out_tensors = [Tensor(np.zeros([2, 8]).astype(np.float32)), Tensor(np.zeros([2, 8]).
 ↪astype(np.float32))]
>>> output = all_gather(out_tensors, input_tensor)
>>> print(out_tensors)
[Tensor(shape=[2, 8], dtype=Float32, value=
[[ 1.00000000e+00,  1.00000000e+00,  1.00000000e+00 ...  1.00000000e+00,  1.00000000e+00,  1.
 ↪00000000e+00],
 [ 1.00000000e+00,  1.00000000e+00,  1.00000000e+00 ...  1.00000000e+00,  1.00000000e+00,  1.
 ↪00000000e+00]]),
Tensor(shape=[2, 8], dtype=Float32, value=
[[ 1.00000000e+00,  1.00000000e+00,  1.00000000e+00 ...  1.00000000e+00,  1.00000000e+00,  1.
 ↪00000000e+00],
 [ 1.00000000e+00,  1.00000000e+00,  1.00000000e+00 ...  1.00000000e+00,  1.00000000e+00,  1.
 ↪00000000e+00]])]
```

4.9.2 mindspore.mint.distributed.all_gather_into_tensor

mindspore.mint.distributed.**all_gather_into_tensor**(*output_tensor*, *input_tensor*, *group=None*, *async_op=False*)

Gathers tensors from the specified communication group and returns the tensor which is all gathered.

Note: The tensors must have the same shape and format in all processes of the collection.

Parameters

- **output_tensor** (Tensor) –The output tensor to be all gathered into tensor.If the number of devices in the group is N, then the shape of output tensor is $(N * x_1, x_2, ..., x_R)$.
- **input_tensor** (Tensor) –The input tensor to be all gathered into tensor. The shape of tensor is $(x_1, x_2, ..., x_R)$.
- **group** (*str, optional*) –The communication group to work on. If None, which means "hccl_world_group" in Ascend. Default: None.
- **async_op** (*bool, optional*) –Whether this operator should be an async operator. Default: False .

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** –If the type of the input_tensor or output_tensor parameter is not Tensor, *group* is not a str, or async_op is not bool.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import mint
>>> from mindspore.mint.distributed import init_process_group
>>> from mindspore.mint.distributed import all_gather_into_tensor
>>> from mindspore import Tensor
>>>
>>> ms.set_device(device_target="Ascend")
>>> init_process_group()
>>> input_tensor = Tensor(np.ones([2, 8]).astype(np.float32))
>>> out_tensor = Tensor(np.zeros([4, 8]).astype(np.float32))
>>> output = all_gather_into_tensor(out_tensor, input_tensor)
>>> print(out_tensor)
[[1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]]
```

4.9.3 mindspore.mint.distributed.all_gather_object

`mindspore.mint.distributed.`**`all_gather_object`**(*object_list*, *obj*, *group=None*)

Aggregates Python objects in a specified communication group.

Note: Similar to *mindspore.mint.distributed.all_gather()*, but Python objects can be passed in.

Parameters

- **object_list** (*list[Any]*) –Output Python object list.
- **obj** (*Any*) –Python object to be broadcast from current process.

- **group** (*str, optional*) –The communication group to work on. If `None`, which means "`hccl_world_group`" in Ascend. Default: `None`.

Raises

- **TypeError** –*group* is not a str.
- **TypeError** –If size of *object_list* is not equal to group size.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> from mindspore.mint.distributed import init_process_group, get_rank
>>> from mindspore.mint.distributed import all_gather_object
>>> init_process_group()
>>> rank = get_rank()
>>> obj = ["test", {1: 2}]
>>> object_gather_list=[None, None]
>>> all_gather_object(object_gather_list, obj[rank])
>>> print(object_gather_list)
# rank_0
['test', {1: 2}]
# rank_1
['test', {1: 2}]
```

4.9.4 mindspore.mint.distributed.all_reduce

mindspore.mint.distributed.**all_reduce**(*tensor*, *op=ReduceOp.SUM*, *group=None*, *async_op=False*)

Reduce tensors across all devices in such a way that all deviceswill get the same final result, returns the tensor which is all reduced.

Note: The tensors must have the same shape and format in all processes of the collection.

Parameters

- **tensor** (Tensor) –The input and output tensor of collective. The shape of tensor is $(x_1, x_2, ..., x_R)$. The function operates in-place.
- **op** (*str, optional*) –Specifies an operation used for element-wise reductions, like sum, prod, max, and min. Default: `ReduceOp.SUM`.
- **group** (*str, optional*) –The communication group to work on. If `None`, which means "`hccl_world_group`" in Ascend. Default: `None`.

- **async_op** (*bool, optional*) –Whether this operator should be an async operator. Default: `False` .

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** –If the type of the first input parameter is not Tensor, or any of *op* and *group* is not a str, *op* range is illegal or async_op is not bool.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> from mindspore.mint.distributed import init_process_group
>>> from mindspore.mint.distributed import all_reduce
>>> from mindspore import Tensor
>>>
>>> init_process_group()
>>> tensor = Tensor(np.ones([2, 8]).astype(np.float32))
>>> output = all_reduce(tensor)
>>> print(tensor)
[[2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]]
```

4.9.5 mindspore.mint.distributed.all_to_all

`mindspore.mint.distributed.`**all_to_all**(*output_tensor_list*, *input_tensor_list*, *group=None*, *async_op=False*)

scatter and gather list of tensor to/from all rank according to input/output tensor list.

Note:

- tensor shape in *output_shape_list* and *input_tensor_list* should be match across ranks.
- Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **output_tensor_list** (*List[Tensor]*) –List of tensors that indicate the gathered from remote ranks.
- **input_tensor_list** (*List[Tensor]*) –List of tensors to scatter to the remote rank.

- **group** (*str, optional*) – The communication group to work on. If `None`, which means "`hccl_world_group`" in Ascend. Default: `None`.
- **async_op** (*bool, optional*) – Whether this operator should be an async operator. Default: `False`.

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** – If not all elements in *input_tensor_list* or *output_tensor_list* are Tensor.
- **TypeError** – If tensors in *input_tensor_list* or *output_tensor_list* are not the same type.
- **TypeError** – If *group* is not str or *async_op* is not bool.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group, get_rank
>>> from mindspore.mint.distributed import all_to_all
>>> from mindspore import Tensor
>>>
>>> init_process_group()
>>> this_rank = get_rank()
>>> if this_rank == 0:
...     send_tensor_list = [Tensor(1.), Tensor([[2, 3], [4, 5.]])]
...     recv_tensor_list = [Tensor((0), dtype=ms.float32), Tensor([0, 0.])]
>>> if this_rank == 1:
...     send_tensor_list = [Tensor([2, 2.]), Tensor([4, 5, 6, 7.])]
...     recv_tensor_list = [Tensor([[0, 0.],[0, 0]]), Tensor([0, 0, 0, 0.])]
>>> handle = all_to_all(recv_tensor_list, send_tensor_list)
>>> print(recv_tensor_list)
rank 0:
(Tensor(shape=[], dtype=Float32, value= 1),
 Tensor(shape=[2], dtype=Float32, value= [2.00000000e+00, 2.00000000e+00]))
rank 1:
(Tensor(shape=[2, 2], dtype=Float32, value=
[[2.00000000e+00, 3.00000000e+00],
 [4.00000000e+00, 5.00000000e+00]]),
 Tensor(shape=[4], dtype=Float32, value=[4.00000000e+00, 5.00000000e+00, 6.00000000e+00, 7.
↪00000000e+00]))
```

4.9.6 mindspore.mint.distributed.all_to_all_single

mindspore.mint.distributed.**all_to_all_single**(*output*, *input*, *output_split_sizes=None*, *input_split_sizes=None*, *group=None*, *async_op=False*)

scatter and gather input with split size to/from all rank, and return result in a single tensor.

Note:

- Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **output** (Tensor) –the output tensor is gathered concatenated from remote ranks.
- **input** (Tensor) –tensor to be scattered to remote rank.
- **output_split_sizes** (*Union(Tuple(int), List(int)), optional*) –output split size at dim 0. If set to None, it means equally split by world_size. Default: None.
- **input_split_sizes** (*Union(Tuple(int), List(int)), optional*) –input split size at dim 0. If set to None, it means equally split by world_size. Default: None.
- **group** (*str, optional*) –The communication group to work on. If None, which means "hccl_world_group " in Ascend. Default: None.
- **async_op** (*bool, optional*) –Whether this operator should be an async operator. Default: False .

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** –If *input* or *output* is not tensor. *group* is not a str, or async_op is not bool.
- **ValueError** –When *input_split_sizes* is empty, input dim 0 can not be divided by world_size.
- **ValueError** –When *output_split_sizes* is empty, output dim 0 can not be divided by world_size.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore.mint.distributed import init_process_group, get_rank
>>> from mindspore.mint.distributed import all_to_all_single
```

(continues on next page)

(continued from previous page)

```
>>> from mindspore import Tensor
>>> from mindspore.ops import zeros
>>>
>>> init_process_group()
>>> this_rank = get_rank()
>>> if this_rank == 0:
...     output = Tensor(np.zeros([3, 3]).astype(np.float32))
...     tensor = Tensor([[0, 1, 2.], [3, 4, 5], [6, 7, 8]])
...     result = all_to_all_single(output, tensor, [2, 1], [2, 1])
...     print(output)
>>> if this_rank == 1:
...     output = Tensor(np.zeros([2, 3]).astype(np.float32))
...     tensor = Tensor([[9, 10., 11], [12, 13, 14]])
...     result = all_to_all_single(output, tensor, [1, 1], [1, 1])
...     print(output)
rank 0:
[[ 0.  1.  2.]
 [ 3.  4.  5.]
 [ 9. 10. 11.]]
rank 1:
[[ 6.  7.  8.]
 [12. 13. 14.]]
```

4.9.7 mindspore.mint.distributed.barrier

mindspore.mint.distributed.**barrier**(*group=None*, *async_op=False*, *device_ids=None*)

Synchronizes all processes in the specified group. Once the process call this operation, it will be blocked until all processes call this operation. After all processes finish calling the operations, the blocked processes will be woken and continue their task.

Parameters

- **group** (*str, optional*) – The communication group to work on. If `None`, which means `"hccl_world_group"` in Ascend. Default: `None`.
- **async_op** (*bool, optional*) – Whether this operator should be an async operator. Default: `False`.
- **device_ids** (*list[int], optional*) – Currently It is a reserved Parameter.

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** – *group* is not a str or *async_op* is not a bool.
- **RuntimeError** – If backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> from mindspore.mint.distributed import init_process_group
>>> from mindspore.communication.comm_func import barrier
>>> # Launch 2 processes.
>>> init_process_group()
>>> barrier()
>>> print("barrier finish!")
barrier finish!
```

4.9.8 mindspore.mint.distributed.batch_isend_irecv

mindspore.mint.distributed.**batch_isend_irecv**(*p2p_op_list*)

Batch send and recv tensors asynchronously.

Note:

- The 'isend' and 'irecv' of *P2POp* in *p2p_op_list* between ranks need to match each other.
- *P2POp* in *p2p_op_list* can only use the same communication group.
- *tag* of *P2POp* in *p2p_op_list* is not support yet.
- *tensor* of *P2POp* in *p2p_op_list* will not be modified by result inplace.
- Only support PyNative mode, Graph mode is not currently supported.

Parameters

p2p_op_list (*list[P2POp]*) – list contains *P2POp*. *P2POp* is type of *mindspore.mint.distributed.P2POp*

Returns

list[CommHandle], CommHandle is an async work handle, Currently only one packaging handle is supported.

Raises

- **TypeError** – If *p2p_op_list* is empty or *p2p_op_list* are not all type of *P2POp*.
- **TypeError** – The group name in *p2p_op_list* are not consistent.
- **TypeError** – The *tensor* in *p2p_op_list* are not Tensor.
- **TypeError** – The *op* in *p2p_op_list* are not isend or irecv.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore.mint.distributed import init_process_group, get_rank, get_world_size
>>> from mindspore.mint.distributed import batch_isend_irecv, P2POp
>>> from mindspore import Tensor
>>>
>>> init_process_group()
>>> this_rank = get_rank()
>>> world_size = get_world_size()
>>> next_rank = (this_rank + 1) % world_size
>>> prev_rank = (this_rank + world_size - 1) % world_size
>>>
>>> send_tensor = Tensor(this_rank + 1, dtype=mindspore.float32)
>>> recv_tensor = Tensor(0., dtype=mindspore.float32)
>>>
>>> send_op = P2POp('isend', send_tensor, next_rank)
>>> recv_op = P2POp('irecv', recv_tensor, prev_rank)
>>>
>>> p2p_op_list = [send_op, recv_op]
>>> output = batch_isend_irecv(p2p_op_list)
>>> print(recv_tensor)
rank 0:
2.0
rank 1:
1.0
```

4.9.9 mindspore.mint.distributed.broadcast

mindspore.mint.distributed.**broadcast**(*tensor*, *src*, *group=None*, *async_op=False*)

Broadcasts the tensor to the whole group.

Note:

- The tensors must have the same shape and format in all processes of the collection.
- Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) – Data to be sent if src is the rank of current process, and tensor to be used to save received data otherwise.
- **src** (*int*) – Specifies the rank(global rank) of the process that broadcast the tensor. And only process *src* will broadcast the tensor.

- **group** (*str, optional*) –The communication group to work on. If `None`, which means "`hccl_world_group`" in Ascend. Default: `None`.
- **async_op** (*bool, optional*) –Whether this operator should be an async operator. Default: `False`.

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** –If the type of the *tensor* parameter is not Tensor, *src* is not an integer, *group* is not a string or *async_op* is not bool.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group, broadcast
>>> import numpy as np
>>> # Launch 2 processes.
>>>
>>> init_process_group()
>>> data = ms.Tensor(np.arange(8).reshape([2, 4]).astype(np.float32))
>>> handle = broadcast(tensor=data, src=0)
>>> print(data)
[[0. 1. 2. 3.]
 [4. 5. 6. 7.]]
```

4.9.10 mindspore.mint.distributed.broadcast_object_list

mindspore.mint.distributed.**broadcast_object_list**(*object_list*, *src=0*, *group=None*, *device=None*)

Broadcasts the entire group of input Python objects.

Note:

- Similar to *mindspore.mint.distributed.broadcast()*, but Python objects can be passed in.
- Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **object_list** (*list[Any]*) –list of input to be sent if src is the rank of current process, and list to be used to save received data otherwise.
- **src** (*int, optional*) –Specifies the rank(global rank) of the process that broadcast the Python objects. And only process *src* will broadcast the Python objects. Default: `0` .
- **group** (*str, optional*) –The communication group to work on. If `None`, which means `"hccl_world_group "` in Ascend. Default: `None`.
- **device** (*str, optional*) –Currently it is a reserved parameter. Default: `None`.

Raises

- **TypeError** –If *src* is not an integer or *group* is not a string.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> from mindspore.mint.distributed import init_process_group, broadcast_object_list, get_
 ↪rank
>>> init_process_group()
>>> rank = get_rank()
>>> obj = ["test", 12, {1: 2}]
>>> if rank == 1:
...     obj = [None, None, None]
>>> broadcast_object_list(obj)
>>> print(obj)
['test', 12, {1: 2}]
```

4.9.11 mindspore.mint.distributed.destroy_process_group

`mindspore.mint.distributed.`**destroy_process_group**(*group=None*)

Destroy the user collective communication group. If group is None or "hccl_world_group", Destroy all group and release collective communication lib.

Note:

- This method isn't supported in GPU and CPU versions of MindSpore.
- This method should be used after *mindspore.mint.distributed.init_process_group()*.

Parameters

group (*str, optional*) –The communication group to work on. Normally, the group should be created by *mindspore.mint.distributed.new_group()*. If None, which means "hccl_world_group" in Ascend. Default: None.

Raises

- **TypeError** –If group is not a string.
- **RuntimeError** –If HCCL is not available or MindSpore is GPU/CPU version.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group, destroy_process_group
>>> ms.set_device(device_target="Ascend")
>>> init_process_group()
>>> destroy_process_group()
```

4.9.12 mindspore.mint.distributed.gather

mindspore.mint.distributed.**gather**(*tensor*, *gather_list*, *dst=0*, *group=None*, *async_op=False*)

Gathers tensors from the specified communication group. The operation will gather the tensor from processes according to dimension 0.

Note:

- Only the tensor in process *dst* (global rank) will keep the gathered tensor. The other process will keep a tensor list which has no mathematical meaning.
- The tensors must have the same shape and format in all processes of the collection.
- Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) –The tensor to be gathered.
- **gather_list** (*list[Tensor]*) –List of same-sized tensors to use for gathered data.
- **dst** (*int, optional*) –Specifies the rank(global rank) of the process that receive the tensor. And only process *dst* will receive the gathered tensor. Default: 0 .
- **group** (*str, optional*) –The communication group to work on. If None, which means "hccl_world_group " in Ascend. Default: None.
- **async_op** (*bool, optional*) –Whether this operator should be an async operator. Default: False .

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** – If the type of input tensor is not Tensor, or gather_list is not Tensor list.
- **TypeError** – If dst is not an integer, group is not a string or async_op is not bool.
- **TypeError** – If size of *gather_list* is not equal to group size.
- **TypeError** – If the type or shape of *tensor* not equal to the member of *gather_list*.
- **RuntimeError** – If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> from mindspore.mint.distributed import init_process_group, gather
>>> from mindspore import Tensor
>>> # Launch 2 processes.
>>> init_process_group()
>>> input = Tensor(np.arange(4).reshape([2, 2]).astype(np.float32))
>>> outputs = [Tensor(np.zeros([2, 2]).astype(np.float32)),Tensor(np.zeros([2, 2]).astype(np.
↪float32))]
>>> gather(input, outputs, dst=0)
>>> print(outputs)
# rank_0
[Tensor(shape=[2, 2], dtype=Float32, value=
[[ 0.00000000e+00,  1.00000000e+00],
 [ 2.00000000e+00,  3.00000000e+00]]), Tensor(shape=[2, 2], dtype=Float32, value=
[[ 0.00000000e+00,  1.00000000e+00], [ 2.00000000e+00,  3.00000000e+00]])]
[Tensor(shape=[2, 2], dtype=Float32, value=
[[ 0.00000000e+00,  1.00000000e+00],
 [ 2.00000000e+00,  3.00000000e+00]]), Tensor(shape=[2, 2], dtype=Float32, value=
[[ 0.00000000e+00,  1.00000000e+00], [ 2.00000000e+00,  3.00000000e+00]])]
# rank_1
[Tensor(shape=[2, 2], dtype=Float32, value=
[[ 0.00000000e+00,  0.00000000e+00],
 [ 0.00000000e+00,  0.00000000e+00]]), Tensor(shape=[2, 2], dtype=Float32, value=
[[ 0.00000000e+00,  0.00000000e+00], [ 0.00000000e+00,  0.00000000e+00]])]
[Tensor(shape=[2, 2], dtype=Float32, value=
[[ 0.00000000e+00,  0.00000000e+00],

[[ 0.00000000e+00,  0.00000000e+00], [ 0.00000000e+00,  0.00000000e+00]])]
```

4.9.13 mindspore.mint.distributed.gather_object

mindspore.mint.distributed.**gather_object**(*obj*, *object_gather_list=None*, *dst=0*, *group=None*)

Gathers python objects from the whole group in a single process.

Note:

- Similar to *mindspore.mint.distributed.gather()*, but Python objects can be passed in.
- Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **obj** (*Any*) –The python objects to be gathered.
- **object_gather_list** (*list[Any], optional*) –List of same-sized tensors to use for gathered data. On the `dst` rank, it should be correctly sized as the size of the group for this collective and will contain the output. Default: `None`.
- **dst** (*int, optional*) –Specifies the rank(global rank) of the process that receive the tensor. And only process *dst* will receive the gathered tensor. Default: `0` .
- **group** (*str, optional*) –The communication group to work on. If `None`, which means "`hccl_world_group`" in Ascend. Default: `None`.

Raises

- **TypeError** –If dst is not an integer, or group is not a string.
- **TypeError** –If size of *object_gather_list* is not equal to group size.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> from mindspore.mint.distributed import init_process_group, gather_object, get_rank
>>> init_process_group()
>>> rank = get_rank()
>>> obj = ["test", {1: 2}]
>>> object_gather_list=[None, None]
>>> gather_object(obj[rank], object_gather_list)
>>> print(object_gather_list)
# rank_0
['test', {1: 2}]
```

4.9.14 mindspore.mint.distributed.get_backend

mindspore.mint.distributed.**get_backend**(*group=None*)

Get the backend of communication process groups.

Note: Only one communication backend is supported by MindSpore for each process. It should be one of *hccl/nccl/mccl*. Currently only support hccl and mccl.

Parameters

group (*str, optional*) – The communication group to work on. Normally, the group should be created by *mindspore.mint.distributed.new_group()*, If None, which means "hccl_world_group" in Ascend. Default: None.

Returns

string, the backend of the group.

Raises

TypeError – If the *group* is not a str.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables. For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group, get_backend
>>> ms.set_device(device_target="Ascend")
>>> init_process_group()
>>> backend = get_backend()
>>> print("backend is: ", backend)
backend is: hccl
```

4.9.15 mindspore.mint.distributed.get_global_rank

mindspore.mint.distributed.**get_global_rank**(*group*, *group_rank*)

A function that returns the rank id in the world group corresponding to the rank which id is 'group_rank' in the user group.

Note: This method should be used after *mindspore.mint.distributed.init_process_group()*.

Parameters

- **group** (*str*) – The communication group to work on. Normally, the group should be created by *mindspore.mint.distributed.new_group()*. If None, which means "hccl_world_group" in Ascend.

- **group_rank** (*int*) –Group rank to query.

Returns

An integer scalar with the rank id in the world group.

Raises

- **TypeError** –If the *group* is not a str.
- **TypeError** –If the *group_rank* is not an integer.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies.

Please see the msrun start up for more details.

This example should be run with 8 devices.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group, get_global_rank, new_group,␣
↪get_rank
>>> ms.set_device(device_target="Ascend")
>>> # Launch 8 processes.
>>> init_process_group()
>>> rank_ids = [0,4]
>>> if get_rank() in rank_ids:
...     group = new_group(rank_ids)
...     world_rank_id = get_global_rank(group, 1)
...     print("world_rank_id is: ", world_rank_id)
#rank 0 and 4:
world_rank_id is: 4
```

4.9.16 mindspore.mint.distributed.get_group_rank

mindspore.mint.distributed.**get_group_rank**(*group*, *global_rank*)

Get the rank ID in the specified user communication group corresponding to the rank ID in the world communication group.

Note: This method should be used after *mindspore.mint.distributed.init_process_group()*.

Parameters

- **group** (*str*) –The communication group to work on. Normally, the group should be created by *mindspore.mint.distributed.new_group()*. If `None`, which means `"hccl_world_group"` in Ascend.
- **global_rank** (*int*) –A rank ID in the world communication group.

Returns

int, the rank ID in the user communication group.

Raises

- **TypeError** –If global_rank is not an integer or the group is not a string.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 8 devices.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group, new_group, get_group_rank,␣
↪get_rank
>>> ms.set_device(device_target="Ascend")
>>> # Launch 8 processes.
>>> init_process_group()
>>> rank_ids = [0,4]
>>> if get_rank() in rank_ids:
...     group = new_group(rank_ids)
...     group_rank_id = get_group_rank(group, 4)
...     print("group_rank_id is: ", group_rank_id)
#rank 0 and 4:
group_rank_id is: 1
```

4.9.17 mindspore.mint.distributed.get_process_group_ranks

mindspore.mint.distributed.**get_process_group_ranks**(*group=None*)

Gets the ranks of the specific group and returns the process ranks in the communication group as a list.

Parameters

group (*str, optional*) –The communication group to work on. Normally, the group should be created by *mindspore.mint.distributed.new_group()*. If `None`, which means `"hccl_world_group"` in Ascend. Default: `None`.

Returns

List (List[int]), List of process ranks in the specified communication group.

Raises

- **TypeError** –If the *group* is not a str.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies.

Please see the msrun start up for more details.

This example should be run with 4 devices.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group, get_process_group_ranks
>>> # Launch 4 processes.
>>> ms.set_device(device_target="Ascend")
>>> init_process_group()
>>> output = get_process_group_ranks()
>>> print(output)
[0, 1, 2, 3]
```

4.9.18 mindspore.mint.distributed.get_rank

mindspore.mint.distributed.**get_rank**(*group=None*)

Get the rank ID for the current device in the specified collective communication group.

Note: This method should be used after *mindspore.mint.distributed.init_process_group()*.

Parameters

group (*str, optional*) – The communication group to work on. Normally, the group should be created by *mindspore.mint.distributed.new_group()*. If None, which means "hccl_world_group" in Ascend. Default: None.

Returns

int, the rank ID of the calling process within the group. return -1, if not part of the group

Raises

TypeError – If group is not a string.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group, get_rank
>>> ms.set_device(device_target="Ascend")
>>> init_process_group()
>>> rank_id = get_rank()
>>> print(rank_id)
>>> # the result is the rank_id in world_group
#rank 0: 0
#rank 1: 1
```

4.9.19 mindspore.mint.distributed.get_world_size

mindspore.mint.distributed.**get_world_size**(*group=None*)

Get the rank size of the specified collective communication group.

Note: This method should be used after *mindspore.mint.distributed.init_process_group()*.

Parameters

group (*str, optional*) – The communication group to work on. Normally, the group should be created by *mindspore.mint.distributed.new_group()*. If None, which means "hccl_world_group" in Ascend. Default: None.

Returns

int, the rank size of the group. return -1, if the group is not available.

Raises

TypeError – If group is not a string.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 8 devices.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group, get_world_size
>>> ms.set_device(device_target="Ascend")
>>> init_process_group()
>>> group_size = get_world_size()
>>> print("group_size is: ", group_size)
group_size is: 8
```

4.9.20 mindspore.mint.distributed.init_process_group

mindspore.mint.distributed.**init_process_group**(*backend='hccl'*, *init_method=None*, *timeout=None*, *world_size=-1*, *rank=-1*, *store=None*, *pg_options=None*, *device_id=None*)

Init collective communication lib. And create a default collective communication group.

Note: This method isn't supported in GPU and CPU versions of MindSpore. In Ascend hardware platforms, this API should be set before the definition of any Tensor and Parameter, and the instantiation and execution of any operation and net.

Parameters

- **backend** (*str, optional*) –The backend to ues. default is hccl and now only support hccl.
- **init_method** (*str, invalid*) –URL specifying how to init collective communication group. Provides parameters consistent with pytorch, but is not currently support, setting is invalid.
- **timeout** (*timedelta, invalid*) –Timeout for API executed. Provides parameters consistent with pytorch, but is not currently support, setting is invalid.
- **world_size** (*int, optional*) –Number of the processes participating in the job.
- **rank** (*int, invalid*) –Rank of the current process. Provides parameters consistent with pytorch, but is not currently support, setting is invalid.
- **store** (*Store, invalid*) –Key/Value store accessible to all workers, used to exchange connection/address information. Provides parameters consistent with pytorch, but is not currently support, setting is invalid.
- **pg_options** (*ProcessGroupOptions, invalid*) –process group options specifying what additional options need to be passed in during the construction of specific process group. Provides parameters consistent with pytorch, but is not currently support, setting is invalid.
- **device_id** (*int, invalid*) –the device id to exeute. Provides parameters consistent with pytorch, but is not currently support, setting is invalid.

Raises

- **ValueError** –If *backend* is not hccl.
- **ValueError** –If *world_size* is not equal to -1 or process group number.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails, or the environment variables RANK_ID/MINDSPORE_HCCL_CONFIG_PATH have not been exported when backend is HCCL.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group, destroy_process_group
>>> ms.set_device(device_target="Ascend")
>>> init_process_group()
>>> destroy_process_group()
```

4.9.21 mindspore.mint.distributed.irecv

mindspore.mint.distributed.**irecv**(*tensor*, *src=0*, *group=None*, *tag=0*)

Receive tensors from src asynchronously.

Note: Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) – Tensor to fill with received data.
- **src** (*int, optional*) – A required integer identifying the source rank(global rank). Default: 0.
- **group** (*str, optional*) – The communication group to work on. If None, which means "hccl_world_group" in Ascend. Default: None.
- **tag** (*int, optional*) – A required integer identifying the send/recv message tag. The message will be received by the Send op with the same "tag". Default: 0. It is a reserved parameter currently.

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** – If the type of *tensor* is not Tensor, If *src* is not an int or *group* is not a str.
- **ValueError** – If the rank ID of the process is greater than the rank size of the communication group.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> from mindspore.mint.distributed import init_process_group
>>> from mindspore.mint.distributed import isend, irecv, get_rank
>>> from mindspore import Tensor
>>> import numpy as np
>>>
# Launch 2 processes, Process 0 sends the array to Process 1.
>>> init_process_group()
>>> this_rank = get_rank()
>>> if this_rank == 0:
...     input_ = Tensor(np.ones([2, 8]).astype(np.float32))
...     handle = isend(input_, 1)
...     handle.wait()
>>> if this_rank == 1:
...     x = Tensor(np.zeros([2, 8]).astype(np.float32))
...     handle = irecv(x, src=0)
...     handle.wait()
...     print(x)
rank 1:
[[1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]]
```

4.9.22 mindspore.mint.distributed.isend

mindspore.mint.distributed.**isend**(*tensor*, *dst=0*, *group=None*, *tag=0*)

Send tensors to the specified dest_rank asynchronously.

Note: Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) – Tensor to send.
- **dst** (*int, optional*) – A required integer identifying the destination rank(global rank). Default: 0.
- **group** (*str, optional*) – The communication group to work on. If None, which means "hccl_world_group" in Ascend. Default: None.
- **tag** (*int, optional*) – A required integer identifying the send/recv message tag. The message will be received by the Receive op with the same "tag". Default: 0. It is a reserved parameter currently.

Returns

CommHandle, it is an async work handle.

Raises

- **TypeError** – If the *tensor* is not Tensor, *dst* is not an int or *group* is not a str.

- **ValueError** – If the *dst* process rank id is same as the current process.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> from mindspore.mint.distributed import init_process_group
>>> from mindspore.mint.distributed import isend, irecv, get_rank
>>> from mindspore import Tensor
>>> import numpy as np
>>>
# Launch 2 processes, Process 0 sends the array to Process 1.
>>> init_process_group()
>>> this_rank = get_rank()
>>> if this_rank == 0:
...     input_ = Tensor(np.ones([2, 8]).astype(np.float32))
...     handle = isend(input_, 1)
...     handle.wait()
>>> if this_rank == 1:
...     x = Tensor(np.zeros([2, 8]).astype(np.float32))
...     handle = irecv(x, src=0)
...     handle.wait()
...     print(x)
rank 1:
[[1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]]
```

4.9.23 mindspore.mint.distributed.is_available

mindspore.mint.distributed.**is_available**()

Checks if distributed module is available.

Note: Always returns *True* because MindSpore always has distributed ability on all platforms.

Returns

bool, whether this distributed module is available.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import is_available
>>> ms.set_device(device_target="Ascend")
>>> is_available()
True
```

4.9.24 mindspore.mint.distributed.is_initialized

mindspore.mint.distributed.**is_initialized**()

Checks if default process group has been initialized.

Returns

bool, whether the default process group has been initialized.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group, is_initialized
>>> ms.set_device(device_target="Ascend")
>>> init_process_group()
>>> print(is_initialized())
True
```

4.9.25 mindspore.mint.distributed.new_group

mindspore.mint.distributed.**new_group**(*ranks=None*, *timeout=None*, *backend=None*, *pg_options=None*, *use_local_synchronization=False*, *group_desc=None*)

Create a new distributed group.

Note: This method should be used after *mindspore.mint.distributed.init_process_group()*.

Parameters

- **ranks** (*list[int], optional*) –List of ranks of group members. If `None`, will be create the world group. Default is `None`.
- **timeout** (*int, invalid*) –Currently it is a reserved parameter.
- **backend** (*str, invalid*) –Support backend Library, Currently support `"hccl"` and `"mccl"`. when backend is `"hccl"` will use Huawei Collective Communication Library(HCCL). when backend is `"mccl"` will use MindSpore Collective Communication Library(MCCL). If `None`, which means `"hccl"` in Ascend. Default is `None`.
- **pg_options** (*str, invalid*) –Currently it is a reserved parameter.
- **use_local_synchronization** (*bool, invalid*) –Currently it is a reserved parameter.
- **group_desc** (*str, invalid*) –Currently it is a reserved parameter.

Returns

A string with group name. Return "" in the abnormal scenarios.

Raises

TypeError –If list ranks in Group has duplicate rank id.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables. For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore.mint.distributed import init_process_group, new_group
>>> ms.set_device(device_target="Ascend")
>>> init_process_group()
>>> group = new_group()
>>> print("group is: ", group)
group is: hccl_world_group
```

4.9.26 mindspore.mint.distributed.P2POp

class mindspore.mint.distributed.**P2POp**(*op*, *tensor*, *peer*, *group=None*, *tag=0*)

Object for *batch_isend_irecv* input, to store information of `"isend"` and `"irecv"`.

Note: *tensor* will be modified in-place by final result when *op* is `"irecv"`.

Parameters

- **op** (*Union[str, function]*) –Only string of `"isend"` and `"irecv"` are allowed. Or function of `distributed.isend` and `distributed.irecv` are allowed.

- **tensor** (Tensor) –tensor for sending/receiving.
- **peer** (*int*) –remote global rank for send/receive.
- **group** (*str, optional*) –The communication group to work on. If None, which means "hccl_world_group " in Ascend. Default: None.
- **tag** (*int, optional*) –currently not supported yet. Default: 0.

Returns

P2POp Object.

Raises

- **TypeError** –when *op* is not string or function of 'isend' and 'irecv'.
- **TypeError** –when *tensor* is not type of Tensor or 'peer' is not int.
- **NotImplementedError** –when *tag* is not 0.

Supported Platforms:

Ascend

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore.mint.distributed import P2POp, isend, irecv
>>> from mindspore import Tensor
>>> # Launch 2 processes.
>>> send_tensor = Tensor(1.)
>>> send_op = P2POp('isend', send_tensor, 1)
>>> send_op = P2POp(isend, send_tensor, 1)
>>> recv_tensor = Tensor(0.)
>>> recv_op = P2POp('irecv', recv_tensor, 0)
>>> recv_op = P2POp(irecv, recv_tensor, 0)
```

4.9.27 mindspore.mint.distributed.recv

mindspore.mint.distributed.**recv**(*tensor*, *src=0*, *group=None*, *tag=0*)

Receive tensors from src.

Note: Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) –Tensor to fill with received data.
- **src** (*int, optional*) –A required integer identifying the source rank(global rank). Default: 0.
- **group** (*str, optional*) –The communication group to work on. If None, which means "hccl_world_group " in Ascend. Default: None.
- **tag** (*int, optional*) –A required integer identifying the send/recv message tag. The message will be received by the Send op with the same "tag". Default: 0. It is a reserved parameter currently.

Returns

int, If success, return `0`.

Raises

- **TypeError** –If the *tensor* is not Tensor, *src* is not an int or *group* is not a str.
- **ValueError** –If the rank ID of the process is greater than the rank size of the communication group.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> from mindspore.mint.distributed import init_process_group
>>> from mindspore.mint.distributed import send, recv, get_rank
>>> from mindspore import Tensor
>>> import numpy as np
>>>
# Launch 2 processes, Process 0 sends the array to Process 1.
>>> init_process_group()
>>> this_rank = get_rank()
>>> if this_rank == 0:
...     input_ = Tensor(np.ones([2, 8]).astype(np.float32))
...     send(input_, 1)
>>> if this_rank == 1:
...     x = Tensor(np.zeros([2, 8]).astype(np.float32))
...     out = recv(x, src=0)
...     print(x)
rank 1:
[[1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]]
```

4.9.28 mindspore.mint.distributed.reduce

`mindspore.mint.distributed.`**`reduce`**(*tensor*, *dst*, *op=ReduceOp.SUM*, *group=None*, *async_op=False*)

Reduces tensors across the processes in the specified communication group, sends the result to the target dst(global rank), and returns the tensor which is sent to the target process.

Note:

- Only process with destination rank receives the reduced output.
- Only support PyNative mode, Graph mode is not currently supported.
- Other processes only get a tensor with shape [1], which has no mathematical meaning.

Parameters

- **tensor** (Tensor) –Input and output of the collective. The function operates in-place.
- **dst** (*int*) –The target rank of the process(global rank) that receives the reduced output.
- **op** (*str, optional*) –Specifies an operation used for element-wise reductions, like sum, prod, max, and min. Default: `ReduceOp.SUM`.
- **group** (*str, optional*) –The communication group to work on. If `None`, which means "`hccl_world_group`" in Ascend. Default: `None`.
- **async_op** (*bool, optional*) –Whether this operator should be an async operator. Default: `False`.

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to `True`. CommHandle will be None, when *async_op* is `False`.

Raises

- **TypeError** –If the type of *tensor* is not Tensor, any of *op* and *group* is not a str. async_op is not bool or 'op' is invalid.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies.

Please see the msrun start up for more details.

This example should be run with 4 devices.

```
>>> from mindspore import mint
>>> import mindspore.nn as nn
>>> from mindspore.mint.distributed import init_process_group, reduce
>>> from mindspore import Tensor
>>> import numpy as np
>>> # Launch 2 processes.
>>> init_process_group()
>>> dest_rank=1
>>> input_tensor = Tensor(np.ones([2, 8]).astype(np.float32))
>>> output = reduce(input_tensor, dest_rank)
>>> print(input_tensor)
Process with rank 0: [[1. 1. 1. 1. 1. 1. 1. 1.]
                      [1. 1. 1. 1. 1. 1. 1. 1.]],
Process with rank 1: [[2. 2. 2. 2. 2. 2. 2. 2.]
                      [2. 2. 2. 2. 2. 2. 2. 2.]],
```

4.9.29 mindspore.mint.distributed.reduce_scatter

mindspore.mint.distributed.**reduce_scatter**(*output*, *input_list*, *op=ReduceOp.SUM*, *group=None*, *async_op=False*)

Reduces and scatters tensors from the specified communication group and returns the tensor which is reduced and scattered.

Note: The tensors must have the same shape and format in all processes of the collection.

Parameters

- **output** (Tensor) –the output tensor.
- **input_list** (*list[Tensor]*) –List of tensors to reduce and scatter.
- **op** (*str, optional*) –Specifies an operation used for element-wise reductions, like SUM and MAX. Default: ReduceOp.SUM.
- **group** (*str, optional*) –The communication group to work on. If None, which means "hccl_world_group" in Ascend. Default: None.
- **async_op** (*bool, optional*) –Whether this operator should be an async operator. Default: False.

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** –If the type of *output* parameter is not Tensor, *input_list* is not Tensor List.
- **TypeError** –If any of *op* and *group* is not a str. async_op is not bool or 'op' is invalid.
- **TypeError** –If size of *input_list* is not equal to group size.
- **TypeError** –If the type or shape of *output* not equal to the member of *input_list*.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> from mindspore import Tensor
>>> from mindspore.mint.distributed import init_process_group
>>> from mindspore.mint.distributed import reduce_scatter
>>> import numpy as np
>>>
>>> init_process_group()
```

(continues on next page)

(continued from previous page)

```
>>> input_tensors = [Tensor(np.ones([4, 8]).astype(np.float32)), Tensor(np.ones([4, 8]).
↪astype(np.float32))]
>>> output_tensor = Tensor(np.zeros([4, 8]).astype(np.float32))
>>> output = reduce_scatter(output_tensor ,input_tensors)
>>> print(output_tensor)
[[2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]]
```

4.9.30 mindspore.mint.distributed.reduce_scatter_tensor

mindspore.mint.distributed.**reduce_scatter_tensor**(*output*, *input*, *op=ReduceOp.SUM*, *group=None*, *async_op=False*)

Reduces and scatters tensors from the specified communication group and returns the tensor which is reduced and scattered.

Note: The tensors must have the same shape and format in all processes of the collection.

Parameters

- **output** (Tensor) –the output tensor has the same dtype as *input_x* with a shape of $(N/rank\_size, *)$
- **input** (Tensor) –The input tensor to be reduced and scattered, suppose it has a shape $(N, *)$, where * means any number of additional dimensions. N must be divisible by rank_size. rank_size refers to the number of cards in the communication group.
- **op** (*str, optional*) –Specifies an operation used for element-wise reductions, like SUM and MAX. Default: ReduceOp.SUM.
- **group** (*str, optional*) –The communication group to work on. If None, which means "hccl_world_group " in Ascend. Default: None.
- **async_op** (*bool, optional*) –Whether this operator should be an async operator. Default: False.

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** –If the type of the input and output parameter is not Tensor, any of *op* and *group* is not a str. async_op is not bool or 'op' is invalid.
- **ValueError** –If the first dimension of the input cannot be divided by the rank_size.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> from mindspore.mint.distributed import init_process_group
>>> from mindspore.mint.distributed import reduce_scatter_tensor
>>> import numpy as np
>>>
>>> ms.set_device(device_target="Ascend")
>>> init_process_group()
>>> input_tensor = Tensor(np.ones([8, 8]).astype(np.float32))
>>> output_tensor = Tensor(np.ones([4, 8]).astype(np.float32))
>>> output = reduce_scatter_tensor(output_tensor ,input_tensor)
>>> print(output_tensor)
[[2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]]
```

4.9.31 mindspore.mint.distributed.scatter

mindspore.mint.distributed.**scatter**(*tensor*, *scatter_list*, *src=0*, *group=None*, *async_op=False*)

Scatter tensor evently across the processes in the specified communication group.

Note:

- The interface behavior only support Tensor List input and scatter evenly.
- Only the tensor in process *src* (global rank) will do scatter.
- Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) – the output tensor.
- **scatter_list** (*list[Tensor]*) – List of same-sized tensors to scatter. default is None, must be specified on the source rank.
- **src** (*int, optional*) – Specifies the rank(global rank) of the process that send the tensor. And only process *src* will send the tensor.
- **group** (*str, optional*) – The communication group to work on. If None, which means "hccl_world_group" in Ascend. Default: None.
- **async_op** (*bool, optional*) – Whether this operator should be an async operator. Default: False .

Returns

CommHandle, CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** –If the type of *tensor* parameter is not Tensor, *scatter_list* is not Tensor List.
- **TypeError** –If any of *op* and *group* is not a str. async_op is not bool or 'op' is invalid.
- **TypeError** –If size of *scatter_list* is not equal to group size.
- **TypeError** –If the type or shape of *tensor* not equal to the member of *scatter_list*.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> from mindspore import Tensor
>>> from mindspore.mint.distributed import init_process_group, scatter
>>> import numpy as np
>>> # Launch 2 processes.
>>>
>>> init_process_group()
>>> inputs = [Tensor(np.ones([2, 2]).astype(np.float32)), Tensor(np.ones([2, 2]).astype(np.
↪float32))]
>>> output = Tensor(np.zeros([2, 2]).astype(np.float32))
>>> scatter(output, inputs, src=0)
>>> print(output)
# rank_0
[[1. 1.]
 [1. 1.]]
# rank_1
[[1. 1.]
 [1. 1.]]
```

4.9.32 mindspore.mint.distributed.scatter_object_list

mindspore.mint.distributed.**scatter_object_list**(*scatter_object_output_list*, *scatter_object_input_list*, *src=0*, *group=None*)

Scatters picklable objects in scatter_object_input_list to the whole group.

Note:

- Similar to *mindspore.mint.distributed.scatter()*, but Python objects can be passed in.

- Only the objects in process *src* (global rank) will do scatter.
- Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **scatter_object_output_list** (*list[Any]*) –Non-empty list whose first element will store the object scattered to this rank.
- **scatter_object_input_list** (*list[Any]*) –List of python objects to scatter. it must be specified on the source rank.
- **src** (*int, optional*) –Specifies the rank(global rank) of the process that send the tensor. And only process *src* will send the tensor. Default: `0` .
- **group** (*str, optional*) –The communication group to work on. If `None`, which means `"hccl_world_group "` in Ascend. Default: `None`.

Raises

- **TypeError** –If *group* is not a str or *src* is not an integer.
- **TypeError** –If size of *scatter_object_input_list* is not equal to group size.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> from mindspore.mint.distributed import init_process_group, scatter_object_list
>>> init_process_group()
>>> obj = ["test",  {1: 2}]
>>> scatter_object_output_list=[None]
>>> scatter_object_list(scatter_object_output_list, obj)
>>> print(scatter_object_output_list)
# rank_0
['test']
# rank_1
[{1: 2}]
```

4.9.33 mindspore.mint.distributed.send

mindspore.mint.distributed.**send**(*tensor*, *dst=0*, *group=None*, *tag=0*)

Send tensors to the specified dest_rank.

Note: Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) – Tensor to send.
- **dst** (*int, optional*) – A required integer identifying the destination rank(global rank). Default: 0.
- **group** (*str, optional*) – The communication group to work on. If None, which means "hccl_world_group" in Ascend. Default: None.
- **tag** (*int, optional*) – A required integer identifying the send/recv message tag. The message will be received by the Receive op with the same "tag". Default: 0. It is a reserved parameter currently.

Raises

- **TypeError** – If the *tensor* is not Tensor, *dst* is not an int or *group* is not a str.
- **ValueError** – If the *dst* process rank id is same as the current process.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> from mindspore.mint.distributed import init_process_group
>>> from mindspore.mint.distributed import send, recv, get_rank
>>> from mindspore import Tensor
>>> import numpy as np
>>>
# Launch 2 processes, Process 0 sends the array to Process 1.
>>> init_process_group()
>>> this_rank = get_rank()
>>> if this_rank == 0:
...     input_ = Tensor(np.ones([2, 8]).astype(np.float32))
...     send(input_, 1)
>>> if this_rank == 1:
...     x = Tensor(np.zeros([2, 8]).astype(np.float32))
...     out = recv(x, src=0)
...     print(x)
rank 1:
[[1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]]
```

CHAPTER

FIVE

MINDSPORE.COMMON.INITIALIZER

Initializer for cell parameters.

class mindspore.common.initializer.**Constant**(*value*)

Generates an array with constant value in order to initialize a tensor.

Parameters

value (*Union[int, numpy.ndarray]*) – The value to initialize.

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, Constant
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(Constant(3), [1, 2, 3], mindspore.float32))
```

class mindspore.common.initializer.**Dirac**(*groups=1*)

Generates an array with the Dirac delta function in order to initialize a tensor. It's usually used in convolution layers, preserves as many identities of the inputs as possible.

Parameters

groups (*int*) – The number of groups in convolution layer. Each group applies the same initialization. Default: `1` .

Raises

- **ValueError** – If the dimension of the initialized tensor is not in [3, 4, 5].
- **ValueError** – The first dimension of the initialized tensor cannot be divisible by group.

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, Dirac
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(Dirac(groups=2), [6, 4, 3, 3], mindspore.float32))
>>> w2 = Parameter(initializer("dirac", [6, 4, 3, 3], mindspore.float32))
```

class mindspore.common.initializer.**HeNormal**(*negative_slope=0*, *mode='fan_in'*, *nonlinearity='leaky_relu'*)

Generates an array with values sampled from HeKaiming Normal distribution $N(0, \text{sigma}^2)$ in order to initialize a tensor, where

$$sigma = \frac{gain}{\sqrt{fan\_mode}}$$

where *gain* is an optional scaling factor. fan_mode is the number of input or output units of the weight tensor, depending on the *mode* is 'fan_in' or 'fan_out'.

For details of HeNormal algorithm, please check https://arxiv.org/abs/1502.01852.

Parameters

- **negative_slope** (*int, float*) –The negative slope of the rectifier used after this layer (only used when *nonlinearity* is 'leaky_relu'). Default: `0` .
- **mode** (*str*) –Either `'fan_in'` or `'fan_out'` . Choosing `'fan_in'` preserves the magnitude of the variance of the weights in the forward pass. Choosing `'fan_out'` preserves the magnitudes in the backwards pass. Default: `'fan_in'` .
- **nonlinearity** (*str*) –The non-linear function, recommended to use only with `'relu'` or `'leaky_relu'` . Default: `'leaky_relu'` .

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, HeNormal
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(HeNormal(), [1, 2, 3], mindspore.float32))
>>> w2 = Parameter(initializer('he_normal', [1, 2, 3], mindspore.float32))
```

class mindspore.common.initializer.**HeUniform**(*negative_slope=0*, *mode='fan_in'*, *nonlinearity='leaky_relu'*)

Generates an array with values sampled from HeKaiming Uniform distribution $U(-\text{boundary}, \text{boundary})$ in order to initialize a tensor, where

$$boundary = \text{gain} \times \sqrt{\frac{3}{fan\_mode}}$$

where *gain* is an optional scaling factor. If *mode* is `'fan_in'`, fan_mode in the formula is the number of input units of the weight tensor. If *mode* is `'fan_out'`, fan_mode is the number of output units of the weight tensor.

For details of HeUniform algorithm, please check https://arxiv.org/abs/1502.01852.

Parameters

- **negative_slope** (*int, float, bool*) –The negative slope of the rectifier used after this layer (only used when *nonlinearity* is 'leaky_relu'). Default: `0` .
- **mode** (*str*) –Either `'fan_in'` or `'fan_out'` . Choosing `'fan_in'` preserves the magnitude of the variance of the weights in the forward pass. Choosing `'fan_out'` preserves the magnitudes in the backwards pass. Default: `'fan_in'` .
- **nonlinearity** (*str*) –The non-linear function, recommended to use only with `'relu'` or `'leaky_relu'` . Default: `'leaky_relu'` .

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, HeUniform
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(HeUniform(), [1, 2, 3], mindspore.float32))
>>> w2 = Parameter(initializer('he_uniform', [1, 2, 3], mindspore.float32))
```

class mindspore.common.initializer.**Identity**(***kwargs*)

Generates a 2 dimension identity matrix array in order to initialize a tensor.

Raises

ValueError – If the dimension of input tensor is not equal to 2.

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, Identity
>>> from mindspore import Parameter
>>> w1 = initializer(Identity(), [2, 3], mindspore.float32)
>>> w2 = initializer('identity', [2, 3], mindspore.float32)
```

class mindspore.common.initializer.**Initializer**(***kwargs*)

The abstract base class of the initializer.

Note: Initializers are intended to be used for delayed initialization in parallel mode rather than Tensor initialization. If you have to use Initializers to create a Tensor, *mindspore.Tensor.init_data()* should be followed in most of the cases. For more information, please refer to *mindspore.Tensor.init_data()* .

Parameters

kwargs (*dict*) – Keyword arguments for Initializer.

class mindspore.common.initializer.**Normal**(*sigma=0.01*, *mean=0.0*)

Generates an array with values sampled from Normal distribution $N(\text{sigma}, \text{mean})$ in order to initialize a tensor.

$$f(x) = \frac{1}{\sqrt{2 * } * sigma} exp(-\frac{(x - mean)^2}{2 * sigma^2})$$

Parameters

- **sigma** (*float*) – The standard deviation of Normal distribution. Default: `0.01` .
- **mean** (*float*) – The mean of Normal distribution. Default: `0.0` .

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, Normal
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(Normal(), [1, 2, 3], mindspore.float32))
>>> w2 = Parameter(initializer('normal', [1, 2, 3], mindspore.float32))
```

class mindspore.common.initializer.**One**(***kwargs*)

Generates an array with constant value of one in order to initialize a tensor.

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, One
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(One(), [1, 2, 3], mindspore.float32))
>>> w2 = Parameter(initializer('ones', [1, 2, 3], mindspore.float32))
```

class mindspore.common.initializer.**Orthogonal**(*gain=1.*)

Generates a (semi) orthogonal matrix array in order to initialize a tensor. The dimension of input tensor must have at least 2 dimensions. If the dimension is greater than 2, the trailing dimensions will be flattened.

Parameters

gain (*float*) – An optional scaling factor. Default: `1.0`.

Raises

ValueError – If the dimension of input tensor is less than 2.

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, Orthogonal
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(Orthogonal(gain=2.), [2, 3, 4], mindspore.float32))
>>> w2 = Parameter(initializer('orthogonal', [2, 3, 4], mindspore.float32))
```

class mindspore.common.initializer.**Sparse**(*sparsity*, *sigma=0.01*)

Generates a 2 dimension sparse matrix array in order to initialize a tensor. The non-zero positions will be filled with the value sampled from the normal distribution $N(0, sigma)$.

Parameters

- **sparsity** (*float*) – The fraction of elements being set to zero in each column.
- **sigma** (*float*) – The standard deviation of the normal distribution. Default: `0.01`.

Raises

ValueError – If the dimension of input tensor is not equal to 2.

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, Sparse
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(Sparse(sparsity=0.1, sigma=0.01), [5, 8], mindspore.float32))
```

class mindspore.common.initializer.**TruncatedNormal**(*sigma=0.01*, *mean=0.0*, *a=- 2.0*, *b=2.0*)

Generates an array with values sampled from Truncated Normal distribution in order to initialize a tensor.

Parameters

- **sigma** (*float*) – The standard deviation of Truncated Normal distribution. Default: `0.01`.
- **mean** (*float*) – The mean of Truncated Normal distribution. Default: `0.0`.
- **a** (*float*) – The lower bound of the truncated interval. Default: `-2.0`.
- **b** (*float*) – The upper bound of the truncated interval. Default: `2.0`.

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, TruncatedNormal
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(TruncatedNormal(), [1, 2, 3], mindspore.float32))
>>> w2 = Parameter(initializer('truncatedNormal', [1, 2, 3], mindspore.float32))
```

class mindspore.common.initializer.**Uniform**(*scale=0.07*)

Generates an array with values sampled from Uniform distribution $U(-\text{scale}, \text{scale})$ in order to initialize a tensor.

Parameters

scale (*float*) – The bound of the Uniform distribution. Default: `0.07`.

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, Uniform
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(Uniform(), [1, 2, 3], mindspore.float32))
>>> w2 = Parameter(initializer('uniform', [1, 2, 3], mindspore.float32))
```

class mindspore.common.initializer.**VarianceScaling**(*scale=1.0*, *mode='fan_in'*, *distribution='truncated_normal'*)

Generates an random array with scaling in order to initialize a tensor.

When *distribution* is 'truncated_normal' or 'untruncated_normal', the value will be sampled from truncated or untruncated normal distribution with a mean of 0 and a scaled standard deviation $stddev = \sqrt{\frac{scale}{n}}$.

n will be the number of input units if *mode* is `'fan_in'`, while n will be the number of output units if *mode* is `'fan_out'`. n will be the average of `'fan_in'` and `'fan_out'` if *mode* is `'fan_avg'`.

When *distribution* is `'uniform'`, the value will be sampled from a uniform distribution within the limit of $[-\sqrt{\frac{3*scale}{n}}, \sqrt{\frac{3*scale}{n}}]$.

Parameters

- **scale** (*float*) –The scaling factor. Default: `1.0`.
- **mode** (*str*) –Should be `'fan_in'`, `'fan_out'` or `'fan_avg'`. Default: `'fan_in'`.
- **distribution** (*str*) –The type of distribution chose to sample values. It should be `'uniform'`, `'truncated_normal'` or `'untruncated_normal'`. Default: `'truncated_normal'`.

Raises

- **ValueError** –If *scale* is not greater than 0.
- **ValueError** –If *mode* is not `'fan_in'`, `'fan_out'` or `'fan_avg'`.
- **ValueError** –If *distribution* is not `'uniform'`, `'truncated_normal'` or `'untruncated_normal'`.

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, VarianceScaling
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(VarianceScaling(scale=1.0, mode='fan_out',
...                                            distribution='untruncated_normal'), [2, 3],␣
↪mindspore.float32))
>>> w2 = Parameter(initializer('varianceScaling', [2, 3], mindspore.float32))
```

class mindspore.common.initializer.**XavierNormal**(*gain=1*)

Generates an array with values sampled from Xavier normal distribution $N(0, \text{sigma}^2)$ in order to initialize a tensor, where

$$sigma = gain * \sqrt{\frac{2}{n_{in} + n_{out}}}$$

where $gain$ is an optional scaling factor, n_{in} is the number of input units in the weight tensor, n_{out} is the number of output units in the weight tensor.

Parameters

gain (*float*) –An optional scaling factor. Default: `1`.

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, XavierNormal
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(XavierNormal(), [1, 2, 3], mindspore.float32))
>>> w2 = Parameter(initializer('xavier_normal', [1, 2, 3], mindspore.float32))
```

class mindspore.common.initializer.**XavierUniform**(*gain=1*)

Generates an array with values sampled from Xavier uniform distribution $U(-\text{boundary}, \text{boundary})$ in order to initialize a tensor, where

$$boundary = gain * \sqrt{\frac{6}{n_{in} + n_{out}}}$$

where $gain$ is an optional scaling factor. n_{in} is the number of input units in the weight tensor, n_{out} is the number of output units in the weight tensor.

For details of XavierUniform algorithm, please check http://proceedings.mlr.press/v9/glorot10a.html.

Parameters

gain (*float*) –An optional scaling factor. Default: `1`.

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, XavierUniform
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(XavierUniform(), [1, 2, 3], mindspore.float32))
>>> w2 = Parameter(initializer('xavier_uniform', [1, 2, 3], mindspore.float32))
```

class mindspore.common.initializer.**Zero**(***kwargs*)

Generates an array with constant value of zero in order to initialize a tensor.

Examples

```
>>> import mindspore
>>> from mindspore.common.initializer import initializer, Zero
>>> from mindspore import Parameter
>>> w1 = Parameter(initializer(Zero(), [1, 2, 3], mindspore.float32))
>>> w2 = Parameter(initializer('zeros', [1, 2, 3], mindspore.float32))
```

mindspore.common.initializer.**initializer**(*init*, *shape=None*, *dtype=mstype.float32*)

Create and initialize a tensor.

Parameters

- **init** (*Union[Tensor, str, Initializer, numbers.Number]*) – Initialize value.
  - *Tensor*: The tensor will be called to initialize tensor.
  - *str*: The *init* should be the alias of the class inheriting from *Initializer* and the corresponding class will be called in practice. The value of *init* can be `"normal"`, `"ones"` or `"zeros"`, etc.
  - *Initializer*: The *init* should be the class inheriting from *Initializer* to initialize tensor.
  - *numbers.Number*: The *Constant* will be called to initialize tensor.
- **shape** (*Union[tuple, list, int]*) – The shape of the initialized tensor. Default: `None` .
- **dtype** (*mindspore.dtype*) – The type of data in initialized tensor. Default: `mstype.float32` .

Returns

Returns a Tensor with the shape specified by the input *shape*. If *shape* is `None`, the returned Tensor will have the same shape as `init`.

Raises

- **TypeError** – The type of the argument 'init' is not correct.
- **ValueError** – The shape of the tensor which is passed through 'init' is not the same as that passed by 'shape'.

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore.common.initializer import initializer, One
>>> from mindspore import Parameter
>>> data = Tensor(np.zeros([1, 2, 3]), mindspore.float32)
>>> w1 = Parameter(initializer(data, [1, 2, 3], mindspore.float32))
>>> w2 = Parameter(initializer('ones', [1, 2, 3], mindspore.float32))
>>> w3 = Parameter(initializer(One(), [1, 2, 3], mindspore.float32))
>>> w4 = Parameter(initializer(0, [1, 2, 3], mindspore.float32))
```

CHAPTER

SIX

MINDSPORE.AMP

6.1 Loss Scale

mindspore.amp.LossScaler	Loss scaler abstract class when using mixed precision.
mindspore.amp.DynamicLossScaler	Manager for dynamically adjusting the loss scaling factor.
mindspore.amp.StaticLossScaler	Static Loss scale class.
mindspore.amp.LossScaleManager	Loss scale (Magnification factor of gradients when mix precision is used) manager abstract class when using mixed precision.
mindspore.amp.DynamicLossScaleManager	Loss scale(Magnification factor of gradients when mix precision is used) manager with loss scale dynamically adjusted, inherits from *mindspore.amp.LossScaleManager*.
mindspore.amp.FixedLossScaleManager	Loss scale (Magnification factor of gradients when mix precision is used) manager with a fixed loss scale value, inherits from *mindspore.amp.LossScaleManager*.

6.1.1 mindspore.amp.LossScaler

class mindspore.amp.**LossScaler**

Loss scaler abstract class when using mixed precision.

Derived class needs to implement all of its methods. During training, *scale* and *unscale* is used to scale and unscale the loss value and gradients to avoid overflow, *adjust* is used to update the loss scale value.

For more information, refer to the tutorials.

> **Warning:** This is an experimental API that is subject to change or deletion.

Examples

```
>>> from mindspore.amp import LossScaler, _grad_scale_map, _grad_unscale_map
>>> from mindspore import ops, Parameter, Tensor
>>> from mindspore.common import dtype as mstype
>>>
>>> class MyLossScaler(LossScaler):
...     def __init__(self, scale_value):
...         self.scale_value = Parameter(Tensor(scale_value, dtype=mstype.float32), name=
↪"scale_value")
```

(continues on next page)

(continued from previous page)

```
...
...     def scale(self, inputs):
...         inputs = mutable(inputs)
...         return _grad_scale_map(self.scale_value, inputs)
...
...     def unscale(self, inputs):
...         inputs = mutable(inputs)
...         return _grad_unscale_map(self.scale_value, inputs)
...
...     def adjust(self, grads_finite):
...         scale_mul_factor = self.scale_value * self.scale_factor
...         scale_value = ops.select(grads_finite, scale_mul_factor, self.scale_value)
...         ops.assign(self.scale_value, scale_value)
...         return True
>>>
>>> loss_scaler = MyLossScaler(1024)
```

abstract adjust(*grads_finite*)

Adjust the *scale_value* dependent on whether grads are finite.

Parameters

grads_finite (Tensor) – a scalar bool Tensor indicating whether the grads are finite.

abstract scale(*inputs*)

Scaling inputs by *scale_value*.

Parameters

inputs (*Union(Tensor, tuple(Tensor))*) – the input loss value or gradients.

abstract unscale(*inputs*)

Unscaling inputs by *scale_value*.

Parameters

inputs (*Union(Tensor, tuple(Tensor))*) – the input loss value or gradients.

6.1.2 mindspore.amp.DynamicLossScaler

class mindspore.amp.**DynamicLossScaler**(*scale_value*, *scale_factor*, *scale_window*)

Manager for dynamically adjusting the loss scaling factor.

Dynamic loss scaling tries to determine the largest loss scale value that will keep gradients finite. It does this by increasing the loss scale every *scale_window* steps by *factor* if the grads remain finite, otherwise it reduces the loss scale by *1 / factor* and resets the counter.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **scale_value** (*Union(float, int)*) – The initial loss scale value.
- **scale_factor** (*int*) – The scale factor.
- **scale_window** (*int*) – Maximum continuous training steps that do not have overflow to increase the loss scale.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import amp, Tensor
>>> import numpy as np
>>> loss_scaler = amp.DynamicLossScaler(scale_value=2**10, scale_factor=2, scale_window=1)
>>> grads = (Tensor(np.array([np.log(-1), 1.0]), mindspore.float16),
...              Tensor(np.array([0.2]), mindspore.float16))
>>> unscaled_grads = loss_scaler.unscale(grads)
>>> grads_finite = amp.all_finite(unscaled_grads)
>>> loss_scaler.adjust(grads_finite)
True
>>> print(loss_scaler.scale_value.asnumpy())
512.0
```

adjust(*grads_finite*)

Adjust the *scale_value* dependent on whether grads are finite.

Parameters

grads_finite (Tensor) – a scalar bool Tensor indicating whether the grads are finite.

Tutorial Examples:

- Automatic Mix Precision - Loss Scaling

scale(*inputs*)

Scaling inputs by *scale_value*.

Parameters

inputs (*Union(Tensor, tuple(Tensor))*) – the input loss value or gradients.

Returns

Union(Tensor, tuple(Tensor)), the scaled value.

Tutorial Examples:

- Automatic Mix Precision - Loss Scaling

unscale(*inputs*)

Unscaling inputs by *scale_value*.

Parameters

inputs (*Union(Tensor, tuple(Tensor))*) – the input loss value or gradients.

Returns

Union(Tensor, tuple(Tensor)), the unscaled value.

Tutorial Examples:

- Automatic Mix Precision - Loss Scaling

6.1.3 mindspore.amp.StaticLossScaler

class mindspore.amp.**StaticLossScaler**(*scale_value*)

Static Loss scale class.

Scales and unscales loss or gradients by a fixed constant.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

scale_value (*Union(float, int)*) – The initial loss scale value.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import amp, Tensor
>>> import numpy as np
>>> loss_scaler = amp.StaticLossScaler(scale_value=2**10)
>>> loss_value = Tensor([1.], mindspore.float32)
>>> scaled_loss_value = loss_scaler.scale(loss_value)
>>> print(scaled_loss_value)
[1024.]
>>> grads = (Tensor(np.array([1.5, 1.0]), mindspore.float16),
...          Tensor(np.array([1.2]), mindspore.float16))
>>> unscaled_grads = loss_scaler.unscale(grads)
>>> print(unscaled_grads)
(Tensor(shape=[2], dtype=Float16, value= [ 1.4648e-03,  9.7656e-04]),
Tensor(shape=[1], dtype=Float16, value= [ 1.1721e-03]))
```

adjust(*grads_finite*)

Adjust *scale_value* in *LossScaler*. *scale_value* is fixed in *StaticLossScaler*, so this method return False directly.

Parameters

grads_finite (Tensor) – a scalar bool Tensor indicating whether the grads are finite.

scale(*inputs*)

Scaling inputs by *scale_value*.

Parameters

inputs (*Union(Tensor, tuple(Tensor))*) – the input loss value or gradients.

Returns

Union(Tensor, tuple(Tensor)), the scaled value.

unscale(*inputs*)

Unscaling inputs by *scale_value*.

Parameters

inputs (*Union(Tensor, tuple(Tensor))*) – the input loss value or gradients.

Returns

Union(Tensor, tuple(Tensor)), the unscaled value.

6.1.4 mindspore.amp.LossScaleManager

class mindspore.amp.**LossScaleManager**

Loss scale (Magnification factor of gradients when mix precision is used) manager abstract class when using mixed precision.

Derived class needs to implement all of its methods. *get_loss_scale* is used to get current loss scale value. *update_loss_scale* is used to update loss scale value, *update_loss_scale* will be called during the training. *get_update_cell* is used to get the instance of *mindspore.nn.Cell* that is used to update the loss scale, the instance will be called during the training. Currently, the *get_update_cell* is mostly used.

For example, *mindspore.amp.FixedLossScaleManager* and *mindspore.amp.DynamicLossScaleManager*.

get_loss_scale()

Get the value of loss scale, which is the amplification factor of the gradients.

get_update_cell()

Get the instance of *mindspore.nn.Cell* that is used to update the loss scale.

update_loss_scale(*overflow*)

Update the loss scale value according to the status of *overflow*.

Parameters

overflow (*bool*) – Whether the overflow occurs during the training.

6.1.5 mindspore.amp.DynamicLossScaleManager

class mindspore.amp.**DynamicLossScaleManager**(*init_loss_scale=2 ** 24*, *scale_factor=2*, *scale_window=2000*)

Loss scale(Magnification factor of gradients when mix precision is used) manager with loss scale dynamically adjusted, inherits from *mindspore.amp.LossScaleManager*.

Parameters

- **init_loss_scale** (*float, optional*) – Initialize loss scale. Default: `2 ** 24`.
- **scale_factor** (*int, optional*) – Coefficient of increase and decrease. Default: `2`.
- **scale_window** (*int, optional*) – Maximum continuous normal steps when there is no overflow. Default: `2000`.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import amp, nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_scale_manager = amp.DynamicLossScaleManager()
>>> optim = nn.Momentum(params=net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> model = ms.Model(net, loss_scale_manager=loss_scale_manager, optimizer=optim)
```

get_drop_overflow_update()
Whether to drop optimizer update for current step when there is an overflow.

Returns

bool, always True.

get_loss_scale()
Get the current loss scale value.

Returns

float, *loss_scale* value.

get_update_cell()
Returns the instance of *mindspore.nn.Cell* that is used to update the loss scale which will be called at *mindspore.nn.TrainOneStepWithLossScaleCell*.

Returns

mindspore.nn.DynamicLossScaleUpdateCell.

update_loss_scale(*overflow*)
Update the loss scale value according to the status of *overflow*. If overflow occurs, decrease loss scale per *scale_window*, otherwise, increase the loss scale.

Parameters

overflow (*bool*) –Whether it overflows.

6.1.6 mindspore.amp.FixedLossScaleManager

class mindspore.amp.**FixedLossScaleManager**(*loss_scale=128.0*, *drop_overflow_update=True*)
Loss scale (Magnification factor of gradients when mix precision is used) manager with a fixed loss scale value, inherits from *mindspore.amp.LossScaleManager*.

Parameters

- **loss_scale** (*float, optional*) –Magnification factor of gradients. Note that if *drop_overflow_update* is set to `False` , the value of *loss_scale* in optimizer should be set to the same as here. Default: `128.0` .
- **drop_overflow_update** (*bool, optional*) –Whether to execute optimizer if there is an overflow. If `True` , the optimizer will not executed when overflow occurs. Default: `True` .

Examples

```
>>> import mindspore as ms
>>> from mindspore import amp, nn
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_scale = 1024.0
>>> loss_scale_manager = amp.FixedLossScaleManager(loss_scale, False)
>>> optim = nn.Momentum(params=net.trainable_params(), learning_rate=0.1, momentum=0.9, loss_
↪scale=loss_scale)
>>> model = ms.Model(net, loss_scale_manager=loss_scale_manager, optimizer=optim)
```

get_drop_overflow_update()
Get *drop_overflow_update*, whether to drop optimizer update for current step when there is an overflow.

Returns

bool, *drop_overflow_update* value.

get_loss_scale()
Get loss scale value.

Returns

bool, *loss_scale* value.

get_update_cell()
Returns the instance of *mindspore.nn.Cell* that used to update the loss scale which will be called at *mindspore.nn.TrainOneStepWithLossScaleCell*. As the loss scale is fixed in this class, the instance will do nothing.

Returns

None or *mindspore.nn.FixedLossScaleUpdateCell*. Instance of *mindspore.nn.FixedLossScaleUpdateCell* when *drop_overflow_update* is `True`. None when *drop_overflow_update* is `False`.

update_loss_scale(*overflow*)
Update loss scale value. The interface at *mindspore.amp.FixedLossScaleManager* will do nothing.

Parameters

overflow (*bool*) –Whether it overflows.

6.2 Dtype Autocast

mindspore.amp.auto_mixed_precision	Returns a network processed with auto mixed precision.
mindspore.amp.build_train_network	Build the mixed precision training cell automatically.
mindspore.amp.custom_mixed_precision	When the *white_list* is provided, primitives and cells in *white_list* will perform the precision conversion.
mindspore.amp.get_black_list	Provide a copy of internal black list used by auto mixed precision with *amp_level* set to `O2`.
mindspore.amp.get_white_list	Provide a copy of internal white list used by auto mixed precision with *amp_level* set to `O1`.

6.2.1 mindspore.amp.auto_mixed_precision

mindspore.amp.**auto_mixed_precision**(*network*, *amp_level='O0'*, *dtype=mstype.float16*)

Returns a network processed with auto mixed precision.

This interface will automatically perform mixed-precision processing on the input network, and the cells and operators in the processed network will add precision conversion operations to calculate with lower precision: `mstype.float16` or `mstype.bfloat16` . Inputs and parameters of cells and operators are converted to lower precision float, and calculation results are converted back to full precision float, i.e. `mstype.float32` .

The *amp_level* and its corresponding lists determine which cells and operators are converted.

When *amp_level* is set to `O0`, no cells and operators are converted.

When *amp_level* is set to `O1`, cells and operators in whitelist will be converted to lower precision operations. For details on whitelist, refer to *mindspore.amp.get_white_list()*.

When *amp_level* is set to `O2`, cells in blacklist will maintain full precision, and cells outside the list will be converted to low precision. For details on blacklist, refer to *mindspore.amp.get_black_list()*.

When *amp_level* is set to `O3`, all cells will be converted to low precision.

When *amp_level* is set to `auto`, operators in *auto_whitelist* will be converted to lower precision operations, operators in *auto_blacklist* will be converted to full precision operations, operators in *promote_list* will be converted to the higher accuracy float type of the operator inputs, and operators not listed will run in the type defined by their inputs.

Operators in *auto_whitelist* are:

`Conv2D`, `Conv3D`, `Conv2DTranspose`, `Conv3DTranspose`, `Convolution`, `MatMul`, `MatMulExt`, `BatchMatMul`, `BatchMatMulExt`, `PReLU`, `Einsum`, `Dense`, `Addmm`

Operators in *auto_blacklist* are:

`Pow`, `ACos`, `Asin`, `Cosh`, `Erfinv`, `Exp`, `Expm1`, `Log`, `Log1p`, `Reciprocal`, `Rsqrt`, `Sinh`, `Tan`, `Softplus`, `SoftplusExt`, `LayerNorm`, `LayerNormExt`, `BatchNorm`, `BatchNormExt`, `GroupNorm`, `KLDivLoss`, `SmoothL1Loss`, `MultilabelMarginLoss`, `SoftMarginLoss`, `TripletMarginLoss`, `MultiMarginLoss`, `BCEWithLogitsLoss`, `Pdist`, `Cdist`, `Renorm`, `ReduceProd`, `Softmax`, `LogSoftmax`, `CumProd`, `CumSum`, `CumsumExt`, `ProdExt`, `SumExt`, `Norm`, `MSELossExt`

Operators in *promote_list* are:

`Addcdiv`, `Addcmul`, `Cross`, `_PyboostCrossPrim`, `Dot`, `GridSampler2D`, `GridSampler3D`, `BiasAdd`, `AddN`, `Concat`

For details on automatic mixed precision, refer to Automatic Mix Precision .

Note:

- Repeatedly calling mixed-precision interfaces, such as *custom_mixed_precision* and *auto_mixed_precision*, can result in a larger network hierarchy and slower performance.
- If interfaces like *Model* and *build_train_network* is used to train the network which is converted by mixed-precision interfaces such as *custom_mixed_precision* and *auto_mixed_precision*, *amp_level* need to be configured to `O0` to avoid the duplicated accuracy conversion.
- When *amp_level* is set to `auto`, the output of the network may be lower precision. In this case, you may need to manually convert the type to avoid type inconsistency errors of the loss function.
- When *amp_level* is set to `auto`, and cells in the network are configured with *to_float*, the accuracy specified by *to_float* takes effect first.

Warning: `auto` level of *amp_level* is an experimental API that is subject to change or deletion.

Parameters

- **network** (*Union[Cell, function]*) –Definition of the network. Function type is supported only when *amp_level* is set to `auto`.
- **amp_level** (*str*) –Supports ["O0", "O1", "O2", "O3", "auto"]. Default: `"O0"`.
  - "O0": Do not change.
  - "O1": Convert cells and operators in whitelist to lower precision operations, and keep full precision operations for the rest.
  - "O2": Keep full precision operations for cells and operators in blacklist, and convert the rest to lower precision operations.
  - "O3": Cast network to lower precision.
  - "auto": Operators in *auto_whitelist* will be converted to lower precision operations, operators in *auto_blacklist* will be converted to full precision, operators in *promote_list* will be converted to the higher accuracy float type of the operator inputs, and operators not listed will run in the type defined by their inputs.
- **dtype** (*Type*) –The type used in lower precision calculations, can be `mstype.float16` or `mstype.bfloat16`, default: `mstype.float16`.

Raises

- **TypeError** –If *network* is not a Cell or a function.
- **ValueError** –If *dtype* is not one of `mstype.float16`, `mstype.bfloat16`.
- **ValueError** –If *amp_level* is not within the supported range.

Examples

```
>>> from mindspore import amp
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> network = LeNet5()
>>> amp_level = "O1"
>>> net = amp.auto_mixed_precision(network, amp_level)
```

6.2.2 mindspore.amp.build_train_network

`mindspore.amp.`**build_train_network**(*network*, *optimizer*, *loss_fn=None*, *level='O0'*, *boost_level='O0'*, ***kwargs*)

Build the mixed precision training cell automatically.

Note:

- After using *custom_mixed_precision* or *auto_mixed_precision* for precision conversion, it is not supported to perform the precision conversion again. If *build_train_network* is used to train a converted network, *level* need to be configured to `O0` to avoid the duplicated accuracy conversion.

Parameters

- **network** (Cell) −Definition of the network.
- **optimizer** (*mindspore.nn.Optimizer*) −Define the optimizer to update the Parameter.
- **loss_fn** (*Union[None, Cell]*) −Define the loss function. If None, the *network* should have the loss inside. Default: None .
- **level** (*str*) −Supports ['O0', 'O1', 'O2', 'O3', 'auto']. Default: 'O0' .

  For details on amp level, refer to *mindspore.amp.auto_mixed_precision()*.

  Property of *keep_batchnorm_fp32*, *cast_model_type* and *loss_scale_manager* determined by *level* setting may be overwritten by settings in *kwargs*.
- **boost_level** (*str*) −Option for argument *level* in *mindspore.boost* , level for boost mode training. Supports ['O0', 'O1', 'O2']. Default: 'O0' .
  - 'O0': Do not change.
  - 'O1': Enable the boost mode, the performance is improved by about 20%, and the accuracy is the same as the original accuracy.
  - 'O2': Enable the boost mode, the performance is improved by about 30%, and the accuracy is reduced by less than 3%.

  If 'O1' or 'O2' mode is set, the boost related library will take effect automatically.
- **cast_model_type** (*mindspore.dtype*) −Supports *mstype.float16* or *mstype.float32* . If set, the network will be casted to *cast_model_type* (*mstype.float16* or *mstype.float32*), but not to be casted to the type determined by *level* setting.
- **keep_batchnorm_fp32** (*bool*) −Keep Batchnorm run in *float32* when the network is set to cast to *float16* . If set, the *level* setting will take no effect on this property.
- **loss_scale_manager** (*Union[None, LossScaleManager]*) −If not None, must be subclass of *mindspore.amp.LossScaleManager* for scaling the loss. If set, the *level* setting will take no effect on this property.

Raises

ValueError −If device is CPU, property *loss_scale_manager* is not *None* or *mindspore.amp.FixedLossScaleManager* (with property *drop_overflow_update=False*).

Examples

```
>>> from mindspore import amp, nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> network = LeNet5()
>>> net_loss = nn.SoftmaxCrossEntropyWithLogits(reduction="mean")
>>> net_opt = nn.Momentum(network.trainable_params(), learning_rate=0.01, momentum=0.9)
>>> amp_level="O3"
>>> net = amp.build_train_network(network, net_opt, net_loss, amp_level)
```

6.2.3 mindspore.amp.custom_mixed_precision

mindspore.amp.**custom_mixed_precision**(*network*, *, *white_list=None*, *black_list=None*, *dtype=mstype.float16*)

When the *white_list* is provided, primitives and cells in *white_list* will perform the precision conversion. When the *black_list* is provided, cells that are not in *black_list* will perform the pereision conversion. Only one of *white_list* and *black_list* should be provided.

Note:

- Repeatedly calling mixed-precision interfaces, such as *custom_mixed_precision* and *auto_mixed_precision*, can result in a larger network hierarchy and slower performance.
- If interfaces like *Model* and *build_train_network* is used to train the network which is converted by mixed-precision interfaces such as *custom_mixed_precision* and *auto_mixed_precision*, *amp_level* or *level* need to be configured to `O0` to avoid the duplicated accuracy conversion.
- Primitives for blacklist is not support yet.

Parameters

network (`Cell`) – Definition of the network.

Keyword Arguments

- **white_list** (*list[Primitive, Cell], optional*) – White list of custom mixed precision. Defaults: `None` , means white list is not used.
- **black_list** (*list[Cell], optional*) – Black list of custom mixed precision. Defaults: `None` , means black list is not used.
- **dtype** (*Type*) – The type used in lower precision calculations, can be `mstype.float16` or `mstype.bfloat16` , default: `mstype.float16` .

Returns

network (Cell), A network supporting mixed precision.

Raises

- **TypeError** – The network type is not Cell.
- **ValueError** – Neither *white_list* nor *black_list* is provided.
- **ValueError** – If *dtype* is not one of `mstype.float16` , `mstype.bfloat16` .
- **ValueError** – Both *white_list* and *black_list* are provided.

Examples

```
>>> from mindspore import amp, nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> custom_white_list = amp.get_white_list()
>>> custom_white_list.append(nn.Flatten)
>>> net = amp.custom_mixed_precision(net, white_list=custom_white_list)
```

6.2.4 mindspore.amp.get_black_list

mindspore.amp.**get_black_list**()

Provide a copy of internal black list used by auto mixed precision with *amp_level* set to `O2`.

The current built-in blacklist contents are:

[*mindspore.nn.BatchNorm1d*, *mindspore.nn.BatchNorm2d*, *mindspore.nn.BatchNorm3d*, *mindspore.nn.LayerNorm*]

Returns

list, A copy of internal black list.

Examples

```
>>> from mindspore import amp
>>> black_list = amp.get_black_list()
>>> print(black_list)
[<class 'mindspore.nn.layer.normalization.BatchNorm1d'>, <class 'mindspore.nn.layer.
↪normalization.BatchNorm2d'>,
 <class 'mindspore.nn.layer.normalization.BatchNorm3d'>, <class 'mindspore.nn.layer.
↪normalization.LayerNorm'>]
```

6.2.5 mindspore.amp.get_white_list

mindspore.amp.**get_white_list**()

Provide a copy of internal white list used by auto mixed precision with *amp_level* set to `O1`.

The current built-in whitelist contents are:

[*mindspore.nn.Conv1d*, *mindspore.nn.Conv2d*, *mindspore.nn.Conv3d*, *mindspore.nn.Conv1dTranspose*, *mindspore.nn.Conv2dTranspose*, *mindspore.nn.Conv3dTranspose*, *mindspore.nn.Dense*, *mindspore.nn.LSTMCell*, *mindspore.nn.RNNCell*, *mindspore.nn.GRUCell*, *mindspore.ops.Conv2D*, *mindspore.ops.Conv3D*, *mindspore.ops.Conv2DTranspose*, *mindspore.ops.Conv3DTranspose*, *mindspore.ops.MatMul*, *mindspore.ops.BatchMatMul*, *mindspore.ops.PReLU*, *mindspore.ops.ReLU*, *mindspore.ops.Ger*]

Returns

list, A copy of internal white list.

Examples

```
>>> from mindspore import amp
>>> white_list = amp.get_white_list()
>>> print(white_list)
[<class 'mindspore.nn.layer.conv.Conv1d'>, <class 'mindspore.nn.layer.conv.Conv2d'>,

6.3 Overflow Detection

mindspore.amp.all_finite	Returns a scalar Tensor indicating whether the inputs are finite.

6.3.1 mindspore.amp.all_finite

mindspore.amp.**all_finite**(*inputs*)

Returns a scalar Tensor indicating whether the inputs are finite.

> **Warning:** This is an experimental API that is subject to change or deletion.
>
> The interface must be used in whole network training scenario to detect whether grads are finite, and the results may be different on different device targets.

Parameters

inputs (*Union(tuple(Tensor), list(Tensor))*) – a iterable Tensor.

Returns

Tensor, a scalar Tensor and the dtype is bool.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import amp, Tensor
>>> import numpy as np
>>> x = (Tensor(np.array([np.log(-1), 1, np.log(0)])), Tensor(np.array([1.0])))
>>> output = amp.all_finite(x)
```

Tutorial Examples:

- Automatic Mix Precision - Loss Scaling

CHAPTER

SEVEN

MINDSPORE.TRAIN

7.1 Model

mindspore.train.Model	High-Level API for training or inference.

7.1.1 mindspore.train.Model

class mindspore.train.**Model**(*network*, *loss_fn=None*, *optimizer=None*, *metrics=None*, *eval_network=None*, *eval_indexes=None*, *amp_level='O0'*, *boost_level='O0'*, ***kwargs*)

High-Level API for training or inference.

Model groups layers into an object with training and inference features based on the arguments.

Note:

- If use mixed precision functions, need to set parameter *optimizer* at the same time, otherwise mixed precision functions do not take effect. When uses mixed precision functions, *global_step* in optimizer may be different from *cur_step_num* in Model.
- After using *custom_mixed_precision* or *auto_mixed_precision* for precision conversion, it is not supported to perform the precision conversion again. If *Model* is used to train a converted network, *amp_level* need to be configured to `O0` to avoid the duplicated accuracy conversion.

Parameters

- **network** (`Cell`) −A training or testing network.
- **loss_fn** (`Cell`) −Objective function. If *loss_fn* is None, the *network* should contain the calculation of loss. Default: `None` .
- **optimizer** (`Cell`) −Optimizer for updating the weights. If *optimizer* is None, the *network* needs to do backpropagation and update weights. Default: `None` .
- **metrics** (*`Union[dict, set]`*) −A Dictionary or a set of metrics for model evaluation. eg: {'accuracy', 'recall'}. Default: `None` .
- **eval_network** (`Cell`) −Network for evaluation. If not defined, *network* and *loss_fn* would be wrapped as *eval_network* . Default: `None` .
- **eval_indexes** (*`list`*) −It is used when eval_network is defined. If *eval_indexes* is None by default, all outputs of the *eval_network* would be passed to metrics. If *eval_indexes* is set, it must contain three elements: the positions of loss value, predicted value and label in outputs of the *eval_network*. In this case, the loss value will be passed

to the *Loss* metric, the predicted value and label will be passed to other metrics. `mindspore.train.Metric.set_indexes()` is recommended instead of *eval_indexes*. Default: `None` .

- **amp_level** (*str*) –Option for argument *level* in `mindspore.amp.build_train_network()`, level for mixed precision training. Supports ["O0", "O1", "O2", "O3", "auto"]. Default: `"O0"` .

  For details on *amp_level* , refer to `mindspore.amp.auto_mixed_precision()`.

  The BatchNorm strategy can be changed by *keep_batchnorm_fp32* settings in *kwargs*. *keep_batchnorm_fp32* must be a bool. The loss scale strategy can be changed by *loss_scale_manager* setting in *kwargs*. *loss_scale_manager* should be a subclass of `mindspore.amp.LossScaleManager`.

- **boost_level** (*str*) –Option for argument *level* in *mindspore.boost*, level for boost mode training. Supports ["O0", "O1", "O2"]. Default: `"O0"` .

  – "O0": Do not change.

  – "O1": Enable the boost mode, the performance is improved by about 20%, and the accuracy is the same as the original accuracy.

  – "O2": Enable the boost mode, the performance is improved by about 30%, and the accuracy is reduced by less than 3%.

  If you want to config boost mode by yourself, you can set boost_config_dict as *boost.py*. In order for this function to work, you need to set the parameter *optimizer*, along with at least one of the parameter *eval_network* or performance *metrics*.

  Notice: The current optimization enabled by default only applies to some networks, and not all networks can obtain the same benefits. It is recommended to enable this function on the Graph mode + Ascend platform, and for better acceleration, refer to `mindspore.boost.AutoBoost` to configure boost_config_dict.

Examples

```
>>> from mindspore import nn
>>> from mindspore.train import Model
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optim = nn.Momentum(params=net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim, metrics=None)
>>> model.train_network
>>> model.predict_network
>>> model.eval_network
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> model.train(2, dataset)
```

build(*train_dataset=None*, *valid_dataset=None*, *sink_size=- 1*, *epoch=1*, *sink_mode=True*)

Build computational graphs and data graphs with the sink mode.

> **Warning:** This is an experimental API that is subject to change or deletion.

Note: The interface builds the computational graphs, when the interface is executed first, 'Model.train' only performs the

graphs execution. Pre-build process only supports *GRAPH_MODE* and *Ascend* target currently. It only supports dataset sink mode.

Parameters

- **train_dataset** (*Dataset*) – A training dataset iterator. If *train_dataset* is defined, training graphs will be built. Default: `None` .
- **valid_dataset** (*Dataset*) – An evaluating dataset iterator. If *valid_dataset* is defined, evaluation graphs will be built, and *metrics* in *Model* can not be None. Default: `None` .
- **sink_size** (*int*) – Control the number of steps for each sinking. Default: `-1` .
- **epoch** (*int*) – Control the training epochs. Default: `1` .
- **sink_mode** (*bool*) – Determines whether to pass the data through dataset channel. Default: `True` .

Examples

```
>>> from mindspore import nn
>>> from mindspore.train import Model
>>> from mindspore.amp import FixedLossScaleManager
>>>
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> loss_scale_manager = FixedLossScaleManager()
>>> optim = nn.Momentum(params=net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim, metrics=None,
...                   loss_scale_manager=loss_scale_manager)
>>> model.build(dataset, epoch=2)
>>> model.train(2, dataset)
```

eval(*valid_dataset*, *callbacks=None*, *dataset_sink_mode=False*)

Evaluation API.

Configure to pynative mode or CPU, the evaluating process will be performed with dataset non-sink mode.

Note: If dataset_sink_mode is True, data will be sent to device. At this point, the dataset will be bound to this model, so the dataset cannot be used by other models. If the device is Ascend, features of data will be transferred one by one. The limitation of data transmission per time is 256M.

The interface builds the computational graphs and then executes the computational graphs. However, when the *Model.build* is executed first, it only performs the graphs execution.

Parameters

- **valid_dataset** (*Dataset*) – Dataset to evaluate the model.
- **callbacks** (*Optional[list(Callback), Callback]*) – List of callback objects or callback object, which should be executed while evaluation. Default: `None` .

- **dataset_sink_mode** (*bool*) –Determines whether to pass the data through dataset channel. Default: `False` .

Returns

Dict, the key is the metric name defined by users and the value is the metrics value for the model in the test mode.

Examples

```
>>> from mindspore import nn
>>> from mindspore.train import Model
>>>
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> model = Model(net, loss_fn=loss, optimizer=None, metrics={'acc'})
>>> acc = model.eval(dataset, dataset_sink_mode=False)
```

property eval_network

Get the model's eval network.

Returns

Object, the instance of evaluate network.

fit(*epoch*, *train_dataset*, *valid_dataset=None*, *valid_frequency=1*, *callbacks=None*, *dataset_sink_mode=False*, *valid_dataset_sink_mode=False*, *sink_size=- 1*, *initial_epoch=0*)

Fit API.

Evaluation process will be performed during training process if *valid_dataset* is provided.

More details please refer to *mindspore.train.Model.train()* and *mindspore.train.Model.eval()*.

Parameters

- **epoch** (*int*) –Total training epochs. Generally, train network will be trained on complete dataset per epoch. If *dataset_sink_mode* is set to True and *sink_size* is greater than 0, each epoch will train *sink_size* steps instead of total steps of dataset. If *epoch* used with *initial_epoch*, it is to be understood as "final epoch".
- **train_dataset** (*Dataset*) –A training dataset iterator. If *loss_fn* is defined, the data and label will be passed to the *network* and the *loss_fn* respectively, so a tuple (data, label) should be returned from dataset. If there is multiple data or labels, set *loss_fn* to None and implement calculation of loss in *network*, then a tuple (data1, data2, data3, ⋯) with all data returned from dataset will be passed to the *network*.
- **valid_dataset** (*Dataset*) –Dataset to evaluate the model. If *valid_dataset* is provided, evaluation process will be performed on the end of training process. Default: `None` .
- **valid_frequency** (*int, list*) –Only relevant if *valid_dataset* is provided. If an integer, specifies how many training epochs to run before a new validation run is performed, e.g. *valid_frequency=2* runs validation every 2 epochs. If a list, specifies the epochs on which to run validation, e.g. *valid_frequency=[1, 5]* runs validation at the end of the 1st, 5th epochs. Default: `1` .
- **callbacks** (*Optional[list[Callback], Callback]*) –List of callback objects or callback object, which should be executed while training. Default: `None` .
- **dataset_sink_mode** (*bool*) –Determines whether to pass the train data through dataset channel. Configure pynative mode or CPU, the training process will be performed with dataset not sink. Default: `False` .

- **valid_dataset_sink_mode** (*bool*) –Determines whether to pass the validation data through dataset channel. Default: `False` .
- **sink_size** (*int*) –Control the number of steps for each sinking. *sink_size* is invalid if *dataset_sink_mode* is False. If sink_size = -1, sink the complete dataset for each epoch. If sink_size > 0, sink sink_size data for each epoch. Default: `-1` .
- **initial_epoch** (*int*) –Epoch at which to start train, it useful for resuming a previous training run. Default: `0` .

Examples

```
>>> from mindspore import nn
>>> from mindspore.train import Model
>>>
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> train_dataset = create_dataset("train")
>>> valid_dataset = create_dataset("test")
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optim = nn.Momentum(params=net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim, metrics={"accuracy"})
>>> model.fit(2, train_dataset, valid_dataset)
```

infer_predict_layout(**predict_data*, *skip_backend_compile=False*)

Generate parameter layout for the predict network when using *AutoParallel(cell)* to enable parallel mode.

Data could be a single tensor or multiple tensors.

Note: Batch data should be put together in one tensor.

Parameters

- **predict_data** (*Union[Tensor, list[Tensor], tuple[Tensor]], optional*) –The predict data, can be a single tensor, a list of tensor, or a tuple of tensor.
- **skip_backend_compile** (*bool*) –Only run the frontend compile process, skip the compile process on the device side. Set this flag to True may lead to recompiling process can not hit cache.

Returns

Dict, Parameter layout dictionary used for load distributed checkpoint. Using as one of input parameters of load_distributed_checkpoint, always.

Raises

RuntimeError –If not in GRAPH_MODE.

Examples

```
>>> import numpy as np
>>> import mindspore.nn as nn
>>> from mindspore import Tensor
>>> from mindspore.train import Model
>>> from mindspore.ops import operations as P
>>> from mindspore import context
>>> from mindspore.communication import init
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>>
>>> class Net(nn.Cell):
>>>     def __init__(self):
>>>         super(Net, self).__init__()
>>>         self.fc1 = nn.Dense(128, 768, activation='relu')
>>>         self.fc2 = nn.Dense(128, 768, activation='relu')
>>>         self.fc3 = nn.Dense(128, 768, activation='relu')
>>>         self.fc4 = nn.Dense(768, 768, activation='relu')
>>>         self.relu4 = nn.ReLU()
>>>         self.relu5 = nn.ReLU()
>>>         self.transpose = P.Transpose()
>>>         self.matmul1 = P.MatMul()
>>>         self.matmul2 = P.MatMul()
>>>
>>>     def construct(self, x):
>>>         q = self.fc1(x)
>>>         k = self.fc2(x)
>>>         v = self.fc3(x)
>>>         k = self.transpose(k, (1, 0))
>>>         c = self.relu4(self.matmul1(q, k))
>>>         s = self.relu5(self.matmul2(c, v))
>>>         s = self.fc4(s)
>>>         return s
>>>
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> init()
>>> inputs = Tensor(np.ones([32, 128]).astype(np.float32))
>>> net = Net()
>>> parallel_net = AutoParallel(net, parallel_mode='semi_auto')
>>> model = Model(parallel_net)
>>> predict_map = model.infer_predict_layout(inputs)
```

infer_train_layout(*train_dataset*, *dataset_sink_mode=True*, *sink_size=-1*)

Generate parameter layout for the train network when using *AutoParallel(cell)* to enable parallel mode.

Only dataset sink mode is supported for now.

> **Warning:** This is an experimental API that is subject to change or deletion.

Note: This is a pre-compile function. The arguments should be the same as model.train() function.

Parameters

- **train_dataset** (*Dataset*) –A training dataset iterator. If there is no loss_fn, a tuple with multiple data

(data1, data2, data3, ···) should be returned and passed to the network. Otherwise, a tuple (data, label) should be returned. The data and label would be passed to the network and loss function respectively.

- **dataset_sink_mode** (*bool*) –Determines whether to pass the data through dataset channel. Configure pynative mode or CPU, the training process will be performed with dataset not sink. Default: `True` .
- **sink_size** (*int*) –Control the number of steps for each sinking. If dataset_sink_mode is False, set sink_size as invalid. If sink_size = -1, sink the complete dataset for each epoch. If sink_size > 0, sink sink_size data for each epoch. Default: `-1` .

Returns

Dict, Parameter layout dictionary used for load distributed checkpoint

Examples

```
>>> # This example should be run with multiple devices. Refer to the tutorial >␣
↪Distributed Training on
>>> # mindspore.cn.
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor, nn
>>> from mindspore.train import Model
>>> from mindspore.communication import init
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>>
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> init()
>>>
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> parallel_net = AutoParallel(net)
>>> loss = nn.SoftmaxCrossEntropyWithLogits()
>>> loss_scale_manager = ms.FixedLossScaleManager()
>>> optim = nn.Momentum(params=net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> model = Model(parallel_net, loss_fn=loss, optimizer=optim, metrics=None,
...                   loss_scale_manager=loss_scale_manager)
>>> layout_dict = model.infer_train_layout(dataset)
```

predict(**predict_data*, *backend=None*, *config=None*)

Generate output predictions for the input samples.

Parameters

- **predict_data** (*Union[Tensor, list[Tensor], tuple[Tensor]], optional*) –The predict data, can be a single tensor, a list of tensor, or a tuple of tensor.
- **backend** (*str*) –Select predict backend, this parameter is an experimental feature and is mainly used for MindSpore Lite cloud-side inference. Default: `None` .
- **config** (*dict, optional*) –The config includes two parts: config_path (configPath, str) and config_item (str, dict). When the config_item is set, its priority is higher than the config_path. Set the ranking table file for inference. The content of the configuration file is as follows:

config_path defines the path of the configuration file, which is used to pass user-defined options during model building. In the following scenarios, users may need to set parameters. For example: "/home/user/config.ini". Default value: `""` , here is the content of the config.ini file:

```
[ascend_context]
rank_table_file = [path_a](storage initial path of the rank table file)
[execution_plan]
[op_name1] = data_type:float16 (operator named op_name1 is set to data type␣
↪float16)
[op_name2] = data_type:float32 (operator named op_name2 is set to data type␣
↪float32)
```

When only the config_path is configured, it is done as follows:

```
config = {"configPath" : "/home/user/config.ini"}
```

When only the config_dict is configured, it is done as follows:

```
config = {"ascend_context" : {"rank_table_file" : "path_b"},
          "execution_plan" : {"op_name1" : "data_type:float16", "op_name2" :
↪"data_type:float32"}}
```

When both the *config_path* and the *config_dict* are configured, it is done as follows:

```
config = {"configPath" : "/home/user/config.ini",
          "ascend_context" : {"rank_table_file" : "path_b"},
          "execution_plan" : {"op_name3" : "data_type:float16", "op_name4" :
↪"data_type:float32"}}
```

Note that both the "configPath" is configured in the config_dict and the config_item, in this case, the path_b in the config_dict takes precedence.

Returns

Tensor, array(s) of predictions.

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore.train import Model
>>>
>>> input_data = Tensor(np.random.randint(0, 255, [1, 1, 32, 32]), mindspore.float32)
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> model = Model(LeNet5())
>>> result = model.predict(input_data)
```

property predict_network

Get the model's predict network.

Returns

Object, the instance of predict network.

train(*epoch*, *train_dataset*, *callbacks=None*, *dataset_sink_mode=False*, *sink_size=- 1*, *initial_epoch=0*)

Training API.

When setting pynative mode or CPU, the training process will be performed with dataset not sink.

Note: If dataset_sink_mode is True, data will be sent to device. If the device is Ascend, features of data will be transferred one by one. The limitation of data transmission per time is 256M.

When dataset_sink_mode is True, the *step_end* method of the instance of Callback will be called at the end of step in PyNative mode, or will be called at the end of epoch in Graph mode.

If dataset_sink_mode is True, dataset will be bound to this model and cannot be used by other models.

If sink_size > 0, each epoch of the dataset can be traversed unlimited times until you get sink_size elements of the dataset. The next epoch continues to traverse from the end position of the previous traversal.

The interface builds the computational graphs and then executes the computational graphs. However, when the *Model.build* is executed first, it only performs the graphs execution.

Parameters

- **epoch** (*int*) –Total training epochs. Generally, train network will be trained on complete dataset per epoch. If *dataset_sink_mode* is set to True and *sink_size* is greater than 0, each epoch will train *sink_size* steps instead of total steps of dataset. If *epoch* used with *initial_epoch*, it is to be understood as "final epoch".
- **train_dataset** (*Dataset*) –A training dataset iterator. If *loss_fn* is defined, the data and label will be passed to the *network* and the *loss_fn* respectively, so a tuple (data, label) should be returned from dataset. If there is multiple data or labels, set *loss_fn* to None and implement calculation of loss in *network*, then a tuple (data1, data2, data3, ⋯) with all data returned from dataset will be passed to the *network*.
- **callbacks** (*Optional[list[Callback], Callback]*) –List of callback objects or callback object, which should be executed while training. Default: `None`.
- **dataset_sink_mode** (*bool*) –Determines whether to pass the data through dataset channel. Configure pynative mode or CPU, the training process will be performed with dataset not sink. Default: `False`.
- **sink_size** (*int*) –Control the number of steps for each sinking. *sink_size* is invalid if *dataset_sink_mode* is False. If sink_size = -1, sink the complete dataset for each epoch. If sink_size > 0, sink sink_size data for each epoch. Default: -1.
- **initial_epoch** (*int*) –Epoch at which to start train, it used for resuming a previous training run. Default: 0.

Examples

```
>>> import mindspore as ms
>>> from mindspore import nn
>>> from mindspore.train import Model
>>>
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> loss_scale_manager = ms.FixedLossScaleManager(1024., False)
>>> optim = nn.Momentum(params=net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim, metrics=None,
...                   loss_scale_manager=loss_scale_manager)
>>> model.train(2, dataset)
```

property train_network
Get the model's train network.

Returns

Object, the instance of train network.

7.2 Callback

mindspore.train.BackupAndRestore	Callback to back up and restore the parameters during training.
mindspore.train.Callback	Abstract base class used to build a Callback class.
mindspore.train.CheckpointConfig	The configuration of model checkpoint.
mindspore.train.EarlyStopping	Stop training when a monitored metric has stopped improving.
mindspore.train.FlopsUtilizationCollector	The FlopsUtilizationCollector interface counts the model utilization information MFU and the hardware utilization information HFU.
mindspore.train.History	Records the network outputs and metrics information into a *History* object.
mindspore.train.LambdaCallback	Callback for creating simple, custom callbacks.
mindspore.train.LearningRateScheduler	Change the learning_rate during training.
mindspore.train.LossMonitor	Monitor the loss in train or monitor the loss and eval metrics in fit.
mindspore.train.TrainFaultTolerance	This callback is used to enable the TFT feature MindIO TFT and will execute TFT operations during training process, such as TFT init, report and exception handle.
mindspore.train.ModelCheckpoint	The checkpoint callback class.
mindspore.train.OnRequestExit	Respond to the user's closing request, exit the training or eval process, and save the checkpoint and mindir.
mindspore.train.ReduceLROnPlateau	Reduce learning rate when the monitor has stopped improving.
mindspore.train.RunContext	Hold and manage information about the model.
mindspore.train.TimeMonitor	Monitor the time in train or eval process.

7.2.1 mindspore.train.BackupAndRestore

class mindspore.train.**BackupAndRestore**(*backup_dir*, *save_freq='epoch'*, *delete_checkpoint=True*)
Callback to back up and restore the parameters during training.

Note: This function can only use in training.

Parameters

- **backup_dir** (*str*) – Path to store and load the checkpoint file.
- **save_freq** (*Union["epoch", int]*) – When set to `"epoch"` the callback saves the checkpoint at the end of each epoch. When set to an integer, the callback saves the checkpoint every *save_freq* epoch. Default: `"epoch"` .
- **delete_checkpoint** (*bool*) – If *delete_checkpoint=True*, the checkpoint will be deleted after training is finished. Default: `True` .

Raises

- **ValueError** –If backup_dir is not str.
- **ValueError** –If save_freq is not "epoch" or int.
- **ValueError** –If delete_checkpoint is not bool.

Examples

```
>>> from mindspore import nn
>>> from mindspore.train import Model, BackupAndRestore, RunContext
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> optim = nn.Momentum(net.trainable_params(), 0.01, 0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim)
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> backup_ckpt = BackupAndRestore("backup")
>>> model.train(10, dataset, callbacks=backup_ckpt)
```

on_train_begin(*run_context*)

Load the backup checkpoint file at the beginning of epoch.

Parameters

run_context (RunContext) –Context of the process running. For more details, please refer to *mindspore.train.RunContext*.

on_train_end(*run_context*)

Deleted checkpoint file at the end of train.

Parameters

run_context (RunContext) –Context of the process running. For more details, please refer to *mindspore.train.RunContext*.

on_train_epoch_end(*run_context*)

Backup checkpoint file at the end of train epoch.

Parameters

run_context (RunContext) –Context of the process running. For more details, please refer to *mindspore.train.RunContext*.

7.2.2 mindspore.train.Callback

class mindspore.train.**Callback**

Abstract base class used to build a Callback class. Callbacks are context managers which will be entered and exited when passing into the Model. You can use this mechanism to do some custom operations.

Each method of Callback class corresponds to a stage in training or eval process, and those methods have the same input *run_context*, which hold context information of the model in training or eval process. When defining a Callback subclass or creating a custom Callback, note that you should override methods with names prefixed with "on_train" or "on_eval", otherwise ValueError will be raised if the custimized Callbacks used in *model.fit*.

When creating a custom Callback, model context information can be obtained in Callback methods by calling *RunContext.original_args()*, which is a dictionary varivable recording current attributes. Users can add custimized attributes to the information. Training process can also be stopped by calling *request_stop* method.

Examples

```
>>> import numpy as np
>>> from mindspore import nn
>>> from mindspore import dataset as ds
>>> from mindspore.train import Model, Callback
>>> class Print_info(Callback):
...     def step_end(self, run_context):
...         cb_params = run_context.original_args()
...         print("step_num: ", cb_params.cur_step_num)
>>>
>>> print_cb = Print_info()
>>> data = {"x": np.float32(np.random.rand(64, 10)), "y": np.random.randint(0, 5, (64,))}
>>> dataset = ds.NumpySlicesDataset(data=data).batch(32)
>>> net = nn.Dense(10, 5)
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> optim = nn.Momentum(net.trainable_params(), 0.01, 0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim)
>>> model.train(1, dataset, callbacks=print_cb)
step_num: 1
step_num: 2
```

begin(*run_context*)

Called once before the network executing. A backwards compatibility alias for *on_train_begin* and *on_eval_begin*.

Note: *begin* is deprecated and will be deleted in a future version, please use *on_train_begin* and *on_eval_begin* instead.

Parameters

run_context (RunContext) – Include some information of the model.

end(*run_context*)

Called once after network training. A backwards compatibility alias for *on_train_end* and *on_eval_end*.

Note: *end* is deprecated and will be deleted in a future version, please use *on_train_end* and *on_eval_end* instead.

Parameters

run_context (RunContext) – Include some information of the model.

epoch_begin(*run_context*)

Called before each epoch beginning. A backwards compatibility alias for *on_train_epoch_begin* and *on_eval_epoch_begin*.

Note: *epoch_begin* is deprecated and will be deleted in a future version, please use *on_train_epoch_begin* and *on_eval_epoch_begin* instead.

Parameters

run_context (RunContext) –Include some information of the model.

epoch_end(*run_context*)
Called after each epoch finished. A backwards compatibility alias for *on_train_epoch_end* and *on_eval_epoch_end*.

Note: *epoch_end* is deprecated and will be deleted in a future version, please use *on_train_epoch_end* and *on_eval_epoch_end* instead.

Parameters

run_context (RunContext) –Include some information of the model.

on_eval_begin(*run_context*)
Called before eval begin.

Parameters

run_context (RunContext) –Include some information of the model.

on_eval_end(*run_context*)
Called after eval end.

Parameters

run_context (RunContext) –Include some information of the model.

on_eval_epoch_begin(*run_context*)
Called before eval epoch begin.

Parameters

run_context (RunContext) –Include some information of the model.

on_eval_epoch_end(*run_context*)
Called after eval epoch end.

Parameters

run_context (RunContext) –Include some information of the model.

on_eval_step_begin(*run_context*)
Called before each eval step begin.

Parameters

run_context (RunContext) –Include some information of the model.

on_eval_step_end(*run_context*)
Called after each eval step end.

Parameters

run_context (RunContext) –Include some information of the model.

on_train_begin(*run_context*)
Called once before the network training.

Parameters

run_context (RunContext) –Include some information of the model.

on_train_end(*run_context*)
Called after training end.

Parameters

run_context (RunContext) –Include some information of the model.

on_train_epoch_begin(*run_context*)
Called before each training epoch begin.

Parameters

run_context (RunContext) –Include some information of the model.

on_train_epoch_end(*run_context*)
Called after each training epoch end.

Parameters

run_context (RunContext) –Include some information of the model.

on_train_step_begin(*run_context*)
Called before each training step begin.

Parameters

run_context (RunContext) –Include some information of the model.

on_train_step_end(*run_context*)
Called after each training step end.

Parameters

run_context (RunContext) –Include some information of the model.

step_begin(*run_context*)
Called before each step beginning. A backwards compatibility alias for *on_train_step_begin* and *on_eval_step_begin*.

Note: *step_begin* is deprecated and will be deleted in a future version, please use *on_train_step_begin* and *on_eval_step_begin* instead.

Parameters

run_context (RunContext) –Include some information of the model.

step_end(*run_context*)
Called after each step finished. A backwards compatibility alias for *on_train_step_end* and *on_eval_step_end*.

Note: *step_end* is deprecated and will be deleted in a future version, please use *on_train_step_end* and *on_eval_step_end* instead.

Parameters

run_context (RunContext) –Include some information of the model.

7.2.3 mindspore.train.CheckpointConfig

class mindspore.train.**CheckpointConfig**(*save_checkpoint_steps=1*, *save_checkpoint_seconds=0*, *keep_checkpoint_max=5*, *keep_checkpoint_per_n_minutes=0*, *integrated_save=True*, *async_save=False*, *saved_network=None*, *append_info=None*, *enc_key=None*, *enc_mode='AES-GCM'*, *exception_save=False*, *crc_check=False*, *remove_redundancy=False*, *format='ckpt'*, ***kwargs*)

The configuration of model checkpoint.

Note:

- During the training process, if dataset is transmitted through the data channel, it is suggested to set 'save_checkpoint_steps' to an integer multiple of loop_size. Otherwise, the time to save the checkpoint may be biased. It is recommended to set only one save strategy and one keep strategy at the same time. If both *save_checkpoint_steps* and *save_checkpoint_seconds* are set, *save_checkpoint_seconds* will be invalid. If both *keep_checkpoint_max* and *keep_checkpoint_per_n_minutes* are set, *keep_checkpoint_per_n_minutes* will be invalid.
- The *enc_mode* and *crc_check* parameters are mutually exclusive and cannot be configured simultaneously.

Parameters

- **save_checkpoint_steps** (*int*) −Steps to save checkpoint. Default: `1` .
- **save_checkpoint_seconds** (*int*) −Seconds to save checkpoint. Can't be used with save_checkpoint_steps at the same time. Default: `0` .
- **keep_checkpoint_max** (*int*) −Maximum number of checkpoint files can be saved. Default: `5` .
- **keep_checkpoint_per_n_minutes** (*int*) −Save the checkpoint file every *keep_checkpoint_per_n_minutes* minutes. Can't be used with keep_checkpoint_max at the same time. Default: `0` .
- **integrated_save** (*bool*) −Whether to merge and save the split Tensor in the automatic parallel scenario. Integrated save function is only supported in automatic parallel scene, not supported in manual parallel. Default: `True` .
- **async_save** (*Union[bool, str], optional*) −Whether to use asynchronous saving of the checkpoint file or safetensors file, if True, the asynchronous thread is used by default. If the type is string, the method of asynchronous saving, it can be "process" or "thread". Default: `False` .
- **saved_network** (`Cell`) −Network to be saved in checkpoint file. If the saved_network has no relation with the network in training, the initial value of saved_network will be saved. Default: `None` .
- **append_info** (*list*) −The information save to checkpoint file. Support "epoch_num", "step_num" and dict. The key of dict must be str, the value of dict must be one of int, float, bool, Parameter or Tensor. Default: `None` .
- **enc_key** (*Union[None, bytes]*) −Byte type key used for encryption. If the value is None, the encryption is not required. Default: `None` .
- **enc_mode** (*str*) −This parameter is valid only when enc_key is not set to None. Specifies the encryption mode, currently supports 'AES-GCM', 'AES-CBC' and 'SM4-CBC'. Default: `'AES-GCM'` .
- **exception_save** (*bool*) −Whether to save the current checkpoint when an exception occurs. Default: `False` .
- **crc_check** (*bool*) −Whether to perform crc32 calculation when saving checkpoint and save the calculation result to the end of ckpt. Default: `False` .
- **remove_redundancy** (*bool*) −Whether to enable saving the checkpoint with redundancy removal. Redundancy removal refers to eliminating redundant data in data parallelism mode. Default: `False` , means redundant-free saving is not enabled.

- **format** (*str*) –Format of the output file, can be "ckpt" or "safetensors". Default: "ckpt".
- **kwargs** (*dict*) –Configuration options dictionary.

Raises

ValueError –If input parameter is not the correct type.

Examples

```
>>> from mindspore import nn
>>> from mindspore.train import Model, CheckpointConfig, ModelCheckpoint
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> optim = nn.Momentum(net.trainable_params(), 0.01, 0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim)
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> config = CheckpointConfig(save_checkpoint_seconds=100, keep_checkpoint_per_n_minutes=5,␣
↪saved_network=net)
>>> config.save_checkpoint_steps
1
>>> config.save_checkpoint_seconds
>>> config.keep_checkpoint_max
5
>>> config.keep_checkpoint_per_n_minutes
>>> config.integrated_save
True
>>> config.async_save
False
>>> config.saved_network
>>> config.enc_key
>>> config.enc_mode
'AES-GCM'
>>> config.append_dict
>>> config.get_checkpoint_policy
>>> ckpoint_cb = ModelCheckpoint(prefix='LeNet5', directory='./checkpoint', config=config)
>>> model.train(10, dataset, callbacks=ckpoint_cb)
```

property append_dict

Get the value of information dict saved to checkpoint file.

Returns

dict, the information saved to checkpoint file.

property async_save

Get the value of whether or how asynchronous execution saves the checkpoint to a file.

Returns

(bool, str), whether or how asynchronous execution saves the checkpoint to a file.

property crc_check

Get the value of the whether to enable crc check.

Returns

bool, whether to enable crc check.

property enc_key
Get the value of byte type key used for encryption.

Returns

(None, bytes), byte type key used for encryption.

property enc_mode
Get the value of the encryption mode.

Returns

str, encryption mode.

get_checkpoint_policy()
Get the policy of checkpoint.

Returns

dict, the information of checkpoint policy.

property integrated_save
Get the value of whether to merge and save the split Tensor in the automatic parallel scenario.

Returns

bool, whether to merge and save the split Tensor in the automatic parallel scenario.

property keep_checkpoint_max
Get the value of maximum number of checkpoint files can be saved.

Returns

int, Maximum number of checkpoint files can be saved.

property keep_checkpoint_per_n_minutes
Get the value of save the checkpoint file every n minutes.

Returns

Int, save the checkpoint file every n minutes.

property map_param_inc
Get the value of whether to save map Parameter incrementally.

Returns

bool, whether to save map Parameter incrementally.

property save_checkpoint_seconds
Get the value of _save_checkpoint_seconds.

Returns

int, seconds to save the checkpoint file.

property save_checkpoint_steps
Get the value of steps to save checkpoint.

Returns

int, steps to save checkpoint.

property saved_network
Get the value of network to be saved in checkpoint file.

Returns

Cell, network to be saved in checkpoint file.

7.2.4 mindspore.train.EarlyStopping

class mindspore.train.**EarlyStopping**(*monitor='eval_loss'*, *min_delta=0*, *patience=0*, *verbose=False*, *mode='auto'*, *baseline=None*, *restore_best_weights=False*)

Stop training when a monitored metric has stopped improving.

Assuming *monitor* is "accuracy", with this, *mode* would be "max" since goal of trianing is to maximize the accuracy, the *model.fit()* training loop will check at end of epoch whether the accuracy is no longer increasing, considering the *min_delta* and *patience* if applicable. Once it's found no longer increasing, *run_context.request_stop()* will be called and the training terminates.

Parameters

- **monitor** (*str*) –quantity to be monitored. If evaluation is performed on the end of train epochs, the valid monitors can be "loss", "eval_loss" or metric names passed when instantiate the *Model*; otherwise the valid monitor is "loss". When monitor is "loss", if train network has multiple outputs, the first element will be returned as training loss. Default: `'eval_loss'` .
- **patience** (*int*) –*monitor* value is better than history best value over *min_delta* is seen as improvement, *patience* is number of epochs with no improvement that would be waited. When the waiting counter *self.wait* is larger than or equal to *patience*, the training process will be stopped. Default: `0` .
- **verbose** (*bool*) –If False: quiet, if True: print related information. Default: `False` .
- **mode** (*str*) –one of *{'auto', 'min', 'max'}*. In "min" mode, the learning rate will be reduced when the quantity monitored has stopped decreasing; in "max" mode it will be reduced when the quantity monitored has stopped increasing; in "auto" mode, the direction is automatically inferred from the name of the monitored quantity. Default: `'auto'` .
- **min_delta** (*float*) –threshold for measuring the new optimum, to only focus on significant changes. Default: `0` .
- **baseline** (*float*) –Baseline value for the monitor. When the monitor value shows improvement over the history best value and the baseline, the internal wait counter will be set to zero. Default: `None` .
- **restore_best_weights** (*bool*) –Whether to restore model weights from the epoch with the best value of the monitored quantity. If False, the model weights obtained at the last step of training are used. Default: `False` .

Raises

- **ValueError** –*mode* not in 'auto', 'min' or 'max'.
- **ValueError** –The monitor value is not a scalar.

Examples

```
>>> from mindspore import nn
>>> from mindspore.train import Model, EarlyStopping
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> optim = nn.Momentum(net.trainable_params(), 0.01, 0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim, metrics={"acc"})
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
```

(continues on next page)

(continued from previous page)

```
>>> cb = EarlyStopping(monitor="acc", patience=3, verbose=True)
>>> model.fit(10, dataset, callbacks=cb)
```

on_train_begin(*run_context*)
Initialize variables at the begin of training.

Parameters

run_context (RunContext) –Context information of the model. For more details, please refer to *mindspore.train.RunContext*.

on_train_end(*run_context*)
If verbose is True, print the stopped epoch.

Parameters

run_context (RunContext) –Context information of the model. For more details, please refer to *mindspore.train.RunContext*.

on_train_epoch_end(*run_context*)
monitors the training process and if no improvement is seen for a 'patience' number of epochs, the training process will be stopped.

Parameters

run_context (RunContext) –Context information of the model. For more details, please refer to *mindspore.train.RunContext*.

7.2.5 mindspore.train.FlopsUtilizationCollector

class mindspore.train.**FlopsUtilizationCollector**(*data_size*, *computility=1*, *full_flops=True*, *enable_ma_collector=False*)

The FlopsUtilizationCollector interface counts the model utilization information MFU and the hardware utilization information HFU. Currently, the API counts only the forward and backward flops of MatMul, BatchMatMul, FlashAttentionScore, and Conv2D operators. Only used in graph mode with static shape.

Parameters

- **data_size** (*int*) –How many steps are the intervals between print information each time.
- **computility** (*int*) –The peak flops of each compute card. Default: `1` .
- **full_flops** (*bool*) –Whether to count the full model flops. If set full_flops to False, FlopsUtilizationCollector would count the shard model flops in each device. Default: `True` .
- **enable_ma_collector** (*bool*) –Whether to write flops into the log and provide them to tasks on the cloud for retrieval. Default: `False` .

Raises

- **TypeError** –If data_size is not positive int.
- **TypeError** –If full_flops is not bool.
- **TypeError** –If enable_ma_collector is not bool.
- **AssertionError** –If the training mode is not a static graph or not a static shape.

Examples

```
>>> import numpy as np
>>> import mindspore.dataset as ds
>>> from mindspore import nn
>>> from mindspore.train import Model, FlopsUtilizationCollector
>>> from mindspore import context
>>> context.set_context(mode=context.GRAPH_MODE)
>>> data = {"x": np.float32(np.random.rand(64, 10)), "y": np.random.randint(0, 5, (64,))}
>>> train_dataset = ds.NumpySlicesDataset(data=data).batch(32)
>>> net = nn.Dense(10, 5)
>>> crit = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> opt = nn.Momentum(net.trainable_params(), 0.01, 0.9)
>>> flops_callback = FlopsUtilizationCollector(train_dataset.get_dataset_size(),␣
↪computility=10e6)
>>> model = Model(network=net, optimizer=opt, loss_fn=crit, metrics={"recall"})
>>> model.train(2, train_dataset, callbacks=[flops_callback])
Full model flops is 6400, Full hardware flops is 6400, Shard model flops is 6400, Shard␣
↪hardware flops is 6400
Train per step time: 135.572 ms, mfu:0.47% hfu:0.47%
Train per step time: 1.317 ms, mfu:48.59% hfu:48.59%
```

step_begin(*run_context*)
Record time at the beginning of step.

Parameters

run_context (RunContext) –Context of the process running. For more details, please refer to *mindspore.train.RunContext*.

step_end(*run_context*)
Print mfu and hfu time at the end of step.

Parameters

run_context (RunContext) –Context of the process running. For more details, please refer to *mindspore.train.RunContext*.

7.2.6 mindspore.train.History

class mindspore.train.**History**
Records the network outputs and metrics information into a *History* object.

- The network outputs information will be the loss value if not custimizing the train network or eval network;
- If the train network or eval network is custimized:
  - if the custimized network returns a *Tensor* or *numpy.ndarray*, the mean value of network output will be recorded.
  - if the custimized network returns a *tuple* or *list*, the first element of network outputs will be recorded.

Note: Normally used in *mindspore.train.Model.train()* or *mindspore.train.Model.fit()*.

Examples

```
>>> import numpy as np
>>> import mindspore.dataset as ds
>>> from mindspore import nn
>>> from mindspore.train import Model, History
>>> data = {"x": np.float32(np.random.rand(64, 10)), "y": np.random.randint(0, 5, (64,))}
>>> train_dataset = ds.NumpySlicesDataset(data=data).batch(32)
>>> net = nn.Dense(10, 5)
>>> crit = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> opt = nn.Momentum(net.trainable_params(), 0.01, 0.9)
>>> history_cb = History()
>>> model = Model(network=net, optimizer=opt, loss_fn=crit, metrics={"recall"})
>>> model.train(2, train_dataset, callbacks=[history_cb])
>>> print(history_cb.epoch)
{'epoch': [1, 2]}
>>> print(history_cb.history)
{'net_output': [1.607877, 1.6033841]}
```

begin(*run_context*)

Initialize the *epoch* property at the begin of training.

Parameters

run_context (RunContext) – Context of the *mindspore.train.Model.{train | eval}*. For more details, please refer to *mindspore.train.RunContext*.

epoch_end(*run_context*)

Records the first element of network outputs and metrics information at the end of epoch.

Parameters

run_context (RunContext) – Context of the *mindspore.train.Model.{train | eval}*. For more details, please refer to *mindspore.train.RunContext*.

7.2.7 mindspore.train.LambdaCallback

class mindspore.train.**LambdaCallback**(*on_train_epoch_begin=None*, *on_train_epoch_end=None*, *on_train_step_begin=None*, *on_train_step_end=None*, *on_train_begin=None*, *on_train_end=None*, *on_eval_epoch_begin=None*, *on_eval_epoch_end=None*, *on_eval_step_begin=None*, *on_eval_step_end=None*, *on_eval_begin=None*, *on_eval_end=None*)

Callback for creating simple, custom callbacks.

This callback is constructed with anonymous functions that will be called at the appropriate time (during *mindspore.train.Model.{train | eval | fit}*). Note that each stage of callbacks expects one positional arguments: *run_context*.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **on_train_epoch_begin** (*Function*) – called at each train epoch begin. Default: None .
- **on_train_epoch_end** (*Function*) – called at each train epoch end. Default: None .
- **on_train_step_begin** (*Function*) – called at each train step begin. Default: None .

- **on_train_step_end** (*Function*) –called at each train step end. Default: None .
- **on_train_begin** (*Function*) –called at the beginning of model train. Default: None .
- **on_train_end** (*Function*) –called at the end of model train. Default: None .
- **on_eval_epoch_begin** (*Function*) –called at each eval epoch begin. Default: None .
- **on_eval_epoch_end** (*Function*) –called at each eval epoch end. Default: None .
- **on_eval_step_begin** (*Function*) –called at each eval step begin. Default: None .
- **on_eval_step_end** (*Function*) –called at each eval step end. Default: None .
- **on_eval_begin** (*Function*) –called at the beginning of model eval. Default: None .
- **on_eval_end** (*Function*) –called at the end of model eval. Default: None .

Examples

```
>>> import numpy as np
>>> import mindspore.dataset as ds
>>> from mindspore import nn
>>> from mindspore.train import Model, LambdaCallback
>>> data = {"x": np.float32(np.random.rand(64, 10)), "y": np.random.randint(0, 5, (64,))}
>>> train_dataset = ds.NumpySlicesDataset(data=data).batch(32)
>>> net = nn.Dense(10, 5)
>>> crit = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> opt = nn.Momentum(net.trainable_params(), 0.01, 0.9)
>>> lambda_callback = LambdaCallback(on_train_epoch_end=
... lambda run_context: print("loss:", run_context.original_args().net_outputs))
>>> model = Model(network=net, optimizer=opt, loss_fn=crit, metrics={"recall"})
>>> model.train(2, train_dataset, callbacks=[lambda_callback])
loss: 1.6127687
loss: 1.6106578
```

7.2.8 mindspore.train.LearningRateScheduler

class mindspore.train.**LearningRateScheduler**(*learning_rate_function*)

Change the learning_rate during training.

Parameters

learning_rate_function (*Function*) –The function about how to change the learning rate during training.

Examples

```
>>> import numpy as np
>>> from mindspore import nn
>>> from mindspore.train import Model, LearningRateScheduler
>>> from mindspore import dataset as ds
...
>>> def learning_rate_function(lr, cur_step_num):
...     if cur_step_num%1000 == 0:
...         lr = lr*0.1
...     return lr
```

(continues on next page)

(continued from previous page)

```
...
>>> lr = 0.1
>>> momentum = 0.9
>>> net = nn.Dense(10, 5)
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> optim = nn.Momentum(net.trainable_params(), learning_rate=lr, momentum=momentum)
>>> model = Model(net, loss_fn=loss, optimizer=optim)
...
>>> data = {"x": np.float32(np.random.rand(64, 10)), "y": np.random.randint(0, 5, (64,))}
>>> dataset = ds.NumpySlicesDataset(data=data).batch(32)
>>> model.train(1, dataset, callbacks=[LearningRateScheduler(learning_rate_function)],
...             dataset_sink_mode=False)
```

step_end(*run_context*)

Change the learning_rate at the end of step.

Parameters

run_context (RunContext) – Include some information of the model.

7.2.9 mindspore.train.LossMonitor

class mindspore.train.**LossMonitor**(*per_print_times=1*)

Monitor the loss in train or monitor the loss and eval metrics in fit.

If the loss is NAN or INF, it will terminate training.

Note: If per_print_times is 0, do not print loss.

Parameters

per_print_times (*int*) – How many steps to print once loss. During sink mode, it will print loss in the nearest step. Default: 1.

Raises

ValueError – If per_print_times is not an integer or less than zero.

Examples

```
>>> from mindspore import nn
>>> from mindspore.train import Model, LossMonitor
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> optim = nn.Momentum(net.trainable_params(), 0.01, 0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim)
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> loss_monitor = LossMonitor()
>>> model.train(10, dataset, callbacks=loss_monitor)
```

on_train_epoch_end(*run_context*)
When LossMonitor used in *mindspore.train.Model.fit()*, print eval metrics at the end of epoch if current epoch should do evaluation.

Parameters

run_context (RunContext) –Include some information of the model. For more details, please refer to *mindspore.train.RunContext*.

step_end(*run_context*)
Print training loss at the end of step.

Parameters

run_context (RunContext) –Include some information of the model. For more details, please refer to *mindspore.train.RunContext*.

7.2.10 mindspore.train.TrainFaultTolerance

class mindspore.train.**TrainFaultTolerance**(*ckpt_save_path=None*, ***kwargs*)
This callback is used to enable the TFT feature MindIO TFT and will execute TFT operations during training process, such as TFT init, report and exception handle.

Note: Required for Ascend graph mode only. And sink size must be less than or equal to 1.

Parameters

- **ckpt_save_path** (*str*) –Checkpoint save directory when failure occurs. When saved, a new directory named 'ttp_saved_checkpoints-step_{cur_step_num}' is created in that directory. Default: `None`.
- **kwargs** (*dict*) –Other dictionary type parameters.

Raises

- **Exception** –TFT init failed.
- **ModuleNotFoundError** –Mindio TFT whl package is not installed.

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

It's recommended to use the msrun startup method. Please see the msrun start up for more details.

This example should be run with 4 devices.

```
>>> import numpy as np
>>> import os
>>> import math
>>> import mindspore as ms
>>> import mindspore.dataset as ds
>>> from mindspore import nn, ops, Parameter, train
>>> from mindspore.communication import init, get_rank
>>> from mindspore.common.initializer import initializer, HeUniform
>>> from mindspore.train import Model, TrainFaultTolerance
```

>>> tft_cb = TrainFaultTolerance()
>>> loss_cb = train.LossMonitor(1)
>>> model.train(1, dataset, callbacks=[tft_cb, loss_cb])
```

end(*run_context*)

Unregister MindIO TFT on train end.

Parameters

run_context (RunContext) –Context of the train running. Refer to *mindspore.train.RunContext* for detail.

classmethod get_optimizer_wrapper(*origin_opt_cls*)

Optimizer wrapper func when using tft.

Parameters

origin_opt_cls (*Class*) –origin optimizer class.

on_train_begin(*run_context*)

Register train params to MindIO TFT on train beginning.

Parameters

run_context (RunContext) –Context of the train running. Refer to *mindspore.train.RunContext* for detail.

on_train_step_end(*run_context*)

Report status to MindIO TFT after every step finished.

Parameters

run_context (RunContext) –Context of the train running. Refer to *mindspore.train.RunContext* for detail.

7.2.11 mindspore.train.ModelCheckpoint

class mindspore.train.**ModelCheckpoint**(*prefix='CKP'*, *directory=None*, *config=None*)

The checkpoint callback class.

It is called to combine with train process and save the model and network parameters after training.

Note: In the distributed training scenario, please specify different directories for each training process to save the checkpoint file. Otherwise, the training may fail. If this callback is used in the Model function, the checkpoint file will saved parameters of the optimizer by default.

Parameters

- **prefix** (*Union[str, callable object]*) – The prefix name or callable object to generate name of checkpoint files. Default: `'CKP'` .
- **directory** (*Union[str, callable object]*) – The folder path where the checkpoint is stored, or the callable object used to generate the path. By default, the file is saved in the current directory. Default: `None` .
- **config** (CheckpointConfig) – Checkpoint strategy configuration. Default: `None` .

Raises

- **ValueError** – If *prefix* is not str or contains the '/' character and is not a callable object.
- **ValueError** – If *directory* is not str and is not a callable object.
- **TypeError** – If the config is not CheckpointConfig type.

Examples

```
>>> import numpy as np
>>> import mindspore.dataset as ds
>>> from mindspore import nn
>>> from mindspore.train import Model, ModelCheckpoint
>>>
>>> data = {"x": np.float32(np.random.rand(64, 10)), "y": np.random.randint(0, 5, (64,))}
>>> train_dataset = ds.NumpySlicesDataset(data=data).batch(32)
>>> net = nn.Dense(10, 5)
>>> crit = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> opt = nn.Momentum(net.trainable_params(), 0.01, 0.9)
>>> ckpt_callback = ModelCheckpoint(prefix="myckpt")
>>> model = Model(network=net, optimizer=opt, loss_fn=crit)
>>> model.train(2, train_dataset, callbacks=[ckpt_callback])
```

end(*run_context*)

Save the last checkpoint after training finished.

Parameters

run_context (RunContext) – Context of the train running.

property latest_ckpt_file_name

Return the latest checkpoint path and file name.

step_end(*run_context*)

Save the checkpoint at the end of step.

Parameters

run_context (RunContext) –Context of the train running.

7.2.12 mindspore.train.OnRequestExit

class mindspore.train.**OnRequestExit**(*save_ckpt=True*, *save_mindir=True*, *file_name='Net'*, *directory='./'*, *config_file=None*, *sig=signal.SIGTERM*)

Respond to the user's closing request, exit the training or eval process, and save the checkpoint and mindir.

Register OnRequestExit Callback before training, when the user want to exit the training process and save the training data, could send the registered exit signal 'sig' to the training process or modify the 'GracefulExit' that a key in the JSON file specified by the 'config_file' to '1'. After the training process executes the current step, saves the current training status, including checkpoint and mindir, and then exit the training process.

Parameters

- **save_ckpt** (*bool*) –Whether save the checkpoint before the training process exit. Default: `True` .
- **save_mindir** (*bool*) –Whether save the mindir before the training process exit. Default: `True` .
- **file_name** (*str*) –The saved checkpoint and mindir file name, the checkpoint file add suffix '.ckpt', the mindir file add suffix '.mindir'. Default: `'Net'` .
- **directory** (*str*) –The path to save files. It will generate a 'rank_{id}' path by rank_id to save checkpoint and mindir. Default: `'./'` .
- **sig** (*int*) –The user registered exit signal, it must be a captureable and negligible signal. When the process receives the signal, exits the training or eval process. Default: `signal.SIGTERM` .
- **config_file** (*str*) –A json config file used to exit training process gracefully. Key: `{"GracefulExit": 1}` . Default: `None` .

Raises

- **ValueError** –If the 'save_ckpt' is not a bool.
- **ValueError** –If the 'save_mindir' is not a bool.
- **ValueError** –If the 'file_name' is not a str.
- **ValueError** –If the 'directory' is not a str.
- **ValueError** –If the 'sig' is not an int or the 'sig' is `signal.SIGTERM`.

Examples

```
>>> from mindspore import nn
>>> from mindspore.train import Model, TimeMonitor
>>> import mindspore as ms
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> optim = nn.Momentum(net.trainable_params(), 0.01, 0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim)
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> on_request_exit = ms.train.OnRequestExit(file_name='LeNet5')
>>> model.train(10, dataset, callbacks=on_request_exit)
```

on_eval_begin(*run_context*)
When the eval begin, register the handler for exit signal transferred by user.

Parameters

run_context (RunContext) –Context information of the model. For more details, please refer to *mindspore.train.RunContext*.

on_eval_end(*run_context*)
When the eval end, if received the exit signal, the checkpoint and mindir would be saved according to the user config.

Parameters

run_context (RunContext) –Include some information of the model. For more details, please refer to *mindspore.train.RunContext*.

on_eval_step_end(*run_context*)
When the eval step end, if received the exit signal, set attribute '_stop_requested' of the 'run_context' to True. Then exit the eval process after this step eval.

Parameters

run_context (RunContext) –Include some information of the model. For more details, please refer to *mindspore.train.RunContext*.

on_train_begin(*run_context*)
When the train begin, register the handler for exit signal transferred by user.

Parameters

run_context (RunContext) –Context information of the model. For more details, please refer to *mindspore.train.RunContext*.

on_train_end(*run_context*)
When the train end, if received the exit signal, the checkpoint and mindir would be saved according to the user config.

Parameters

run_context (RunContext) –Include some information of the model. For more details, please refer to *mindspore.train.RunContext*.

on_train_epoch_end(*run_context*)
When the train epoch end, if received the exit signal, set the 'run_context' attribute '_stop_requested' to True. Then exit the training process after this epoch training.

Parameters

run_context (RunContext) –Include some information of the model. For more details, please refer to *mindspore.train.RunContext*.

on_train_step_begin(*run_context*)
Check whether received the exit signal or whether the value of 'GracefulExit' in 'config_file' was changed to '1'.

Parameters

run_context (RunContext) –Context information of the model. For more details, please refer to *mindspore.train.RunContext*.

on_train_step_end(*run_context*)
Save checkpoint file or mindir file according to config, and exit the training process.

Parameters

run_context (RunContext) –Include some information of the model. For more details, please refer to *mindspore.train.RunContext*.

7.2.13 mindspore.train.ReduceLROnPlateau

class mindspore.train.**ReduceLROnPlateau**(*monitor='eval_loss'*, *factor=0.1*, *patience=10*, *verbose=False*, *mode='auto'*, *min_delta=1e-4*, *cooldown=0*, *min_lr=0*)

Reduce learning rate when the monitor has stopped improving.

Models often benefit from reducing the learning rate by a factor of 2-10 once learning stagnates. This callback monitors the training process and if no improvement is seen for a 'patience' number of epochs, the learning rate is reduced.

Note: Learning rate grouping is not supported now.

Parameters

- **monitor** (*str*) – quantity to be monitored. If evaluation is performed on the end of train epochs, the valid monitors can be `"loss"`, `"eval_loss"` or metric names passed when instantiate the *Model*; otherwise the valid monitor is `"loss"`. When *monitor* is `"loss"`, if train network has multiple outputs, the first element will be returned as training loss. Default: `'eval_loss'`.
- **factor** (*float*) – factor by which the learning rate will be reduced. *new_lr = lr * factor*. Default: `0.1` .
- **patience** (*int*) – *monitor* value is better than history best value over *min_delta* is seen as improvement, *patience* is number of epochs with no improvement that would be waited. When the waiting counter *self.wait* is larger than or equal to *patience*, the lr will be reduced. Default: `10` .
- **verbose** (*bool*) – If False: quiet, if True: print related information. Default: `False` .
- **mode** (*str*) – one of *{'auto', 'min', 'max'}*. Default: `'auto'` .
  - In `'min'` mode, the learning rate will be reduced when the quantity monitored has stopped decreasing.
  - In `'max'` mode it will be reduced when the quantity monitored has stopped increasing.
  - In `'auto'` mode, the direction is automatically inferred from the name of the monitored quantity.
- **min_delta** (*float*) – threshold for measuring the new optimum, to only focus on significant changes. Default: `1e-4` .
- **cooldown** (*int*) – number of epochs to wait before resuming normal operation after lr has been reduced. Default: `0` .
- **min_lr** (*float*) – lower bound on the learning rate. Default: `0` .

Raises

- **ValueError** – *mode* not in `'auto'`, `'min'` or `'max'`.
- **ValueError** – The monitor value is not a scalar.
- **ValueError** – The learning rate is not a Parameter.

Examples

```
>>> from mindspore import nn
>>> from mindspore.train import Model, ReduceLROnPlateau
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> optim = nn.Momentum(net.trainable_params(), 0.01, 0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim, metrics={"acc"})
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> cb = ReduceLROnPlateau(monitor="acc", patience=3, verbose=True)
>>> model.fit(10, dataset, callbacks=cb)
```

on_train_begin(*run_context*)

Initialize variables at the begin of training.

Parameters

run_context (RunContext) –Context information of the model. For more details, please refer to *mindspore.train.RunContext*.

on_train_epoch_end(*run_context*)

monitors the training process and if no improvement is seen for a 'patience' number of epochs, the learning rate is reduced.

Parameters

run_context (RunContext) –Context information of the model. For more details, please refer to *mindspore.train.RunContext*.

7.2.14 mindspore.train.RunContext

class mindspore.train.**RunContext**(*original_args*)

Hold and manage information about the model.

RunContext is mainly used to collect context-related information about the model during training or eval and pass it into the Callback object as an input parameter to share information.

Callback objects not only can obtain the Model context information by calling by *RunContext.original_args()* and add extra attributes to the information, but also can stop the training process by calling *request_stop* method.

RunContext.original_args() holds the model context information as a dictionary variable, and different attributes of the dictionary are stored in training or eval process. Details are as follows:

Attributes supported in train	Attributes supported in eval	meaning
train_network		train network with optimizer and loss
epoch_num		Number of train epochs
train_dataset		the train dataset
loss_fn		the loss function
optimizer		the optimizer
parallel_mode		the parallel mode
device_number		the device number
train_dataset_element		the train data element of current step
last_save_ckpt_step		the last step num of save ckpt
latest_ckpt_file		the ckpt file
cur_epoch_num		number of current epoch
	eval_network	the evaluate network
	valid_dataset	the valid dataset
	metrics	the evaluate metrics
mode	mode	"train" or "eval"
batch_num	batch_num	the train/eval batch number
list_callback	list_callback	callback list
network	network	basic network
cur_step_num	cur_step_num	the train/eval step number
dataset_sink_mode	dataset_sink_mode	the train/eval sink mode
net_outputs	net_outputs	network output results

Parameters

original_args (*dict*) – Holding the related information of model.

Examples

```
>>> from mindspore import Tensor
>>> from mindspore.train import RunContext
>>> cb_params = {}
>>> cb_params["cur_epoch_num"] = 4
>>> cb_params["epoch_num"] = 4
>>> cb_params["cur_step_num"] = 2
>>> cb_params["batch_num"] = 2
>>> cb_params["net_outputs"] = Tensor(2.0)
>>> run_context = RunContext(cb_params)
>>> whether_stop = run_context.get_stop_requested()
```

get_stop_requested()

Return whether a stop is requested or not.

Returns

bool, if true, model.train() stops iterations.

original_args()

Get the _original_args object.

Returns

Dict, an object that holds the original arguments of model.

request_stop()
Set stop requirement during training or eval.

Callbacks can use this function to request stop of iterations. model.train() checks whether this is called or not.

7.2.15 mindspore.train.TimeMonitor

class mindspore.train.**TimeMonitor**(*data_size=None*, *data_time=False*)
Monitor the time in train or eval process.

Parameters

- **data_size** (*int*) –How many steps are the intervals between print information each time. if the program get *batch_num* during training, *data_size* will be set to *batch_num*, otherwise *data_size* will be used. If the program does not get *batch_num* during training, meanwhile *data_size* does not set, the program will report an error. Default: `None` .
- **data_time** (*bool*) –Whether to show the average time of fetching data in Host. Note that data fetch and network compute are processed sequentially in non dataset sink mode, while they are asynchronous in dataset sink mode. Default: `False` .

Raises

- **ValueError** –If data_size is not positive int.
- **TypeError** –If data_time is not bool.

Examples

```
>>> from mindspore import nn
>>> from mindspore.train import Model, TimeMonitor
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss = nn.SoftmaxCrossEntropyWithLogits(sparse=True, reduction='mean')
>>> optim = nn.Momentum(net.trainable_params(), 0.01, 0.9)
>>> model = Model(net, loss_fn=loss, optimizer=optim)
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> time_monitor = TimeMonitor()
>>> model.train(10, dataset, callbacks=time_monitor)
```

epoch_begin(*run_context*)
Record time at the beginning of epoch.

Parameters

run_context (RunContext) –Context of the process running. For more details, please refer to *mindspore.train.RunContext*.

epoch_end(*run_context*)
Print process cost time at the end of epoch.

Parameters

run_context (RunContext) –Context of the process running. For more details, please refer to *mindspore.train.RunContext*.

on_train_step_begin(*run_context*)
Record time at the beginning of step.

Parameters

run_context (RunContext) –Context of the process running. For more details, please refer to *mindspore.train.RunContext*.

on_train_step_end(*run_context*)
Record time at the end of step.

Parameters

run_context (RunContext) –Context of the process running. For more details, please refer to *mindspore.train.RunContext*.

7.3 Evaluation Metrics

API Name	Description	Supported Platforms
mindspore.train.Accuracy	Calculates the accuracy for classification and multilabel data.	Ascend GPU CPU
mindspore.train.BleuScore	Calculates the BLEU score.	Ascend GPU CPU
mindspore.train.ConfusionMatrix	Computes the Confusion Matrix, which is commonly used to evaluate the performance of classification models, including binary classification and multiple classification.	Ascend GPU CPU
mindspore.train.ConfusionMatrixMetric	Computes metrics related to confusion matrix.	Ascend GPU CPU
mindspore.train.CosineSimilarity	Computes representation similarity.	Ascend GPU CPU
mindspore.train.Dice	The Dice coefficient is a set similarity metric.	Ascend GPU CPU
mindspore.train.F1	Calculates the F1 score.	Ascend GPU CPU
mindspore.train.Fbeta	Calculates the Fbeta score.	Ascend GPU CPU
mindspore.train.HausdorffDistance	Calculates the Hausdorff distance.	Ascend GPU CPU
mindspore.train.Loss	Calculates the average of the loss.	Ascend GPU CPU
mindspore.train.MAE	Calculates the mean absolute error(MAE).	Ascend GPU CPU
mindspore.train.MeanSurfaceDistance	Computes the Average Surface Distance from *y_pred* to *y* under the default setting.	Ascend GPU CPU
mindspore.train.Metric	Base class of metric, which is used to evaluate metrics.	Ascend GPU CPU
mindspore.train.MSE	Measures the mean squared error(MSE).	Ascend GPU CPU
mindspore.train.OcclusionSensitivity	Calculates the occlusion sensitivity of the model for a given image, which illustrates which parts of an image are most important for a network's classification.	Ascend GPU CPU
mindspore.train.Perplexity	Computes perplexity.	Ascend GPU CPU
mindspore.train.Precision	Calculates precision for classification and multilabel data.	Ascend GPU CPU
mindspore.train.Recall	Calculates recall for classification and multilabel data.	Ascend GPU CPU
mindspore.train.ROC	Calculates the ROC curve.	Ascend GPU CPU
mindspore.train.RootMeanSquareDistance	Computes the Root Mean Square Surface Distance from *y_pred* to *y* under the default setting.	Ascend GPU CPU

continues on next page

Table 3 – continued from previous page

mindspore.train.Top1CategoricalAccuracy	Calculates the top-1 categorical accuracy.	Ascend GPU CPU
mindspore.train.Top5CategoricalAccuracy	Calculates the top-5 categorical accuracy.	Ascend GPU CPU
mindspore.train.TopKCategoricalAccuracy	Calculates the top-k categorical accuracy.	Ascend GPU CPU

7.3.1 mindspore.train.Accuracy

class mindspore.train.**Accuracy**(*eval_type='classification'*)

Calculates the accuracy for classification and multilabel data.

The accuracy class creates two local variables, the correct number and the total number that are used to compute the frequency with which y_pred matches y. This frequency is the accuracy.

$$\text{accuracy} = \frac{\text{true\_positive} + \text{true\_negative}}{\text{true\_positive} + \text{true\_negative} + \text{false\_positive} + \text{false\_negative}}$$

Parameters

eval_type (*str*) – The metric to calculate the accuracy over a dataset. Supports `'classification'` and `'multilabel'`. `'classification'` means the dataset label is single. `'multilabel'` means the dataset has multiple labels. Default: `'classification'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore.train import Accuracy
>>>
>>> y_pred = Tensor(np.array([[0.2, 0.5], [0.3, 0.1], [0.9, 0.6]]), mindspore.float32)
>>> y_true = Tensor(np.array([1, 0, 1]), mindspore.float32)
>>> metric = Accuracy('classification')
>>> metric.clear()
>>> metric.update(y_pred, y_true)
>>> accuracy = metric.eval()
>>> print(accuracy)
0.6666666666666666
```

clear()

Clears the internal evaluation result.

eval()

Computes the accuracy.

Returns

np.float64, the computed result.

Raises

RuntimeError –If the sample size is 0.

update(**inputs*)

Updates the local variables. For `'classification'`, if the index of the maximum of the predict value matches the label, the predict result is correct. For `'multilabel'`, the predict value match the label, the predict result is correct.

Parameters

inputs –Logits and labels. *y_pred* stands for logits, *y* stands for labels. *y_pred* and *y* must be a *Tensor*, a list or an array.

- For the `'classification'` evaluation type, *y_pred* is a list of floating numbers in range $[0, 1]$ and the shape is (N, C) in most cases (not strictly), where N is the number of cases and C is the number of categories. *y* must be in one-hot format that shape is (N, C), or can be transformed to one-hot format that shape is $(N,)$.
- For `'multilabel'` evaluation type, the value of *y_pred* and *y* can only be 0 or 1, indices with 1 indicate the positive category. The shape of *y_pred* and *y* are both (N, C).

Raises

- **ValueError** –If the number of the inputs is not 2.
- **ValueError** –class numbers of last input predicted data and current predicted data not match.

7.3.2 mindspore.train.BleuScore

class mindspore.train.**BleuScore**(*n_gram=4*, *smooth=False*)

Calculates the BLEU score. BLEU (bilingual evaluation understudy) is a metric for evaluating the quality of text translated by machine.

Parameters

- **n_gram** (*int*) –The n_gram value ranges from 1 to 4. Default: `4` .
- **smooth** (*bool*) –Whether or not to apply smoothing. Default: `False` .

Raises

ValueError –If the value range of n_gram is not from 1 to 4.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> from mindspore.train import BleuScore
>>>
>>> candidate_corpus = [['i', 'have', 'a', 'pen', 'on', 'my', 'desk']]
>>> reference_corpus = [[['i', 'have', 'a', 'pen', 'in', 'my', 'desk'],
...                      ['there', 'is', 'a', 'pen', 'on', 'the', 'desk']]]
>>> metric = BleuScore()
>>> metric.clear()
>>> metric.update(candidate_corpus, reference_corpus)
>>> bleu_score = metric.eval()
>>> print(bleu_score)
0.5946035575013605
```

clear()

Clear the internal evaluation result.

eval()
Computes the bleu score.

Returns

numpy.float64, the bleu score.

Raises

RuntimeError –If the update method is not called first, an error will be reported.

update(**inputs*)
Updates the internal evaluation result with *candidate_corpus* and *reference_corpus*.

Parameters

inputs (*iterator*) –Input *candidate_corpus* and *reference_corpus*. *candidate_corpus* and *reference_corpus* are both a list. The *candidate_corpus* is an iterable of machine translated corpus. The *reference_corpus* is an iterable object of iterables of reference corpus.

Raises

- **ValueError** –If the number of inputs is not 2.
- **ValueError** –If the lengths of *candidate_corpus* and *reference_corpus* are not equal.

7.3.3 mindspore.train.ConfusionMatrix

class mindspore.train.**ConfusionMatrix**(*num_classes*, *normalize='no_norm'*, *threshold=0.5*)
Computes the Confusion Matrix, which is commonly used to evaluate the performance of classification models, including binary classification and multiple classification.

If you only need Confusion Matrix, use this class. If you want to calculate other metrics, such as 'PPV', 'TPR', 'TNR', etc., use class *mindspore.train.ConfusionMatrixMetric*.

Parameters

- **num_classes** (*int*) –Number of classes in the dataset.
- **normalize** (*str*) –Normalization mode for Confusion Matrix. Default: `"no_norm"`. Choose from:
  - `"no_norm"`: No Normalization is used. Default: `None`.
  - `"target"`: Normalization based on target value.
  - `"prediction"`: Normalization based on predicted value.
  - `"all"`: Normalization over the whole matrix.
- **threshold** (*float*) –The threshold used to compare with the input tensor. Default: `0.5`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import ConfusionMatrix
>>>
>>> x = Tensor(np.array([1, 0, 1, 0]))
>>> y = Tensor(np.array([1, 0, 0, 1]))
>>> metric = ConfusionMatrix(num_classes=2, normalize='no_norm', threshold=0.5)
>>> metric.clear()
>>> metric.update(x, y)
>>> output = metric.eval()
>>> print(output)
[[1. 1.]
 [1. 1.]]
```

clear()
Clears the internal evaluation result.

eval()
Computes confusion matrix.

Returns

numpy.ndarray, the computed result.

update(**inputs*)
Update state with *y_pred* and *y*.

Parameters

inputs (*tuple*) −Input *y_pred* and *y*. *y_pred* and *y* are a *Tensor*, list or numpy.ndarray. *y_pred* is the predicted value, *y* is the true value. The shape of *y_pred* is $(N, C, ...)$ or $(N, ...)$. The shape of *y* is $(N, ...)$.

Raises

- **ValueError** −If the number of inputs is not 2.
- **ValueError** −If the dims of *y_pred* and *y* are not equal.

7.3.4 mindspore.train.ConfusionMatrixMetric

class mindspore.train.**ConfusionMatrixMetric**(*skip_channel=True*, *metric_name='sensitivity'*, *calculation_method=False*, *decrease='mean'*)
Computes metrics related to confusion matrix. The calculation based on full-scale tensor, average values of batch, class channel and iteration are collected. All metrics supported by the interface are listed in comments of *metric_name*.

- If you want to calculate metrics related to confusion matrix, such as 'PPV', 'TPR', 'TNR', use this class.
- If you only want to calculate confusion matrix, please use *mindspore.train.ConfusionMatrix*.

Parameters

- **skip_channel** (*bool*) −Whether to skip the measurement calculation on the first channel of the predicted output. Default: `True`.
- **metric_name** (*str*) −Names of supported metrics , users can also set the industry common aliases for them. Choose from: ["sensitivity", "specificity", "precision", "negative predictive value", "miss rate", "fall out", "false discovery rate", "false omission rate", "prevalence threshold", "threat score", "accuracy", "balanced accuracy", "f1 score", "matthews correlation coefficient", "fowlkes mallows index", "informedness", "markedness"]. Default: `"sensitivity"`.

- **calculation_method** (*bool*) –If `True`, the measurement for each sample will be calculated first. If not, the confusion matrix of all samples will be accumulated first. As for classification task, 'calculation_method' should be `False`. Default: `False` .
- **decrease** (*str*) –The reduction method on data batch. *decrease* takes effect only when calculation_method is True. Default: `"mean"` . Choose from: ["none", "mean", "sum", "mean_batch", "sum_batch", "mean_channel", "sum_channel"].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import ConfusionMatrixMetric
>>>
>>> metric = ConfusionMatrixMetric(skip_channel=True, metric_name="tpr",
...                                calculation_method=False, decrease="mean")
>>> metric.clear()
>>> x = Tensor(np.array([[[0], [1]], [[1], [0]]]))
>>> y = Tensor(np.array([[[0], [1]], [[0], [1]]]))
>>> metric.update(x, y)
>>> avg_output = metric.eval()
>>> print(avg_output)
[0.5]
```

clear()
Clears the internal evaluation result.

eval()
Computes confusion matrix metric.

Returns

ndarray, the computed result.

update(**inputs*)
Update state with predictions and targets.

Parameters

inputs (*tuple*) –Input *y_pred* and *y*. *y_pred* and *y* are a *Tensor*, list or numpy.ndarray.

- y_pred (ndarray): The batch data shape is $(N, C, ...)$ or $(N, ...)$, representing onehot format or category index format respectively. As for classification tasks, y_pred should have the shape (B, N) where N is larger than 1. As for segmentation tasks, the shape should be (B, N, H, W) or (B, N, H, W, D).
- y (ndarray): It must be one-hot format. The batch data shape is $(N, C, ...)$.

Raises

ValueError –If the number of the inputs is not 2.

7.3.5 mindspore.train.CosineSimilarity

class mindspore.train.**CosineSimilarity**(*similarity='cosine'*, *reduction='none'*, *zero_diagonal=True*)

Computes representation similarity.

Parameters

- **similarity** (*str*) – the computation logit. `'cosine'` means computing similarity. `'dot'` means computing dots of arrays, Default: `'cosine'` .
- **reduction** (*str*) – Specifies the reduction to be applied to the output. Support `'none'`, `'sum'`, `'mean'` (all along dim -1). Default: `'none'` .
- **zero_diagonal** (*bool*) – If `True`, diagonals of results will be set to zero. Default: `True` .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore.train import CosineSimilarity
>>>
>>> test_data = np.array([[1, 3, 4, 7], [2, 4, 2, 5], [3, 1, 5, 8]])
>>> metric = CosineSimilarity()
>>> metric.clear()
>>> metric.update(test_data)
>>> square_matrix = metric.eval()
>>> print(square_matrix)
[[0.  0.94025615  0.95162452]
 [0.94025615  0.  0.86146098]
 [0.95162452  0.86146098  0.]]
```

clear()

Clears the internal evaluation result.

eval()

Computes the similarity matrix.

Returns

numpy.ndarray. The similarity matrix.

Raises

RuntimeError – If the update method is not called first, an error will be reported.

update(*inputs*)

Updates the internal evaluation result with 'inputs'.

Parameters

inputs (*Union[Tensor, list, numpy.ndarray]*) – The input matrix including *y* and *y_pred*.

7.3.6 mindspore.train.Dice

class mindspore.train.**Dice**(*smooth=1e-5*)

The Dice coefficient is a set similarity metric. It is used to calculate the similarity between two samples. The value of the Dice coefficient is 1 when the segmentation result is the best and is 0 when the segmentation result is the worst. The Dice coefficient indicates the ratio of the area between two objects to the total area. The function is shown as follows:

$$dice = \frac{2 * (pred \bigcap true)}{pred \bigcup true}$$

Parameters

smooth (*float*) – A term added to the denominator to improve numerical stability. Should be greater than 0. Default: `1e-5`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import Dice
>>>
>>> x = Tensor(np.array([[0.2, 0.5], [0.3, 0.1], [0.9, 0.6]]))
>>> y = Tensor(np.array([[0, 1], [1, 0], [0, 1]]))
>>> metric = Dice(smooth=1e-5)
>>> metric.clear()
>>> metric.update(x, y)
>>> dice = metric.eval()
>>> print(dice)
0.20467791371802546
```

clear()

Clears the internal evaluation result.

eval()

Computes the Dice.

Returns

Float, the computed result.

Raises

RuntimeError – If the total number of samples is 0.

update(**inputs*)

Updates the internal evaluation result *y_pred* and *y*.

Parameters

inputs (*tuple*) – Input *y_pred* and *y*. *y_pred* and *y* are Tensor, list or numpy.ndarray. *y_pred* is the predicted value, *y* is the true value. The shape of *y_pred* and *y* are both $(N, ...)$.

Raises

- **ValueError** – If the number of the inputs is not 2.
- **ValueError** – If y_pred and y do not have the same shape.

7.3.7 mindspore.train.F1

class mindspore.train.**F1**

Calculates the F1 score. F1 is a special case of Fbeta when beta is 1. Refer to class *mindspore.train.Fbeta* for more details.

$$F_1 = \frac{2 \cdot true\_positive}{2 \cdot true\_positive + false\_negative + false\_positive}$$

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import F1
>>>
>>> x = Tensor(np.array([[0.2, 0.5], [0.3, 0.1], [0.9, 0.6]]))
>>> y = Tensor(np.array([1, 0, 1]))
>>> metric = F1()
>>> metric.update(x, y)
>>> result = metric.eval()
>>> print(result)
[0.66666667 0.66666667]
```

7.3.8 mindspore.train.Fbeta

class mindspore.train.**Fbeta**(*beta*)

Calculates the Fbeta score.

Fbeta score is a weighted mean of precision and recall.

$$F_\beta = \frac{(1+\beta^2) \cdot true\_positive}{(1+\beta^2) \cdot true\_positive + \beta^2 \cdot false\_negative + false\_positive}$$

Parameters

beta (*Union[float, int]*) – Beta coefficient in the F measure. *beta* should be greater than 0.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import Fbeta
>>>
>>> x = Tensor(np.array([[0.2, 0.5], [0.3, 0.1], [0.9, 0.6]]))
>>> y = Tensor(np.array([1, 0, 1]))
>>> metric = Fbeta(1)
```

(continues on next page)

(continued from previous page)

```
>>> metric.clear()
>>> metric.update(x, y)
>>> fbeta = metric.eval()
>>> print(fbeta)
[0.66666667 0.66666667]
```

clear()
Clears the internal evaluation result.

eval(*average=False*)
Computes the fbeta.

Parameters

average (*bool*) −Whether to calculate the average fbeta. Default: `False`.

Returns

numpy.ndarray or numpy.float64, the computed result.

update(**inputs*)
Updates the internal evaluation result *y_pred* and *y*.

Parameters

inputs −Input *y_pred* and *y*. *y_pred* and *y* are Tensor, list or numpy.ndarray. *y_pred* is in most cases (not strictly) a list of floating numbers in range $[0, 1]$ and the shape is (N, C), where N is the number of cases and C is the number of categories. y contains values of integers. The shape is (N, C) if one-hot encoding is used. Shape can also be $(N,)$ if category index is used.

Raises

- **ValueError** −class numbers of last input predicted data and current predicted data not match.
- **ValueError** −If the predicted value and true value contain different classes.

7.3.9 mindspore.train.HausdorffDistance

class mindspore.train.**HausdorffDistance**(*distance_metric='euclidean'*, *percentile=None*, *directed=False*, *crop=True*)

Calculates the Hausdorff distance. Hausdorff distance is the maximum and minimum distance between two point sets. Given two feature sets A and B, the Hausdorff distance between two point sets A and B is defined as follows:

$$
\begin{aligned}
H(A, B) &= \max[h(A, B), h(B, A)] \\
h(A, B) &= \max_{a \in A}\{\min_{b \in B}\|a - b\|\} \\
h(B, A) &= \max_{b \in B}\{\min_{a \in A}\|b - a\|\}
\end{aligned}
$$

where $h(A, B)$ is the maximum distance of a set A to the nearest point in the set B, $h(B, A)$ is the maximum distance of a set B to the nearest point in the set A. The distance calculation is oriented, which means that most of times $h(A, B)$ is not equal to $h(B, A)$. $H(A, B)$ is the two-way Hausdorff distance.

Parameters

- **distance_metric** (*str*) −Three distance measurement methods are supported: `"euclidean"` (Euclidean Distance) , `"chessboard"` (Chessboard Distance, Chebyshev Distance) or `"taxicab"` (Taxicab Distance, Manhattan Distance). Default: `"euclidean"` .

- **percentile** (*float*) –Floating point numbers between 0 and 100. Specify the percentile parameter to get the percentile of the Hausdorff distance. Default: `None` .
- **directed** (*bool*) –If True, it only calculates h(y_pred, y) distance, otherwise, max(h(y_pred, y), h(y, y_pred)) will be returned. Default: `False` .
- **crop** (*bool*) –Crop input images and only keep the foregrounds. In order to maintain two inputs' shapes, here the bounding box is achieved by (y_pred | y) which represents the union set of two images. Default: `True` .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import HausdorffDistance
>>>
>>> x = Tensor(np.array([[3, 0, 1], [1, 3, 0], [1, 0, 2]]))
>>> y = Tensor(np.array([[0, 2, 1], [1, 2, 1], [0, 0, 1]]))
>>> metric = HausdorffDistance()
>>> metric.clear()
>>> metric.update(x, y, 0)
>>> mean_average_distance = metric.eval()
>>> print(mean_average_distance)
1.4142135623730951
```

clear()
Clears the internal evaluation result.

eval()
Calculate the no-directed or directed Hausdorff distance.

Returns

numpy.float64, the hausdorff distance.

Raises

RuntimeError –If the update method is not called first, an error will be reported.

update(**inputs*)
Updates the internal evaluation result with the inputs: 'y_pred', 'y' and 'label_idx'.

Parameters

inputs –Input 'y_pred', 'y' and 'label_idx'. 'y_pred' and 'y' are a *Tensor*, list or numpy.ndarray. 'y_pred' is the predicted binary image. 'y' is the actual binary image. Data type of 'label_idx' is int or float.

Raises

- **ValueError** –If the number of the inputs is not 3.
- **TypeError** –If the data type of *label_idx* is not int or float.
- **ValueError** –If the value of *label_idx* is not in *y_pred* or *y*.
- **ValueError** –If *y_pred* and *y* have different shapes.

7.3.10 mindspore.train.Loss

class mindspore.train.**Loss**

Calculates the average of the loss. If method 'update' is called every n iterations, the result of evaluation will be:

$$loss = \frac{\sum_{k=1}^{n} loss_k}{n}$$

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore.train import Loss
>>>
>>> x = Tensor(np.array(0.2), mindspore.float32)
>>> loss = Loss()
>>> loss.clear()
>>> loss.update(x)
>>> result = loss.eval()
>>> print(result)
0.20000000298023224
```

clear()

Clears the internal evaluation result.

eval()

Calculates the average of the loss.

Returns

numpy.float64. The average of the loss.

Raises

RuntimeError – If the total number is 0.

update(**inputs*)

Updates the internal evaluation result.

Parameters

inputs – Inputs contain only one element, the element is loss. The dimension of loss must be 0 or 1.

Raises

- **ValueError** – If the length of inputs is not 1.
- **ValueError** – If the dimension of loss is not 1 or 0.

7.3.11 mindspore.train.MAE

class mindspore.train.**MAE**

Calculates the mean absolute error(MAE).

Creates a criterion that measures the MAE between each element in the input: y_pred and the target: y.

$$\text{MAE} = \frac{\sum_{i=1}^{n} \|y\_pred_i - y_i\|}{n}$$

where n is batch size.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore.train import MAE
>>>
>>> x = Tensor(np.array([0.1, 0.2, 0.6, 0.9]), mindspore.float32)
>>> y = Tensor(np.array([0.1, 0.25, 0.7, 0.9]), mindspore.float32)
>>> error = MAE()
>>> error.clear()
>>> error.update(x, y)
>>> result = error.eval()
>>> print(result)
0.037499990314245224
```

clear()

Clears the internal evaluation result.

eval()

Computes the mean absolute error(MAE).

Returns

numpy.float64. The computed result.

Raises

RuntimeError – If the total number of samples is 0.

update(**inputs*)

Updates the internal evaluation result y_{pred} and y.

Parameters

inputs – Input *y_pred* and *y* for calculating MAE where the shape of *y_pred* and *y* are both N-D and the shape should be the same.

Raises

ValueError – If the number of the input is not 2.

7.3.12 mindspore.train.MeanSurfaceDistance

class mindspore.train.**MeanSurfaceDistance**(*symmetric=False*, *distance_metric='euclidean'*)

Computes the Average Surface Distance from *y_pred* to *y* under the default setting. It measures how much, on average, the surface varies between the segmentation and the GT (ground truth).

Given two sets A and B, S(A) denotes the set of surface voxels of A, the shortest distance of an arbitrary voxel v to S(A) is defined as:

$$\text{dis}(v, S(A)) = \min_{s_A \in S(A)} \|v - s_A\|$$

The Average Surface Distance from set(B) to set(A) is given by:

$$AvgSurDis(B \to A) = \frac{\sum_{s_B \in S(B)} \text{dis}(s_B, S(A))}{|S(B)|}$$

Where the ||*|| denotes a distance measure. |*| denotes the number of elements.

The mean of surface distance from set(B) to set(A) and from set(A) to set(B) is:

$$MeanSurDis(A \leftrightarrow B) = \frac{\sum_{s_A \in S(A)} \text{dis}(s_A, S(B)) + \sum_{s_B \in S(B)} \text{dis}(s_B, S(A))}{|S(A)| + |S(B)|}$$

Parameters

- **distance_metric** (*str*) –Three measurement methods are supported: `"euclidean"` (Euclidean Distance) , `"chessboard"` (Chessboard Distance, Chebyshev Distance) or `"taxicab"` (Taxicab Distance, Manhattan Distance) Default: `"euclidean"` .
- **symmetric** (*bool*) –Whether to calculate the Mean Surface Distance between y_pred and y. If False, it only calculates $AvgSurDis(y\_pred \to y)$, otherwise, the mean of distance from *y_pred* to *y* and from *y* to *y_pred*, i.e. $MeanSurDis(y\_pred \leftrightarrow y)$, will be returned. Default: `False` .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import MeanSurfaceDistance
>>> x = Tensor(np.array([[3, 0, 1], [1, 3, 0], [1, 0, 2]]))
>>> y = Tensor(np.array([[0, 2, 1], [1, 2, 1], [0, 0, 1]]))
>>> metric = MeanSurfaceDistance(symmetric=False, distance_metric="euclidean")
>>> metric.clear()
>>> metric.update(x, y, 0)
>>> mean_average_distance = metric.eval()
>>> print(mean_average_distance)
0.8047378541243649
```

clear()

Clears the internal evaluation result.

eval()

Calculate mean surface distance.

Returns

numpy.float64. The mean surface distance value.

Raises

RuntimeError –If the update method is not called first, an error will be reported.

update(**inputs*)

Updates the internal evaluation result 'y_pred', 'y' and 'label_idx'.

Parameters

inputs –Input 'y_pred', 'y' and 'label_idx'. 'y_pred' and 'y' are a Tensor, list or numpy.ndarray. 'y_pred' is the predicted binary image. 'y' is the actual binary image. 'label_idx', the data type of *label_idx* is int.

Raises

- **ValueError** –If the number of the inputs is not 3.
- **TypeError** –If the data type of label_idx is not int or float.
- **ValueError** –If the value of label_idx is not in *y_pred* or *y*.
- **ValueError** –If *y_pred* and *y* have different shapes.

7.3.13 mindspore.train.Metric

class mindspore.train.**Metric**

Base class of metric, which is used to evaluate metrics.

The *clear*, *update*, and *eval* should be called when evaluating metric, and they should be overridden by subclasse. *update* will accumulate intermediate results in the evaluation process, *eval* will evaluate the final result, and *clear* will reinitialize the intermediate results.

Never use this class directly, but instantiate one of its subclasses instead, for examples, *mindspore.train.MAE*, *mindspore.train.Recall* etc.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>>
>>> class MyMAE(ms.train.Metric):
...     def __init__(self):
...         super(MyMAE, self).__init__()
...         self.clear()
...
...     def clear(self):
...         self._abs_error_sum = 0
...         self._samples_num = 0
...
...     def update(self, *inputs):
...         y_pred = inputs[0].asnumpy()
...         y = inputs[1].asnumpy()
...         abs_error_sum = np.abs(y - y_pred)
...         self._abs_error_sum += abs_error_sum.sum()
```

(continues on next page)

(continued from previous page)

```
...         self._samples_num += y.shape[0]
...
...     def eval(self):
...         return self._abs_error_sum / self._samples_num
>>>
>>> x = ms.Tensor(np.array([[0.1, 0.2, 0.6, 0.9], [0.1, 0.2, 0.6, 0.9]]), ms.float32)
>>> y = ms.Tensor(np.array([[0.1, 0.1, 0.1, 0.1], [0.1, 0.1, 0.1, 0.1]]), ms.float32)
>>> y2 = ms.Tensor(np.array([[0.1, 0.25, 0.7, 0.9], [0.1, 0.25, 0.7, 0.9]]), ms.float32)
>>> metric = MyMAE().set_indexes([0, 2])
>>> metric.clear()
>>> # indexes is [0, 2], using x as logits, y2 as label.
>>> metric.update(x, y, y2)
>>> accuracy = metric.eval()
>>> print(accuracy)
1.399999976158142
>>> print(metric.indexes)
[0, 2]
```

abstract clear()

An interface describes the behavior of clearing the internal evaluation result.

Note: All subclasses must override this interface.

---

abstract eval()

An interface describes the behavior of computing the evaluation result.

Note: All subclasses must override this interface.

---

property indexes

Get the current indexes value. The default value is None and can be changed by *set_indexes*.

set_indexes(*indexes*)

This interface is to rearrange the inputs of *update*.

Given (label0, label1, logits), set the *indexes* to [2, 1] then the (logits, label1) will be the actually inputs of *update*.

Note: When customize a metric, decorate the *update* function with the decorator *mindspore.train.rearrange_inputs()* for the *indexes* to take effect.

Parameters

indexes (*List(int)*) – The order of logits and labels to be rearranged.

Outputs:

Metric, its original Class instance.

Raises

ValueError – If the type of input 'indexes' is not a list or its elements are not all int.

abstract update(**inputs*)

An interface describes the behavior of updating the internal evaluation result.

Note: All subclasses must override this interface.

Parameters

inputs –A variable-length input argument list, usually are the logits and the corresponding labels.

7.3.14 mindspore.train.MSE

class mindspore.train.**MSE**

Measures the mean squared error(MSE).

Creates a criterion that measures the MSE (squared L2 norm) between each element in the prediction and the ground truth: y_pred and: y.

$$\text{MSE}(y\_pred,\ y) = \frac{\sum_{i=1}^{n}(y\_pred_i - y_i)^2}{n}$$

where n is batch size.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore.train import MSE
>>>
>>> x = Tensor(np.array([0.1, 0.2, 0.6, 0.9]), mindspore.float32)
>>> y = Tensor(np.array([0.1, 0.25, 0.5, 0.9]), mindspore.float32)
>>> error = MSE()
>>> error.clear()
>>> error.update(x, y)
>>> result = error.eval()
>>> print(result)
0.0031250009778887033
```

clear()

Clear the internal evaluation result.

eval()

Computes the mean squared error(MSE).

Returns

numpy.float64. The computed result.

Raises

RuntimeError –If the number of samples is 0.

update(**inputs*)

Updates the internal evaluation result y_{pred} and y.

Parameters

inputs – Input y_pred and y for calculating the MSE where the shape of y_pred and y are both N-D and the shape should be the same.

Raises

ValueError – If the number of inputs is not 2.

7.3.15 mindspore.train.OcclusionSensitivity

class mindspore.train.**OcclusionSensitivity**(*pad_val=0.0*, *margin=2*, *n_batch=128*, *b_box=None*)

Calculates the occlusion sensitivity of the model for a given image, which illustrates which parts of an image are most important for a network's classification.

Occlusion sensitivity refers to how the predicted probability changes with the change of the occluded part of an image. The higher the value in the output image is, the greater the certainty decline of the category after masking, indicating that the occluded area is more important in the decision-making process.

Parameters

- **pad_val** (*float*) – The padding value of the occluded part in an image. Default: `0.0` .
- **margin** (*Union[int, Sequence]*) – Create a cuboid / cube size of pixel points around the voxel you want to occlude. Default: `2` .
- **n_batch** (*int*) – number of images in a batch. Default: `128` .
- **b_box** (*Sequence*) – Bounding box on which to perform the analysis. The output image will also match in size. There should be a minimum and maximum for all dimensions except batch: `[min1, max1, min2, max2,...]`. If no bounding box is supplied, this will be the same size as the input image. If a bounding box is used, the output image will be cropped to this size. Default: `None` .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import nn, Tensor
>>> from mindspore.train import OcclusionSensitivity
>>>
>>> class DenseNet(nn.Cell):
...     def __init__(self):
...         super(DenseNet, self).__init__()
...         w = np.array([[0.1, 0.8, 0.1, 0.1],[1, 1, 1, 1]]).astype(np.float32)
...         b = np.array([0.3, 0.6]).astype(np.float32)
...         self.dense = nn.Dense(4, 2, weight_init=Tensor(w), bias_init=Tensor(b))
...
...     def construct(self, x):
...         return self.dense(x)
>>>
>>> model = DenseNet()
>>> test_data = np.array([[0.1, 0.2, 0.3, 0.4]]).astype(np.float32)
>>> label = np.array(1).astype(np.int32)
>>> metric = OcclusionSensitivity()
>>> metric.clear()
>>> metric.update(model, test_data, label)
```

(continues on next page)

(continued from previous page)

```
>>> score = metric.eval()
>>> print(score)
[0.29999995    0.6    1.    0.9]
```

clear()
Clears the internal evaluation result.

eval()
Computes the occlusion_sensitivity.

Returns

A numpy ndarray.

Raises

RuntimeError –If the update method is not called first, an error will be reported.

update(**inputs*)
Updates input, including *model*, *y_pred* and *label*.

Parameters

inputs –*y_pred* and *label* are a Tensor, list or numpy.ndarray. *y_pred*: a batch of images to test, which could be 2D or 3D. *label*: classification labels to check for changes. *label* is normally the true label, but doesn't have to be. *model* is the neural network.

Raises

- **ValueError** –If the number of inputs is not 3.
- **RuntimeError** –If y_pred.shape[0] is not 1.
- **RuntimeError** –If the number of labels is different from the number of batches.

7.3.16 mindspore.train.Perplexity

class mindspore.train.**Perplexity**(*ignore_label=None*)
Computes perplexity. Perplexity is a measurement about how well a probability distribution or a model predicts a sample. A low perplexity indicates the model can predict the sample well. The function is shown as follows:

$$PP(W) = P(w_1 w_2 ... w_N)^{-\frac{1}{N}} = \sqrt[N]{\frac{1}{P(w_1 w_2 ... w_N)}}$$

Where *w* represents words in corpus. The root sign is the reciprocal of the probability of a sentence, and the better the sentence (with a higher probability), the lower the perplexity.

Parameters

ignore_label (*Union[int, None]*) –Index of an invalid label to be ignored when counting. If set to *None*, it will include all entries. Default: `None` .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import Perplexity
>>> x = Tensor(np.array([[0.2, 0.5], [0.3, 0.1], [0.9, 0.6]]))
>>> y = Tensor(np.array([1, 0, 1]))
>>> metric = Perplexity(ignore_label=None)
>>> metric.clear()
>>> metric.update(x, y)
>>> perplexity = metric.eval()
>>> print(perplexity)
2.231443166940565
```

clear()
Clears the internal evaluation result.

eval()
Returns the current evaluation result.

Returns

numpy.float64. The computed result.

Raises

RuntimeError –If the sample size is 0.

update(**inputs*)
Updates the internal evaluation result *preds* and *labels*.

Parameters

inputs –Input *preds* and *labels*. *preds* and *labels* are a *Tensor*, list or numpy.ndarray. *preds* is the predicted values, *labels* is the labels of the data. The shape of *preds* and *labels* are both (N, C).

Raises

- **ValueError** –If the number of the inputs is not 2.
- **RuntimeError** –If preds and labels have different lengths.
- **RuntimeError** –If label shape is not equal to pred shape.

7.3.17 mindspore.train.Precision

class mindspore.train.**Precision**(*eval_type='classification'*)
Calculates precision for classification and multilabel data.

The precision function creates two local variables, true_positive and false_positive, which are used to compute the precision. The calculation formula is:

$$\text{precision} = \frac{\text{true\_positive}}{\text{true\_positive} + \text{false\_positive}}$$

Parameters

eval_type (*str*) –'classification' or 'multilabel' are supported. See the update method below for what it does. Default: 'classification' .

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import Precision
>>>
>>> x = Tensor(np.array([[0.2, 0.5], [0.3, 0.1], [0.9, 0.6]]))
>>> y = Tensor(np.array([1, 0, 1]))
>>> metric = Precision('classification')
>>> metric.clear()
>>> metric.update(x, y)
>>> precision = metric.eval()
>>> print(precision)
[0.5 1. ]
```

clear()
Clears the internal evaluation result.

eval(*average=False*)
Computes the precision.

Parameters

average (*bool*) –Specify whether calculate the average precision. Default: `False` .

Returns

numpy.float64, the computed result.

update(**inputs*)
Updates the internal evaluation result with y_pred and y. In the multi-label cases, the elements of y and y_pred must be 0 or 1.

Parameters

inputs –Input y_pred and y. y_pred and y are Tensor, list or numpy.ndarray. For 'classification' evaluation type, y_pred is in most cases (not strictly) a list of floating numbers in range $[0, 1]$ and the shape is (N, C), where N is the number of cases and C is the number of categories. Shape of y can be (N, C) with values 0 and 1 if one-hot encoding is used or the shape is $(N,)$ with integer values if index of category is used. For 'multilabel' evaluation type, y_pred and y can only be one-hot encoding with values 0 or 1. Indices with 1 indicate positive category. The shape of y_pred and y are both (N, C).

Raises

ValueError –If the number of inputs is not 2.

7.3.18 mindspore.train.Recall

class mindspore.train.**Recall**(*eval_type='classification'*)
Calculates recall for classification and multilabel data.

The recall class creates two local variables, true_positive and false_negative, that are used to compute the recall. The calculation formula is:

$$\text{recall} = \frac{\text{true\_positive}}{\text{true\_positive} + \text{false\_negative}}$$

Note: In the multi-label cases, the elements of y and y_{pred} must be 0 or 1.

Parameters

eval_type (*str*) – `'classification'` or `'multilabel'` is supported. Default: `'classification'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import Recall
>>>
>>> x = Tensor(np.array([[0.2, 0.5], [0.3, 0.1], [0.9, 0.6]]))
>>> y = Tensor(np.array([1, 0, 1]))
>>> metric = Recall('classification')
>>> metric.clear()
>>> metric.update(x, y)
>>> recall = metric.eval()
>>> print(recall)
[1. 0.5]
```

clear()
Clears the internal evaluation result.

eval(*average=False*)
Computes the recall.

Parameters

average (*bool*) – Specify whether calculate the average recall. Default: `False`.

Returns

numpy.float64, the computed result.

update(**inputs*)
Updates the internal evaluation result with *y_pred* and *y*.

Parameters

inputs – Input *y_pred* and *y*. *y_pred* and *y* are a *Tensor*, a list or an array.

- For 'classification' scenario, *y_pred* is in most cases (not strictly) a list of floating numbers in range $[0, 1]$ and the shape is (N, C), where N is the number of cases and C is the number of categories. Shape of *y* can be (N, C) with values 0 and 1 if one-hot encoding is used or the shape is $(N,)$ with integer values if index of category is used.
- For 'multilabel' scenario, *y_pred* and *y* can only be one-hot encoding with values 0 or 1. Indices with 1 indicate positive category. The shape of *y_pred* and *y* are both (N, C).

Raises

ValueError – If the number of inputs is not 2.

7.3.19 mindspore.train.ROC

class mindspore.train.**ROC**(*class_num=None*, *pos_label=None*)

Calculates the ROC curve. It is suitable for solving binary classification and multi classification problems. In the case of multiclass, the values will be calculated based on a one-vs-the-rest approach.

Parameters

- **class_num** (*int*) –The number of classes. It is not necessary to provide this argument under the binary classification scenario. Default: None .
- **pos_label** (*int*) –Determine the integer of positive class. For binary problems, it is translated to 1 by default. For multiclass problems, this argument should not be set, as it will iteratively changed in the range [0, num_classes-1]. Default: None .

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import ROC
>>>
>>> # 1) binary classification example
>>> x = Tensor(np.array([0.28, 0.55, 0.15, 0.05]))
>>> y = Tensor(np.array([0, 1, 2, 3]))
>>> metric = ROC(pos_label=2)
>>> metric.clear()
>>> metric.update(x, y)
>>> fpr, tpr, thresholds = metric.eval()
>>> print(fpr)
[0.         0.33333333 0.66666667 0.66666667 1.        ]
>>> print(tpr)
[0. 0. 0. 1. 1.]
>>> print(thresholds)
[1.55 0.55 0.28 0.15 0.05]
>>>
>>> # 2) multiclass classification example
>>> x = Tensor(np.array([[0.28, 0.55, 0.15, 0.05], [0.10, 0.20, 0.05, 0.05], [0.20, 0.05, 0.
↪15, 0.05],
...                      [0.05, 0.05, 0.05, 0.75]]))
>>> y = Tensor(np.array([0, 1, 2, 3]))
>>> metric = ROC(class_num=4)
>>> metric.clear()
>>> metric.update(x, y)
>>> fpr, tpr, thresholds = metric.eval()
>>> print(fpr)
[array([0., 0., 0.33333333, 0.66666667, 1.]), array([0., 0.33333333, 0.33333333, 1.]),
array([0., 0.33333333, 1.]), array([0., 0., 1.])]
>>> print(tpr)
[array([0., 1., 1., 1., 1.]), array([0., 0., 1., 1.]), array([0., 1., 1.]), array([0., 1., 1.
↪])]
>>> print(thresholds)
```

(continues on next page)

(continued from previous page)

```
[array([1.28, 0.28, 0.2, 0.1, 0.05]), array([1.55, 0.55, 0.2, 0.05]), array([1.15, 0.15, 0.
↪05]),
array([1.75, 0.75, 0.05])]
```

clear()
Clear the internal evaluation result.

eval()
Computes the ROC curve.

Returns

A tuple, composed of *fpr*, *tpr*, and *thresholds*.

- **fpr** (np.array) - False positive rate. In binary classification case, a fpr numpy array under different thresholds will be returned, otherwise in multiclass case, a list of fpr numpy arrays will be returned and each element represents one category.
- **tpr** (np.array) - True positive rates. n binary classification case, a tpr numpy array under different thresholds will be returned, otherwise in multiclass case, a list of tpr numpy arrays will be returned and each element represents one category.
- **thresholds** (np.array) - Thresholds used for computing fpr and tpr.

Raises

RuntimeError – If the update method is not called first, an error will be reported.

update(**inputs*)
Update state with predictions and targets.

Parameters

inputs – Input *y_pred* and *y*. *y_pred* and *y* are *Tensor*, list or numpy.ndarray. In most cases (not strictly), y_pred is a list of floating numbers in range $[0, 1]$ and the shape is (N, C), where N is the number of cases and C is the number of categories. y contains values of integers. The shape is (N, C) if one-hot encoding is used. Shape can also be $(N,)$ if category index is used.

7.3.20 mindspore.train.RootMeanSquareDistance

class mindspore.train.**RootMeanSquareDistance**(*symmetric=False*, *distance_metric='euclidean'*)
Computes the Root Mean Square Surface Distance from *y_pred* to *y* under the default setting.

Given two sets A and B, S(A) denotes the set of surface voxels of A, the shortest distance of an arbitrary voxel v to S(A) is defined as:

$$\operatorname{dis}(v, S(A)) = \min_{s_A \in S(A)} \|v - s_A\|$$

The Root Mean Square Surface Distance from set(B) to set(A) is:

$$RmsSurDis(B \to A) = \sqrt{\frac{\sum_{s_B \in S(B)} \operatorname{dis}^2(s_B, S(A))}{|S(B)|}}$$

Where the ||*|| denotes a distance measure. |*| denotes the number of elements.

The Root Mean Square Surface Distance from set(B) to set(A) and from set(A) to set(B) is:

$$RmsSurDis(A \leftrightarrow B) = \sqrt{\frac{\sum_{s_A \in S(A)} \operatorname{dis}(s_A, S(B))^2 + \sum_{s_B \in S(B)} \operatorname{dis}(s_B, S(A))^2}{|S(A)| + |S(B)|}}$$

Parameters

- **distance_metric** (*str*) −Three measurement methods are supported: "euclidean" (Euclidean Distance) , "chessboard" (Chessboard Distance, Chebyshev Distance) or "taxicab" (Taxicab Distance, Manhattan Distance). Default: "euclidean" .
- **symmetric** (*bool*) −Whether to calculate the symmetric average root mean square distance between *y_pred* and *y*. If False, only calculates $RmsSurDis(y\_pred, y)$ surface distance, otherwise, the mean of distance from *y_pred* to *y* and from *y* to *y_pred*, i.e. $RmsSurDis(y\_pred \leftrightarrow y)$ will be returned. Default: False .

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import RootMeanSquareDistance
>>>
>>> x = Tensor(np.array([[3, 0, 1], [1, 3, 0], [1, 0, 2]]))
>>> y = Tensor(np.array([[0, 2, 1], [1, 2, 1], [0, 0, 1]]))
>>> metric = RootMeanSquareDistance(symmetric=False, distance_metric="euclidean")
>>> metric.clear()
>>> metric.update(x, y, 0)
>>> root_mean_square_distance = metric.eval()
>>> print(root_mean_square_distance)
1.0000000000000002
```

clear()
Clears the internal evaluation result.

eval()
Calculate Root Mean Square Distance.

Returns

numpy.float64, root mean square surface distance.

Raises

RuntimeError −If the update method is not called first, an error will be reported.

update(**inputs*)
Updates the internal evaluation result 'y_pred', 'y' and 'label_idx'.

Parameters

inputs −Input 'y_pred', 'y' and 'label_idx'. 'y_pred' and 'y' are *Tensor*, list or numpy.ndarray. 'y_pred' is the predicted binary image. 'y' is the actual binary image. 'label_idx', the data type of *label_idx* is int.

Raises

- **ValueError** −If the number of the inputs is not 3.
- **TypeError** −If the data type of label_idx is not int or float.
- **ValueError** −If the value of label_idx is not in y_pred or y.
- **ValueError** −If y_pred and y have different shapes.

7.3.21 mindspore.train.Top1CategoricalAccuracy

class mindspore.train.**Top1CategoricalAccuracy**

Calculates the top-1 categorical accuracy. This class is a specialized class for TopKCategoricalAccuracy. Refer to *mindspore.train.TopKCategoricalAccuracy* for more details.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore.train import Top1CategoricalAccuracy
>>>
>>> x = Tensor(np.array([[0.2, 0.5, 0.3, 0.6, 0.2], [0.1, 0.35, 0.5, 0.2, 0.],
...          [0.9, 0.6, 0.2, 0.01, 0.3]]), mindspore.float32)
>>> y = Tensor(np.array([2, 0, 1]), mindspore.float32)
>>> topk = Top1CategoricalAccuracy()
>>> topk.clear()
>>> topk.update(x, y)
>>> output = topk.eval()
>>> print(output)
0.0
```

7.3.22 mindspore.train.Top5CategoricalAccuracy

class mindspore.train.**Top5CategoricalAccuracy**

Calculates the top-5 categorical accuracy. This class is a specialized class for TopKCategoricalAccuracy. Refer to *mindspore.train.TopKCategoricalAccuracy* for more details.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore.train import Top5CategoricalAccuracy
>>>
>>> x = Tensor(np.array([[0.2, 0.5, 0.3, 0.6, 0.2], [0.1, 0.35, 0.5, 0.2, 0.],
...             [0.9, 0.6, 0.2, 0.01, 0.3]]), mindspore.float32)
>>> y = Tensor(np.array([2, 0, 1]), mindspore.float32)
>>> topk = Top5CategoricalAccuracy()
>>> topk.clear()
>>> topk.update(x, y)
>>> output = topk.eval()
>>> print(output)
1.0
```

7.3.23 mindspore.train.TopKCategoricalAccuracy

class mindspore.train.**TopKCategoricalAccuracy**(*k*)

Calculates the top-k categorical accuracy.

Parameters

k (*int*) –Specifies the top-k categorical accuracy to compute.

Raises

- **TypeError** –If *k* is not int.
- **ValueError** –If *k* is less than 1.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.train import TopKCategoricalAccuracy
>>>
>>> x = Tensor(np.array([[0.2, 0.5, 0.3, 0.6, 0.2], [0.1, 0.35, 0.5, 0.2, 0.],
...          [0.9, 0.6, 0.2, 0.01, 0.3]]), mindspore.float32)
>>> y = Tensor(np.array([2, 0, 1]), mindspore.float32)
>>> topk = TopKCategoricalAccuracy(3)
>>> topk.clear()
>>> topk.update(x, y)
>>> output = topk.eval()
>>> print(output)
0.6666666666666666
```

clear()

Clear the internal evaluation result.

eval()

Computes the top-k categorical accuracy.

Returns

numpy.float64, computed result.

update(**inputs*)

Updates the internal evaluation result *y_pred* and *y*.

Parameters

inputs –Input *y_pred* and *y*. *y_pred* and *y* are Tensor, list or numpy.ndarray. *y_pred* is in most cases (not strictly) a list of floating numbers in range $[0, 1]$ and the shape is (N, C), where N is the number of cases and C is the number of categories. *y* contains values of integers. The shape is (N, C) if one-hot encoding is used. Shape can also be $(N,)$ if category index is used.

Note: The method *update* must receive input of the form (y_pred, y). If some samples have the same accuracy, the first sample will be chosen.

7.4 Utils

API Name	Description	Supported Platforms
mindspore.train.auc	Computes the AUC(Area Under the Curve) using the trapezoidal rule.	Ascend GPU CPU
mindspore.train.get_metric_fn	Gets the metric method based on the input name.	Ascend GPU CPU
mindspore.train.names	Gets all names of the metric methods.	Ascend GPU CPU
mindspore.train.rearrange_inputs	This decorator is used to rearrange the inputs according to its *indexes* attribute of the class.	Ascend GPU CPU

7.4.1 mindspore.train.auc

mindspore.train.**auc**(*x*, *y*, *reorder=False*)

Computes the AUC(Area Under the Curve) using the trapezoidal rule. This is a general function, given points on a curve, for computing the area under the ROC-curve.

Parameters

- **x** (*Union[np.array, list]*) –From the ROC curve(fpr), np.array with false positive rates. If multiclass, this is a list of such np.array, one for each class. The shape (N).
- **y** (*Union[np.array, list]*) –From the ROC curve(tpr), np.array with true positive rates. If multiclass, this is a list of such np.array, one for each class. The shape (N).
- **reorder** (*bool*) –If False, x must rise or fall monotonously. If True, x will be sorted in ascending order. Default: False.

Returns

float, the area under the ROC-curve.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore.train import ROC, auc
>>>
>>> y_pred = np.array([[3, 0, 1], [1, 3, 0], [1, 0, 2]])
>>> y = np.array([[0, 2, 1], [1, 2, 1], [0, 0, 1]])
>>> metric = ROC(pos_label=2)
>>> metric.clear()
>>> metric.update(y_pred, y)
>>> fpr, tpr, thre = metric.eval()
>>> output = auc(fpr, tpr)
>>> print(output)
0.5357142857142857
```

7.4.2 mindspore.train.get_metric_fn

mindspore.train.**get_metric_fn**(*name*, **args*, ***kwargs*)

Gets the metric method based on the input name.

Parameters

- **name** (*str*) −The name of metric method. Names can be obtained by *mindspore.train.names()* . object for the currently supported metrics.
- **args** −Arguments for the metric function.
- **kwargs** −Keyword arguments for the metric function.

Returns

Metric object, class instance of the metric method.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore.train import get_metric_fn
>>> metric = get_metric_fn('precision', eval_type='classification')
```

7.4.3 mindspore.train.names

mindspore.train.**names**()

Gets all names of the metric methods.

Returns

List, the name list of metric methods.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> ms.train.names()
['F1', 'acc', 'accuracy', 'auc', 'bleu_score', 'confusion_matrix', 'confusion_matrix_metric',
'cosine_similarity', 'dice', 'hausdorff_distance', 'loss', 'mae', 'mean_surface_distance',
 ↪'mse',
'occlusion_sensitivity', 'perplexity', 'precision', 'recall', 'roc', 'root_mean_square_
 ↪distance',
'top_1_accuracy', 'top_5_accuracy', 'topk']
```

7.4.4 mindspore.train.rearrange_inputs

mindspore.train.**rearrange_inputs**(*func*)

This decorator is used to rearrange the inputs according to its *indexes* attribute of the class.

This decorator is currently applied on the *update* of *mindspore.train.Metric*.

Parameters

func (*Callable*) – A candidate function to be wrapped whose input will be rearranged.

Returns

Callable, used to exchange metadata between functions.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore.train import rearrange_inputs
>>> class RearrangeInputsExample:
...     def __init__(self):
...         self._indexes = None
...
...     @property
...     def indexes(self):
...         return getattr(self, '_indexes', None)
...
...     def set_indexes(self, indexes):
...         self._indexes = indexes
...         return self
...
...     @rearrange_inputs
...     def update(self, *inputs):
...         return inputs
>>>
>>> rearrange_inputs_example = RearrangeInputsExample().set_indexes([1, 0])

```

CHAPTER

EIGHT

MINDSPORE.PARALLEL

mindspore.parallel provides a large number of interfaces for automatic parallelization, including parallel base configuration, model loading and transformation, and functional parallel slicing.

The module import method is as follows:

```
from mindspore import parallel
```

8.1 Parallel Base Configuration

mindspore.parallel.auto_parallel.AutoParallel	Encapsulation of top-level Cells or functions to realize static graph parallelism for a single network.
mindspore.parallel.nn.GradAccumulation	Implementation of parallel gradient accumulation for static graphs.
mindspore.parallel.nn.MicroBatchInterleaved	Implement the static graph parallel multi-copy splitting function to enable concurrent computation and communication.
mindspore.parallel.nn.Pipeline	Specify the number of micro_batch for pipeline parallelism and the division rules for stage.
mindspore.parallel.nn.PipelineGradReducer	Functional training scenarios for gradient statute and accumulation of pipeline parallel.

8.1.1 mindspore.parallel.auto_parallel.AutoParallel

class mindspore.parallel.auto_parallel.**AutoParallel**(*network*, *parallel_mode='semi_auto'*)

Encapsulation of top-level Cells or functions to realize static graph parallelism for a single network.

Note:

- When using the *Model* API, the network passed to the *Model* must be wrapped with *AutoParallel*.
- When using *functional* API, the outermost layer must be wrapped with *AutoParallel*.
- When using *functional* API, data sinking mode are not currently supported.

Parameters

- **network** (*Union[Cell, Function]*) –Top-level cell or function in the forward network. Defines the core computational graph structure that will be parallelized.

- **parallel_mode** (*str, optional*) –Specifies the parallelization strategy engine. Available modes: "semi_auto", "sharding_propagation", "recursive_programming". Default: "semi_auto".
  - semi_auto: Achieves data and model parallelism by setting parallel strategies.
  - sharding_propagation: Automatic strategy propagation mode. Infers sharding strategies for non-annotated operators based on configured operator strategies. Dynamic shapes are not supported currently.
  - recursive_programming: Full automatic parallelization mode. Dynamically generates parallel strategies through recursive program analysis.

Supported Platforms:

Ascend

Examples

Note: You need to use the msrun command to run the following examples.

```
>>> import os
>>> import mindspore as ms
>>> import mindspore.dataset as ds
>>> from mindspore import nn, ops
>>> from mindspore.communication import init, get_rank
>>> from mindspore.common.initializer import initializer
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>> from mindspore.train import Model
>>> from mindspore.train import LossMonitor
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> init()
>>> ms.set_seed(1)
>>>
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>>
>>> def create_dataset(batch_size):
...     dataset_path = os.getenv("DATA_PATH")
...     dataset = ds.MnistDataset(dataset_path)
...     image_transforms = [
...         ds.vision.Rescale(1.0 / 255.0, 0),
...         ds.vision.Normalize(mean=(0.1307,), std=(0.3081,)),
...         ds.vision.HWC2CHW()
...     ]
...     label_transform = ds.transforms.TypeCast(ms.int32)
...     dataset = dataset.map(image_transforms, 'image')
...     dataset = dataset.map(label_transform, 'label')
...     dataset = dataset.batch(batch_size)
...     return dataset
>>>
>>> dataset = create_dataset(32)
>>>
>>> from mindspore import nn, ops, Parameter
>>> from mindspore.common.initializer import initializer, HeUniform
>>> import math
>>>
>>> class MatMulCell(nn.Cell):
```

(continues on next page)

(continued from previous page)

```
...     def __init__(self, param=None, shape=None):
...         super().__init__()
...         if shape is None:
...             shape = [28 * 28, 512]
...         weight_init = HeUniform(math.sqrt(5))
...         self.param = Parameter(initializer(weight_init, shape), name="param")
...         if param is not None:
...             self.param = param
...         self.print = ops.Print()
...         self.matmul = ops.MatMul()
...
...     def construct(self, x):
...         out = self.matmul(x, self.param)
...         self.print("out is:", out)
...         return out
>>>
>>> class Network(nn.Cell):

>>> model = Model(network=parallel_net, optimizer=optimizer)
>>> model.train(epoch=2, train_dataset=dataset, callbacks=[loss_monitor])
```

comm_fusion(*config*)

Set fusion configuration of parallel communication operators.

Parameters

config (*dict*) – A dict contains the types and configurations for setting the communication fusion. Each communication fusion config has two keys: "mode" and "config". It supports following communication fusion types and configurations:

- openstate: Whether turn on the communication fusion or not. If *openstate* is *True*, turn on the communication fusion, otherwise, turn off the communication fusion. Default: *True*.
- allreduce: if communication fusion type is *allreduce*. The *mode* contains: *auto*, *size* and *index*. In *auto* mode, allreduce fusion is configured by gradients size, and the default fusion threshold is *64* MB. In 'size' mode, allreduce fusion is configured by gradients size manually, and the fusion threshold must be larger than *0* MB. In *index* mode, it is same as *all_reduce_fusion_config*.
- allgather: If communication fusion type is *allgather*. The *mode* contains: *auto*, *size*. In *auto* mode, AllGather fusion is configured by gradients size, and the default fusion threshold is *64* MB. In 'size' mode, AllGather fusion is configured by gradients size manually, and the fusion threshold must be larger than *0* MB.
- reducescatter: If communication fusion type is *reducescatter*. The *mode* contains: *auto* and *size*. Config is same as *allgather*.

Raises

TypeError – If the type of config is not dict.

Examples

```
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> parallel_net = AutoParallel(net, parallel_mode="semi_auto")
>>> comm_config = {"openstate": True, "allreduce": {"mode": "auto", "config": None}}
>>> net.comm_fusion(config=comm_config)
```

dataset_strategy(*config*)

Set dataset sharding strategy.

Parameters

config (*Union[str, tuple(tuple), tuple(Layout)]*) – The dataset sharding strategy. Default: "data_parallel". If you want to split dataset across devices, you can set the dataset strategy as "data_parallel". If you load whole batch datasets, you need to set the dataset strategy as "full_batch". For dataset load into net by dataset strategy like ds_stra((1, 8), (1, 8)),it requires using AutoParallel.dataset_strategy(ds_stra).Besides, dataset strategy also supports tuple of Layout.

Raises

- **TypeError** –When 'config' is not str type nor tuple type.
- **TypeError** –If 'config' is tuple type, but its element is not tuple type nor Layout type.
- **TypeError** –If 'config' is tuple type and its element is tuple type, the element in subtuple isn't int type.
- **ValueError** –If 'config' is None.
- **ValueError** –If the type of 'config' is str, but it's value is not 'full_batch' or 'data_parallel'.

disable_gradient_fp32_sync()
Disable convert tensor type from fp16 to fp32 before parameter gradients allreduce.

disable_loss_repeated_mean()
The mean operator is not executed backwards when the calculation is repeated.

disable_strategy_file_only_for_trainable_params()
By default, MindSpore only loads and saves trainable parameters. This API enables the loading and saving of non-trainable parameters as well.

dump_local_norm(*file_path*)
Enable local norm printing with disk storage only (no console output).

Parameters

file_path (*str*) –The path to save local_norm.

Raises

TypeError –If the type of 'file_path' is not str.

enable_device_local_norm()
Enable device local norm printing.

enable_fp32_communication()
Enable reduce operators (AllReduce, ReduceScatter) are forced to use the fp32 data type for communication during communication.

enable_gradients_mean()
Perform mean operator after allreduce of gradients in parallel mode.

hsdp(*shard_size=- 1*, *threshold=64*, *optimizer_level='level1'*)
Set optimizer parallel configs.

Parameters

- **shard_size** (*int, optional*) –Set the optimizer weight shard group size if you want to specific the maximum group size across devices when the parallel optimizer is enabled. The numerical range can be (0, device_num] or -1. Default value is -1, which means the optimizer weight shard group size will the data parallel group of each parameter.
- **threshold** (*int, optional*) –Set the threshold of parallel optimizer. When parallel optimizer is enabled, parameters with size smaller than this threshold will not be sharded across the devices. Parameter size = shape[0] * ···* shape[n] * size(dtype). Non-negative. Unit: KB. Default: 64.
- **optimizer_level** (*str, optional*) –optimizer_level configuration is used to specify the splitting level for optimizer sharding. It is important to note that the implementation of optimizer sharding in static graph is inconsistent with dynamic graph like megatron, but the memory optimization effect is the same. It must be one of [`level1`, `level2`, `level3`]. Default: `level1`.
  - level1: Splitting is performed on weights and optimizer state.
  - level2: Splitting is performed on weights, optimizer state, and gradients.

- level3: Splitting is performed on weights, optimizer state, gradients, additionally, before the backward pass, the weights are further applied with allgather communication to release the memory used by the forward pass allgather.

Raises

- **ValueError** –If the *shard_size* is not a positive integer or -1.
- **ValueError** –If *threshold* is not a positive integer or 0.
- **ValueError** –If *optimizer_level* is not one of the [`level1`, `level2`, `level3`].

load_operator_strategy_file(*file_path*)

Set the path to load strategy json when using sharding propagation.

> **Warning:** This is an experimental interface, may be changed or canceled in the future; This interface currently doesn't support loading strategies using layout.

Note:

- It only works when *parallel_mode=sharding_propagation*.
- When performing distributed training, users can first save the strategy using dryrun on a single device and then load strategy to perform distributed training.

Parameters

file_path (*str*) –Path to load parallel strategy json, must be an absolute path.

Raises

- **TypeError** –If the type of 'file_path' is not str.
- **KeyError** –When 'file_path' is not an absolute path.
- **KeyError** –When 'file_path' does not end in `".json"` .

Examples

```
>>> import math
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import nn, ops
>>> from mindspore.communication.management import init
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>> from mindspore.common.initializer import initializer, HeUniform
>>>
>>> class ParallelNetwork(nn.Cell):
...     def __init__(self, strategy=None):
...         super().__init__()
...         self.flatten = ops.Flatten()
...         self.fc1_weight = ms.Parameter(initializer(HeUniform(math.sqrt(5)), shape=[
...             16, 10], dtype=ms.float32), name="fc1")
...         self.matmul1 = ops.MatMul().shard(strategy)
...         self.relu1 = ops.ReLU()
...
```

(continues on next page)

(continued from previous page)

```
...     def construct(self, x):
...         x = self.flatten(x)
...         x = self.matmul1(x, self.fc1_weight)
...         x = self.relu1(x)
...         return x
>>>
>>> init(backend_name='hccl')
>>> strategy = ((1, 1), (1, 2))
>>> net = ParallelNetwork(strategy)
>>> parallel_net = AutoParallel(net, parallel_mode='sharding_propagation')
>>> parallel_net.load_operator_strategy_file("/tmp/strategy.json")
```

load_param_strategy_file(*file_path*)

Set the path to load parallel sharding strategy file. By default, load strategy information for trainable parameters only.

Parameters

file_path (*str*) – The path to load parameter strategy checkpoint.

Raises

TypeError – If the type of 'file_path' is not str.

Examples

```
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>> parallel_net = AutoParallel(net)
>>> parallel_net.load_param_strategy_file(file_path="./train_strategy.ckpt")
```

no_init_parameters_in_compile()

When enabled, the model weight parameters will not be initialized during the compilation process.

> **Warning:** This is an experimental interface, may be changed or canceled in the future.

Examples

```
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> parallel_net = AutoParallel(net, parallel_mode="semi_auto")
>>> parallel_net.no_init_parameters_in_compile()
```

pipeline(*stages=1*, *output_broadcast=False*, *interleave=False*, *scheduler='1f1b'*)

Configure the number of pipelin_dages, whether to broadcast the results, whether to enable interleaving scheduling, configure type of scheduler when using pipeline parallel.

Parameters

- **stages** (*int, optional*) – Set the stage information for pipeline parallelism This indicates how the devices are individually distributed on the pipeline. All devices will be divided into stages of pipine_dags. Default value: 1.
- **output_broadcast** (*bool, optional*) – When performing pipeline parallel inference, whether the result of the last stage is broadcasted to the other stages. Default value: False.

- **interleave** (*bool, optional*) –Whether to enable interleaving scheduling.
- **scheduler** (*str, optional*) –The type of scheduler

Raises

- **TypeError** –If the type of 'stages is not int.
- **ValueError** –When stages <= 0.
- **TypeError** –If the type of 'output_broadcast' is not bool.
- **TypeError** –If the type of 'interleave' is not bool.
- **TypeError** –If the type of 'scheduler' is not str.
- **ValueError** –If the type of 'scheduler' is not supported.

print_local_norm()

Print local norm value for auto parallel.

Examples

```
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> parallel_net = AutoParallel(net, parallel_mode="semi_auto")
>>> parallel_net.print_local_norm()
```

save_operator_strategy_file(*file_path*)

Set the path to save strategy json when using sharding propagation.

> **Warning:** This is an experimental interface, may be changed or canceled in the future; This interface currently doesn't support saving strategies using layout.

Note:

- It only works when *parallel_mode=sharding_propagation*.
- When performing distributed training, users can first save the strategy using dryrun on a single device and then load strategy to perform distributed training.

Parameters

file_path (*str*) –Path to save parallel strategy json, must be an absolute path.

Raises

- **TypeError** –If the type of 'file_path' is not str.
- **KeyError** –When 'file_path' is not an absolute path.
- **KeyError** –When 'file_path' does not end in `".json"` .

Examples

```
>>> import math
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import nn, ops
>>> from mindspore.communication.management import init
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>> from mindspore.common.initializer import initializer, HeUniform
>>>
>>> class ParallelNetwork(nn.Cell):
...     def __init__(self, strategy=None):
...         super().__init__()
...         self.flatten = ops.Flatten()
...         self.fc1_weight = ms.Parameter(initializer(HeUniform(math.sqrt(5)), shape=[
...             16, 10], dtype=ms.float32), name="fc1")
...         self.matmul1 = ops.MatMul().shard(strategy)
...         self.relu1 = ops.ReLU()
...
...     def construct(self, x):
...         x = self.flatten(x)
...         x = self.matmul1(x, self.fc1_weight)
...         x = self.relu1(x)
...         return x
>>>
>>> init(backend_name='hccl')
>>> strategy = ((1, 1), (1, 2))
>>> net = ParallelNetwork(strategy)
>>> parallel_net = AutoParallel(net, parallel_mode='sharding_propagation')
>>> parallel_net.save_operator_strategy_file("/tmp/strategy.json")
```

save_param_strategy_file(*file_path*)

Set the path to save parallel sharding strategy file. By default, save strategy information for trainable parameters only.

Parameters

file_path (*str*) – The path where the parallel sharding strategy is saved.

Raises

TypeError – If the type of 'file_path' is not str.

set_group_ckpt_save_file(*file_path*)

Set the save path of the communication group.

Parameters

file_path (*str*) – The path to save parallel group checkpoint.

Raises

TypeError – If the type of 'file_path' is not str.

transformer_opt(*file_path*)

Check and set speedup config for auto parallel, configuration can refer to parallel_speed_up.json . If this parameter is set to None, it is disabled.

Parameters

file_path (*Union[str, None]*) – The path to the parallel speed up json file, configuration can refer to parallel_speed_up.json . If its value is None or '', it does not take effect. Default None.

- recomputation_communication_overlap (bool): Enable overlap between recompute ops and communication ops if True. Default: False.
- grad_matmul_communication_overlap (bool): Enable overlap between dw matmul and tensor parallel communication ops if True. Default: False.
- grad_fa_allgather_overlap (bool): Enable overlap between duplicated allgather by recomputing in sequence parallel and flashattentionscoregrad ops if True. Default: False.
- enable_communication_fusion (bool): Enable communication fusion to optimize the number of communication operator tasks if True. Default: False.
- grad_computation_allreduce_overlap (bool): Enable overlap between dx ops and data parallel communication ops if True. Currently, do not support O2 Default: False.
- computation_allgather_overlap (bool): Enable overlap between forward ops and optimizer parallel allgather communication if True. Currently, do not support O2 Default: False.
- computation_communication_fusion_level (int): Enable the fusion between compute and communicate. Default: `0`. Note: This function must be used with Ascend Training Solution 24.0.RC2 or later. This is an experimental configuration, may be changed or canceled in the future.
  - 0: Disable fusion.
  - 1: Apply fusion to forward nodes.
  - 2: Apply fusion to backward nodes.
  - 3: Apply fusion to all nodes.
- dataset_broadcast_opt_level (int): Optimize the scenario that the dataset repeated reading. Only support O0/O1 jit level. It doesn't work in O2 mode. Default: `0`.
  - 0: Disable this optimize.
  - 1: Optimize dataset reader between pipeline stage.
  - 2: Optimize dataset reader within pipeline stage.
  - 3: Optimize dataset reader with all scenes.
- allreduce_and_biasadd_swap (bool): Enable node execution order swap communication operators and add operators if `True`. Only 1-dimension bias node is supported. Default: `False`.
- enable_allreduce_slice_to_reducescatter (bool): Enable allreduce optimization. In the scenario where the batchmatmul model introduces allreduce in parallel, if the subsequent nodes are stridedslice operator with model parallel, allreduce will be optimized as reducescatter according to the identified patterns. Typical used in MoE module with groupwise alltoall. Default: `False`.
- enable_interleave_split_concat_branch (bool): Enable communication computation parallel optimization for branches formed by split and concat operators with `enable_interleave` attribute. It is typical used in MoE parallel scenario. After splitting the input data, each slice of data is processed by the MoE module, and then the branch results are concatenated. When the optimization is enable, communication and computation will be executed in parallel between branches. Default: `False`.
- enable_interleave_parallel_branch (bool): Enable communication computation parallel optimization for parallel branches with `parallel_branch` attribute in branches merge node. It is typical used in MoE parallel scenario with routed and shared expert. When the optimization is enable, communication and computation will be executed in parallel between branches. Default: `False`.

Examples

```
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>>
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> net = AutoParallel(net, parallel_mode="semi_auto")
>>> net.transformer_opt("./parallel_speed_up.json")
```

8.1.2 mindspore.parallel.nn.GradAccumulation

class mindspore.parallel.nn.**GradAccumulation**(*network*, *micro_size*)

Implementation of parallel gradient accumulation for static graphs.

Parameters

- **network** (Cell) –The target network to wrap.
- **micro_size** (*int*) –MicroBatch size.

Raises

- **TypeError** –The type of *network* is not cell.
- **TypeError** –If the type of *micro_size* is not int.
- **ValueError** –When *micro_size* is 0 or negative value.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore.parallel.nn import GradAccumulation
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> net = GradAccumulation(net, 4)
```

8.1.3 mindspore.parallel.nn.MicroBatchInterleaved

class mindspore.parallel.nn.**MicroBatchInterleaved**(*network*, *interleave_num=2*)

Implement the static graph parallel multi-copy splitting function to enable concurrent computation and communication. Application scenario: When there is model parallelism in semi-automatic mode and network, if the first slice data is calculating forward, the second slice data will execute the communication operators at the same time, to achieve the performance acceleration of communication and computing concurrency.

Parameters

- **network** (Cell) –The target network to wrap.
- **interleave_num** (*int, optional*) –split num of batch size. Default: 2 .

Inputs:

tuple[Tensor]. It's the same with the input of the *network* .

Outputs:

The wrapped input. The output of the input *network* should be a Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore.nn as nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> net = nn.MicroBatchInterleaved(net, 2)
```

8.1.4 mindspore.parallel.nn.Pipeline

class mindspore.parallel.nn.**Pipeline**(*network*, *micro_size*, *stage_config=None*)

Specify the number of micro_batch for pipeline parallelism and the division rules for stage.

Note: micro_size must be greater or equal to pipeline stages.

Parameters

- **network** (*Cell*) – The target network to wrap.
- **micro_size** (*int*) – MicroBatch size.
- **stage_config** (*dict, optional*) – Stage configuration for cell's execution in pipeline parallel. Default `None`.

Raises

- **TypeError** – The type of *net* is not cell.
- **TypeError** – If the type of *micro_size* is not int.
- **ValueError** – When *micro_size* is 0 or negative value.
- **KeyError** – *dict* cell name matching exception, there are remaining configuration items after traversing all *cell* under the current net.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore.parallel.nn import Pipeline
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> net = Pipeline(net, 4, stage_config={"cell_name_0": 0, "cell_name_1": 1})
```

8.1.5 mindspore.parallel.nn.PipelineGradReducer

class mindspore.parallel.nn.**PipelineGradReducer**(*parameters*, *scale_sense=1.0*, *opt_shard=None*)

Functional training scenarios for gradient statute and accumulation of pipeline parallel.

Parameters

- **parameters** (*list*) – the parameters to be updated.
- **scale_sense** (*float, optional*) – the scale sense of the gradient. Default: 1.0.
- **opt_shard** (*bool, optional*) – if use parallel optimizer, set opt_shard True. Default: None.

Raises

RuntimeError – If the mode is not graph mode.

Supported Platforms:

Ascend GPU

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For the Ascend devices, users need to prepare the rank table, set rank_id and device_id. Please see the rank table Startup for more details.

This example should be run with multiple devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import nn, ops, Tensor
>>> from mindspore.communication import init
>>>
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> ms.reset_auto_parallel_context()
>>> init()

8.2 Model Loading and Transformation

mindspore.parallel.convert_checkpoints	Convert distributed checkpoint from source sharding strategy to destination sharding strategy for a rank.
mindspore.parallel.convert_checkpoint_by_rank	Convert distributed checkpoint from source sharding strategy to destination sharding strategy by rank for a network.
mindspore.parallel.load_distributed_checkpoint	Load checkpoint into net for distributed predication.

continues on next page

Table 2 – continued from previous page

mindspore.parallel.load_segmented_checkpoints	Load checkpoint info from a specified file.
mindspore.parallel.rank_list_for_convert	List of original distributed checkpoint rank index for obtaining the target checkpoint of a rank_id during the distributed checkpoint conversion.
mindspore.parallel.unified_safetensors	Merge multiple safetensor files into a unified safetensor file.

8.2.1 mindspore.parallel.convert_checkpoints

mindspore.parallel.**convert_checkpoints**(*src_checkpoints_dir*, *dst_checkpoints_dir*, *ckpt_prefix*, *src_strategy_file=None*, *dst_strategy_file=None*, *process_num=1*, *output_format='ckpt'*)

Convert distributed checkpoint from source sharding strategy to destination sharding strategy for a rank.

Note: The *src_checkpoints_dir* directory structure should be organized like "src_checkpoints_dir/rank_0/a.ckpt", the rank number should be set to a subdirectory and the checkpoint file is stored in this subdirectory. If multiple files exist in a rank directory, the last file in the lexicgraphic order would be selected.

The number of multiprocess settings is related to the size of the host, and it is not recommended to set it too large, otherwise it may cause freezing.

Parameters

- **src_checkpoints_dir** (*str*) –The source checkpoints directory.
- **dst_checkpoints_dir** (*str*) –The destination checkpoints directory to save the converted checkpoints.
- **ckpt_prefix** (*str*) –The destination checkpoint name prefix.
- **src_strategy_file** (*str, optional*) –Name of source sharding strategy file which saved by 'mindspore.parallel.auto_parallel.AutoParallel.save_param_strategy_file'. when the 'src_strategy_file' is None, it means that the source sharding strategy is without any sharing for each parameter. Default:None.
- **dst_strategy_file** (*str, optional*) –Name of destination sharding strategy file which saved by 'mindspore.parallel.auto_parallel.AutoParallel.save_param_strategy_file'. when the 'dst_strategy_file' is None, it means that the destination sharding strategy is without any sharing for each parameter. Default:None.
- **process_num** (*int, optional*) –Number of processes to use for parallel processing. Defaults: 1.
- **output_format** (*str, optional*) –Control the format of the output checkpoint after conversion. It can be set to either "ckpt" or "safetensors". Default: "ckpt".

Raises

- **ValueError** –*src_strategy_file* or *dst_strategy_file* is incorrect.
- **NotADirectoryError** –*src_checkpoints_dir* or *dst_checkpoints_dir* is not a directory.
- **ValueError** –The checkpoint file is missing in *src_checkpoints_dir*.
- **TypeError** –*src_strategy_file* or *dst_strategy_file* is not a string.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore.parallel import convert_checkpoints
>>> convert_checkpoints(src_checkpoints_dir, dst_checkpoints_dir, "dst_checkpoint",
...                     "./src_strategy.ckpt", "./dst_strategy.ckpt")
```

8.2.2 mindspore.parallel.convert_checkpoint_by_rank

mindspore.parallel.**convert_checkpoint_by_rank**(*rank_id*, *checkpoint_files_map*, *save_checkpoint_file_name*, *src_strategy_file=None*, *dst_strategy_file=None*)

Convert distributed checkpoint from source sharding strategy to destination sharding strategy by rank for a network.

Parameters

- **rank_id** (*int*) –The rank of which distributed checkpoint needs to be obtained after conversion.
- **checkpoint_files_map** (*dict*) –The checkpoint files map whose key is the rank id and the value is the checkpoint file name.
- **save_checkpoint_file_name** (*str*) –The file name to save the converted checkpoint.
- **src_strategy_file** (*str*) –Name of source sharding strategy file which saved by *mindspore.parallel.auto_parallel.AutoParallel.save_param_strategy_file()*. when the *src_strategy_file* is None, it means that the source sharding strategy is without any sharing for each parameter. Default: `None`.
- **dst_strategy_file** (*str*) –Name of destination sharding strategy file which saved by *mindspore.parallel.auto_parallel.AutoParallel.save_param_strategy_file()*. when the *dst_strategy_file* is `None`, it means that the destination sharding strategy is without any sharing for each parameter. Default: `None`.

Raises

- **ValueError** –*src_strategy_file* or *dst_strategy_file* is incorrect.
- **ValueError** –item in *checkpoint_files_map* is incorrect.
- **ValueError** –*save_checkpoint_file_name* is not end with ".ckpt".
- **TypeError** –*checkpoint_files_map* is not a dict.
- **TypeError** –*src_strategy_file* or *dst_strategy_file* is not a string.
- **TypeError** –*rank_id* is not an int.
- **TypeError** –*save_checkpoint_file_name* is not a string.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore.parallel import rank_list_for_convert, convert_checkpoint_by_rank
>>> dst_device_num = 8
>>> for rank_id in range(dst_device_num):
...     rank_list = rank_list_for_convert(rank_id, "./src_strategy.ckpt", "./dst_strategy.
↪ckpt")
...     checkpoint_files_map = {}
...     for rank in rank_list:
...         checkpoint_files_map[rank] = "./origin_checkpoint_rank{}/pangu{}-100_2.ckpt".
↪format(rank)
...     save_checkpoint_file_name = "./new_checkpoint_rank{}/pangu{}-100_2.ckpt".format(rank_
↪id)
...     convert_checkpoint_by_rank(rank_id, checkpoint_files_map, save_checkpoint_file_name,
...                                "./src_strategy.ckpt", "./dst_strategy.ckpt")
```

8.2.3 mindspore.parallel.load_distributed_checkpoint

mindspore.parallel.**load_distributed_checkpoint**(*network*, *checkpoint_filenames=None*, *predict_strategy=None*, *train_strategy_filename=None*, *strict_load=False*, *dec_key=None*, *dec_mode='AES-GCM'*, *format='ckpt'*, *unified_safetensors_dir=None*, *dst_safetensors_dir=None*, *rank_id=None*, *output_format='safetensors'*, *name_map=None*, *max_process_num=64*, *return_param_dict=False*)

Load checkpoint into net for distributed predication. Used in the case of distributed inference.

Note: *output_format* will only take effect when *format* is set to *safetensors* and *network* is set to *None*.

Parameters

- **network** (Cell) –Network for distributed predication, When the format is *safetensors*, the network parameter can be left blank or passed as None, and the interface will execute save mode.
- **checkpoint_filenames** (*list[str]*) –The name of Checkpoint files in order of rank id. Default: None .
- **predict_strategy** (*Union[dict, str]*) –Strategy of predication process. It means that using one device to predict when setting predict_strategy as None. Default: None .
- **train_strategy_filename** (*str*) –The filename of training strategy protocol buffer file. When train_strategy_filename is None, the training strategy file will be obtained from context.get_auto_parallel_context("strategy_ckpt_load_file"). Therefore, the training strategy file needs to be specified in at least one of them. Default: None .
- **strict_load** (*bool*) –Whether to strict load the parameter into net. If False , it will load parameter into net when parameter name's suffix in checkpoint file is the same as the parameter in the network. When the types are inconsistent, perform type conversion on the parameters of the same type, such as float32 to float16. Default: False .
- **dec_key** (*Union[None, bytes]*) –Byte type key used for decryption. If the value is None , the decryption is not required. Default: None .
- **dec_mode** (*str*) –Specifies the decryption mode, currently supports 'AES-GCM' , 'AES-CBC' and 'SM4-CBC' . This parameter is valid only when dec_key is not set to None . Default: 'AES-GCM' .
- **format** (*str*) –Input weight format to be loaded into the network. It can be set to either "ckpt" or "safetensors". Default: "ckpt".

- **unified_safetensors_dir** (*str*) –Directory of input weight files to be loaded into the network. Default: `None`.
- **dst_safetensors_dir** (*str*) –In the save mode scenario, the save directory for weights.
- **rank_id** (*int*) –The logical sequence number of the card. In non save mode, it is automatically obtained globally by initializing the network; In save mode, save the file according to the input sequence number. If it is not input, save the entire file.
- **output_format** (*str, optional*) –Control the format of the output checkpoint after conversion. It can be set to either "ckpt" or "safetensors". Default: "safetensors".
- **name_map** (*dict*) –The weight mapping dictionary will modify the weight names according to the mapping dictionary before loading or saving the segmented weights into the network. Default: None.
- **max_process_num** (*int*) –Maximum number of processes. Default: 64.
- **return_param_dict** (*bool*) –Whether to return the param_dict. Default: `False`.

Raises

- **TypeError** –The type of inputs do not match the requirements.
- **ValueError** –Failed to load checkpoint into net.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For the Ascend devices, users need to prepare the rank table, set rank_id and device_id. Please see the rank table startup for more details.

For the CPU device, users need to write a dynamic cluster startup script, please see the Dynamic Cluster Startup .

```
>>> import os

8.2.4 mindspore.parallel.load_segmented_checkpoints

mindspore.parallel.**load_segmented_checkpoints**(*ckpt_file_dir*, *net=None*, *strict_load=False*, *filter_prefix=None*, *dec_key=None*, *dec_mode='AES-GCM'*, *specify_prefix=None*, *choice_func=None*)

Load checkpoint info from a specified file. If the specified ckpt_file_dir path contains multiple checkpoint files, all checkpoint files will be loaded one by one and the combined dictionary will be return.

Note:

- *specify_prefix* and *filter_prefix* do not affect each other.
- If none of the parameters are loaded from checkpoint file, it will throw ValueError.
- *specify_prefix* and *filter_prefix* are in the process of being deprecated, *choice_func* is recommended instead. And using either of those two args will override *choice_func* at the same time.

Parameters

- **ckpt_file_dir** (*str*) – Checkpoint file directory.
- **net** (Cell) – The network where the parameters will be loaded. Default: None .
- **strict_load** (*bool*) – Whether to strict load the parameter into net. If False , it will load parameter into net when parameter name's suffix in checkpoint file is the same as the parameter in the network. When the types are inconsistent perform type conversion on the parameters of the same type, such as float32 to float16. Default: False .
- **filter_prefix** (*Union[str, list[str], tuple[str]]*) – Deprecated(see *choice_func*). Parameters starting with the filter_prefix will not be loaded. Default: None .
- **dec_key** (*Union[None, bytes]*) – Byte type key used for decryption. If the value is None , the decryption is not required. Default: None .
- **dec_mode** (*str*) – This parameter is valid only when dec_key is not set to None . Specifies the decryption mode, currently supports "AES-GCM" and "AES-CBC" and "SM4-CBC" . Default: "AES-GCM" .
- **specify_prefix** (*Union[str, list[str], tuple[str]]*) – Deprecated(see *choice_func*). Parameters starting with the specify_prefix will be loaded. Default: None .

- **choice_func** (*Union[None, function]*) –Input value of the function is a Parameter name of type string, and the return value is a bool. If returns `True` , the Parameter that matches the custom condition will be loaded. If returns `False` , the Parameter that matches the custom condition will be removed. Default: `None` .

Returns

Dict, key is parameter name, value is a Parameter or string. When the *append_dict* parameter of *mindspore.save_checkpoint()* and the *append_info* parameter of *mindspore.train.CheckpointConfig* are used to save the checkpoint, *append_dict* and *append_info* are dict types, and their value are string, then the return value obtained by loading checkpoint is string, and in other cases the return value is Parameter.

Raises

- **TypeError** –Input ckpt_file_dir is not a string.
- **ValueError** –Checkpoint file directory doesn't exist. Or it's not a directory
- **ValueError** –Checkpoint file's format is incorrect.
- **ValueError** –Parameter's dict is None after load checkpoint file.
- **TypeError** –The type of *specify_prefix* or *filter_prefix* is incorrect.

Supported Platforms:

`Ascend`

8.2.5 mindspore.parallel.rank_list_for_convert

mindspore.parallel.**rank_list_for_convert**(*rank_id*, *src_strategy_file=None*, *dst_strategy_file=None*)

List of original distributed checkpoint rank index for obtaining the target checkpoint of a rank_id during the distributed checkpoint conversion.

Parameters

- **rank_id** (*int*) –The rank of which distributed checkpoint needs to be obtained after conversion.
- **src_strategy_file** (*str*) –Name of source sharding strategy file which saved by *mindspore.parallel.auto_parallel.AutoParallel(cell).save_param_strategy_file(file_path)*. when the *src_strategy_file* is `None`, it means that the source sharding strategy is without any sharing for each parameter. Default: `None`.
- **dst_strategy_file** (*str*) –Name of destination sharding strategy file which saved by *mindspore.parallel.auto_parallel.AutoParallel(cell).save_param_strategy_file(file_path)*. when the *dst_strategy_file* is `None`, it means that the destination sharding strategy is without any sharing for each parameter. Default: `None`.

Returns

List, the rank list required for converting the distributed checkpoint of rank_id.

Raises

- **ValueError** –*src_strategy_file* or *dst_strategy_file* is incorrect.
- **TypeError** –*src_strategy_file* or *dst_strategy_file* is not a string.
- **TypeError** –*rank_id* is not an int.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore.parallel import rank_list_for_convert
>>> rank_id = 0
>>> rank_list = rank_list_for_convert(rank_id, "./src_strategy.ckpt", "./dst_strategy.ckpt")
>>> checkpoint_files_map = {}
>>> for rank in rank_list:
...     checkpoint_files_map[rank] = "./pangu{}-100_2.ckpt".format(rank)
```

8.2.6 mindspore.parallel.unified_safetensors

mindspore.parallel.**unified_safetensors**(*src_dir*, *src_strategy_file*, *dst_dir*, *merge_with_redundancy=True*, *file_suffix=None*, *max_process_num=64*, *choice_func=None*, *split_dst_file=()*)

Merge multiple safetensor files into a unified safetensor file.

Parameters

- **src_dir** (*str*) –Source weight saving directory.
- **src_strategy_file** (*str*) –Source weight segmentation strategy file.
- **dst_dir** (*str*) –Target save directory.
- **merge_with_redundancy** (*bool, optional*) –Whether the merged source weight files are de-duplicated and saved safetensors files. Default: `True`, indicating that the merged source weight files are complete.
- **file_suffix** (*str, optional*) –Specify the filename suffix for merging safetensors files. Default: `None`, meaning all safetensors files in the source weight directory will be merged.
- **max_process_num** (*int, optional*) –Maximum number of processes. Default: `64`.
- **choice_func** (*callable, optional*) –A callable function used to filter parameters or modify parameter names. The return value of the function must be of type str (string) or bool (boolean). Default: `None`.
- **split_dst_file** (*tuple, optional*) –execution, represented as a tuple containing two elements. The first element indicates the number of the current subtask, and the second element indicates the total number of tasks. This parameter supports splitting and executing tasks multiple times on a single machine, and also supports executing different subtasks on multiple machines respectively. Default: `()`.

Raises

ValueError –If the safetensors file of rank is missing.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore as ms
>>> src_dir = "/usr/safetensors/llama31B/4p_safetensors/"
>>> src_strategy_file = "/usr/safetensors/llama31B/strategy_4p.ckpt"
>>> dst_dir = "/usr/safetensors/llama31B/merge_llama31B_4p/"
>>> ms.parallel.unified_safetensors(src_dir, src_strategy_file, dst_dir)
```

8.3 Functional Parallel Slicing

mindspore.parallel.function.reshard	Converting a tensor from one distributed arrangement to another distributed arrangement.
mindspore.parallel.Layout	Topological abstraction describing cluster devices for tensor slice placement on the cluster.
mindspore.parallel.shard	Specify the input and output slicing strategy for a Cell or function.

8.3.1 mindspore.parallel.function.reshard

mindspore.parallel.function.**reshard**(*tensor*, *layout*)

Converting a tensor from one distributed arrangement to another distributed arrangement. The given layout must be type mindspore.parallel.Layout, can check *mindspore.parallel.Layout* for reference.

Note:

- In the Graph mode, this function can set the sharding propagation strategy of a tensor. For those tensor do not manually be set, their strategies are decided by the sharding strategy propagation algorithm automatically.
- In PyNative mode, you can use this method to arrange tensors in a cell (that is, cells that use Cell.shard/F.shard in PyNative mode) that is executed in parallel in graph mode.

Parameters

- **tensor** (Tensor) −The tensor to be set the sharding strategy.
- **layout** (Layout) −The layout to shard the tensor precisely, including the device arrangement (device_matrix) and the alias for the device matrix (alias_name).

Returns

Tensor. The mathematically equivalent of the input tensor.

Raises

- **TypeError** −If the type of input param *tensor* is not mindspore.Tensor.
- **TypeError** −If the type of input param *layout* is not mindspore.parallel.Layout.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start-up for more details.

This example should be run with 8 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import ops, nn, Tensor, context, Layout
>>> from mindspore.parallel.function import reshard
>>> from mindspore.nn.utils import no_init_parameters
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>> from mindspore.communication import init
>>> context.set_context(mode=ms.GRAPH_MODE)
>>> init()
>>> class Network(nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.matmul = ops.MatMul()
...         self.relu = ops.ReLU()
...     def construct(self, x, layout):
...         x = self.relu(x)
...         x_reshard = reshard(x, layout)
...         y = Tensor(np.ones(shape=(128, 128)), dtype=ms.float32)
...         x = self.matmul(x_reshard, y)
...         return x
>>> layout = Layout((4, 2), ("dp", "mp"))
>>> input_layout = layout("dp", "mp")
>>> with no_init_parameters():
...     net = Network()
>>> parallel_net = AutoParallel(net, parallel_mode='sharding_propagation')
>>> tensor = Tensor(np.ones(shape=(128, 128)), dtype=ms.float32)
>>> out = parallel_net(tensor, input_layout)
```

8.3.2 mindspore.parallel.Layout

class mindspore.parallel.**Layout**(*device_matrix*, *alias_name*, *rank_list=None*)

Topological abstraction describing cluster devices for tensor slice placement on the cluster.

Note:

- It is valid only in semi auto parallel or auto parallel mode.
- The multiplication result of the *device_matrix* must be equal to the device count in a pipeline stage.
- When the layout function is invoked to constructs a sharding strategy, each alias name is only allowed to be used once to shard a tensor.

Parameters

- **device_matrix** (*tuple*) – Describe the shape of devices arrangement, its element type is int.
- **alias_name** (*tuple*) – The alias name for each axis of device_matrix, its length shoits element type is string. When using "interleaved_parallel" as an alias name, the tensor would be split into multiple copies on the corresponding partition dimension on a single card.
- **rank_list** (*list, optional*) – Data is allocated to the device according to rank_list. Default: None.

Raises

- **TypeError** – *device_matrix* is not a tuple type.
- **TypeError** – *alias_name* is not a tuple type.

- **TypeError** – 'rank_list' is not a list type.
- **ValueError** – *device_matrix* length is not equal to *alias_name* length.
- **TypeError** – The element of *device_matrix* is not int type.
- **TypeError** – The element of *alias_name* is not a str type.
- **TypeError** – The element of *rank_list* is not int type.
- **ValueError** – The element of *alias_name* is an empty str.
- **ValueError** – The element of *alias_name* is "None".
- **ValueError** – *alias_name* contains repeated element.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore.parallel import Layout
>>> layout = Layout((2, 2, 2), ("dp", "sp", "mp"))
>>> layout0 = layout("dp", "mp")
>>> print(layout0.to_dict())
{'device_matrix': (2, 2, 2), 'tensor_map': (2, 0), 'interleaved_parallel': False,
'alias_name': {'dp', 'sp', 'mp'}, 'rank_list': [0, 1, 2, 3, 4, 5, 6, 7]}
>>> layout = Layout((2, 2, 2), ("dp", "sp", "interleaved_parallel"))
>>> layout1 = layout(("dp", "interleaved_parallel"), "sp")
```

to_dict()
Transform layout to a dictionary.

8.3.3 mindspore.parallel.shard

mindspore.parallel.**shard**(*fn*, *in_strategy*, *out_strategy=None*, *parameter_plan=None*, *device='Ascend'*, *level=0*)
Specify the input and output slicing strategy for a Cell or function. In PyNative mode, use this method to specify a Cell for distributed execution in graph mode. In Graph mode, use this method to specify distribution strategy for a Cell, strategy for others will be set by sharding propagation. in_strategy and out_strategy define the input and output layout respectively. in_strategy/out_strategy should be a tuple, each element of which corresponds to the desired layout of this input/output, and None represents data_parallel, which can refer to the description of *mindspore.ops.Primitive.shard()*. The parallel strategies of remaining operators are derived from the strategy specified by the input and output.

Note:

- It is valid only in semi auto parallel or auto parallel mode. In other parallel modes, strategies set here will be ignored.
- If the input contain Parameter, its strategy should be set in *in_strategy*.
- This method currently does not support dynamic shapes.

Parameters

- **fn** (*Union[Cell, Function]*) – Function to be executed in parallel. Its arguments and return value must be Tensor. If *fn* is a Cell with parameters, *fn* needs to be an instantiated object, otherwise its arguments cannot be accessed.

- **in_strategy** (*tuple*) –Define the layout of inputs, each element of the tuple should be a tuple(int) or tuple(mindspore.parallel.Layout). Tuple defines the layout of the corresponding input.
- **out_strategy** (*Union[tuple, None], optional*) –Define the layout of outputs similar with *in_strategy*. Default: `None` .
- **parameter_plan** (*Union[dict, None], optional*) –Define the layout for the specified parameters. Each element in dict defines the layout of the parameter like "param_name: layout". The key is a parameter name of type 'str'. The value is a 1-D integer tuple or a 1-D mindspore.parallel.Layout tuple, indicating the corresponding layout. If the parameter name is incorrect or the corresponding parameter has been set, the parameter setting will be ignored. Supported only when *fn* is a Cell with parameters. Default: `None` .
- **device** (*str, optional*) –Select a certain *device* target. It is not in use right now. Support ["CPU", "GPU", "Ascend"]. Default: `"Ascend"` .
- **level** (*int, optional*) –Option for parallel strategy infer algorithm, namely the object function, maximize computation over communication ratio, maximize speed performance, minimize memory usage etc. It is not in use right now. Support [0, 1, 2]. Default: `0` .

Returns

Function, return the function that will be executed under auto parallel process.

Raises

- **AssertionError** –If parallel mode is not "auto_parallel" nor "semi_auto_parallel".
- **AssertionError** –If device_target it not "Ascend" or "GPU".
- **TypeError** –If *in_strategy* is not a tuple.
- **TypeError** –If *out_strategy* is not a tuple or None.
- **TypeError** –If any element in *in_strategy* is not a tuple(int) or tuple(mindspore.parallel.Layout).
- **TypeError** –If any element in *out_strategy* is not a tuple(int) or tuple(mindspore.parallel.Layout).
- **TypeError** –If *parameter_plan* is not a dict or None.
- **TypeError** –If any key in *parameter_plan* is not a str.
- **TypeError** –If any value in *parameter_plan* is not a tuple(int) or a tuple(mindspore.parallel.Layout).
- **TypeError** –If *device* is not a str.
- **TypeError** –If *level* is not an integer.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor, nn, ops
>>> from mindspore.communication import init
>>> from mindspore.parallel import shard
>>> from mindspore.parallel import Layout
>>> from mindspore.nn.utils import no_init_parameters
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>> ms.set_context(mode=ms.GRAPH_MODE)

>>> print(output.shape)
(32, 10)
```

8.4 Others

mindspore.parallel.build_searched_strategy	Extract the sharding strategy for each parameter in the network from the strategy file for distributed inference scenarios.
mindspore.parallel.merge_pipeline_strategys	Aggregate the sharding strategy files of all pipeline parallel sub-graphs to the destination file.
mindspore.parallel.parameter_broadcast	Broadcast parameter to other rank in data parallel dimension.
mindspore.parallel.restore_group_info_list	Extract rank list information from communication domain files.
mindspore.parallel.sync_pipeline_shared_parameters	Synchronization of shared weights between stages for pipeline parallel inference scenarios.

8.4.1 mindspore.parallel.build_searched_strategy

mindspore.parallel.**build_searched_strategy**(*strategy_filename*)

Extract the sharding strategy for each parameter in the network from the strategy file for distributed inference scenarios.

Parameters

strategy_filename (*str*) – Name of strategy file.

Returns

Dict, whose key is parameter name and value is slice strategy of this parameter.

Raises

- **ValueError** –Strategy file is incorrect.
- **TypeError** –*strategy_filename* is not a string.

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore.parallel import build_searched_strategy
>>> strategy = build_searched_strategy("./strategy_train.ckpt")
```

8.4.2 mindspore.parallel.merge_pipeline_strategys

mindspore.parallel.**merge_pipeline_strategys**(*src_strategy_dirs*, *dst_strategy_file*)

Aggregate the sharding strategy files of all pipeline parallel subgraphs to the destination file.

Note: Strategy file of each pipeline stage should be included in src_strategy_dirs.

Parameters

- **src_strategy_dirs** (*str*) –The directory of strategy files including all pipeline stage which is saved by *mindspore.parallel.auto_parallel.AutoParallel.save_param_strategy_file()*.
- **dst_strategy_file** (*str*) –The file merged strategy to save.

Raises

NotADirectoryError –*src_strategy_dirs* is not a directory.

Examples

```
>>> import mindspore as ms
>>> # src_strategy_dir/stra0.ckpt, src_strategy_dir/stra1.ckpt ... src_strategy_dir/stra127.
↪ckpt
>>> ms.parallel.merge_pipeline_strategys("./src_strategy_dir", "./dst_strategy.ckpt")
```

8.4.3 mindspore.parallel.parameter_broadcast

mindspore.parallel.**parameter_broadcast**(*net*, *layout*, *cur_rank=0*, *initial_rank=0*)

Broadcast parameter to other rank in data parallel dimension.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **net** (Cell) –The network where the parameters will be broadcasted.

- **layout** (*Dict*) –Parameter layout dictionary. Come from *mindspore.nn.Cell.parameter_layout_dict()* or read from file(for example: "strategy.ckpt" saved by using the *strategy_ckpt_config* parameter of *mindspore.parallel.auto_parallel.AutoParallel.save_param_strategy_file()*). The key is param name, the value is the layout of this parameter.
- **cur_rank** (*int, optional*) –current rank id. Default: `0`.
- **initial_rank** (*int, optional*) –Start rank id for each pipeline. Default: `0`.

Raises

- **ValueError** –*cur_rank* is not rank id of current rank.
- **ValueError** –*initial_rank* is not the start rank id of current pipeline stage.
- **ValueError** –Parameter name in *layout* can not be found in *mindspore.nn.Cell.parameters_dict()*.

Supported Platforms:

`Ascend`

Examples

```
>>> import os
>>> import mindspore as ms
>>> import mindspore.dataset as ds
>>> from mindspore import nn, ops
>>> from mindspore.communication import init
>>> from mindspore.common.initializer import initializer
>>> from mindspore.train import Model
>>> from mindspore.train.serialization import load_checkpoint, load_param_into_net
>>> from mindspore.parallel.auto_parallel import AutoParallel
>>> from mindspore.parallel import parameter_broadcast
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> ms.runtime.set_memory(max_size="28GB")
>>> init()
>>> ms.set_seed(1)
>>> class Network(nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.flatten = ops.Flatten()

...         self.fc2_weight = ms.Parameter(initializer("normal", [512, 512], ms.float32))
...         self.fc3_weight = ms.Parameter(initializer("normal", [512, 10], ms.float32))
...         self.matmul1 = ops.MatMul()
...         self.relu1 = ops.ReLU()
...         self.matmul2 = ops.MatMul()
...         self.relu2 = ops.ReLU()
...         self.matmul3 = ops.MatMul()
...     def construct(self, x):
...         x = self.flatten(x)
...         x = self.matmul1(x, self.fc1_weight)
...         x = self.relu1(x)
...         x = self.matmul2(x, self.fc2_weight)
...         x = self.relu2(x)
...         logits = self.matmul3(x, self.fc3_weight)
...         return logits
>>> net = Network()
```

(continues on next page)

(continued from previous page)

```
>>> net.matmul1.shard(((2, 4), (4, 1)))
>>> net.relu1.shard(((4, 1),))
>>> net.matmul2.shard(((1, 8), (8, 1)))
>>> net.relu2.shard(((8, 1),))
>>> # Create the dataset taking MNIST as an example. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
>>> dataset = create_dataset()
>>> optim = nn.SGD(net.trainable_params(), 1e-2)
>>> loss = nn.CrossEntropyLoss()
>>> parallel_net = AutoParallel(net)
>>> model = Model(parallel_net, loss_fn=loss, optimizer=optim)
>>> model.train(1, dataset)
>>> ms.save_checkpoint(net, "./simple.ckpt", False)
>>> layout = model.train_network.parameter_layout_dict
>>> param_dict = load_checkpoint("./simple.ckpt")
>>> load_param_into_net(net, param_dict)
>>> rank_id = os.environ["RANK_ID"]
>>> parameter_broadcast(model.train_network, layout, int(rank_id), 0)
>>> class LossCallBack(Callback):
...     def step_end(self, run_context):
...         cb_params = run_context.original_args()
...         print("step end, cur step num: ", cb_params.cur_step_num, flush=True)
>>> model.train(1, dataset, callbacks=[LossCallBack()])
```

8.4.4 mindspore.parallel.restore_group_info_list

mindspore.parallel.**restore_group_info_list**(*group_info_file_name*)

Extract rank list information from communication domain files. To save the group info file, please export GROUP_INFO_FIL environment variables like "export GROUP_INFO_FILE=/data/group_info.pb".

Parameters

group_info_file_name (*str*) – Name of group information file.

Returns

List, the rank list.

Raises

- **ValueError** – group information file is incorrect.
- **TypeError** – *group_info_file_name* is not str.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore as ms
>>> from mindspore.parallel import restore_group_info_list
>>> ms.restore_list = restore_group_info_list("./group_info.pb")
```

8.4.5 mindspore.parallel.sync_pipeline_shared_parameters

mindspore.parallel.**sync_pipeline_shared_parameters**(*net*)

Synchronization of shared weights between stages for pipeline parallel inference scenarios. For example, *embedding table* is shared by *WordEmbedding* layer and *LMHead* layer, which are usually split into different stages. It is necessary to perform synchronization after *embedding table* changes.

Note: The network should be compiled before shared parameters are synchronized in the pipeline parallel stage.

Parameters

net (Cell) – the inference network.

Raises

TypeError – *net* is not in Cell type.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For the Ascend device, users need to write a dynamic cluster startup script, please see the Dynamic Cluster Startup .

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.communication.management as D
>>> from mindspore import lazy_inline, context, nn, ops, Parameter, Tensor

CHAPTER

NINE

MINDSPORE.RUNTIME

Runtime encapsulates interfaces for executor, memory, stream and event. MindSpore abstracts the corresponding modules from different backends, allowing users to schedule hardware resources at the Python layer.

9.1 Executor

mindspore.runtime.set_cpu_affinity	Enable thread-level core binding to assign specific CPU cores to MindSpore's main modules (main thread, pynative, runtime, minddata), to prevent unstable performance caused by MindSpore's threads seizing CPU.
mindspore.runtime.launch_blocking	Indicates that synchronizing the execution of the startup device reduces the execution performance of the program.
mindspore.runtime.dispatch_threads_num	Set the threads number of runtime used.
mindspore.runtime.set _kernel_launch_group	O0 mode supports operator batch parallel delivery interface, supports enabling parallel delivery, and configures parallel number.

9.1.1 mindspore.runtime.set_cpu_affinity

mindspore.runtime.**set_cpu_affinity**(*enable_affinity*, *affinity_cpu_list=None*)

Enable thread-level core binding to assign specific CPU cores to MindSpore's main modules (main thread, pynative, runtime, minddata), to prevent unstable performance caused by MindSpore's threads seizing CPU.

Note:

- Provides two binding modes: 1. Automatically generates binding policies based on available CPUs, NUMA nodes, and device resources in the environment to bind cores at thread level. 2. Thread-level bonding based on customized bonding policies passed in by *affinity_cpu_list*.
- The automated bind-core policy generation scenario invokes system commands to obtain CPU, NUMA node, and device resources on the environment, and some commands cannot be executed successfully due to environment differences; the automated bind-core policy generated will vary according to the resources available on the environment:
  1. *cat /sys/fs/cgroup/cpuset/cpuset.cpus*, to obtain the available CPU resources on the environment; if the execution of this command fails, the bind-core function will not take effect.
  2. *npu-smi info -m*, get the available NPU resources on the environment; if the execution of this command fails, the bind-core policy will be generated only based on the available CPU resources, without considering the device affinity.
  3. *npu-smi info -t board -i {NPU_ID} -c {CHIP_ID}*, get NPU details based on the logical ID of the device; if the execution of this command fails, the bind-core policy is generated based on the available CPU resources only, regardless of device

affinity.

4. *lspci -s {PCIe_No} -vvv*, get the hardware information of the device on the environment; if the execution of this command fails, the bind-core policy is generated only based on the available CPU resources, without considering the device affinity.
5. *lscpu*, get information about CPUs and NUMA nodes on the environment; if the execution of this command fails, only the available CPU resources are used to generate the bind-core policy, without considering the device affinity.

Parameters

- **enable_affinity** (*bool*) –Switches on/off thread-level core binding.
- **affinity_cpu_list** (*dict, optional*) –Specifies a customized bind-core policy. The key to be passed into the dict needs to be in string `"deviceX"` format, and the value needs to be in list `["cpuidX-cpuidY"]` format. Default: `None`, i.e., use the bind-core policy generated automatically based on the environment. It is allowed to pass the empty dict `{}`, in which case the bind-core policy generated automatically based on the environment will be used.

Raises

- **TypeError** –The parameter *enable_affinity* is not a boolean.
- **TypeError** –The parameter *affinity_cpu_list* is neither a dictionary nor a `None`.
- **ValueError** –The key of parameter *affinity_cpu_list* is not a string.
- **ValueError** –The key of parameter *affinity_cpu_list* is not in `"deviceX"` format.
- **ValueError** –The parameter *affinity_cpu_list* has a value that is not a list.
- **ValueError** –The element in value of parameter *affinity_cpu_list* is not a string.
- **ValueError** –The element in value for parameter *affinity_cpu_list* does not match `["cpuidX-cpuidY"]`.
- **RuntimeError** –Automatically generated binding policy or customized binding policy scenario where the number of CPU cores assigned to each device is less than 7.
- **RuntimeError** –A custom-specified binding policy scenario where the CPU assigned to a device is not available in the environment.
- **RuntimeError** –The *mindspore.runtime.set_cpu_affinity* API is called repeatedly.

Examples

```
>>> import mindspore as ms
>>> ms.set_device("Ascend", 1)
>>> ms.runtime.set_cpu_affinity(True)
>>>
>>> import mindspore as ms
>>> ms.set_device("Ascend", 1)
>>> ms.runtime.set_cpu_affinity(True, {"device0":["0-9"],"device1":["10-15","20-29"],"device2
↪":["35-45"]})
```

9.1.2 mindspore.runtime.launch_blocking

mindspore.runtime.**launch_blocking**()

Indicates that synchronizing the execution of the startup device reduces the execution performance of the program.

- In the initial state when this interface is not called, the operator executes asynchronously on the device. In this case, when an error occurs in the execution of the operator, it will not be possible to locate the position of the particular error script code.
- When this interface is called, the operator is executed in a synchronized manner on the device. At this point, when an error occurs in the execution of the operator, the location of the erroneous script code can be located based on the error call stack.

Examples

```
>>> import mindspore as ms
>>> ms.set_device("Ascend", 1)
>>> ms.runtime.launch_blocking()
```

9.1.3 mindspore.runtime.dispatch_threads_num

mindspore.runtime.**dispatch_threads_num**(*threads_num*)

Set the threads number of runtime used.

The framework set the runtime number of threads are 5 by default.

Parameters

threads_num (*int*) – The threads number of runtime used.

Examples

```
>>> import mindspore as ms
>>> ms.set_device("Ascend", 1)
>>> ms.runtime.dispatch_threads_num(6)
```

9.1.4 mindspore.runtime.set_kernel_launch_group

mindspore.runtime.**set_kernel_launch_group**(*thread_num=2*, *kernel_group_num=8*)

O0 mode supports operator batch parallel delivery interface, supports enabling parallel delivery, and configures parallel number.

Parameters

- **thread_num** (*int, optional*) – The number of concurrent threads, generally not recommended to increase. The *thread_num* and the number of threads configured by the existing interface mindspore.runtime.dispatch_threads_num are independent of each other. Default value is 2.
- **kernel_group_num** (*int, optional*) – Total number of operator groups, kernel_group_num/thread_num groups per thread. Default value is 8.

Examples

```
>>> import mindspore as ms
>>> ms.runtime.set_kernel_launch_group(thread_num=2, kernel_group_num=8)
```

9.2 Memory

mindspore.runtime.max_memory_allocated	Returns the peak memory size of the memory pool actually occupied by Tensor since the process was started.
mindspore.runtime.max_memory_reserved	Returns the peak value of the total memory managed by the memory pool since the process was started.
mindspore.runtime.memory_allocated	Returns the actual memory size currently occupied by Tensor.
mindspore.runtime.memory_reserved	Returns the total amount of memory currently managed by the memory pool.
mindspore.runtime.memory_stats	Returns status information queried from the memory pool.
mindspore.runtime.memory_summary	Returns readable memory pool status information.
mindspore.runtime.reset _max_memory_reserved	Reset the peak memory size managed by the memory pool.
mindspore.runtime.reset _max_memory_allocated	Reset the peak memory size of the memory pool actually occupied by Tensor.
mindspore.runtime.reset _peak_memory_stats	Reset the "peak" stats tracked by memory manager.
mindspore.runtime.empty_cache	Empty cache in the memory pool.
mindspore.runtime.set_memory	Set the memory parameters of runtime device memory management that is implemented using a memory pool.

9.2.1 mindspore.runtime.max_memory_allocated

mindspore.runtime.**max_memory_allocated**()

Returns the peak memory size of the memory pool actually occupied by Tensor since the process was started.

Note:

- For the *CPU* backend, 0 is always returned.

Returns

int, in Byte.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1, 2]), ms.float32)
>>> b = Tensor(np.ones([1, 2]), ms.float32)
>>> c = ops.add(a, b).asnumpy()
>>> print(ms.runtime.max_memory_allocated())
1536
```

9.2.2 mindspore.runtime.max_memory_reserved

mindspore.runtime.**max_memory_reserved**()

Returns the peak value of the total memory managed by the memory pool since the process was started.

Note:

- For the *CPU* backend, 0 is always returned.

Returns

int, in Byte.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1, 2]), ms.float32)
>>> b = Tensor(np.ones([1, 2]), ms.float32)
>>> c = ops.add(a, b).asnumpy()
>>> print(ms.runtime.max_memory_reserved())
1073741824
```

9.2.3 mindspore.runtime.memory_allocated

mindspore.runtime.**memory_allocated**()

Returns the actual memory size currently occupied by Tensor.

Note:

- For the *CPU* backend, 0 is always returned.

Returns

int, in Byte.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1, 2]), ms.float32)
>>> b = Tensor(np.ones([1, 2]), ms.float32)
>>> c = ops.add(a, b).asnumpy()
>>> print(ms.runtime.memory_allocated())
1024
```

9.2.4 mindspore.runtime.memory_reserved

`mindspore.runtime.`**`memory_reserved`**`()`

Returns the total amount of memory currently managed by the memory pool.

Note:

- For the *CPU* backend, 0 is always returned.

Returns

int, in Byte.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1, 2]), ms.float32)
>>> b = Tensor(np.ones([1, 2]), ms.float32)
>>> c = ops.add(a, b).asnumpy()
>>> print(ms.runtime.memory_reserved())
1073741824
```

9.2.5 mindspore.runtime.memory_stats

mindspore.runtime.**memory_stats**()

Returns status information queried from the memory pool.

Note: For the *CPU* backend, a dictionary with empty data is always returned.

Returns

dict, the queried memory information.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1, 2]), ms.float32)
>>> b = Tensor(np.ones([1, 2]), ms.float32)
>>> c = ops.add(a, b).asnumpy()
>>> print(ms.runtime.memory_stats())
{'total_reserved_memory': 1073741824, 'total_allocated_memory': 1024, 'total_idle_memory':␣
↪1073740800,
'total_eager_free_memory': 0, 'max_reserved_memory': 1073741824, 'max_allocated_memory':␣
↪1536,
'common_mem_pool_stats': {'block_unit_size': 1073741824, 'block_counts': 1, 'blocks_info':
{<capsule object NULL at 0x7f7e8c27b030>: {'block_stream_id': 0, 'block_memory_size':␣
↪1073741824}}},
'persistent_mem_pool_stats': {'block_unit_size': 1073741824, 'block_counts': 0, 'blocks_info
↪': {}}}
```

9.2.6 mindspore.runtime.memory_summary

mindspore.runtime.**memory_summary**()

Returns readable memory pool status information.

Returns

str, readable memory pool status information in tabular form.

Supported Platforms:

Ascend GPU CPU

9.2.7 mindspore.runtime.reset_max_memory_reserved

mindspore.runtime.**reset_max_memory_reserved**()

Reset the peak memory size managed by the memory pool.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1, 2]), ms.float32)
>>> b = Tensor(np.ones([1, 2]), ms.float32)
>>> c = ops.add(a, b).asnumpy()
>>> print(ms.runtime.max_memory_reserved())
1073741824
>>> ms.runtime.reset_max_memory_reserved()
>>> print(ms.runtime.max_memory_reserved())
0
```

9.2.8 mindspore.runtime.reset_max_memory_allocated

mindspore.runtime.**reset_max_memory_allocated**()

Reset the peak memory size of the memory pool actually occupied by Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1, 2]), ms.float32)
>>> b = Tensor(np.ones([1, 2]), ms.float32)
>>> c = ops.add(a, b).asnumpy()
>>> print(ms.runtime.max_memory_allocated())
1536
>>> ms.runtime.reset_max_memory_allocated()
>>> print(ms.runtime.max_memory_allocated())
0
```

9.2.9 mindspore.runtime.reset_peak_memory_stats

mindspore.runtime.**reset_peak_memory_stats**()

Reset the "peak" stats tracked by memory manager.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1, 2]), ms.float32)
>>> b = Tensor(np.ones([1, 2]), ms.float32)
>>> c = ops.add(a, b).asnumpy()
>>> print(ms.runtime.max_memory_reserved())
1073741824
>>> print(ms.runtime.max_memory_allocated())
1536
>>> ms.runtime.reset_peak_memory_stats()
>>> print(ms.runtime.max_memory_reserved())
0
>>> print(ms.runtime.max_memory_allocated())
0
```

9.2.10 mindspore.runtime.empty_cache

mindspore.runtime.**empty_cache**()

Empty cache in the memory pool.

Note:

- Empty cache help reduce the fragmentation of device memory.
- Support Atlas A2 series products.

Supported Platforms:

Ascend

9.2.11 mindspore.runtime.set_memory

mindspore.runtime.**set_memory**(*init_size='2GB'*, *increase_size='2GB'*, *max_size='1024GB'*, *optimize_level='O0'*, *huge_page_reserve_size='0GB'*)

Set the memory parameters of runtime device memory management that is implemented using a memory pool.

The framework will set all the args by default as follows.

Parameters

- **init_size** (*str*) –The init size of memory pool. The format is "xxGB". Default: 2GB .

- **increase_size** (*str*) –The increase size of memory pool. When the current memory pool has no enough memory, the memory pool will be expanded by this value. The format is "xxGB". Default: `2GB` .
- **max_size** (*str*) –The maximum memory available for memory pool. The actual used memory size is the minimum of the available memory of the device and max_device_memory. The format is "xxGB". Default is the maximum available memory of the device, expressed as `1024GB`.
- **optimize_level** (*str*) –The memory optimize level. The value must be in ['O0', 'O1']. Default: `O0` .
- **huge_page_reserve_size** (*str*) –The reserved size of huge page memory. The format is "xxGB". Default: `0GB`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> ms.set_device("Ascend", 1)
>>> ms.runtime.set_memory("10GB", "2GB", "60GB", "O1", "0GB")
```

9.3 Stream

mindspore.runtime.communication_stream	Return communication stream on this device.
mindspore.runtime.current_stream	Return current stream used on this device.
mindspore.runtime.default_stream	Return default stream on this device.
mindspore.runtime.set_cur_stream	Sets the current stream.This is a wrapper API to set the stream.
mindspore.runtime.synchronize	Synchronize all streams on current device.(Each MindSpore process only occupies one device)
mindspore.runtime.Stream	Wrapper around a device stream.
mindspore.runtime.StreamCtx	Context-manager that selects a given stream.

9.3.1 mindspore.runtime.communication_stream

mindspore.runtime.**communication_stream**()

Return communication stream on this device.

Returns

stream (Stream), communication stream.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore as ms
>>> ms.set_device("Ascend", 0)
>>> ms.runtime.communication_stream()
Stream(device_name=Ascend, device_id:0, stream id:1)
```

9.3.2 mindspore.runtime.current_stream

mindspore.runtime.**current_stream**()

Return current stream used on this device.

Returns

stream (Stream), current stream.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore as ms
>>> ms.set_device("Ascend", 0)
>>> cur_stream = ms.runtime.current_stream()
>>> assert cur_stream == ms.runtime.default_stream()
```

9.3.3 mindspore.runtime.default_stream

mindspore.runtime.**default_stream**()

Return default stream on this device.

Returns

stream (Stream), default stream.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore as ms
>>> ms.set_device("Ascend", 0)
>>> cur_stream = ms.runtime.current_stream()
>>> assert cur_stream == ms.runtime.default_stream()
```

9.3.4 mindspore.runtime.set_cur_stream

mindspore.runtime.**set_cur_stream**(*stream*)

Sets the current stream.This is a wrapper API to set the stream. Usage of this function is discouraged in favor of the `stream` context manager.

Parameters

stream (Stream) –selected stream. This function is a no-op if this argument is None.

Raises

TypeError –If 'stream' is neither a *mindspore.runtime.Stream* nor a None.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore as ms
>>> ms.set_device("Ascend", 0)
>>> cur_stream = ms.runtime.current_stream()
>>> assert cur_stream == ms.runtime.default_stream()
>>> s1 = ms.runtime.Stream()
>>> ms.runtime.set_cur_stream(s1)
>>> assert ms.runtime.current_stream() == s1
>>> ms.runtime.set_cur_stream(ms.runtime.default_stream())
```

9.3.5 mindspore.runtime.synchronize

mindspore.runtime.**synchronize**()

Synchronize all streams on current device.(Each MindSpore process only occupies one device)

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1024, 2048]), ms.float32)
>>> b = Tensor(np.ones([2048, 4096]), ms.float32)
>>> s1 = ms.runtime.Stream()
>>> with ms.runtime.StreamCtx(s1):
...     c = ops.matmul(a, b)
>>> ms.runtime.synchronize()
>>> assert s1.query()
```

9.3.6 mindspore.runtime.Stream

class mindspore.runtime.**Stream**(*priority=0*, ***kwargs*)

Wrapper around a device stream.

A device stream is a linear sequence of execution that belongs to a specific device, independent from other streams.

Parameters

- **priority** (*int, optional*) – priority of the stream, lower numbers represent higher priorities. By default, streams have priority `0`.
- **kwargs** (*dict*) – keyword arguments.

Supported Platforms:

`Ascend` `GPU`

query()

Checks if all the work submitted has been completed.

Returns

A boolean indicating if all kernels in this stream are completed.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1024, 2048]), ms.float32)
>>> b = Tensor(np.ones([2048, 4096]), ms.float32)
>>> s1 = ms.runtime.Stream()
>>> with ms.runtime.StreamCtx(s1):
...     c = ops.matmul(a, b)
>>> s1.synchronize()
>>> assert s1.query()
```

record_event(*event=None*)

Records an event.

Parameters

event (*Event, optional*) – event to record. If not given, a new one will be allocated. Default is `None`.

Returns

Event, recorded event. If this argument is `None`, a new one will be allocated. Default is `None`.

Raises

TypeError – If 'event' is neither a *mindspore.runtime.Event* nor a `None`.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([3, 3]), ms.float32)
>>> b = Tensor(np.ones([3, 3]), ms.float32)
>>> s1 = ms.runtime.Stream()
>>> with ms.runtime.StreamCtx(s1):
...     c = a + b
...     event = s1.record_event()
...     d = a * b
>>> cur_stream = ms.runtime.current_stream()
>>> cur_stream.wait_event(event)
>>> e = c + 3
>>> print(e)
[[5. 5. 5.]
 [5. 5. 5.]
 [5. 5. 5.]]
```

synchronize()

Wait for all the kernels in this stream to complete.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1024, 2048]), ms.float32)
>>> b = Tensor(np.ones([2048, 4096]), ms.float32)
>>> s1 = ms.runtime.Stream()
>>> with ms.runtime.StreamCtx(s1):
...     c = ops.matmul(a, b)
>>> s1.synchronize()
>>> assert s1.query()
```

wait_event(*event*)

Makes all future work submitted to the stream wait for an event.

Parameters

event (Event) – an event to wait for.

Raises

TypeError – If 'event' is not a *mindspore.runtime.Event*.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([3, 3]), ms.float32)
>>> b = Tensor(np.ones([3, 3]), ms.float32)
>>> s1 = ms.runtime.Stream()
>>> with ms.runtime.StreamCtx(s1):
...     c = a + b
...     event = s1.record_event()
...     d = a * b
>>> cur_stream = ms.runtime.current_stream()
>>> cur_stream.wait_event(event)
>>> e = c + 3
>>> print(e)
[[5. 5. 5.]
 [5. 5. 5.]
 [5. 5. 5.]]
```

wait_stream (*stream*)

Synchronizes with another stream.

All future work submitted to this stream will wait until all kernels submitted to a given stream at the time of call complete.

Parameters

stream (Stream) – a stream to synchronize.

Raises

TypeError – If 'stream' is not a *mindspore.runtime.Stream*.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> s1 = ms.runtime.Stream()
>>> s2 = ms.runtime.Stream()
>>> a = Tensor(np.ones([1, 2]), ms.float32)
>>> b = Tensor(np.ones([2, 2]), ms.float32)
>>> with ms.runtime.StreamCtx(s1):
...     c = ops.matmul(a, b)
>>> with ms.runtime.StreamCtx(s2):
...     s2.wait_stream(s1)
...     d = ops.matmul(c, b)
>>> ms.runtime.synchronize()
>>> print(d)
[[4. 4.]]
```

9.3.7 mindspore.runtime.StreamCtx

class mindspore.runtime.**StreamCtx**(*ctx_stream*)

Context-manager that selects a given stream.

All kernels queued within its context will be enqueued on a selected stream.

Parameters

ctx_stream (Stream) –selected stream. This manager is a no-op if it's None.

Raises

TypeError –If 'stream' is neither a *mindspore.runtime.Stream* nor a None.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1024, 2048]), ms.float32)
>>> b = Tensor(np.ones([2048, 4096]), ms.float32)
>>> s1 = ms.runtime.Stream()
>>> with ms.runtime.StreamCtx(s1):
...     c = ops.matmul(a, b)
>>> ms.runtime.synchronize()
>>> assert s1.query()
```

9.4 Event

mindspore.runtime.Event	Wrapper around a device event.

9.4.1 mindspore.runtime.Event

class mindspore.runtime.**Event**(*enable_timing=False*, *blocking=False*)

Wrapper around a device event.

Device events are synchronization markers that can be used to monitor the device' s progress, to accurately measure timing, and to synchronize device streams.

The underlying device events are lazily initialized when the event is first recorded.

Parameters

- **enable_timing** (*bool, optional*) –indicates if the event should measure time (default: False)
- **blocking** (*bool, optional*) –if True, *wait* will be blocking (default: False)

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> start = ms.runtime.Event(enable_timing=True)
>>> end = ms.runtime.Event(enable_timing=True)
>>> s1 = ms.runtime.Stream()
>>> s2 = ms.runtime.Stream()
>>> a = Tensor(np.ones([2, 2]), ms.float32)
>>> b = Tensor(np.ones([2, 2]), ms.float32)
>>> c = Tensor(np.ones([2, 2]), ms.float32)
>>> with ms.runtime.StreamCtx(s1):
...     d = ops.matmul(a, b)
...     start.record()
>>> c += 2
>>> end.record()
>>> with ms.runtime.StreamCtx(s2):
...     start.synchronize()
...     end.synchronize()
...     e = c + d
>>> ms.runtime.synchronize()
>>> print(e)
[[5. 5.]
 [5. 5.]]
>>> elapsed_time = start.elapsed_time(end)
```

elapsed_time(*end_event*)

Returns the time elapsed in milliseconds after the event was recorded and before the end_event was recorded.

Parameters

end_event (Event) – end event.

Returns

float, the time elapsed in milliseconds.

Raises

TypeError – If 'end_event' is not a *mindspore.runtime.Event*.

query()

Checks if all work currently captured by event has completed.

Returns

A boolean indicating if all work currently captured by event has completed.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> a = Tensor(np.ones([1024, 2048]), ms.float32)
>>> b = Tensor(np.ones([2048, 4096]), ms.float32)
>>> s1 = ms.runtime.Stream()
>>> with ms.runtime.StreamCtx(s1):
...     c = ops.matmul(a, b)
...     ev = s1.record_event()
>>> s1.synchronize()
>>> assert ev.query()
```

record(*stream=None*)

Records the event in a given stream.

Uses *mindspore.runtime.current_stream()* if no *stream* is specified. The stream's device must match the event's device.

Parameters

stream (Stream, *optional*) –a stream to record. If this argument is None, current stream will be used. Default value: None.

Raises

TypeError –If 'stream' is neither a *mindspore.runtime.Stream* nor a None.

synchronize()

Waits for the event to complete.

Waits until the completion of all work currently captured in this event. This prevents the CPU thread from proceeding until the event completes.

wait(*stream=None*)

Makes all future work submitted to the given stream wait for this event.

Use *mindspore.runtime.current_stream()* if no *stream* is specified.

Parameters

stream (Stream, *optional*) –a stream to record. If this argument is None, current stream will be used. Default value: None.

Raises

TypeError –If 'stream' is neither a *mindspore.runtime.Stream* nor a None.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.set_device("Ascend", 0)
>>> event = ms.runtime.Event()
>>> s1 = ms.runtime.Stream()
>>> s2 = ms.runtime.Stream()
>>> a = Tensor(np.ones([2, 2]), ms.float32)
>>> b = Tensor(np.ones([2, 2]), ms.float32)
>>> with ms.runtime.StreamCtx(s1):
...     c = ops.matmul(a, b)
...     event.record()
>>> event.wait()
>>> d = c + 2
>>> ms.runtime.synchronize()
>>> print(d)
[[4. 4.]
 [4. 4.]]
```

CHAPTER

TEN

MINDSPORE.DEVICE_CONTEXT

The device_context encapsulates the interface for querying the number of devices with whether the currently specified backend is available.

10.1 Cpu Device Backend Management

mindspore.device_context.cpu.device_count	Returns compute-capable device count of CPU.
mindspore.device_context.cpu.is_available	Return whether cpu backend is available.
mindspore.device_context.cpu.op_tuning.threads_num	Set the threads number of CPU kernel used.

10.1.1 mindspore.device_context.cpu.device_count

mindspore.device_context.cpu.**device_count**()

Returns compute-capable device count of CPU.

Note:

- For CPU hardware, 1 is always returned.

Returns

int, The number of compute-capable CPU devices.

Examples

```
>>> import mindspore as ms
>>> print(ms.device_context.cpu.device_count())
1
```

10.1.2 mindspore.device_context.cpu.is_available

mindspore.device_context.cpu.**is_available**()

Return whether cpu backend is available.

Returns

Bool, whether the cpu backend is available for this MindSpore package.

Examples

```
>>> import mindspore as ms
>>> print(ms.device_context.cpu.is_available())
True
```

10.1.3 mindspore.device_context.cpu.op_tuning.threads_num

mindspore.device_context.cpu.op_tuning.**threads_num**(*num*)

Set the threads number of CPU kernel used.

The framework set the threads number of CPU kernel used are 25 by default.

Parameters

num (*int*) −The threads number of CPU kernel used.

Examples

```
>>> import mindspore as ms
>>> ms.set_device("Ascend", 1)
>>> ms.device_context.cpu.op_tuning.threads_num(10)
```

10.2 Gpu Device Backend Management

mindspore.device_context.gpu.device_count	Return the number of GPUs available.
mindspore.device_context.gpu.is_available	Return a bool indicating if CUDA is currently available.
mindspore.device_context.gpu.op_precision.conv_allow_tf32	Whether to convert FP32 to TF32 for Conv operators.
mindspore.device_context.gpu.op_precision.matmul_allow_tf32	Whether to convert FP32 to TF32 for Matmul operators.
mindspore.device_context.gpu.op_tuning.conv_dgrad_algo	Specifies convolution data grad algorithm.
mindspore.device_context.gpu.op_tuning.conv_fprop_algo	Specifies convolution forward algorithm.
mindspore.device_context.gpu.op_tuning.conv_wgrad_algo	Specifies convolution filter grad algorithm.

10.2.1 mindspore.device_context.gpu.device_count

mindspore.device_context.gpu.**device_count**()

Return the number of GPUs available.

Returns

Bool, the number of GPUs available.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.gpu.device.device_count()
```

10.2.2 mindspore.device_context.gpu.is_available

mindspore.device_context.gpu.**is_available**()

Return a bool indicating if CUDA is currently available.

Returns

Bool, indicating if CUDA is currently available.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.gpu.device.is_available()
```

10.2.3 mindspore.device_context.gpu.op_precision.conv_allow_tf32

mindspore.device_context.gpu.op_precision.**conv_allow_tf32**(*value*)

Whether to convert FP32 to TF32 for Conv operators. For detailed information, please refer to CUBLAS_COMPUTE_32F_FAST_TF32.

Parameters

value (*bool*) – Whether to convert FP32 to HF32 for Conv operators. If not configured, the framework defaults to `True`.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.gpu.op_precision.conv_allow_tf32(False)
```

10.2.4 mindspore.device_context.gpu.op_precision.matmul_allow_tf32

mindspore.device_context.gpu.op_precision.**matmul_allow_tf32**(*value*)

Whether to convert FP32 to TF32 for Matmul operators. For detailed information, please refer to CUBLAS_COMPUTE_32F_FAST_TF32.

Parameters

value (*bool*) – Whether to convert FP32 to TF32 for Matmul operators. If not configured, the framework defaults to `False`.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.gpu.op_precision.matmul_allow_tf32(True)
```

10.2.5 mindspore.device_context.gpu.op_tuning.conv_dgrad_algo

mindspore.device_context.gpu.op_tuning.**conv_dgrad_algo**(*mode*)

Specifies convolution data grad algorithm. For detailed information, please refer to NVIDA cuDNN.

Parameters

mode (*str*) – convolution data grad algorithm. If not configured, the framework defaults to 'normal'. The value range is as follows:

- normal: Use the cuDNN's heuristic search algorithm, the appropriate convolution algorithm will be quickly selected based on the convolution shape and type. This parameter does not guarantee optimal performance.
- performance: Use the cuDNN's trial search algorithm, all convolution algorithms will be trial run based on the convolution shape and type, and the optimal algorithm will be selected. This parameter ensures optimal performance.
- algo_0: This algorithm expresses the convolution as a sum of matrix products without actually explicitly forming the matrix that holds the input tensor data. The sum is done using the atomic add operation, thus the results are non-deterministic.
- algo_1: This algorithm expresses the convolution as a matrix product without actually explicitly forming the matrix that holds the input tensor data. The results are deterministic.
- fft: This algorithm uses a Fast-Fourier Transform approach to compute the convolution. A significant memory workspace is needed to store intermediate results. The results are deterministic.
- fft_tiling: This algorithm uses the Fast-Fourier Transform approach but splits the inputs into tiles. A significant memory workspace is needed to store intermediate results but less than fft for large size images. The results are deterministic.
- winograd: This algorithm uses the Winograd Transform approach to compute the convolution. A reasonably sized workspace is needed to store intermediate results. The results are deterministic.
- winograd_nonfused: This algorithm uses the Winograd Transform approach to compute the convolution. A significant workspace may be needed to store intermediate results. The results are deterministic.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.gpu.op_tuning.conv_dgrad_algo("performance")
```

10.2.6 mindspore.device_context.gpu.op_tuning.conv_fprop_algo

mindspore.device_context.gpu.op_tuning.**conv_fprop_algo**(*mode*)

Specifies convolution forward algorithm. For detailed information, please refer to NVIDA cuDNN about cudnnConvolutionForward.

Parameters

mode (*str*) – convolution forward algorithm. If not configured, the framework defaults to 'normal'. The value range is as follows:

- normal: Use the cuDNN's heuristic search algorithm, the appropriate convolution algorithm will be quickly selected based on the convolution shape and type. This parameter does not guarantee optimal performance.
- performance: Use the cuDNN's trial search algorithm, all convolution algorithms will be trial run based on the convolution shape and type, and the optimal algorithm will be selected. This parameter ensures optimal performance.
- implicit_gemm: This algorithm expresses the convolution as a matrix product without actually explicitly forming the matrix that holds the input tensor data.
- precomp_gemm: This algorithm expresses convolution as a matrix product without actually explicitly forming the matrix that holds the input tensor data, but still needs some memory workspace to precompute some indices in order to facilitate the implicit construction of the matrix that holds the input tensor data.
- gemm: This algorithm expresses the convolution as an explicit matrix product. A significant memory workspace is needed to store the matrix that holds the input tensor data.
- direct: This algorithm expresses the convolution as a direct convolution, without implicitly or explicitly doing a matrix multiplication.
- fft: This algorithm uses the Fast-Fourier Transform approach to compute the convolution. A significant memory workspace is needed to store intermediate results.
- fft_tiling: This algorithm uses the Fast-Fourier Transform approach but splits the inputs into tiles. A significant memory workspace is needed to store intermediate results but less than fft algorithm for large size images.
- winograd: This algorithm uses the Winograd Transform approach to compute the convolution. A reasonably sized workspace is needed to store intermediate results.
- winograd_nonfused: This algorithm uses the Winograd Transform approach to compute the convolution. A significant workspace may be needed to store intermediate results.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.gpu.op_tuning.conv_fprop_algo("performance")
```

10.2.7 mindspore.device_context.gpu.op_tuning.conv_wgrad_algo

mindspore.device_context.gpu.op_tuning.**conv_wgrad_algo**(*mode*)

Specifies convolution filter grad algorithm. For detailed information, please refer to NVIDA cuDNN.

Parameters

mode (*str*) – convolution filter grad algorithm. If not configured, the framework defaults to 'normal'. The value range is as follows:

- normal: Use the cuDNN's heuristic search algorithm, the appropriate convolution algorithm will be quickly selected based on the convolution shape and type. This parameter does not guarantee optimal performance.
- performance: Use the cuDNN's trial search algorithm, all convolution algorithms will be trial run based on the convolution shape and type, and the optimal algorithm will be selected. This parameter ensures optimal performance.
- algo_0: This algorithm expresses the convolution as a sum of matrix products without actually explicitly forming the matrix that holds the input tensor data. The sum is done using the atomic add operation, thus the results are non-deterministic.
- algo_1: This algorithm expresses the convolution as a matrix product without actually explicitly forming the matrix that holds the input tensor data. The results are deterministic.
- algo_3: This algorithm is similar to algo_0 but uses some small workspace to precompute some indices. The results are also non-deterministic.
- fft: This algorithm uses a Fast-Fourier Transform approach to compute the convolution. A significant memory workspace is needed to store intermediate results. The results are deterministic.
- fft_tiling: This algorithm uses the Fast-Fourier Transform approach but splits the inputs into tiles. A significant memory workspace is needed to store intermediate results but less than fft for large size images. The results are deterministic.
- winograd_nonfused: This algorithm uses the Winograd Transform approach to compute the convolution. A significant workspace may be needed to store intermediate results. The results are deterministic.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.gpu.op_tuning.conv_wgrad_algo("performance")
```

10.3 Ascend Device Backend Management

mindspore.device_context.ascend.device_count	Return compute-capable device count of Ascend.
mindspore.device_context.ascend.is_available	Returns whether ascend backend is available.
mindspore.device_context.ascend.op_precision.conv_allow_hf32	Whether to convert FP32 to HF32 for Conv operators.
mindspore.device_context.ascend.op_precision.matmul_allow_hf32	Whether to convert FP32 to HF32 for Matmul operators.
mindspore.device_context.ascend.op_precision.precision_mode	Configure mixed precision mode setting.
mindspore.device_context.ascend.op_precision.op_precision_mode	Path to config file of op precision mode.

continues on next page

Table 3 – continued from previous page

mindspore.device_context.ascend.op_debug.execute_timeout	Set the maximum duration of executing an operator in seconds.
mindspore.device_context.ascend.op_debug.debug_option	Enable debugging options for Ascend operators, default not enabled.
mindspore.device_context.ascend.op_debug.aclinit_config	Configure the configuration items for the aclInit interface.
mindspore.device_context.ascend.op_tuning.op_compile	Whether to select online compilation.The default settings by the framework are online compilation for static shape, and compiled operator binary files for dynamic shape.
mindspore.device_context.ascend.op_tuning.aoe_tune_mode	AOE tuning mode setting, which is not set by default.
mindspore.device_context.ascend.op_tuning.aoe_job_type	Set the parameters specific to Ascend Optimization Engine.It needs to be used in conjunction with mindspore.device_context.op_tuning.aoe_tune_mode(tune_mode).

10.3.1 mindspore.device_context.ascend.device_count

mindspore.device_context.ascend.**device_count**()

Return compute-capable device count of Ascend.

Returns

int, the number of compute-capable Ascend devices.

Examples

```
>>> import mindspore as ms
>>> print(ms.device_context.ascend.device_count())
8
```

10.3.2 mindspore.device_context.ascend.is_available

mindspore.device_context.ascend.**is_available**()

Returns whether ascend backend is available.

Returns

Bool, whether the ascend backend is available for this MindSpore package.

Examples

```
>>> import mindspore as ms
>>> print(ms.device_context.ascend.is_available())
True
```

10.3.3 mindspore.device_context.ascend.op_precision.conv_allow_hf32

mindspore.device_context.ascend.op_precision.**conv_allow_hf32**(*value*)

Whether to convert FP32 to HF32 for Conv operators. CANN enables FP32 to HF32 for Conv operators by default. For detailed information, please refer to Ascend community .

Note:

- This is an experimental prototype that is subject to change and/or deletion.

Parameters

value (*bool*) – Whether to convert FP32 to HF32 for Conv operators.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.ascend.op_precision.conv_allow_hf32(True)
```

10.3.4 mindspore.device_context.ascend.op_precision.matmul_allow_hf32

mindspore.device_context.ascend.op_precision.**matmul_allow_hf32**(*value*)

Whether to convert FP32 to HF32 for Matmul operators. CANN disables FP32 to HF32 for Matmul operators by default. For detailed information, please refer to Ascend community .

Note:

- This is an experimental prototype that is subject to change and/or deletion.

Parameters

value (*bool*) – Whether to convert FP32 to HF32 for Matmul operators

Examples

```
>>> import mindspore as ms
>>> ms.device_context.ascend.op_precision.matmul_allow_hf32(True)
```

10.3.5 mindspore.device_context.ascend.op_precision.precision_mode

mindspore.device_context.ascend.op_precision.**precision_mode**(*mode*)

Configure mixed precision mode setting. The framework set the configuration of Atlas training series products to "force_fp16" by default, and set the configuration for other products such as the Atlas A2 training series products to "must_keep_origin_dtype" by default. For detailed information, please refer to Ascend community .

Note:

- The default value of *precision_mode* is experimental parameter, may change in the future.

Parameters

mode (*str*) –The operator precision mode setting. The value range is as follows:

- force_fp16: When the operator supports both float16 and float32, directly choose float16.
- allow_fp32_to_fp16: For matrix-type operators, use float16. For vector-type operators, prioritize the original precision. If the operator in the network model supports float32, retain the original precision float32. If the operator in the network model does not support float32, directly reduce the precision to float16.
- allow_mix_precision: Automatic mixed precision, for all operators in the network, according to the built-in optimization strategy, automatically reduce the precision of some operators to float16 or bfloat16.
- must_keep_origin_dtype: Maintain the original precision.
- force_fp32: When the input of the matrix calculation operator is float16, and the output supports both float16 and float32, force the output to be converted to float32.
- allow_fp32_to_bf16: For matrix-type operators, use bfloat16. For vector-type operators, prioritize the original precision. If the operator in the network model supports float32, retain the original precision float32. If the operator in the network model does not support float32, directly reduce the precision to bfloat16.
- allow_mix_precision_fp16: Automatic mixed precision, for all operators in the network, according to the built-in optimization strategy, automatically reduce the precision of some operators to float16.
- allow_mix_precision_bf16: Automatic mixed precision, for all operators in the network, according to the built-in optimization strategy, automatically reduce the precision of some operators to bfloat16.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.ascend.op_precision.precision_mode("force_fp16")
```

10.3.6 mindspore.device_context.ascend.op_precision.op_precision_mode

mindspore.device_context.ascend.op_precision.**op_precision_mode**(*path*)

Path to config file of op precision mode. For detailed information, please refer to Ascend community .

Parameters

path (*str*) –Directory of the configuration file (.ini format) for setting the operator precision mode. The directory can contain letters, digits, underscores (_), hyphens (-), and periods (.).

Examples

```
>>> import mindspore as ms
>>> ms.device_context.ascend.op_precision.op_precision_mode("./op_precision_config_file")
```

10.3.7 mindspore.device_context.ascend.op_debug.execute_timeout

mindspore.device_context.ascend.op_debug.**execute_timeout**(*op_timeout*)

Set the maximum duration of executing an operator in seconds. The framework operator execution timeout time is 900 by default. please refer to Ascend Community document about aclrtSetOpExecuteTimeOut.

Parameters

op_timeout (*int*) −Set the maximum duration of executing an operator in seconds. If the execution time exceeds this value, system will terminate the task. 0 means endless wait. The defaults for AI Core and AI CPU operators vary on different hardware.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.ascend.op_debug.execute_timeout(100)
```

10.3.8 mindspore.device_context.ascend.op_debug.debug_option

mindspore.device_context.ascend.op_debug.**debug_option**(*option_value*)

Enable debugging options for Ascend operators, default not enabled.

Parameters

option_value (*str*) −Ascend operators debugging configuration. Currently, only memory access violation detection is supported. The value currently only supports being set to "oom".

- "oom": When there is a memory out of bounds during the execution of an operator, AscendCL will return an error code of EZ9999.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.ascend.op_debug.debug_option("oom")
```

10.3.9 mindspore.device_context.ascend.op_debug.aclinit_config

mindspore.device_context.ascend.op_debug.**aclinit_config**(*config*)

Configure the configuration items for the aclInit interface. please refer to Ascend Community document about aclInit..

Parameters

config (*dict*) −When initializing AscendCL, you can enable or configure the following features through this configuration interface.

- "max_opqueue_num": When executing using the single-operator model method, to save memory and balance the performance of calls, you can configure the maximum length of the single-operator model mapping queue through the max_opqueue_num parameter. If the length reaches the maximum, the system will first delete the mapping information that has not been used for a long time and the cached single-operator model, and then load the latest mapping information and the corresponding single-operator model. If the maximum length of the mapping queue is not configured, the default maximum length is 20,000.

- "err_msg_mode": This parameter is used to control the level at which error information is retrieved, either by process or by thread. The default level is by process. "0" indicating that error information is retrieved by thread. "1" is the default value, indicates that error information is retrieved by process.
- "dump": This parameter is used to enable exception dump for Ascend operators. The value can be set to {"dump_scene": "lite_exception"}, {"dump_scene": "lite_exception:disable"}. {"dump_scene": "lite_exception"} indicates that the exception dump is enabled. {"dump_scene": "lite_exception:disable"} indicates that the exception dump is disabled. {"dump_scene": "lite_exception"} is the default value, indicates that the exception dump is enabled.

Examples

```
>>> import mindspore as ms
>>> ms.set_device("Ascend", 0)
>>> ms.device_context.ascend.op_debug.aclinit_config({"max_opqueue_num": "20000", "err_msg_
↪mode": "1",
...                                                   "dump": {"dump_scene": "lite_exception
↪"}})
```

10.3.10 mindspore.device_context.ascend.op_tuning.op_compile

mindspore.device_context.ascend.op_tuning.**op_compile**(*value*)

Whether to select online compilation.The default settings by the framework are online compilation for static shape, and compiled operator binary files for dynamic shape. The default settings may change in the future. For detailed information, please refer to Ascend community .

Parameters

value (*bool*) – Whether to select online compilation or not.

- True: online compilation is prioritized.
- False: compiled operator binary files are prioritized to improve compilation performance.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.ascend.op_tuning.op_compile(True)
```

10.3.11 mindspore.device_context.ascend.op_tuning.aoe_tune_mode

mindspore.device_context.ascend.op_tuning.**aoe_tune_mode**(*tune_mode*)

AOE tuning mode setting, which is not set by default.

Parameters

tune_mode (*str*) – AOE tuning mode setting.

- "online": the online tuning function is turned on.
- "offline": ge graph will be saved for offline tuning.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.ascend.op_tuning.aoe_tune_mode("online")
```

10.3.12 mindspore.device_context.ascend.op_tuning.aoe_job_type

mindspore.device_context.ascend.op_tuning.**aoe_job_type**(*config*)

Set the parameters specific to Ascend Optimization Engine.It needs to be used in conjunction with mindspore.device_context.op_tuning.aoe_tune_mode(tune_mode). The framework set to "2" by default.

Parameters

config (*str*) – Choose the tuning type.

- "1": Set to subgraph tuning.
- "2": Set to operator tuning.

Examples

```
>>> import mindspore as ms
>>> ms.device_context.ascend.op_tuning.aoe_job_type("1")
```

CHAPTER

ELEVEN

MINDSPORE.COMMUNICATION

Collective communication interface.

Note that the APIs in the following list need to preset communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

mindspore.communication.GlobalComm	World communication information.
mindspore.communication.init	Initialize distributed backends required by communication services, e.g.
mindspore.communication.release	Release distributed resource.
mindspore.communication.create_group	Create a user collective communication group.
mindspore.communication.destroy_group	Destroy the user collective communication group.
mindspore.communication.get_comm_name	Get the communicator name of the specified collective communication group.
mindspore.communication.get_group_size	Get the rank size of the specified collective communication group.
mindspore.communication.get_group_rank_from_world_rank	Get the rank ID in the specified user communication group corresponding to the rank ID in the world communication group.
mindspore.communication.get_local_rank	Gets local rank ID for current device in specified collective communication group.
mindspore.communication.get_local_rank_size	Gets local rank size of the specified collective communication group.
mindspore.communication.get_process_group_ranks	Gets the ranks of the specific group and returns the process ranks in the communication group as a list.
mindspore.communication.get_rank	Get the rank ID for the current device in the specified collective communication group.
mindspore.communication.get_world_rank_from_group_rank	Get the rank ID in the world communication group corresponding to the rank ID in the specified user communication group.
mindspore.communication.HCCL_WORLD_COMM_GROUP	str(object='') -> str str(bytes_or_buffer[, encoding[, errors]]) -> str
mindspore.communication.NCCL_WORLD_COMM_GROUP	str(object='') -> str str(bytes_or_buffer[, encoding[, errors]]) -> str
mindspore.communication.MCCL_WORLD_COMM_GROUP	str(object='') -> str str(bytes_or_buffer[, encoding[, errors]]) -> str

11.1 mindspore.communication.GlobalComm

class mindspore.communication.**GlobalComm**

World communication information. The GlobalComm is a global class. The members contain:

- BACKEND : The communication library used, using "hccl" / "nccl" / "mccl" . "hccl" means Huawei Collective Communication Library(HCCL), "nccl" means NVIDIA Collective Communication Library(NCCL), "mccl" means MindSpore Collective Communication Library(MCCL).
- WORLD_COMM_GROUP : Global communication domain, using "hccl_world_group" / "nccl_world_group" / "mccl_world_group" .

11.2 mindspore.communication.init

mindspore.communication.**init**(*backend_name=None*)

Initialize distributed backends required by communication services, e.g. "hccl" / "nccl" / "mccl". It is usually used in distributed parallel scenarios and set before using communication services.

Note:

- The full name of "hccl" is Huawei Collective Communication Library(HCCL).
- The full name of "nccl" is NVIDIA Collective Communication Library(NCCL).
- The full name of "mccl" is MindSpore Collective Communication Library(MCCL).
- In Ascend hardware platforms, init() should be set before the definition of any Tensor and Parameter, and the instantiation and execution of any operation and net.

Parameters

backend_name (*str*) –Backend, using "hccl" / "nccl" / "mccl". "hccl" should be used for Ascend hardware platforms, "nccl" for GPU hardware platforms and "mccl" for CPU hardware platforms. If not set, inference is automatically made based on the hardware platform type (device_target). Default: None .

Raises

- **TypeError** –If *backend_name* is not a string.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails, or the environment variables RANK_ID/MINDSPORE_HCCL_CONFIG_PATH have not been exported when backend is HCCL.

Supported Platforms:

Ascend GPU CPU

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> from mindspore.communication import init
>>> init()
```

11.3 mindspore.communication.release

mindspore.communication.**release**()
Release distributed resource. e.g. HCCL/NCCL/MCCL.

Note: This method should be used after init(). If not, resource will be released when program ends.

Raises

RuntimeError – If failed to release distributed resource.

Supported Platforms:

Ascend GPU CPU

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> from mindspore.communication import init, release
>>> init()
>>> release()
```

11.4 mindspore.communication.create_group

mindspore.communication.**create_group**(*group*, *rank_ids*)
Create a user collective communication group.

Note: This method isn't supported in GPU and CPU versions of MindSpore. The size of rank_ids should be larger than 1, rank_ids should not have duplicate data. This method should be used after init(). Only support global single communication group in PyNative mode if you do not start with mpirun.

Parameters

- **group** (*str*) −The name of the communication group to be created.
- **rank_ids** (*list*) −A list of device IDs.

Raises

- **TypeError** −If group is not a string or *rank_ids* is not a list.
- **ValueError** −If *rank_ids* size is not larger than 1, or *rank_ids* has duplicate data, or backend is invalid.
- **RuntimeError** −If HCCL is not available or MindSpore is GPU/CPU version.

Supported Platforms:

Ascend GPU CPU

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore import set_context
>>> from mindspore import ops
>>> from mindspore.communication import init, create_group, get_rank
>>> set_context(mode=ms.GRAPH_MODE)
>>> ms.set_device(device_target="Ascend")
>>> init()
>>> group = "0-7"
>>> rank_ids = [0,7]
>>> if get_rank() in rank_ids:
...     create_group(group, rank_ids)
...     allreduce = ops.AllReduce(group)
```

11.5 mindspore.communication.destroy_group

mindspore.communication.**destroy_group**(*group*)

Destroy the user collective communication group.

Note: This method isn't supported in GPU and CPU versions of MindSpore. The parameter group should not be "hccl_world_group". This method should be used after init().

Parameters

group (*str*) −The communication group to destroy, the group should be created by create_group.

Raises

- **TypeError** −If group is not a string.

- **ValueError** –If group is "hccl_world_group" or backend is invalid.
- **RuntimeError** –If HCCL is not available or MindSpore is GPU/CPU version.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore import set_context
>>> from mindspore import ops
>>> from mindspore.communication import init, create_group, destroy_group, get_rank
>>> set_context(mode=ms.GRAPH_MODE)
>>> ms.set_device(device_target="Ascend")
>>> init()
>>> group = "0-2"
>>> rank_ids = [0,2]
>>> if get_rank() in rank_ids:
...     create_group(group, rank_ids)
...     destroy_group(group)
```

11.6 mindspore.communication.get_comm_name

mindspore.communication.**get_comm_name**(*group=GlobalComm.WORLD_COMM_GROUP*)

Get the communicator name of the specified collective communication group.

Note: This method isn't supported in GPU and CPU versions of MindSpore. This method should be used after init().

Parameters

group (*str*) –The communication group to work on. Normally, the group should be created by create_group, otherwise, using the default group. Default: `GlobalComm.WORLD_COMM_GROUP` .

Returns

string, the inner communicator name of the group.

Raises

- **TypeError** –If group is not a string.
- **ValueError** –If backend is invalid.
- **RuntimeError** –If HCCL is not available or MindSpore is GPU/CPU version.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore.communication import init, create_group, get_rank, get_comm_name
>>> ms.set_device(device_target="Ascend")
>>> init()
>>> world_group_comm_name = get_comm_name()
>>> group = "0-7"
>>> rank_ids = [0,7]
>>> if get_rank() in rank_ids:
...     create_group(group, rank_ids)
...     customizd_group_comm_name = get_comm_name(group)
...     print("comm_name of customizd group is ", customizd_group_comm_name)
>>> print("comm_name of world group is: ", world_group_comm_name)
comm_name of customizd group is: 11.22.33.44%eth0_60000_0_0123456789101112
comm_name of world group is: 11.22.33.44%eth0_60000_0_1211109876543210
```

11.7 mindspore.communication.get_group_size

mindspore.communication.**get_group_size**(*group=GlobalComm.WORLD_COMM_GROUP*)

Get the rank size of the specified collective communication group.

Note: This method should be used after init().

Parameters

group (*str*) – The communication group to work on. Normally, the group should be created by create_group, otherwise, using the default group. Default: `GlobalComm.WORLD_COMM_GROUP`.

Returns

int, the rank size of the group.

Raises

- **TypeError** – If group is not a string.
- **ValueError** – If backend is invalid.
- **RuntimeError** – If HCCL/NCCL/MCCL is not available.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore.communication import init, get_group_size
>>> init()
>>> group_size = get_group_size()
>>> print("group_size is: ", group_size)
group_size is: 8
```

11.8 mindspore.communication.get_group_rank_from_world_rank

mindspore.communication.**get_group_rank_from_world_rank**(*world_rank_id*, *group*)

Get the rank ID in the specified user communication group corresponding to the rank ID in the world communication group.

Note: This method isn't supported in GPU and CPU versions of MindSpore. The parameter group should not be "hccl_world_group". This method should be used after init().

Parameters

- **world_rank_id** (*int*) –A rank ID in the world communication group.
- **group** (*str*) –The communication group to work on. The group is created by create_group.

Returns

int, the rank ID in the user communication group.

Raises

- **TypeError** –If world_rank_id is not an integer or the group is not a string.
- **ValueError** –If group is 'hccl_world_group' or backend is invalid.
- **RuntimeError** –If HCCL is not available or MindSpore is GPU/CPU version.

Supported Platforms:

Ascend GPU CPU

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore import set_context
>>> from mindspore.communication import init, create_group, get_group_rank_from_world_rank,␣
↪get_rank
>>> set_context(mode=ms.GRAPH_MODE)
>>> ms.set_device(device_target="Ascend")
>>> init()
>>> group = "0-4"
>>> rank_ids = [0,4]
>>> if get_rank() in rank_ids:
...     create_group(group, rank_ids)
...     group_rank_id = get_group_rank_from_world_rank(4, group)
...     print("group_rank_id is: ", group_rank_id)
group_rank_id is: 1
```

11.9 mindspore.communication.get_local_rank

mindspore.communication.**get_local_rank**(*group=GlobalComm.WORLD_COMM_GROUP*)

Gets local rank ID for current device in specified collective communication group.

Note: This method isn't supported in GPU and CPU versions of MindSpore. This method should be used after init().

Parameters

group (*str*) – The communication group to work on. Normally, the group should be created by create_group, otherwise, using the default group. Default: GlobalComm.WORLD_COMM_GROUP.

Returns

int, the local rank ID of the calling process within the group.

Raises

- **TypeError** – If group is not a string.
- **ValueError** – If backend is invalid.
- **RuntimeError** – If HCCL is not available or MindSpore is GPU/CPU version.

Supported Platforms:

Ascend GPU CPU

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore.communication import init, get_rank, get_local_rank
>>> ms.set_device(device_target="Ascend")
>>> init()
>>> world_rank = get_rank()
>>> local_rank = get_local_rank()
>>> print("local_rank is: {}, world_rank is {}".format(local_rank, world_rank))
local_rank is: 1, world_rank is 9
```

11.10 mindspore.communication.get_local_rank_size

mindspore.communication.**get_local_rank_size**(*group=GlobalComm.WORLD_COMM_GROUP*)

Gets local rank size of the specified collective communication group.

Note: This method isn't supported in GPU and CPU versions of MindSpore. This method should be used after init().

Parameters

group (*str*) – The communication group to work on. The group is created by create_group or the default world communication group. Default: `GlobalComm.WORLD_COMM_GROUP` .

Returns

int, the local rank size where the calling process is within the group.

Raises

- **TypeError** – If group is not a string.
- **ValueError** – If backend is invalid.
- **RuntimeError** – If HCCL is not available or MindSpore is GPU/CPU version.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore.communication import init, get_local_rank_size
>>> ms.set_device(device_target="Ascend")
>>> init()
>>> local_rank_size = get_local_rank_size()
>>> print("local_rank_size is: ", local_rank_size)
local_rank_size is: 8
```

11.11 mindspore.communication.get_process_group_ranks

mindspore.communication.**get_process_group_ranks**(*group=GlobalComm.WORLD_COMM_GROUP*)

Gets the ranks of the specific group and returns the process ranks in the communication group as a list.

Parameters

group (*str, optional*) – The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`, which means `"hccl_world_group"` in Ascend, and `"nccl_world_group"` in GPU.

Returns

List (List[int]), List of process ranks in the specified communication group.

Raises

- **TypeError** – If the *group* is not a str.
- **RuntimeError** – If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend` `GPU`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies.

Please see the msrun start up for more details.

This example should be run with 4 devices.

```
>>> import numpy as np
>>> from mindspore.communication import init, get_process_group_ranks
>>>
```

(continues on next page)

(continued from previous page)

```
>>> init()
>>> output = get_process_group_ranks()
>>> print(output)
[0, 1, 2, 3]
```

11.12 mindspore.communication.get_rank

mindspore.communication.**get_rank**(*group=GlobalComm.WORLD_COMM_GROUP*)

Get the rank ID for the current device in the specified collective communication group.

Note: This method should be used after init().

Parameters

group (*str*) – The communication group to work on. Normally, the group should be created by create_group, otherwise, using the default group. Default: `GlobalComm.WORLD_COMM_GROUP` .

Returns

int, the rank ID of the calling process within the group.

Raises

- **TypeError** – If group is not a string.
- **ValueError** – If backend is invalid.
- **RuntimeError** – If HCCL/NCCL/MCCL is not available.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> from mindspore.communication import init, get_rank
>>> init()
>>> rank_id = get_rank()
>>> print(rank_id)
>>> # the result is the rank_id in world_group
```

11.13 mindspore.communication.get_world_rank_from_group_rank

mindspore.communication.**get_world_rank_from_group_rank**(*group*, *group_rank_id*)

Get the rank ID in the world communication group corresponding to the rank ID in the specified user communication group.

Note: This method isn't supported in GPU and CPU versions of MindSpore. The parameter group should not be "hccl_world_group". This method should be used after init().

Parameters

- **group** (*str*) −The communication group to work on. The group is created by create_group.
- **group_rank_id** (*int*) −A rank ID in the communication group.

Returns

int, the rank ID in world communication group.

Raises

- **TypeError** −If *group_rank_id* is not an integer or the group is not a string.
- **ValueError** −If group is 'hccl_world_group' or backend is invalid.
- **RuntimeError** −If HCCL is not available or MindSpore is GPU/CPU version.

Supported Platforms:

Ascend GPU CPU

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

```
>>> import mindspore as ms
>>> from mindspore import set_context
>>> from mindspore.communication import init, create_group, get_world_rank_from_group_rank,␣
 ↪get_rank
>>> set_context(mode=ms.GRAPH_MODE)
>>> ms.set_device(device_target="Ascend")
>>> init()
>>> group = "0-4"
>>> rank_ids = [0,4]
>>> if get_rank() in rank_ids:
...     create_group(group, rank_ids)
...     world_rank_id = get_world_rank_from_group_rank(group, 1)
...     print("world_rank_id is: ", world_rank_id)
world_rank_id is: 4
```

11.14 mindspore.communication.HCCL_WORLD_COMM_GROUP

mindspore.communication.**HCCL_WORLD_COMM_GROUP**

The string of "hccl_world_group" referring to the default communication group created by HCCL. On the Ascend hardware platforms, the string is equivalent to `GlobalComm.WORLD_COMM_GROUP` after the communication service is initialized. It is recommended to use `GlobalComm.WORLD_COMM_GROUP` to obtain the current global communication group.

11.15 mindspore.communication.NCCL_WORLD_COMM_GROUP

mindspore.communication.**NCCL_WORLD_COMM_GROUP**

The string of "nccl_world_group" referring to the default communication group created by NCCL. On the GPU hardware platforms, the string is equivalent to `GlobalComm.WORLD_COMM_GROUP` after the communication service is initialized. It is recommended to use `GlobalComm.WORLD_COMM_GROUP` to obtain the current global communication group.

11.16 mindspore.communication.MCCL_WORLD_COMM_GROUP

mindspore.communication.**MCCL_WORLD_COMM_GROUP**

The string of "mccl_world_group" referring to the default communication group created by MCCL. On the CPU hardware platforms, the string is equivalent to `GlobalComm.WORLD_COMM_GROUP` after the communication service is initialized. It is recommended to use `GlobalComm.WORLD_COMM_GROUP` to obtain the current global communication group.

11.17 mindspore.communication.comm_func

Collection communication functional interface

mindspore.communication.comm_func.all_gather_into_tensor	Gathers tensors from the specified communication group and returns the tensor which is all gathered.
mindspore.communication.comm_func.all_reduce	Reduce tensors across all devices in such a way that all deviceswill get the same final result, returns the tensor which is all reduced.
mindspore.communication.comm_func.all_to_all_single_with_output_shape	Based on the slice size of the user input, the input *tensor* is sliced and sent to other devices and receives the sliced chunks from the other devices, which are then merged into an output Tensor.
mindspore.communication.comm_func.all_to_all_with_output_shape	scatter and gather list of tensor to/from all rank according to input/output tensor list.
mindspore.communication.comm_func.barrier	Synchronizes all processes in the specified group.
mindspore.communication.comm_func.batch_isend_irecv	Batch send and recv tensors asynchronously.
mindspore.communication.comm_func.broadcast	Broadcasts the tensor to the whole group.
mindspore.communication.comm_func.gather_into_tensor	Gathers tensors from the specified communication group.
mindspore.communication.comm_func.irecv	Receive tensors from src asynchronously.
mindspore.communication.comm_func.isend	Send tensors to the specified dest_rank asynchronously.
mindspore.communication.comm_func.recv	Receive tensors from src.
mindspore.communication.comm_func.send	Send tensors to the specified dest_rank.

continues on next page

Table 2 – continued from previous page

mindspore.communication.comm_func.P2POp	Object for *batch_isend_irecv* input, to store information of "isend" and "irecv".
mindspore.communication.comm_func.reduce	Reduces tensors across the processes in the specified communication group, sends the result to the target dst(global rank), and returns the tensor which is sent to the target process.
mindspore.communication.comm_func.reduce_scatter_tensor	Reduces and scatters tensors from the specified communication group and returns the tensor which is reduced and scattered.
mindspore.communication.comm_func.scatter_tensor	Scatter tensor evently across the processes in the specified communication group.

11.17.1 mindspore.communication.comm_func.all_gather_into_tensor

mindspore.communication.comm_func.**all_gather_into_tensor**(*tensor*, *group=GlobalComm.WORLD_COMM_GROUP*, *async_op=False*)

Gathers tensors from the specified communication group and returns the tensor which is all gathered.

Note:

- The tensors must have the same shape and format in all processes of the collection.

Parameters

- **tensor** (Tensor) – The input tensor to be all gathered into tensor. The shape of tensor is $(x_1, x_2, ..., x_R)$.
- **group** (*str, optional*) – The communication group to work on. Default: GlobalComm.WORLD_COMM_GROUP , which means "hccl_world_group" in Ascend, and "nccl_world_group" in GPU.
- **async_op** (*bool, optional*) – Whether this operator should be an async operator. Default: False .

Returns

Tuple(Tensor, CommHandle), if the number of devices in the group is N, then the shape of output tensor is $(N, x_1, x_2, ..., x_R)$. CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** – If the type of the first input parameter is not Tensor, or *group* is not a str.
- **ValueError** – If the local rank id of the calling process in the group is larger than the group's rank size.
- **RuntimeError** – If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.communication as comm
>>>
>>> comm.init()
>>> input_tensor = ms.Tensor(np.ones([2, 8]).astype(np.float32))
>>> output, _ = comm.comm_func.all_gather_into_tensor(input_tensor)
>>> print(output)
[[1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]]
```

11.17.2 mindspore.communication.comm_func.all_reduce

mindspore.communication.comm_func.**all_reduce**(*tensor*, *op=ReduceOp.SUM*, *group=GlobalComm.WORLD_COMM_GROUP*, *async_op=False*)

Reduce tensors across all devices in such a way that all deviceswill get the same final result, returns the tensor which is all reduced.

Note: The tensors must have the same shape and format in all processes of the collection.

Parameters

- **tensor** (Tensor) –The input tensor to be all reduced. The shape of tensor is $(x_1, x_2, ..., x_R)$.
- **op** (*str, optional*) –Specifies an operation used for element-wise reductions, like sum, prod, max, and min. On the CPU, only 'sum' is supported. Default: `ReduceOp.SUM`.
- **group** (*str, optional*) –The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`, which means `"hccl_world_group"` in Ascend, and `"nccl_world_group"` in GPU.
- **async_op** (*bool, optional*) –Whether this operator should be an async operator. Default: `False`.

Returns

Tuple(Tensor, CommHandle), the output tensor has the same shape of the input, i.e., $(x_1, x_2, ..., x_R)$. The contents depend on the specified operation. CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** –If the type of the first input parameter is not Tensor, or any of *op* and *group* is not a str.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.communication as comm
>>>
>>> comm.init()
>>> input_tensor = ms.Tensor(np.ones([2, 8]).astype(np.float32))
>>> output, _ = comm.comm_func.all_reduce(input_tensor)
>>> print(output)
[[2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]]
```

11.17.3 mindspore.communication.comm_func.all_to_all_single_with_output_shape

mindspore.communication.comm_func.**all_to_all_single_with_output_shape**(*output_shape*, *tensor*, *output_split_sizes=None*, *input_split_sizes=None*, *group=None*, *async_op=False*)

Based on the slice size of the user input, the input *tensor* is sliced and sent to other devices and receives the sliced chunks from the other devices, which are then merged into an output Tensor.

Note: 'output_shape' and 'tensor' shape should be match across ranks. Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **output_shape** (*Union(Tensor, Tuple(int))*) –shape to indicate the shape of tensor gathered concatenated from remote rank.
- **tensor** (Tensor) –tensor to be scattered to remote rank.
- **output_split_sizes** (*Union(Tuple(int), List(int))*) –output split size at dim 0. If set to None, it means equally split by `world_size`. Default: None.
- **input_split_sizes** (*Union(Tuple(int), List(int))*) –input split size at dim 0. If set to None, it means equally split by `world_size`. Default: None.
- **group** (*str, optional*) –The communication group to work on. Default: None, which means "hccl_world_group" on Ascend, "nccl_world_group" on GPU.
- **async_op** (*bool, optional*) –Whether this operator should be an async operator. Default: `False` .

Returns

Tuple(Tensor, CommHandle), the output tensor is gathered concatenated from remote ranks. If the numel of tensor gathered from remote is zero, it will return a Tensor with shape *()*, and value has no actual meanning. CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** – If *tensor* is not tensor.
- **TypeError** – If *output_shape* is not tuple or tensors.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.communication as comm
>>>
>>> comm.init()
>>> rank = comm.get_rank()
>>> input = ms.Tensor([0, 1]) + rank * 2
>>> output_shape = (2,)
>>> result, _ = comm.comm_func.all_to_all_single_with_output_shape(output_shape, input)
>>> print(result)
rank 0:
[ 0.  2.]
rank 1:
[ 1.  3.]
```

11.17.4 mindspore.communication.comm_func.all_to_all_with_output_shape

mindspore.communication.comm_func.**all_to_all_with_output_shape**(*output_shape_list*, *input_tensor_list*, *group=None*, *async_op=False*)

scatter and gather list of tensor to/from all rank according to input/output tensor list.

Note: tensor shape in *output_shape_list* and *input_tensor_list* should be match across ranks. Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **output_shape_list** (*Union[Tuple(Tensor), List(Tensor), Tuple(Tuple(int))]*) – List of shape that indicate the gathered tensors shape from remote ranks.

- **input_tensor_list** (*Union[Tuple(Tensor), List(Tensor)]*) – List of tensors to scatter to the remote rank.
- **group** (*str, optional*) – The communication group to work on. Default: None, which means "hccl_world_group" on Ascend, "nccl_world_group" on GPU.
- **async_op** (*bool, optional*) – Whether this operator should be an async operator. Default: `False`.

Returns

Tuple(Tuple(Tensor), CommHandle), the tensors is gathered from remote ranks. CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** – If *input_tensor_list* is not list of tensors.
- **TypeError** – If *output_shape_list* is not list of tuple or tensors.
- **TypeError** – If tensors in *input_tensor_list* are not the same type.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.communication as comm
>>>
>>> comm.init()
>>> this_rank = comm.get_rank()
>>> if this_rank == 0:
...     send_tensor_list = [ms.Tensor(1.), ms.Tensor([[2, 3], [4, 5.]])]
...     recv_tensor_list = [(), (2,)]
>>> if this_rank == 1:
...     send_tensor_list = [ms.Tensor([2, 2.]), ms.Tensor([4, 5, 6, 7.])]
...     recv_tensor_list = [(2, 2), (4,)]
>>> output, _ = comm.comm_func.all_to_all_with_output_shape(recv_tensor_list, send_tensor_
↪list)
>>> print(output)
rank 0:
(Tensor(shape=[], dtype=Float32, value= 1),
 Tensor(shape=[2], dtype=Float32, value= [2.00000000e+00, 2.00000000e+00]))
rank 1:
(Tensor(shape=[2, 2], dtype=Float32, value=
[[2.00000000e+00, 3.00000000e+00],
 [4.00000000e+00, 5.00000000e+00]]),
 Tensor(shape=[4], dtype=Float32, value=[4.00000000e+00, 5.00000000e+00, 6.00000000e+00, 7.
↪00000000e+00]))
```

11.17.5 mindspore.communication.comm_func.barrier

mindspore.communication.comm_func.**barrier**(*group=GlobalComm.WORLD_COMM_GROUP*)

Synchronizes all processes in the specified group. Once the process call this operation, it will be blocked until all processes call this operation. After all processes finish calling the operations, the blocked processes will be woken and continue their task.

Parameters

group (*str, optional*) – The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`.

Raises

RuntimeError – If backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import mindspore as ms
>>> import mindspore.communication as comm
>>>
>>> # Launch 2 processes.
>>> comm.init()
>>> comm.comm_func.barrier()
>>> print("barrier finish!")
barrier finish!
```

Tutorial Examples:

- Distributed Set Communication Primitives - Barrier

11.17.6 mindspore.communication.comm_func.batch_isend_irecv

mindspore.communication.comm_func.**batch_isend_irecv**(*p2p_op_list*)

Batch send and recv tensors asynchronously.

Note:

- The 'isend' and 'irecv' of *P2POp* in *p2p_op_list* between ranks need to match each other.
- *P2POp* in *p2p_op_list* can only use the same communication group.
- *tag* of *P2POp* in *p2p_op_list* is not support yet.
- *tensor* of *P2POp* in *p2p_op_list* will not be modified by result inplace.
- Only support PyNative mode, Graph mode is not currently supported.

Parameters

p2p_op_list (P2POp) – list contains *P2POp*. *P2POp* is type of *mindspore.communication.comm_func.P2POp*

Returns

tuple(Tensor). Output tensors is corresponding to *p2p_op_list*. At *P2POp* with 'isend' position, output tensor is a fake tensor with scalar, which has no meaning. At *P2POp* with 'irecv' position, output tensor is a tensor received from remote device.

Raises

TypeError – If *p2p_op_list* are not all type of *P2POp*.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.communication as comm
>>>
>>> comm.init()
>>> this_rank = comm.get_rank()
>>> world_size = comm.get_group_size()
>>> next_rank = (this_rank + 1) % world_size
>>> prev_rank = (this_rank + world_size - 1) % world_size
>>>
>>> send_tensor = ms.Tensor(this_rank + 1, dtype=ms.float32)
>>> recv_tensor = ms.Tensor(0., dtype=ms.float32)
>>>
>>> send_op = comm.comm_func.P2POp('isend', send_tensor, next_rank)
>>> recv_op = comm.comm_func.P2POp('irecv', recv_tensor, prev_rank)
>>>
>>> p2p_op_list = [send_op, recv_op]
>>> output = comm.comm_func.batch_isend_irecv(p2p_op_list)
>>> print(output)
rank 0:
(Tensor(shape=[], dtype=Float32, value= 0), Tensor(shape=[], dtype=Float32, value= 2))
rank 1:
(Tensor(shape=[], dtype=Float32, value= 0), Tensor(shape=[], dtype=Float32, value= 1))
```

11.17.7 mindspore.communication.comm_func.broadcast

mindspore.communication.comm_func.**broadcast**(*tensor*, *src=0*, *group=GlobalComm.WORLD_COMM_GROUP*)

Broadcasts the tensor to the whole group.

Note: The tensors must have the same shape and format in all processes of the collection. Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) –The tensor to be broadcasted. The shape of tensor is $(x_1, x_2, ..., x_R)$.
- **src** (*int, optional*) –Specifies the rank(global rank) of the process that broadcast the tensor. And only process *src* will broadcast the tensor.
- **group** (*str, optional*) –The communication group to work on. Default: GlobalComm.WORLD_COMM_GROUP.

Returns

Tensor, tensor has the same shape as input tensor $(x_1, x_2, ..., x_R)$.

Raises

- **TypeError** –If src is not an integer or group is not a string.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

Ascend GPU

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.communication as comm
>>>
>>> # Launch 2 processes.
>>>
>>> comm.init()
>>> data = ms.Tensor(np.arange(8).reshape([2, 4]).astype(np.float32))
>>> out = comm.comm_func.broadcast(tensor=data, src=0)
>>> print(out)
[[0. 1. 2. 3.]
 [4. 5. 6. 7.]]
```

Tutorial Examples:

- Distributed Set Communication Primitives - Broadcast

11.17.8 mindspore.communication.comm_func.gather_into_tensor

mindspore.communication.comm_func.**gather_into_tensor**(*tensor*, *dst=0*, *group=GlobalComm.WORLD_COMM_GROUP*)

Gathers tensors from the specified communication group. The operation will gather the tensor from processes according to dimension 0.

Note: Only the tensor in process *dst* (global rank) will keep the gathered tensor. The other process will keep a tensor with shape [1], which has no mathematical meaning. Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) –The tensor to be gathered. The shape of tensor is $(x_1, x_2, ..., x_R)$.
- **dst** (*int, optional*) –Specifies the rank(global rank) of the process that receive the tensor. And only process *dst* will receive the gathered tensor. Default: 0.
- **group** (*str, optional*) –The communication group to work on. Default: GlobalComm.WORLD_COMM_GROUP.

Returns

Tensor, the shape of output is $(\sum x_1, x_2, ..., x_R)$. The dimension 0 of data is equal to sum of the dimension of input tensor, and the other dimension keep the same.

Raises

- **TypeError** –If the type of the first input parameter is not Tensor, or any of *op* and *group* is not a str.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.communication as comm
>>>
>>> # Launch 2 processes.
>>>
>>> comm.init()
>>> input = ms.Tensor(np.arange(4).reshape([2, 2]).astype(np.float32))
```

(continues on next page)

(continued from previous page)

```
>>> output = comm.comm_func.gather_into_tensor(tensor=input, dst=0)
>>> print(output)
Process with rank 0: [[0. 1.],
                      [2. 3.],
                      [0. 1.],
                      [2. 3.]]
Process with rank 1: [0]
```

11.17.9 mindspore.communication.comm_func.irecv

mindspore.communication.comm_func.**irecv**(*tensor*, *src=0*, *group=GlobalComm.WORLD_COMM_GROUP*, *tag=0*)

Receive tensors from src asynchronously.

Note: Send and Receive must be used in combination and have same tag. The shape and dtype of input *tensor* is used to receive tensor, but the value of input *tensor* would not take effect. Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) −The shape of tensor is $(x_1, x_2, ..., x_R)$. The shape and dtype of this tensor is used to receive tensor, but the value of input *tensor* would not take effect.
- **src** (*int, optional*) −A required integer identifying the source rank(global rank). Default: 0.
- **group** (*str, optional*) −The communication group to work on. Default: "hccl_world_group" on Ascend, "nccl_world_group" on GPU.
- **tag** (*int, optional*) −A required integer identifying the send/recv message tag. The message will be received by the Send op with the same "tag". Default: 0.

Returns

Tuple(Tensor, CommHandle), the shape of output is $(x_1, x_2, ..., x_R)$. CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** −If *src* is not an int or *group* is not a str.
- **ValueError** −If the rank ID of the process is greater than the rank size of the communication group.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore.communication import init
>>> from mindspore.communication.comm_func import isend, irecv
>>> from mindspore.communication import get_rank, get_group_size
>>>
>>> np.random.seed(1)
>>> init()
>>> rank = get_rank()
>>> size = get_group_size()
>>> x = np.ones([2, 2]).astype(np.float32) * 0.01 * (rank + 1)
>>> x2 = np.ones([2, 2]).astype(np.float32)
>>>
>>>
>>> if rank < size / 2:
...     _x = ms.Tensor(x)
...     isend(_x, rank + size // 2)
... else:
...     _x2 = ms.Tensor(x2)
...     output, handle = irecv(_x2, rank - size // 2)
...     handle.wait()
...     print(output)
rank1:
[[0.01  0.01]
 [0.01  0.01]]
```

11.17.10 mindspore.communication.comm_func.isend

mindspore.communication.comm_func.**isend**(*tensor*, *dst=0*, *group=GlobalComm.WORLD_COMM_GROUP*, *tag=0*)

Send tensors to the specified dest_rank asynchronously.

Note: Send and Receive must be used in combination and have same tag. Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) –The shape of tensor is $(x_1, x_2, ..., x_R)$.
- **dst** (*int, optional*) –A required integer identifying the destination rank(global rank). Default: 0.
- **group** (*str, optional*) –The communication group to work on. Default: "hccl_world_group" on Ascend, "nccl_world_group" on GPU.
- **tag** (*int, optional*) –A required integer identifying the send/recv message tag. The message will be received by the Receive op with the same "tag". Default: 0.

Returns

CommHandle, it is an async work handle.

Raises

- **TypeError** –*dst* is not an int or *group* is not a str。
- **ValueError** –If the rank ID of the process is greater than the rank size of the communication group.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore.communication import init
>>> from mindspore.communication.comm_func import isend, irecv
>>> from mindspore.communication import get_rank, get_group_size
>>>
>>> np.random.seed(1)
>>> init()
>>> rank = get_rank()
>>> size = get_group_size()
>>> x = np.ones([2, 2]).astype(np.float32) * 0.01 * (rank + 1)
>>> x2 = np.ones([2, 2]).astype(np.float32)
>>>
>>>
>>> if rank < size / 2:
...     _x = ms.Tensor(x)
...     isend(_x, rank + size // 2)
... else:
...     _x2 = ms.Tensor(x2)
...     output, handle = irecv(_x2, rank - size // 2)
...     handle.wait()
...     print(output)
rank1:
[[0.01  0.01]
 [0.01  0.01]]
```

11.17.11 mindspore.communication.comm_func.recv

mindspore.communication.comm_func.**recv**(*tensor*, *src=0*, *group=GlobalComm.WORLD_COMM_GROUP*, *tag=0*)

Receive tensors from src.

Note: Send and Receive must be used in combination and have same tag. The shape and dtype of input *tensor* is used to receive tensor, but the value of input *tensor* would not take effect. Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) –The shape of tensor is $(x_1, x_2, ..., x_R)$. The shape and dtype of this tensor is used to receive tensor, but the value of input *tensor* would not take effect.
- **src** (*int, optional*) –A required integer identifying the source rank(global rank). Default: 0.

- **group** (*str, optional*) –The communication group to work on. Default: "hccl_world_group" on Ascend, "nccl_world_group" on GPU.
- **tag** (*int, optional*) –A required integer identifying the send/recv message tag. The message will be received by the Send op with the same "tag". Default: 0.

Returns

Tensor, the shape of output is $(x_1, x_2, ..., x_R)$.

Raises

- **TypeError** –If *src* is not an int or *group* is not a str.
- **ValueError** –If the rank ID of the process is greater than the rank size of the communication group.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore.communication import init
>>> from mindspore.communication.comm_func import send, recv
>>> from mindspore.communication import get_rank, get_group_size
>>>
>>> np.random.seed(1)
>>> init()
>>> rank = get_rank()
>>> size = get_group_size()
>>> x = np.ones([2, 2]).astype(np.float32) * 0.01 * (rank + 1)
>>> x2 = np.ones([2, 2]).astype(np.float32)
>>>
>>>
>>> if rank < size / 2:
...     _x = ms.Tensor(x)
...     send(_x, rank + size // 2)
... else:
...     _x2 = ms.Tensor(x2)
...     output = recv(_x2, rank - size // 2)
...     print(output)
rank1:
[[0.01  0.01]
 [0.01  0.01]]
```

11.17.12 mindspore.communication.comm_func.send

mindspore.communication.comm_func.**send**(*tensor*, *dst=0*, *group=GlobalComm.WORLD_COMM_GROUP*, *tag=0*)

Send tensors to the specified dest_rank.

Note: Send and Receive must be used in combination and have same tag.

Parameters

- **tensor** (Tensor) – The shape of tensor is $(x_1, x_2, ..., x_R)$.
- **dst** (*int, optional*) – A required integer identifying the destination rank(global rank). Default: 0.
- **group** (*str, optional*) – The communication group to work on. Default: "hccl_world_group" on Ascend, "nccl_world_group" on GPU.
- **tag** (*int, optional*) – A required integer identifying the send/recv message tag. The message will be received by the Receive op with the same "tag". Default: 0.

Raises

- **TypeError** – *dst* is not an int or *group* is not a str。
- **ValueError** – If the rank ID of the process is greater than the rank size of the communication group.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore.communication import init
>>> from mindspore.communication.comm_func import send, recv
>>> from mindspore.communication import get_rank, get_group_size
>>>
>>> np.random.seed(1)
>>> init()
>>> rank = get_rank()
>>> size = get_group_size()
>>> x = np.ones([2, 2]).astype(np.float32) * 0.01 * (rank + 1)
>>> x2 = np.ones([2, 2]).astype(np.float32)
>>>
>>>
>>> if rank < size / 2:
...     _x = ms.Tensor(x)
...     send(_x, rank + size // 2)
```

(continues on next page)

(continued from previous page)

```
... else:
...     _x2 = ms.Tensor(x2)
...     output = recv(_x2, rank - size // 2)
...     print(output)
rank1:
[[0.01  0.01]
 [0.01  0.01]]
```

11.17.13 mindspore.communication.comm_func.P2POp

class mindspore.communication.comm_func.**P2POp**(*op*, *tensor*, *peer*, *group=None*, *tag=0*, ***, *recv_dtype=None*)

Object for *batch_isend_irecv* input, to store information of `"isend"` and `"irecv"`.

Note:

- Allow pass-in recv shape rather than tensor when *op* is 'irecv'.
- *tensor* will not be modified in-place by final result.

Parameters

- **op** (*Union[str, function]*) – Only string of `"isend"` and `"irecv"` are allow. Or function of `comm_func.isend` and `comm_func.irecv` are allow.
- **tensor** (*Union[Tensor, Tuple(int)]*) – tensor for sending/receiving or receive tensor shape when *op* is `"irecv"`.
- **peer** (*int*) – remote global rank for send/receive.
- **group** (*str, optional*) – The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP` , which means `"hccl_world_group"` in Ascend, and `"nccl_world_group"` in GPU.
- **tag** (*int, optional*) – currently not supported yet. default: `0`.

Keyword Arguments

recv_dtype (*mindspore.dtype, optional*) – when *tensor* is a tuple shape, this arg will be used and has to be configured. default: `None`

Returns

P2POp Object.

Raises

- **ValueError** – when *op* is not string or function of 'isend' and 'irecv'.
- **TypeError** – when *tensor* is not type of Tensor or Tuple.
- **NotImplementedError** – when *tag* is not 0.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.communication as comm
>>>
>>> send_tensor = ms.Tensor(1.)
>>> send_op = comm.comm_func.P2POp('isend', send_tensor, 1)
>>> send_op = comm.comm_func.P2POp(comm.comm_func.isend, send_tensor, 1)
>>> recv_tensor = ms.Tensor(0.)
>>> recv_op = comm.comm_func.P2POp('irecv', recv_tensor, 0)
>>> recv_op = comm.comm_func.P2POp(comm.comm_func.irecv, recv_tensor, 0)
>>> recv_op = comm.comm_func.P2POp('irecv', (), 0, recv_dtype=ms.float32)
```

11.17.14 mindspore.communication.comm_func.reduce

mindspore.communication.comm_func.**reduce**(*tensor*, *dst*, *op=ReduceOp.SUM*, *group=GlobalComm.WORLD_COMM_GROUP*)

Reduces tensors across the processes in the specified communication group, sends the result to the target dst(global rank), and returns the tensor which is sent to the target process.

Note: Only process with destination rank receives the reduced output. Only support PyNative mode, Graph mode is not currently supported. Other processes only get a tensor with shape [1], which has no mathematical meaning.

Parameters

- **tensor** (Tensor) –The input tensor to be reduced. The shape of tensor is $(x_1, x_2, ..., x_R)$.
- **dst** (*int*) –The target rank of the process(global rank) that receives the reduced output.
- **op** (*str, optional*) –Specifies an operation used for element-wise reductions, like sum, prod, max, and min. On the CPU, only 'sum' is supported. Default: `ReduceOp.SUM`.
- **group** (*str, optional*) –The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`, which means `"hccl_world_group"` in Ascend, and `"nccl_world_group"` in GPU.

Returns

Tensor. Return the tensor in the specific rank of the process after reduction. The shape of tensor is $(x_1, x_2, ..., x_R)$.

Raises

- **TypeError** –If the type of the first input parameter is not Tensor, or any of *op* and *group* is not a str.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies.

Please see the msrun start up for more details.

This example should be run with 4 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.communication as comm
>>>
>>> # Launch 4 processes.
>>> comm.init()
>>> dest_rank=1
>>> input_tensor = ms.Tensor(np.ones([2, 8]).astype(np.float32))
>>> output = comm.comm_func.reduce(input_tensor, dst=dest_rank)
>>> print(output)
Process with rank 1: [[4. 4. 4. 4. 4. 4. 4. 4.]
                      [4. 4. 4. 4. 4. 4. 4. 4.]],
Other proesses: [0.].
```

11.17.15 mindspore.communication.comm_func.reduce_scatter_tensor

mindspore.communication.comm_func.**reduce_scatter_tensor**(*tensor*, *op=ReduceOp.SUM*, *group=GlobalComm.WORLD_COMM_GROUP*, *async_op=False*)

Reduces and scatters tensors from the specified communication group and returns the tensor which is reduced and scattered.

Note: The tensors must have the same shape and format in all processes of the collection.

Parameters

- **tensor** (Tensor) –The input tensor to be reduced and scattered, suppose it has a shape $(N, *)$, where * means any number of additional dimensions. N must be divisible by rank_size. rank_size refers to the number of cards in the communication group.
- **op** (*str, optional*) –Specifies an operation used for element-wise reductions, like SUM and MAX. Default: `ReduceOp.SUM`.
- **group** (*str, optional*) –The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`, which means `"hccl_world_group"` in Ascend, and `"nccl_world_group"` in GPU.
- **async_op** (*bool, optional*) –Whether this operator should be an async operator. Default: `False`.

Returns

Tuple(Tensor, CommHandle), the output tensor has the same dtype as *input_x* with a shape of $(N/rank\_size, *)$. CommHandle is an async work handle, if *async_op* is set to True. CommHandle will be None, when *async_op* is False.

Raises

- **TypeError** –If the type of the first input parameter is not Tensor, or any of *op* and *group* is not a str.
- **ValueError** –If the first dimension of the input cannot be divided by the rank_size.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.communication as comm
>>>
>>> comm.init()
>>> input_tensor = ms.Tensor(np.ones([8, 8]).astype(np.float32))
>>> output, _ = comm.comm_func.reduce_scatter_tensor(input_tensor)
>>> print(output)
[[2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]]
```

11.17.16 mindspore.communication.comm_func.scatter_tensor

mindspore.communication.comm_func.**scatter_tensor**(*tensor*, *src=0*, *group=GlobalComm.WORLD_COMM_GROUP*)

Scatter tensor evently across the processes in the specified communication group.

Note: The interface behavior only support Tensor input and scatter evenly, which is different from that of *pytoch.distributed.scatter*. Only the tensor in process *src* (global rank) will do scatter. Only support PyNative mode, Graph mode is not currently supported.

Parameters

- **tensor** (Tensor) –The input tensor to be scattered. The shape of tensor is $(x_1, x_2, ..., x_R)$.
- **src** (*int, optional*) –Specifies the rank(global rank) of the process that send the tensor. And only process *src* will send the tensor.
- **group** (*str, optional*) –The communication group to work on. Default: "GlobalComm.WORLD_COMM_GROUP".

Returns

Tensor, the shape of output is $(x_1/src\_rank, x_2, ..., x_R)$. The dimension 0 of data is equal to the dimension of input tensor divided by *src*, and the other dimension keep the same.

Raises

- **TypeError** –If the type of the first input parameter is not Tensor, or any of *op* and *group* is not a str.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend` `GPU`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.communication as comm
>>>
>>> # Launch 2 processes.
>>>
>>> comm.init()
>>> input = ms.Tensor(np.arange(8).reshape([4, 2]).astype(np.float32))
>>> out = comm.comm_func.scatter_tensor(tensor=input, src=0)
>>> print(out)
# rank_0
[[0. 1.]
 [2. 3.]]
# rank_1
[[4. 5.]
 [6. 7.]]
```

CHAPTER

TWELVE

MINDSPORE.DATASET

MindSpore Dataset is a high-performance data engine module specifically designed within the MindSpore framework, dedicated to providing efficient, flexible, and user-friendly data loading and preprocessing solutions for deep learning tasks. It supports multiple data formats (such as MindRecord, TFRecord, etc.) and includes a rich set of built-in public dataset interfaces, enabling users to quickly construct data pipelines. With MindSpore Dataset, users can effortlessly perform data reading, transformation, and augmentation, meeting the processing needs of various data types such as images, text, and audio.

Additionally, MindSpore Dataset offers powerful data transformation capabilities, supporting a variety of data augmentation operations (e.g., cropping, rotation, normalization, etc.), which can effectively enhance the generalization ability of models. By leveraging the efficient MindRecord data storage format, users can further optimize data reading performance, significantly accelerating large-scale data training tasks. The design of MindSpore Dataset balances flexibility and performance, supporting both single-machine and distributed training scenarios. It seamlessly integrates into the model development and training workflows of MindSpore, providing users with end-to-end efficient support from data preprocessing to model training.

- Dataset Loading(mindspore.dataset), this module provides multiple data loading methods to help users load datasets into MindSpore.
- Data Argumentation(mindspore.dataset.transforms), this module provides common data transformations in the fields of image, text and audio, and also supports customized data transformations to help users apply data argumentation online.
- MindRecord format(mindspore.mindrecord), this module provides an efficient data format that helps users to easily convert data sources to a standard format and supports high-speed reads during training.

CHAPTER

THIRTEEN

MINDSPORE.NUMPY

MindSpore Numpy package contains a set of Numpy-like interfaces, which allows developers to build models on MindSpore with similar syntax of Numpy.

MindSpore Numpy operators can be classified into four functional modules: *array generation*, *array operation*, *logic operation* and *math operation*.

Common imported modules in corresponding API examples are as follows:

```
import mindspore.numpy as np
```

Note: MindSpore numpy provides a consistent programming experience with native numpy by assembling the low-level operators. Compared with MindSpore's function and ops interfaces, it is easier for user to understand and use. However, please notice that to be more compatible with native numpy, the performance of some MindSpore numpy interfaces may be weaker than the corresponding function/ops interfaces. Users can choose which to use as needed.

13.1 Array Generation

Array generation operators are used to generate tensors.

Here is an example to generate an array:

```
import mindspore.numpy as np
import mindspore.ops as ops

input_x = np.array([1, 2, 3], np.float32)
print("input_x =", input_x)
print("type of input_x =", ops.typeof(input_x))
```

The result is as follows:

```
input_x = [1. 2. 3.]
type of input_x = Tensor[Float32]
```

Here we have more examples:

- Generate a tensor filled with the same element

  np.full can be used to generate a tensor with user-specified values:

  ```
  input_x = np.full((2, 3), 6, np.float32)
  print(input_x)
  ```

The result is as follows:

```
[[6. 6. 6.]
 [6. 6. 6.]]
```

Here is another example to generate an array with the specified shape and filled with the value of 1:

```
input_x = np.ones((2, 3), np.float32)
print(input_x)
```

The result is as follows:

```
[[1. 1. 1.]
 [1. 1. 1.]]
```

- Generate tensors in a specified range

  Generate an arithmetic array within the specified range:

```
input_x = np.arange(0, 5, 1)
print(input_x)
```

  The result is as follows:

```
[0 1 2 3 4]
```

- Generate tensors with specific requirement

  Generate a matrix where the lower elements are 1 and the upper elements are 0 on the given diagonal:

```
input_x = np.tri(3, 3, 1)
print(input_x)
```

  The result is as follows:

```
[[1. 1. 0.]
 [1. 1. 1.]
 [1. 1. 1.]]
```

  Another example, generate a 2-D matrix with a diagonal of 1 and other elements of 0:

```
input_x = np.eye(2, 2)
print(input_x)
```

  The result is as follows:

```
[[1. 0.]
 [0. 1.]]
```

API Name	Description	Supported Platforms
mindspore.numpy.arange	Returns evenly spaced values within a given interval.	Ascend GPU CPU
mindspore.numpy.array	Creates a tensor.	Ascend GPU CPU
mindspore.numpy.asarray	Converts the input to tensor.	Ascend GPU CPU
mindspore.numpy.asfarray	Similar to asarray, converts the input to a float tensor.	Ascend GPU CPU

continues on next page

Table 1 – continued from previous page

mindspore.numpy.bartlett	Returns the Bartlett window.	Ascend GPU CPU
mindspore.numpy.blackman	Returns the Blackman window.	Ascend GPU CPU
mindspore.numpy.copy	Returns a tensor copy of the given object.	Ascend GPU CPU
mindspore.numpy.diag	Extracts a diagonal or construct a diagonal array.	Ascend GPU CPU
mindspore.numpy.diag_indices	Returns the indices to access the main diagonal of an array.	Ascend GPU CPU
mindspore.numpy.diagflat	Creates a two-dimensional array with the flattened input as a diagonal.	Ascend GPU CPU
mindspore.numpy.diagonal	Returns specified diagonals.	Ascend GPU CPU
mindspore.numpy.empty	Returns a new array of given shape and type, without initializing entries.	Ascend GPU CPU
mindspore.numpy.empty_like	Returns a new array with the same shape and type as a given array.	Ascend GPU CPU
mindspore.numpy.eye	Returns a 2-D tensor with ones on the diagonal and zeros elsewhere.	Ascend GPU CPU
mindspore.numpy.full	Returns a new tensor of given shape and type, filled with *fill_value*.	Ascend GPU CPU
mindspore.numpy.full_like	Returns a full array with the same shape and type as a given array.	Ascend GPU CPU
mindspore.numpy.geomspace	Returns numbers spaced evenly on a log scale (a geometric progression).	Ascend GPU CPU
mindspore.numpy.hamming	Returns the Hamming window.	Ascend GPU CPU
mindspore.numpy.hanning	Returns the Hanning window.	Ascend GPU CPU
mindspore.numpy.histogram_bin_edges	Function to calculate only the edges of the bins used by the histogram function.	Ascend GPU CPU
mindspore.numpy.identity	Returns the identity tensor.	Ascend GPU CPU
mindspore.numpy.indices	Returns an array representing the indices of a grid.	Ascend GPU CPU
mindspore.numpy.ix_	Constructs an open mesh from multiple sequences.	Ascend GPU CPU
mindspore.numpy.linspace	Returns evenly spaced values within a given interval.	Ascend GPU CPU
mindspore.numpy.logspace	Returns numbers spaced evenly on a log scale.	Ascend GPU CPU
mindspore.numpy.meshgrid	Returns coordinate matrices from coordinate vectors.	Ascend GPU CPU
mindspore.numpy.mgrid	mgrid is an *NdGrid* instance with `sparse=False`.	Ascend GPU CPU
mindspore.numpy.ogrid	ogrid is an *NdGrid* instance with `sparse=True`.	Ascend GPU CPU
mindspore.numpy.ones	Returns a new tensor of given shape and type, filled with ones.	Ascend GPU CPU
mindspore.numpy.ones_like	Returns an array of ones with the same shape and type as a given array.	Ascend GPU CPU
mindspore.numpy.pad	Pads an array.	Ascend GPU CPU
mindspore.numpy.rand	Returns a new Tensor with given shape and dtype, filled with random numbers from the uniform distribution on the interval $[0, 1)$.	Ascend GPU CPU
mindspore.numpy.randint	Return random integers from minval (inclusive) to maxval (exclusive).	Ascend GPU CPU
mindspore.numpy.randn	Returns a new Tensor with given shape and dtype, filled with a sample (or samples) from the standard normal distribution.	Ascend GPU CPU
mindspore.numpy.trace	Return the sum along diagonals of the tensor.	Ascend GPU CPU

continues on next page

Table 1 – continued from previous page

mindspore.numpy.tri	Returns a tensor with ones at and below the given diagonal and zeros elsewhere.	Ascend GPU CPU
mindspore.numpy.tril	Returns a lower triangle of a tensor.	Ascend GPU CPU
mindspore.numpy.tril_indices	Returns the indices for the lower-triangle of an (n, m) array.	Ascend GPU CPU
mindspore.numpy.tril_indices_from	Returns the indices for the lower-triangle of *arr*.	Ascend GPU CPU
mindspore.numpy.triu	Returns an upper triangle of a tensor.	Ascend GPU CPU
mindspore.numpy.triu_indices	Returns the indices for the upper-triangle of an (n, m) array.	Ascend GPU CPU
mindspore.numpy.triu_indices_from	Returns the indices for the upper-triangle of *arr*.	Ascend GPU CPU
mindspore.numpy.vander	Generates a Vandermonde matrix.	Ascend GPU CPU
mindspore.numpy.zeros	Returns a new tensor of given shape and type, filled with zeros.	Ascend GPU CPU
mindspore.numpy.zeros_like	Returns an array of zeros with the same shape and type as a given array.	Ascend GPU CPU

13.1.1 mindspore.numpy.arange

mindspore.numpy.**arange**(*start*, *stop=None*, *step=None*, *dtype=None*)

Returns evenly spaced values within a given interval.

Parameters

- **start** (*Union[int, float]*) –Start of interval. The interval includes this value. When *stop* is provided as a position argument, *start* must be given, when *stop* is a normal argument, *start* can be optional, and default: `0` . Please see additional examples below.
- **stop** (*Union[int, float], optional*) –End of interval. The interval does not include this value, except in some cases where *step* is not an integer and floating point round-off affects the length of out.
- **step** (*Union[int, float], optional*) –Spacing between values. For any output *out*, this is the distance between two adjacent values, $out[i+1] - out[i]$. The default step size is 1. If *step* is specified as a position argument, *start* must also be given.
- **dtype** (Union[*mindspore.dtype*, str], optional) –Designated tensor dtype. If dtype is None, the data type of the new tensor will be inferred from start, stop and step. Default: `None` .

Returns

Tensor with evenly spaced values.

Raises

- **TypeError(PyNative Mode)** –If input arguments have types not specified above, or arguments are not given in the correct orders specified above.
- **RuntimeError(Graph Mode)** –The inputs that lead to TypeError in Pynative Mode will lead to RuntimeError in Graph Mode.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.arange(0, 5, 1))
[0 1 2 3 4]
>>> print(np.arange(3))
[0 1 2]
>>> print(np.arange(start=0, stop=3))
[0 1 2]
>>> print(np.arange(0, stop=3, step=0.5))
[0.  0.5 1.  1.5 2.  2.5]
```

13.1.2 mindspore.numpy.array

mindspore.numpy.**array**(*obj*, *dtype=None*, *copy=True*, *ndmin=0*)

Creates a tensor.

This function creates tensors from an array-like object.

Parameters

- **obj** (*Union[int, float, bool, list, tuple]*) – Input data, in any form that can be converted to a *Tensor*. This includes Tensor, list, tuple and numbers.
- **dtype** (Union[*mindspore.dtype*, str], optional) – Designated tensor dtype, can be in format of np.int32, or 'int32'. If dtype is `None`, the data type of the new tensor will be inferred from obj. Default is `None`.
- **copy** (*bool*) – If *True*, then the object is copied. Otherwise, a copy will only be made if necessary. Default: `True`.
- **ndmin** (*int*) – Specifies the minimum number of dimensions that the resulting tensor should have. Ones will be pre-pended to the shape as needed to meet this requirement. Default: `0` .

Returns

Tensor, generated tensor with the specified dtype.

Raises

- **TypeError** – If input arguments have types not specified above.
- **ValueError** – If input *obj* has different sizes at different dimensions.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.array([1,2,3]))
[1 2 3]
```

13.1.3 mindspore.numpy.asarray

mindspore.numpy.**asarray**(*a*, *dtype=None*)

Converts the input to tensor.

This function converts tensors from an array-like object.

Parameters

- **a** (*Union[int, float, bool, list, tuple, Tensor]*) −Input data, in any form that can be converted to a *Tensor*. This includes Tensor, list, tuple and numbers.
- **dtype** (Union[*mindspore.dtype*, str], optional) −Designated tensor dtype, can be in format of np.int32, or 'int32'. If dtype is `None`, the data type of the new tensor will be inferred from obj. Default is `None` .

Returns

Tensor, generated tensor with the specified dtype.

Raises

- **TypeError** −If input arguments have types not specified above.
- **ValueError** −If input *a* has different sizes at different dimensions.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.asarray([1,2,3]))
[1 2 3]
```

13.1.4 mindspore.numpy.asfarray

mindspore.numpy.**asfarray**(*a*, *dtype=mstype.float32*)

Similar to asarray, converts the input to a float tensor.

If non-float dtype is defined, this function will return a float32 tensor instead.

Parameters

- **a** (*Union[int, float, bool, list, tuple, Tensor]*) −Input data, in any form that can be converted to a *Tensor*. This includes Tensor, list, tuple and numbers.
- **dtype** (Union[*mindspore.dtype*, str], optional) −Designated tensor dtype, can be in format of np.int32, or 'int32'. If dtype is `None`, the data type of the new tensor will be inferred from *a*. Default is `mstype.float32`.

Returns

Tensor, generated tensor with the specified float dtype.

Raises

- **TypeError** −If input arguments have types not specified above.
- **ValueError** −If input *a* has different sizes at different dimensions.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> print(np.asfarray([1,2,3]))
[1. 2. 3.]
```

13.1.5 mindspore.numpy.bartlett

mindspore.numpy.**bartlett**(*M*)

Returns the Bartlett window. The Bartlett window is very similar to a triangular window, except that the end points are at zero. It is often used in signal processing for tapering a signal, without generating too much ripple in the frequency domain.

Parameters

M (*int*) −Number of points in the output window. If zero or less, an empty array is returned.

Returns

Tensor, the triangular window, with the maximum value normalized to one (the value one appears only if the number of samples is odd), with the first and last samples equal to zero.

Raises

TypeError −If *M* is not an int.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> print(np.bartlett(12))
[0.         0.18181819 0.36363637 0.5454545  0.72727275 0.9090909
0.9090909  0.72727275 0.5454545  0.36363637 0.18181819 0.        ]
```

13.1.6 mindspore.numpy.blackman

mindspore.numpy.**blackman**(*M*)

Returns the Blackman window. The Blackman window is a taper formed by using the first three terms of a summation of cosines. It was designed to have close to the minimal leakage possible. It is close to optimal, only slightly worse than a Kaiser window.

Parameters

M (*int*) −Number of points in the output window. If zero or less, an empty array is returned.

Returns

Tensor, the window, with the maximum value normalized to one (the value one appears only if the number of samples is odd).

Raises

TypeError −If *M* is not an int.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> print(np.blackman(12))
[-1.4901161e-08  3.2606430e-02  1.5990365e-01  4.1439798e-01
7.3604518e-01  9.6704674e-01  9.6704674e-01  7.3604518e-01
4.1439798e-01  1.5990365e-01  3.2606430e-02 -1.4901161e-08]
```

13.1.7 mindspore.numpy.copy

mindspore.numpy.**copy**(*a*)

Returns a tensor copy of the given object.

Parameters

a (*Union[int, float, bool, list, tuple, Tensor]*) – Input data, in any form that can be converted to a Tensor. This includes Tensor, list, tuple and numbers.

Returns

Tensor, has the same data as *a*.

Raises

- **TypeError** – If input *a* has type not specified above.
- **ValueError** – If input *a* has different sizes at different dimensions.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.ones((2,2))
>>> print(np.copy(x))
[[1. 1.]
 [1. 1.]]
```

13.1.8 mindspore.numpy.diag

mindspore.numpy.**diag**(*v*, *k=0*)

Extracts a diagonal or construct a diagonal array.

Parameters

- **v** (Tensor) – If *v* is a 2-D array, return a copy of its *k-th* diagonal. If *v* is a 1-D array, return a 2-D array with v on the *k-th* diagonal.
- **k** (*int, optional*) – Diagonal in question. The default is 0. Use `k>0` for diagonals above the main diagonal, and `k<0` for diagonals below the main diagonal.

Returns

Tensor, the extracted diagonal or constructed diagonal array.

Raises

ValueError – If input is not 1-D or 2-D.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(9).reshape((3,3))
>>> print(x)
[[0 1 2]
[3 4 5]
[6 7 8]]
>>> output = np.diag(x)
>>> print(output)
[0 4 8]
>>> output = np.diag(x, k=1)
>>> print(output)
[1 5]
>>> output = np.diag(x, k=-1)
>>> print(output)
[3 7]
```

13.1.9 mindspore.numpy.diag_indices

mindspore.numpy.**diag_indices**(*n*, *ndim=2*)

Returns the indices to access the main diagonal of an array.

This returns a tuple of indices that can be used to access the main diagonal of an array a with `a.ndim >= 2` dimensions and shape *(n, n, ···, n)*. For `a.ndim = 2` this is the usual diagonal, for `a.ndim > 2` this is the set of indices to access `a[i, i, ..., i]` for `i = [0..n-1]`.

Parameters

- **n** (*int*) – The size, along each dimension, of the arrays for which the returned indices can be used.
- **ndim** (*int, optional*) – The number of dimensions.

Returns

Tuple of Tensor.

Raises

TypeError – If input are not integers.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.diag_indices(5, 3)
>>> print(output)
(Tensor(shape=[5], dtype=Int32, value= [0, 1, 2, 3, 4]),
Tensor(shape=[5], dtype=Int32, value= [0, 1, 2, 3, 4]),
Tensor(shape=[5], dtype=Int32, value= [0, 1, 2, 3, 4]))
```

13.1.10 mindspore.numpy.diagflat

mindspore.numpy.**diagflat**(*v*, *k=0*)

Creates a two-dimensional array with the flattened input as a diagonal.

Note: On GPU, the supported dtypes are np.float16, and np.float32.

Parameters

- **v** (Tensor) −Input data, which is flattened and set as the *k-th* diagonal of the output.
- **k** (*int, optional*) −Diagonal to set; 0, the default, corresponds to the "main" diagonal, a positive (negative) *k* giving the number of the diagonal above (below) the main.

Returns

Tensor, The 2-D output array.

Raises

TypeError −If the input is not a tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.diagflat(np.asarray([[1,2], [3,4]]))
>>> print(output)
[[1 0 0 0]
[0 2 0 0]
[0 0 3 0]
[0 0 0 4]]
>>> output = np.diagflat(np.asarray([1,2]), 1)
>>> print(output)
[[0 1 0]
[0 0 2]
[0 0 0]]
```

13.1.11 mindspore.numpy.diagonal

mindspore.numpy.**diagonal**(*a*, *offset=0*, *axis1=0*, *axis2=1*)

Returns specified diagonals.

If *a* is 2-D, returns the diagonal of *a* with the given offset, i.e., the collection of elements of the form `a[i, i+offset]`. If *a* has more than two dimensions, then the axes specified by *axis1* and *axis2* are used to determine the 2-D sub-array whose diagonal is returned. The shape of the resulting array can be determined by removing *axis1* and *axis2* and appending an index to the right equal to the size of the resulting diagonals.

Parameters

- **a** (Tensor) – Array from which the diagonals are taken.
- **offset** (*int, optional*) – Offset of the diagonal from the main diagonal. Can be positive or negative. Defaults to main diagonal.
- **axis1** (*int, optional*) – Axis to be used as the first axis of the 2-D sub-arrays from which the diagonals should be taken. Defaults to first axis (0).
- **axis2** (*int, optional*) – Axis to be used as the second axis of the 2-D sub-arrays from which the diagonals should be taken. Defaults to second axis.

Returns

Tensor, if *a* is 2-D, then *a* 1-D array containing the diagonal. If `a.ndim > 2`, then the dimensions specified by *axis1* and *axis2* are removed, and a new axis inserted at the end corresponding to the diagonal.

Raises

ValueError – If the input tensor has less than two dimensions.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.arange(4).reshape(2,2).astype(np.float32)
>>> print(a)
[[0. 1.]
[2. 3.]]
>>> output = np.diagonal(a)
>>> print(output)
[0. 3.]
>>> output = np.diagonal(a, 1)
>>> print(output)
[1.]
>>> a = np.arange(8).reshape(2, 2, 2).astype(np.float32)
>>> print(a)
[[[0. 1.]
[2. 3.]]
[[4. 5.]
[6. 7.]]]
>>> output = np.diagonal(a, 0, 0, 1)
>>> print(output)
[[0. 6.]
[1. 7.]]
```

13.1.12 mindspore.numpy.empty

mindspore.numpy.**empty**(*shape*, *dtype=mstype.float32*)

Returns a new array of given shape and type, without initializing entries.

Note: Numpy argument *order* is not supported. Object arrays are not supported.

Parameters

- **shape** (*Union[int, tuple(int)]*) –Shape of the empty array, e.g., (2, 3) or 2.
- **dtype** (*mindspore.dtype*, optional) –Desired output data-type for the array, e.g, mstype.int8. Default: `mstype.float32`.

Returns

Tensor, array of uninitialized (arbitrary) data of the given shape and dtype.

Raises

TypeError –If the input shape or dtype is invalid.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.empty((2, 3))
>>> print(output)
[[0. 0. 0.]
 [0. 0. 0.]]
```

13.1.13 mindspore.numpy.empty_like

mindspore.numpy.**empty_like**(*prototype*, *dtype=None*, *shape=None*)

Returns a new array with the same shape and type as a given array.

Note: Input array must have the same size across a dimension. If *prototype* is not a Tensor, dtype is float32 by default if not provided.

Parameters

- **prototype** (*Union[Tensor, list, tuple]*) –The shape and data-type of *prototype* define these same attributes of the returned array.
- **dtype** (*mindspore.dtype*, optional) –Overrides the data type of the result.
- **shape** (*int or sequence of ints, optional*) –Overrides the shape of the result.

Returns

Tensor, array of uninitialized (arbitrary) data with the same shape and type as *prototype*.

Raises

ValueError – If *prototype* is not a Tensor, list or tuple.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.ones((4,1,2))
>>> output = np.empty_like(a)
>>> print(output)
[[[0. 0.]]
 [[0. 0.]]
 [[0. 0.]]
 [[0. 0.]]]
```

13.1.14 mindspore.numpy.eye

`mindspore.numpy.`**`eye`**(*N*, *M=None*, *k=0*, *dtype=mstype.float32*)

Returns a 2-D tensor with ones on the diagonal and zeros elsewhere.

Parameters

- **N** (*int*) – Number of rows in the output, must be larger than 0.
- **M** (*int, optional*) – Number of columns in the output. If is `None`, default: `N` , if defined, must be larger than 0. Default: `None`.
- **k** (*int, optional*) – Index of the diagonal: `0` (the default) refers to the main diagonal, a positive value refers to an upper diagonal, and a negative value to a lower diagonal. Default: `0` .
- **dtype** (Union[*mindspore.dtype*, str], optional) – Designated tensor dtype. Default: `mstype.float32` .

Returns

A tensor of shape (N, M). A tensor where all elements are equal to zero, except for the k-th diagonal, whose values are equal to one.

Raises

TypeError – If input arguments have types not specified above.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.eye(2, 2))
[[1. 0.]
[0. 1.]]
```

13.1.15 mindspore.numpy.full

mindspore.numpy.**full**(*shape*, *fill_value*, *dtype=None*)

Returns a new tensor of given shape and type, filled with *fill_value*.

Parameters

- **shape** (*Union[int, tuple(int), list(int)]*) –Shape of the new tensor, e.g., $(2, 3)$ or 2.
- **fill_value** (*Union[int, float, bool, list, tuple]*) –Scalar or array_like fill value.
- **dtype** (Union[*mindspore.dtype*, str], optional) –Designated tensor dtype, if *dtype* is `None`, the data type of the new tensor will be inferred from *fill_value*. Default is `None`.

Returns

Tensor, with the designated shape and dtype, filled with *fill_value*.

Raises

- **TypeError** –If input arguments have types not specified above.
- **ValueError** –If *shape* has entries < 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.full((2,2), True))
[[True True]
[True True]]
```

13.1.16 mindspore.numpy.full_like

mindspore.numpy.**full_like**(*a*, *fill_value*, *dtype=None*, *shape=None*)

Returns a full array with the same shape and type as a given array.

Note:

- Input array must have the same size across a dimension.
- If *a* is not a Tensor, dtype is float32 by default if not provided.

Parameters

- **a** (*Union[Tensor, list, tuple]*) –The shape and data-type of *a* define these same attributes of the returned array.
- **fill_value** (*scalar*) –Fill value.
- **dtype** (*mindspore.dtype*, optional) –Overrides the data type of the result.
- **shape** (*int, sequence of ints, optional*) –Overrides the shape of the result.

Returns

Tensor, array of fill_value with the same shape and type as *a*.

Raises

ValueError –If *a* is not a Tensor, list or tuple.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.ones((4,1,2))
>>> output = np.full_like(a, 0.5)
>>> print(output)
[[[0.5 0.5]]
[[0.5 0.5]]
[[0.5 0.5]]
[[0.5 0.5]]]
```

13.1.17 mindspore.numpy.geomspace

`mindspore.numpy.`**geomspace**(*start*, *stop*, *num=50*, *endpoint=True*, *dtype=None*, *axis=0*)

Returns numbers spaced evenly on a log scale (a geometric progression).

This is similar to logspace, but with endpoints specified directly. Each output sample is a constant multiple of the previous.

Parameters

- **start** (*Union[int, list(int), tuple(int), tensor]*) –The starting value of the sequence.
- **stop** (*Union[int, list(int), tuple(int), tensor]*) –The final value of the sequence, unless endpoint is False. In that case, num + 1 values are spaced over the interval in log-space, of which all but the last (a sequence of length num) are returned.
- **num** (*int, optional*) –Number of samples to generate. Default: `50` .
- **endpoint** (*bool, optional*) –If True, *stop* is the last sample. Otherwise, it is not included. Default: `True` .
- **dtype** (Union[*mindspore.dtype*, str], optional) –Designated tensor dtype, can be in format of np.float32, or *float32*.If *dtype* is None, infer the data type from other input arguments. Default: `None` .
- **axis** (*int, optional*) –The axis in the result to store the samples. Relevant only if start or stop is array-like. By default (0), the samples will be along a new axis inserted at the beginning. Use -1 to get an axis at the end. Default: `0` .

Returns

Tensor, with samples equally spaced on a log scale.

Raises

TypeError – If input arguments have types not specified above.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.geomspace(1, 256, num=9)
>>> print(output)
[  1.   2.   4.   8.  16.  32.  64. 128. 256.]
>>> output = np.geomspace(1, 256, num=8, endpoint=False)
>>> print(output)
[  1.   2.   4.   8.  16.  32.  64. 128.]
```

13.1.18 mindspore.numpy.hamming

mindspore.numpy.**hamming**(*M*)

Returns the Hamming window. The Hamming window is a taper formed by using a weighted cosine.

Parameters

M (*int*) – Number of points in the output window. If zero or less, an empty array is returned.

Returns

Tensor, the window, with the maximum value normalized to one (the value one appears only if the number of samples is odd).

Raises

TypeError – If *M* is not an int.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> print(np.hamming(12))
[0.08000001 0.15302339 0.34890914 0.6054648  0.841236   0.9813669
0.9813668  0.8412359  0.6054647  0.34890908 0.15302327 0.08000001]
```

13.1.19 mindspore.numpy.hanning

mindspore.numpy.**hanning**(*M*)

Returns the Hanning window. The Hanning window is a taper formed by using a weighted cosine.

Parameters

M (*int*) – Number of points in the output window. If zero or less, an empty array is returned.

Returns

Tensor, the window, with the maximum value normalized to one (the value one appears only if the number of samples is odd).

Raises

TypeError – If *M* is not an int.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> print(np.hanning(12))
[0.         0.07937324 0.29229254 0.5711574  0.8274304  0.9797465
0.97974646 0.82743025 0.5711573  0.29229245 0.07937312 0.        ]
```

13.1.20 mindspore.numpy.histogram_bin_edges

mindspore.numpy.**histogram_bin_edges**(*a*, *bins=10*, *range=None*, *weights=None*)

Function to calculate only the edges of the bins used by the histogram function.

Note: String values for *bins* is not supported.

Parameters

- **a** (*Union[int, float, bool, list, tuple, Tensor]*) – Input data. The histogram is computed over the flattened array.
- **bins** (*Union[int, tuple, list, Tensor], optional*) – If *bins* is an int, it defines the number of equal-width bins in the given range (10, by default). If *bins* is a sequence, it defines the bin edges, including the rightmost edge, allowing for non-uniform bin widths.
- **range** (*(float, float), optional*) – The lower and upper range of the bins. If not provided, *range* is simply `(a.min(), a.max())`. Values outside the range are ignored. The first element of the range must be less than or equal to the second. Default: `None` .
- **weights** (*Union[int, float, bool, list, tuple, Tensor], optional*) – An array of weights, of the same shape as *a*. Each value in *a* only contributes its associated weight towards the bin count (instead of 1). This is currently not used by any of the bin estimators, but may be in the future. Default: `None` .

Returns

Tensor, the edges to pass into *histogram*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Raises

TypeError – If *bins* is an array and not one-dimensional.

Examples

```
>>> import mindspore.numpy as np
>>> arr = np.array([0, 0, 0, 1, 2, 3, 3, 4, 5])
>>> print(np.histogram_bin_edges(arr, bins=2))
[0.  2.5 5. ]
```

13.1.21 mindspore.numpy.identity

mindspore.numpy.**identity**(*n*, *dtype=mstype.float32*)

Returns the identity tensor.

Parameters

- **n** (*int*) – Number of rows and columns in the output, must be larger than 0.
- **dtype** (Union[*mindspore.dtype*, str], optional) – Designated tensor dtype, default is *mstype.float32*.

Returns

A tensor of shape *(n, n)*, where all elements are equal to zero, except for the diagonal, whose values are equal to one.

Supported Platforms:

`Ascend` `GPU` `CPU`

Raises

TypeError – If input arguments have types not specified above.

Examples

```
>>> import mindspore.numpy as np
>>> print(np.identity(2))
[[1. 0.]
[0. 1.]]
```

13.1.22 mindspore.numpy.indices

mindspore.numpy.**indices**(*dimensions*, *dtype=mstype.int32*, *sparse=False*)

Returns an array representing the indices of a grid.

Computes an array where the subarrays contain index values 0, 1, ···varying only along the corresponding axis.

Parameters

- **dimensions** (*Union[list(int), tuple]*) –The shape of the grid.
- **dtype** (*mindspore.dtype*, optional) –Data type of the result. Default: `mstype.int32`.
- **sparse** (*boolean, optional*) –Default: `False` . Return a sparse representation of the grid instead of a dense representation.

Returns

Tensor or tuple of Tensor, If *sparse* is False, returns one array of grid indices, `grid.shape = (len(dimensions),) + tuple(dimensions)`. If sparse is True, returns a tuple of arrays, with `grid[i].shape = (1, ..., 1, dimensions[i], 1, ..., 1)` with `dimensions[i]` in the *ith* place

Raises

TypeError –If input dimensions is not a tuple or list.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> grid = np.indices((2, 3))
>>> print(grid)
[Tensor(shape=[2, 3], dtype=Int32, value=
[[0, 0, 0],
[1, 1, 1]]), Tensor(shape=[2, 3], dtype=Int32, value=
[[0, 1, 2],
[0, 1, 2]])]
```

13.1.23 mindspore.numpy.ix

mindspore.numpy.**ix_**(**args*)

Constructs an open mesh from multiple sequences.

This function takes *N* 1-D sequences and returns *N* outputs with *N* dimensions each, such that the shape is 1 in all but one dimension and the dimension with the non-unit shape value cycles through all N dimensions. Using ix_ one can quickly construct index arrays that will index the cross product. `a[np.ix_([1,3],[2,5])]` returns the array `[[a[1,2] a[1,5]], [a[3,2] a[3,5]]]`.

Note: Boolean masks are not supported.

Parameters

***args** (`Tensor`) –1-D sequences.

Returns

Tuple of Tensor, *N* arrays with *N* dimensions each, with *N* the number of input sequences. Together these arrays form an open mesh.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore.numpy as np
>>> ixgrid = np.ix_(np.array([0, 1]), np.array([2, 4]))
>>> print(ixgrid)
(Tensor(shape=[2, 1], dtype=Int32, value=
[[0],
[1]]), Tensor(shape=[1, 2], dtype=Int32, value=
[[2, 4]]))
```

13.1.24 mindspore.numpy.linspace

`mindspore.numpy.`**linspace**(*start*, *stop*, *num=50*, *endpoint=True*, *retstep=False*, *dtype=None*, *axis=0*)

Returns evenly spaced values within a given interval.

Parameters

- **start** (*Union[int, list(int), tuple(int), tensor]*) –The starting value of the sequence.
- **stop** (*Union[int, list(int), tuple(int), tensor]*) –The end value of the sequence, unless *endpoint* is set to False. In that case, the sequence consists of all but the last of *num + 1* evenly spaced samples, so that *stop* is excluded. Note that the step size changes when *endpoint* is False.
- **num** (*int, optional*) –Number of samples to generate. Default: `50` .
- **endpoint** (*bool, optional*) –If True, *stop* is the last sample. Otherwise, it is not included. Default: `True` .
- **retstep** (*bool, optional*) –If True, return (*samples*, *step*), where *step* is the spacing between samples.
- **dtype** (Union[*mindspore.dtype*, str], optional) –Designated tensor dtype, If *dtype* is None, infer the data type from other input arguments. Default: `None` .
- **axis** (*int, optional*) –The axis in the result to store the samples. Relevant only if start or stop are array-like. By default, the samples will be along a new axis inserted at the beginning. Use -1 to get an axis at the end. Default: `0` .

Returns

Tensor, with *num* equally spaced samples in the closed interval $[start, stop]$ or the half-open interval $[start, stop)$ (depending on whether *endpoint* is True or False).

Step, the size of spacing between samples, only returned if *retstep* is True.

Raises

TypeError –If input arguments have types not specified above.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.linspace(0, 5, 6))
[0. 1. 2. 3. 4. 5.]
```

13.1.25 mindspore.numpy.logspace

`mindspore.numpy.`**`logspace`**(*start*, *stop*, *num=50*, *endpoint=True*, *base=10.0*, *dtype=None*, *axis=0*)

Returns numbers spaced evenly on a log scale.

In linear space, the sequence starts at base ** start (base to the power of start) and ends with base ** stop (see endpoint below).

Parameters

- **start** (*Union[int, list(int), tuple(int), tensor]*) –`base ** start` is the starting value of the sequence.
- **stop** (*Union[int, list(int), tuple(int), tensor]*) –`base ** stop` is the final value of the sequence, unless *endpoint* is False. In that case, `num + 1` values are spaced over the interval in log-space, of which all but the last (a sequence of length num) are returned.
- **num** (*int, optional*) –Number of samples to generate. Default: `50` .
- **endpoint** (*bool, optional*) –If True, *stop* is the last sample. Otherwise, it is not included. Default: `True` .
- **base** (*Union[int, float], optional*) –The base of the log space. The step size between the elements in $ln(samples)/ln(base)$ (or $log_{base}(samples)$) is uniform. Default: `10.0` .
- **dtype** (Union[*mindspore.dtype*, str], optional) –Designated tensor dtype. If *dtype* is None, infer the data type from other input arguments. Default: `None` .
- **axis** (*int, optional*) –The axis in the result to store the samples. Relevant only if start or stop is array-like. By default, the samples will be along a new axis inserted at the beginning. Use -1 to get an axis at the end. Default: `0` .

Returns

Tensor, equally spaced on a log scale.

Raises

TypeError –If input arguments have types not specified above.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.logspace(0, 5, 6, base=2.0))
[ 1.  2.  4.  8. 16. 32.]
```

13.1.26 mindspore.numpy.meshgrid

mindspore.numpy.**meshgrid**(**xi*, *sparse=False*, *indexing='xy'*)

Returns coordinate matrices from coordinate vectors.

Make *N-D* coordinate arrays for vectorized evaluations of *N-D* scalar/vector fields over *N-D* grids, given one-dimensional coordinate arrays *x1, x2,···, xn*.

Note: Numpy argument copy is not supported, and a copy is always returned.

Parameters

- ***xi** (Tensor) – 1-D arrays representing the coordinates of a grid.
- **indexing** (*'xy', 'ij', optional*) – Cartesian ('xy', default) or matrix ('ij') indexing of output. In the 2-D case with inputs of length *M* and *N*, the outputs are of shape *(N, M)* for 'xy' indexing and *(M, N)* for 'ij' indexing. In the 3-D case with inputs of length *M*, *N* and *P*, outputs are of shape *(N, M, P)* for 'xy' indexing and *(M, N, P)* for 'ij' indexing.
- **sparse** (*bool, optional*) – If True a sparse grid is returned in order to conserve memory. Default is False.

Returns

Tuple of tensors, for vectors *x1, x2,···, xn* with lengths `Ni=len(xi)`, return *(N1, N2, N3,···Nn)* shaped arrays if `indexing='ij'` or *(N2, N1, N3,···Nn)* shaped arrays if `indexing='xy'` with the elements of *xi* repeated to fill the matrix along the first dimension for *x1*, the second for *x2* and so on.

Raises

TypeError – If the input is not a tensor, or sparse is not boolean, or indexing is not 'xy' or 'ij'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.linspace(0, 1, 3)
>>> y = np.linspace(0, 1, 2)
>>> xv, yv = np.meshgrid(x, y)
>>> print(xv)
[[0.  0.5 1. ]
[0.  0.5 1. ]]
>>> print(yv)
[[0.  0.  0.]
[1.  1.  1.]]
>>> xv, yv = np.meshgrid(x, y, sparse=True)
```

(continues on next page)

(continued from previous page)

```
>>> print(xv)
[[0.  0.5  1. ]]
>>> print(yv)
[[0.]
[1.]]
```

13.1.27 mindspore.numpy.mgrid

mindspore.numpy.**mgrid**()

mgrid is an *NdGrid* instance with `sparse=False`.

The dimension and number of the output arrays are equal to the number of indexing dimensions. If the step length is not a complex number, then the stop is not inclusive. However, if the step length is a complex number (e.g. 5j), then the integer part of its magnitude is interpreted as specifying the number of points to create between the start and stop values, where the stop value is inclusive.

Note: Not supported in graph mode. Unlike Numpy, if the step length is a complex number with a real component, the step length is handled as equivalent to `int(abs(step))`.

Returns

Tensor or tuple of tensor, a meshgrid.

Raises

TypeError – If slicing indices are not integers.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.mgrid[0:5, 0:5]
>>> print(output)
[[[0 0 0 0 0]
[1 1 1 1 1]
[2 2 2 2 2]
[3 3 3 3 3]
[4 4 4 4 4]]
[[0 1 2 3 4]
[0 1 2 3 4]
[0 1 2 3 4]
[0 1 2 3 4]
[0 1 2 3 4]]]
>>> output = mgrid[-1:1:5j]
>>> print(output)
[-1.  -0.5  0.   0.5  1. ]
```

13.1.28 mindspore.numpy.ogrid

mindspore.numpy.**ogrid**()

ogrid is an *NdGrid* instance with `sparse=True`.

The dimension and number of the output arrays are equal to the number of indexing dimensions. If the step length is not a complex number, then the stop is not inclusive. However, if the step length is a complex number (e.g. 5j), then the integer part of its magnitude is interpreted as specifying the number of points to create between the start and stop values, where the stop value is inclusive.

Note: Not supported in graph mode. Unlike Numpy, if the step length is a complex number with a real component, the step length is handled as equivalent to `int(abs(step))`.

Raises

TypeError –If slicing indices are not integers.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.ogrid[0:5,0:5]
>>> print(output)
[Tensor(shape=[5, 1], dtype=Int32, value=
[[0],
[1],
[2],
[3],
[4]]), Tensor(shape=[1, 5], dtype=Int32, value=
[[0, 1, 2, 3, 4]])]
>>> output = ogrid[-1:1:5j]
>>> print(output)
[-1.  -0.5  0.   0.5  1. ]
```

13.1.29 mindspore.numpy.ones

mindspore.numpy.**ones**(*shape*, *dtype=mstype.float32*)

Returns a new tensor of given shape and type, filled with ones.

Parameters

- **shape** (*Union[int, tuple, list]*) –the shape of the new tensor.
- **dtype** (Union[*mindspore.dtype*, str], optional) –Designated tensor dtype. Default is `mstype.float32`.

Returns

Tensor, with the designated *shape* and *dtype*, filled with ones.

Raises

- **TypeError** –If input arguments have types not specified above.

- **ValueError** –If *shape* entries have values < 0.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> print(np.ones((2,2)))
[[1. 1.]
[1. 1.]]
```

13.1.30 mindspore.numpy.ones_like

mindspore.numpy.**ones_like**(*a*, *dtype=None*, *shape=None*)

Returns an array of ones with the same shape and type as a given array.

Note: Input array must have the same size across a dimension. If *a* is not a Tensor, dtype is float32 by default if not provided.

Parameters

- **a** (*Union[Tensor, list, tuple]*) –The shape and data-type of a define these same attributes of the returned array.
- **dtype** (*mindspore.dtype*, optional) –Overrides the data type of the result. Default: None.
- **shape** (*int, sequence of ints, optional*) –Overrides the shape of the result. Default: None.

Returns

Tensor, array of ones with the same shape and type as *a*.

Raises

ValueError –If *a* is not a Tensor, list or tuple.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.ones((4,1,2))
>>> output = np.ones_like(a)
>>> print(output)
[[[1. 1.]]
[[1. 1.]]
[[1. 1.]]
[[1. 1.]]]
```

13.1.31 mindspore.numpy.pad

mindspore.numpy.**pad**(*arr*, *pad_width*, *mode='constant'*, *stat_length=None*, *constant_values=0*, *end_values=0*, *reflect_type='even'*, ***kwargs*)

Pads an array.

Note: Currently, *median* mode is not supported. *reflect* and *symmetric* mode only supports GPU backend.

Parameters

- **arr** (*Union[list, tuple, Tensor]*) –The array to pad.
- **pad_width** (*Union[int, tuple, list]*) –Number of values padded to the edges of each axis. `((before_1, after_1), ... (before_N, after_N))` creates unique pad widths for each axis. `((before, after),)` yields same before and after pad for each axis. `(pad,)` or int is a shortcut for `before = after = pad width` for all axes.
- **mode** (*string, optional*) –One of the following string values:
  - constant (default): Pads with a constant value.
  - edge: Pads with the edge values of *arr*.
  - linear_ramp: Pads with the linear ramp between end_value and the *arr* edge value.
  - maximum: Pads with the maximum value of all or part of the vector along each axis.
  - mean: Pads with the mean value of all or part of the vector along each axis.
  - median: Pads with the median value of all or part of the vector along each axis.
  - minimum: Pads with the minimum value of all or part of the vector along each axis.
  - reflect: Pads with the reflection of the vector mirrored on the first and last values of the vector along each axis.
  - symmetric: Pads with the reflection of the vector mirrored along the edge of the *arr*.
  - wrap: Pads with the wrap of the vector along the axis. The first values are used to pad the end and the end values are used to pad the beginning.
  - empty: Pads with undefined values.
  - <function>: The padding function, if used, should modify and return a new 1-d tensor. It has the following signature: `padding_func(tensor, iaxis_pad_width, iaxis, kwargs)`
- **stat_length** (*Union[tuple, list, int], optional*) –Used in 'maximum', 'mean', 'median', and 'minimum'. Number of values at edge of each axis used to calculate the statistic value. `((before_1, after_1), ... (before_N, after_N))` creates unique statistic lengths for each axis. `((before, after),)` yields same before and after statistic lengths for each axis. `(stat_length,)` or int is a shortcut for `before = after = statistic length` for all axes. Default: `None`, to use the entire axis.
- **constant_values** (*Union[tuple, list, int], optional*) –Used in `constant mode`. The values to set the padded values for each axis. `((before_1, after_1), ... (before_N, after_N))` creates unique pad constants for each axis. `((before, after),)` yields same before and after constants for each axis. `(constant,)` or `constant` is a shortcut for `before = after = constant` for all axes. Default: `0` .
- **end_values** (*Union[tuple, list, int], optional*) –Used in 'linear_ramp'. The values used for the ending value of the linear_ramp and that will form the edge of the padded *arr*. `((before_1, after_1), ... (before_N, after_N))` unique end values for each axis. `((before, after),)` yields same before and after end values for each axis. `(constant,)` or `constant` is a shortcut for `before = after = constant` for all axes. Default: `0` .

- **reflect_type** (*string, optional*) –'reflect', and 'symmetric'. The 'even' style is the default with an unaltered reflection around the edge value. For the 'odd' style, the extended part of the *arr* is created by subtracting the reflected values from two times the edge value.
- **kwargs** (*anytype, optional*) –Any keyword arguments that will be used only in <function> mode.

Returns

Padded tensor of rank equal to *arr* with shape increased according to *pad_width*.

Raises

- **TypeError** –If *arr*, *pad_width*, *stat_length*, *constant_values* or *end_values* have types not specified above.
- **ValueError** –If *mode* cannot be recognized, or if *pad_width*, *stat_length*, *constant_values*, *end_values* cannot broadcast to `(arr.ndim, 2)`, or if keyword arguments got unexpected inputs.
- **NotImplementedError** –If mode is function or 'median'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> tensor = np.array([1., 2., 3., 4., 5.])
>>> print(np.pad(tensor, (3, 4)))
[0. 0. 0. 1. 2. 3. 4. 5. 0. 0. 0. 0.]
>>> print(np.pad(tensor, (3, 4), mode="wrap"))
[3. 4. 5. 1. 2. 3. 4. 5. 1. 2. 3. 4.]
>>> print(np.pad(tensor, (3, 4), mode="linear_ramp", end_values=(10, 10)))
[10.    7.    4.    1.    2.    3.    4.    5.    6.25  7.5   8.75 10.  ]
```

13.1.32 mindspore.numpy.rand

`mindspore.numpy.`**rand**(**shape*, *dtype=mstype.float32*)

Returns a new Tensor with given shape and dtype, filled with random numbers from the uniform distribution on the interval $[0, 1)$.

Parameters

- ***shape** (*Union[int, tuple(int), list(int)]*) –Shape of the new tensor, e.g., $(2, 3)$ or 2.
- **dtype** (Union[*mindspore.dtype*, str], optional) –Designated tensor dtype, it must be float type. Default is `mindspore.float32`.

Returns

Tensor, with the designated shape and dtype, filled with random numbers from the uniform distribution on the interval $[0, 1)$.

Raises

- **TypeError** –If input arguments have types not specified above.
- **ValueError** –If *dtype* is not float type.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> from mindspore import set_seed
>>> set_seed(1)
>>> print(np.rand((2,3)))
[[4.1702199e-01 9.9718481e-01 7.2032452e-01]
[9.3255734e-01 1.1438108e-04 1.2812445e-01]]
```

13.1.33 mindspore.numpy.randint

mindspore.numpy.**randint**(*minval*, *maxval=None*, *shape=None*, *dtype=mstype.int32*)

Return random integers from minval (inclusive) to maxval (exclusive). Return random integers from the discrete uniform distribution of the specified dtype in the "half-open" interval $[minval, maxval)$. If maxval is None (the default), the value range will be $[0, minval)$, in this case, minval must be greater than 0.

Parameters

- **minval** (*Union[int]*) –Start value of interval. The interval includes this value. When *maxval* is None, *minval* must be greater than 0. When *maxval* is not None, *minval* must be less than *maxval*.
- **maxval** (*Union[int], optional*) –End value of interval. The interval does not include this value.
- **shape** (*Union[int, tuple(int)]*) –Shape of the new tensor, e.g., $(2, 3)$ or 2.
- **dtype** (Union[*mindspore.dtype*, str], optional) –Designated tensor dtype, it must be int type. Default is *mindspore.int32*.

Returns

Tensor, with the designated shape and dtype, filled with random integers from minval (inclusive) to maxval (exclusive).

Raises

- **TypeError** –If input arguments have types not specified above.
- **ValueError** –If input arguments have values not specified above.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> from mindspore import set_seed
>>> set_seed(1)
>>> print(np.randint(1, 10, (2,3)))
[[4 9 7]
[9 1 2]]
```

13.1.34 mindspore.numpy.randn

mindspore.numpy.**randn**(**shape*, *dtype=mstype.float32*)

Returns a new Tensor with given shape and dtype, filled with a sample (or samples) from the standard normal distribution.

Parameters

- ***shape** (*Union[int, tuple(int), list(int)]*) – Shape of the new tensor, e.g., (2, 3) or 2.
- **dtype** (Union[*mindspore.dtype*, str], optional) – Designated tensor dtype, it must be float type. Default is `mindspore.float32`.

Returns

Tensor, with the designated shape and dtype, filled with a sample (or samples) from the "standard normal" distribution.

Raises

- **TypeError** – If input arguments have types not specified above.
- **ValueError** – If *dtype* is not float type.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> from mindspore import set_seed
>>> set_seed(1)
>>> print(np.randn((2,3)))
[[ 0.30639967 -0.42438635 -0.20454668]
[-0.4287376   1.3054721   0.64747655]]
```

13.1.35 mindspore.numpy.trace

mindspore.numpy.**trace**(*a*, *offset=0*, *axis1=0*, *axis2=1*, *dtype=None*)

Return the sum along diagonals of the tensor.

Note:

- *trace* is currently only used in *mindscience* scientific computing scenarios and dose not support other usage scenarios.
- *trace* is not supported on Windows platform yet.

Parameters

- **a** (`Tensor`) – A matrix to be calculated.
- **offset** (*int, optional*) – Offset of the diagonal from the main diagonal. Can be positive or negative. Default: `0`.
- **axis1** (*int, optional*) – Axis to be used as the first axis of the 2-D sub-arrays from which the diagonals should be taken. Default: `0`.
- **axis2** (*int, optional*) – Axis to be used as the second axis of the 2-D sub-arrays from which the diagonals should be taken. Default: `1`.

- **dtype** (*mindspore.dtype*, optional) –Overrides the dtype of the output Tensor if not `None`. Default: `None`.

Returns

Tensor, the sum along diagonals. If *a* is 2-D, the sum along the diagonal is returned. If *a* has more than two dimensions, then the axes specified by *axis1* and *axis2* are used to determine the 2-D sub-arrays whose traces are returned. The shape of the resulting array is the same as that of *a* with *axis1* and *axis2* removed.

Raises

- **ValueError** –If *a* has less than two dimensions.
- **ValueError** –If *axis1* or *axis2* is not in [-dims, dims), which dims is dimension of *a*.
- **ValueError** –If axes specified by *axis1* and *axis2* are same.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.numpy import trace
>>> x = Tensor(np.eye(3, dtype=np.float32))
>>> print(trace(x))
3.0
```

13.1.36 mindspore.numpy.tri

`mindspore.numpy.tri`(*N*, *M=None*, *k=0*, *dtype=mstype.float32*)

Returns a tensor with ones at and below the given diagonal and zeros elsewhere.

Parameters

- **N** (*int*) –Number of rows in the array.
- **M** (*int, optional*) –Number of columns in the array. By default, *M* is taken equal to N. Default: `None` .
- **k** (*int, optional*) –The sub-diagonal at and below which the array is filled. $k = 0$ is the main diagonal, while $k < 0$ is below it, and $k > 0$ is above. Default: `0` .
- **dtype** (*mindspore.dtype*, optional) –Data type of the returned array. Default: `mstype.float32` .

Returns

Tensor with shape *(N, M)*, with its lower triangle filled with ones and zeros elsewhere; in other words $T[i, j] = 1$ for $j <= i + k$, 0 otherwise.

Raises

TypeError –If input arguments have types not specified above.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.tri(3, 3, 1)
>>> print(output)
[[1. 1. 0.]
[1. 1. 1.]
[1. 1. 1.]]
```

13.1.37 mindspore.numpy.tril

mindspore.numpy.**tril**(*m*, *k=0*)

Returns a lower triangle of a tensor.

Returns a copy of a tensor with elements above the *k-th* diagonal zeroed.

Parameters

- **m** (*Union[Tensor, list, tuple]*) – The shape and data-type of *m* define these same attributes of the returned tensor.
- **k** (*int, optional*) – Diagonal above which to zero elements. $k = 0$ (the default) is the main diagonal, $k < 0$ is below it and $k > 0$ is above.

Returns

Lower triangle of *m*, of same shape and data-type as *m*.

Supported Platforms:

Ascend GPU CPU

Raises

- **TypeError** – If input arguments have types not specified above.
- **ValueError** – If input *m*'s rank < 1.

Examples

```
>>> import mindspore.numpy as np
>>> output = np.tril(np.ones((3, 3)))
>>> print(output)
[[1. 0. 0.]
[1. 1. 0.]
[1. 1. 1.]]
```

13.1.38 mindspore.numpy.tril_indices

mindspore.numpy.**tril_indices**(*n*, *k=0*, *m=None*)

Returns the indices for the lower-triangle of an (n, m) array.

Parameters

- **n** (*int*) –The size of the arrays for which the returned indices will be valid.
- **k** (*int, optional*) –Diagonal offset, default: `0` .
- **m** (*int, optional*) –The column dimension of the arrays for which the returned arrays will be valid. By default *m* is taken equal to *n*. Default: `None` .

Returns

The indices for the triangle. The returned tuple contains two tensors, each with the indices along one dimension of the tensor.

Raises

TypeError –If *n*, *k*, *m* are not numbers.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.tril_indices(3))
(Tensor(shape=[6], dtype=Int32, value= [0, 1, 1, 2, 2, 2]),
Tensor(shape=[6], dtype=Int32, value= [0, 0, 1, 0, 1, 2]))
```

13.1.39 mindspore.numpy.tril_indices_from

mindspore.numpy.**tril_indices_from**(*arr*, *k=0*)

Returns the indices for the lower-triangle of *arr*.

Parameters

- **arr** (*Union[Tensor, list, tuple]*) –2-dimensional array.
- **k** (*int, optional*) –Diagonal offset, default: `0` .

Returns

triu_indices_from, tuple of 2 tensor, shape(N) Indices for the lower-triangle of *arr*.

Raises

- **TypeError** –If *arr* cannot be converted to tensor, or *k* is not a number.
- **ValueError** –If *arr* cannot be converted to a 2-dimensional tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> tensor = np.ones((3,3))
>>> print(np.tril_indices_from(tensor))
(Tensor(shape=[6], dtype=Int32, value= [0, 1, 1, 2, 2, 2]),
 Tensor(shape=[6], dtype=Int32, value= [0, 0, 1, 0, 1, 2]))
```

13.1.40 mindspore.numpy.triu

mindspore.numpy.**triu**(*m*, *k=0*)

Returns an upper triangle of a tensor.

Returns a copy of a tensor with elements below the *k-th* diagonal zeroed.

Parameters

- **m** (*Union[Tensor, list, tuple]*) –The shape and data-type of *m* define these same attributes of the returned tensor.
- **k** (*int, optional*) –Diagonal below which to zero elements. $k = 0$ (the default) is the main diagonal, $k < 0$ is below it and $k > 0$ is above.

Returns

Upper triangle of *m*, of same shape and data-type as *m*.

Raises

- **TypeError** –If input arguments have types not specified above.
- **ValueError** –If input *m*'s rank < 1.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.triu(np.ones((3, 3)))
>>> print(output)
[[1. 1. 1.]
[0. 1. 1.]
[0. 0. 1.]]
```

13.1.41 mindspore.numpy.triu_indices

mindspore.numpy.**triu_indices**(*n*, *k=0*, *m=None*)

Returns the indices for the upper-triangle of an (n, m) array.

Parameters

- **n** (*int*) –The size of the arrays for which the returned indices will be valid.
- **k** (*int, optional*) –Diagonal offset, default: 0 .

- **m** (*int, optional*) –The column dimension of the arrays for which the returned arrays will be valid. By default *m* is taken equal to *n*. Default: `None` .

Returns

The indices for the triangle. The returned tuple contains two tensors, each with the indices along one dimension of the tensor.

Raises

TypeError –If *n*, *k*, *m* are not numbers.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.triu_indices(3))
(Tensor(shape=[6], dtype=Int32, value= [0, 0, 0, 1, 1, 2]),
 Tensor(shape=[6], dtype=Int32, value= [0, 1, 2, 1, 2, 2]))
```

13.1.42 mindspore.numpy.triu_indices_from

mindspore.numpy.**triu_indices_from**(*arr*, *k=0*)

Returns the indices for the upper-triangle of *arr*.

Parameters

- **arr** (*Union[Tensor, list, tuple]*) –2-dimensional array.
- **k** (*int, optional*) –Diagonal offset, default: `0` .

Returns

triu_indices_from, tuple of 2 tensor, shape(N) Indices for the upper-triangle of *arr*.

Raises

- **TypeError** –If *arr* cannot be converted to tensor, or *k* is not a number.
- **ValueError** –If *arr* cannot be converted to a 2-dimensional tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> tensor = np.ones((3,3))
>>> print(np.triu_indices_from(tensor))
(Tensor(shape=[6], dtype=Int32, value= [0, 0, 0, 1, 1, 2]),
Tensor(shape=[6], dtype=Int32, value= [0, 1, 2, 1, 2, 2]))
```

13.1.43 mindspore.numpy.vander

mindspore.numpy.**vander**(*x*, *N=None*, *increasing=False*)

Generates a Vandermonde matrix.

The columns of the output matrix are powers of the input vector. The order of the powers is determined by the increasing boolean argument. Specifically, when increasing is *False*, the i-th output column is the input vector raised element-wise to the power of $N - i - 1$. Such a matrix with a geometric progression in each row is named for Alexandre-Theophile Vandermonde.

Parameters

- **x** (*Union[list, tuple, Tensor]*) –1-D input array.
- **N** (*int, optional*) –Number of columns in the output. If N is not specified, a square array is returned (`N = len(x)`).
- **increasing** (*bool, optional*) –Order of the powers of the columns. If True, the powers increase from left to right, if False (the default) they are reversed.

Returns

Vandermonde matrix. If *increasing* is *False*, the first column is $x^{(N-1)}$, the second $x^{(N-2)}$ and so forth. If *increasing* is *True*, the columns are $x^0, x^1, ..., x^{(N-1)}$.

Raises

- **TypeError** –If inputs have types not specified above.
- **ValueError** –If x is not 1-D, or $N < 0$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.vander([1., 2., 3., 4., 5.]))
[[  1.   1.   1.   1.   1.]
 [ 16.   8.   4.   2.   1.]
 [ 81.  27.   9.   3.   1.]
 [256.  64.  16.   4.   1.]
 [625. 125.  25.   5.   1.]]
```

13.1.44 mindspore.numpy.zeros

mindspore.numpy.**zeros**(*shape*, *dtype=mstype.float32*)

Returns a new tensor of given shape and type, filled with zeros.

Parameters

- **shape** (*Union[int, tuple, list]*) –the shape of the new tensor.
- **dtype** (Union[*mindspore.dtype*, str], optional) –Designated tensor dtype. Default is mstype.float32.

Returns

Tensor, with the designated *shape* and *dtype*, filled with zeros.

Raises

- **TypeError** –If input arguments have types not specified above.
- **ValueError** –If *shape* entries have values < 0.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> print(np.zeros((2,2)))
[[0. 0.]
[0. 0.]]
```

13.1.45 mindspore.numpy.zeros_like

mindspore.numpy.**zeros_like**(*a*, *dtype=None*, *shape=None*)

Returns an array of zeros with the same shape and type as a given array.

Note: Input array must have the same size across a dimension. If *a* is not a Tensor, dtype is float32 by default if not provided.

Parameters

- **a** (*Union[Tensor, list, tuple]*) –The shape and data-type of a define these same attributes of the returned array.
- **dtype** (*mindspore.dtype*, optional) –Overrides the data type of the result.
- **shape** (*int, sequence of ints, optional*) –Overrides the shape of the result.

Returns

Tensor, array of zeros with the same shape and type as *a*.

Raises

ValueError –If *a* is not a Tensor, list or tuple.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.ones((4,1,2))
>>> output = np.zeros_like(a)
>>> print(output)
[[[0. 0.]]
[[0. 0.]]
[[0. 0.]]
[[0. 0.]]]
```

13.2 Array Operation

Array operations focus on tensor manipulation.

- Manipulate the shape of the tensor

  For example, transpose a matrix:

```
input_x = np.arange(10).reshape(5, 2)
output = np.transpose(input_x)
print(output)
```

  The result is as follows:

```
[[0 2 4 6 8]
 [1 3 5 7 9]]
```

  Another example, swap two axes:

```
input_x = np.ones((1, 2, 3))
output = np.swapaxes(input_x, 0, 1)
print(output.shape)
```

  The result is as follows:

```
(2, 1, 3)
```

- Tensor splitting

  Divide the input tensor into multiple tensors equally, for example:

```
input_x = np.arange(9)
output = np.split(input_x, 3)
print(output)
```

  The result is as follows:

```
(Tensor(shape=[3], dtype=Int32, value= [0, 1, 2]), Tensor(shape=[3], dtype=Int32, value= [3,␣
↪4, 5]), Tensor(shape=[3], dtype=Int32, value= [6, 7, 8]))
```

- Tensor combination

  Concatenate the two tensors according to the specified axis, for example:

```
input_x = np.arange(0, 5)
input_y = np.arange(10, 15)
output = np.concatenate((input_x, input_y), axis=0)
print(output)
```

  The result is as follows:

```
[ 0  1  2  3  4 10 11 12 13 14]
```

API Name	Description	Supported Platforms
mindspore.numpy.append	Appends values to the end of a tensor.	Ascend GPU CPU
mindspore.numpy.apply_along_axis	Applies a function to 1-D slices along the given axis.	Ascend GPU CPU
mindspore.numpy.apply_over_axes	Applies a function repeatedly over multiple axes.	Ascend GPU CPU

continues on next page

Table 2 – continued from previous page

mindspore.numpy.argwhere	Find the indices of Tensor elements that are non-zero, grouped by element.	Ascend GPU CPU
mindspore.numpy.array_split	Splits a tensor into multiple sub-tensors.	Ascend GPU CPU
mindspore.numpy.array_str	Returns a string representation of the data in an array.	Ascend GPU CPU
mindspore.numpy.atleast_1d	Converts inputs to arrays with at least one dimension.	Ascend GPU CPU
mindspore.numpy.atleast_2d	Reshapes inputs as arrays with at least two dimensions.	Ascend GPU CPU
mindspore.numpy.atleast_3d	Reshapes inputs as arrays with at least three dimensions.	Ascend GPU CPU
mindspore.numpy.broadcast_arrays	Broadcasts any number of arrays against each other.	Ascend GPU CPU
mindspore.numpy.broadcast_to	Broadcasts an array to a new shape.	Ascend GPU CPU
mindspore.numpy.choose	Construct an array from an index array and a list of arrays to choose from.	Ascend GPU CPU
mindspore.numpy.column_stack	Stacks 1-D tensors as columns into a 2-D tensor.	Ascend GPU CPU
mindspore.numpy.concatenate	Joins a sequence of tensors along an existing axis.	Ascend GPU CPU
mindspore.numpy.dsplit	Splits a tensor into multiple sub-tensors along the 3rd axis (depth).	Ascend GPU CPU
mindspore.numpy.dstack	Stacks tensors in sequence depth wise (along the third axis).	Ascend GPU CPU
mindspore.numpy.expand_dims	Expands the shape of a tensor.	Ascend GPU CPU
mindspore.numpy.flip	Reverses the order of elements in an array along the given axis.	GPU CPU
mindspore.numpy.fliplr	Flips the entries in each row in the left/right direction.	GPU CPU
mindspore.numpy.flipud	Flips the entries in each column in the up/down direction.	GPU CPU
mindspore.numpy.hsplit	Splits a tensor into multiple sub-tensors horizontally (column-wise).	Ascend GPU CPU
mindspore.numpy.hstack	Stacks tensors in sequence horizontally.	Ascend GPU CPU
mindspore.numpy.intersect1d	Find the intersection of two Tensors.	Ascend GPU CPU
mindspore.numpy.moveaxis	Moves axes of an array to new positions.	Ascend GPU CPU
mindspore.numpy.piecewise	Evaluates a piecewise-defined function.	Ascend GPU CPU
mindspore.numpy.ravel	Returns a contiguous flattened tensor.	Ascend GPU CPU
mindspore.numpy.repeat	Repeats elements of an array.	Ascend GPU CPU
mindspore.numpy.reshape	Reshapes a tensor without changing its data.	Ascend GPU CPU
mindspore.numpy.roll	Rolls a tensor along given axes.	Ascend GPU CPU
mindspore.numpy.rollaxis	Rolls the specified axis backwards, until it lies in the given position.	Ascend GPU CPU
mindspore.numpy.rot90	Rotates a tensor by 90 degrees in the plane specified by axes.	GPU
mindspore.numpy.select	Returns an array drawn from elements in *choicelist*, depending on conditions.	Ascend GPU CPU
mindspore.numpy.setdiff1d	Find the set difference of two Tensors.	Ascend GPU CPU
mindspore.numpy.size	Returns the number of elements along a given axis.	Ascend GPU CPU
mindspore.numpy.split	Splits a tensor into multiple sub-tensors along the given axis.	Ascend GPU CPU
mindspore.numpy.squeeze	Return the Tensor after deleting the dimension of size 1 in the specified *axis*.	Ascend GPU CPU
mindspore.numpy.stack	Joins a sequence of arrays along a new axis.	Ascend GPU CPU

continues on next page

Table 2 – continued from previous page

mindspore.numpy.swapaxes	Interchanges two axes of a tensor.	Ascend GPU CPU
mindspore.numpy.take	Takes elements from an array along an axis.	Ascend GPU CPU
mindspore.numpy.take_along_axis	Takes values from the input array by matching 1d index and data slices.	Ascend GPU CPU
mindspore.numpy.tile	Constructs an array by repeating *a* the number of times given by *reps*.	Ascend GPU CPU
mindspore.numpy.transpose	Reverses or permutes the axes of a tensor; returns the modified tensor.	Ascend GPU CPU
mindspore.numpy.unique	Finds the unique elements of a tensor.	Ascend GPU CPU
mindspore.numpy.unravel_index	Converts a flat index or array of flat indices into a tuple of coordinate arrays.	Ascend GPU CPU
mindspore.numpy.vsplit	Splits a tensor into multiple sub-tensors vertically (row-wise).	Ascend GPU CPU
mindspore.numpy.vstack	Stacks tensors in sequence vertically.	Ascend GPU CPU
mindspore.numpy.where	Returns elements chosen from *x* or *y* depending on *condition*.	Ascend GPU CPU

13.2.1 mindspore.numpy.append

mindspore.numpy.**append**(*arr*, *values*, *axis=None*)

Appends values to the end of a tensor.

Parameters

- **arr** (Tensor) –Values are appended to a copy of this tensor.
- **values** (Tensor) –These values are appended to a copy of *arr*. It must be of the correct shape (the same shape as *arr*, excluding *axis*). If *axis* is not specified, *values* can be any shape and will be flattened before use.
- **axis** (*int, optional*) –The *axis* along which values are appended. If *axis* is not given, both *arr* and *values* are flattened before use, default is None.

Returns

Tensor, a copy of tensor with values appended to axis.

Raises

- **TypeError** –If input arguments have types not specified above.
- **ValueError** –If specified axis exceeds *arr.ndim*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.ones((2, 3))
>>> b = np.ones((2, 1))
>>> print(np.append(a, b, axis=1).shape)
(2, 4)
```

13.2.2 mindspore.numpy.apply_along_axis

mindspore.numpy.**apply_along_axis**(*func1d*, *axis*, *arr*, **args*, ***kwargs*)

Applies a function to 1-D slices along the given axis. Executes `func1d(a, *args, **kwargs)` where *func1d* operates on 1-D arrays and *a* is a 1-D slice of arr along axis.

Parameters

- **func1d** (*function*) –Maps *(M,) -> (Nj…)*. This function should accept 1-D arrays. It is applied to 1-D slices of arr along the specified axis.
- **axis** (*int*) –Axis along which arr is sliced.
- **arr** (Tensor) –Input array with shape *(Ni…, M, Nk…)*.
- **args** (*any*) –Additional arguments to *func1d*.
- **kwargs** (*any*) –Additional named arguments to *func1d*.

Returns

Tensor with shape *(Ni…, Nj…, Nk…)*, the output array. Its shape is identical to the shape of *arr*, except along the *axis* dimension. This axis is removed, and replaced with new dimensions equal to the shape of the return value of *func1d*. So if *func1d* returns a scalar, the output will have one fewer dimensions than *arr*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Raises

ValueError –If axis is out of the range.

Examples

```
>>> import mindspore.numpy as np
>>> b = np.array([[1,2,3], [4,5,6], [7,8,9]])
>>> print(np.apply_along_axis(np.diag, -1, b))
[[[1 0 0]
[0 2 0]
[0 0 3]]
[[4 0 0]
[0 5 0]
[0 0 6]]
[[7 0 0]
[0 8 0]
[0 0 9]]]
```

13.2.3 mindspore.numpy.apply_over_axes

mindspore.numpy.**apply_over_axes**(*func*, *a*, *axes*)

Applies a function repeatedly over multiple axes.

func is called as *res* = *func(a, axis)*, where *axis* is the first element of *axes*. The result *res* of the function call must have either the same dimensions as *a* or one less dimension. If *res* has one less dimension than *a*, a dimension is inserted before *axis*. The call to *func* is then repeated for each axis in *axes*, with *res* as the first argument.

Parameters

- **func** (*function*) – This function must take two arguments, *func(a, axis)*.
- **a** (*Union[int, float, bool, list, tuple, Tensor]*) – Input tensor.
- **axes** (*Union[int, list, tuple]*) – Axes over which *func* is applied; the elements must be integers.

Returns

Tensor. The number of dimensions is the same as *a*, but the shape can be different. This depends on whether *func* changes the shape of its output with respect to its input.

Raises

- **TypeError** – If input *a* is not array_like or *axes* is not int or sequence of ints.
- **ValueError** – If any axis is out of range or duplicate axes exist.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(10).reshape(2, 5).astype('float32')
>>> print(x)
[[0. 1. 2. 3. 4.]
 [5. 6. 7. 8. 9.]]
>>> print(np.apply_over_axes(np.sum, x, axes=0))
[[ 5.  7.  9. 11. 13.]]
```

13.2.4 mindspore.numpy.argwhere

mindspore.numpy.**argwhere**(*a*)

Find the indices of Tensor elements that are non-zero, grouped by element.

Parameters

a (*Union[list, tuple, Tensor]*) – Input tensor.

Returns

Tensor. Indices of elements that are non-zero. Indices are grouped by element. This Tensor will have shape $(N, a.ndim)$ where N is the number of non-zero items.

Raises

- **TypeError** – If input *a* is not array_like.
- **ValueError** – If dim of *a* equals to 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([[[1, 0], [-5, 0]]])
>>> np.argwhere(x)
Tensor(shape=[2, 3], dtype=Int64, value=[[0, 0, 0], [0, 1, 0]])
```

13.2.5 mindspore.numpy.array_split

`mindspore.numpy.`**`array_split`**(*x*, *indices_or_sections*, *axis=0*)

Splits a tensor into multiple sub-tensors.

Note: Currently, array_split only supports `mindspore.float32` on `CPU`.

The only difference between `np.split` and `np.array_split` is that `np.array_split` allows indices_or_sections to be an integer that does not equally divide the axis. For a tensor of length l that should be split into n sections, it returns $l\%n$ sub-arrays of size $l//n+1$ and the rest of size $l//n$.

Parameters

- **`x`** (`Tensor`) –A Tensor to be divided.
- **`indices_or_sections`** (*`Union[int, tuple(int), list(int)]`*) –If integer, N, the tensor will be divided into N tensors along axis. If tuple(int), list(int) or of sorted integers, the entries indicate where along axis the array is split. For example, $[2, 3]$ would, for $axis = 0$, result in three sub-tensors $x[: 2]$, $x[2 : 3]$ and $x[3 :]$. If an index exceeds the dimension of the array along axis, an empty sub-array is returned correspondingly.
- **`axis`** (*`int`*) –The axis along which to split. Default: `0` .

Returns

A list of sub-tensors.

Raises

- **`TypeError`** –If argument *indices_or_sections* is not integer, tuple(int) or list(int) or argument *axis* is not integer.
- **`ValueError`** –If argument *axis* is out of range of $[-x.ndim, x.ndim)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> input_x = np.arange(9).astype("float32")
>>> output = np.array_split(input_x, 4)
>>> print(output)
(Tensor(shape=[3], dtype=Float32,
    value= [ 0.00000000e+00,  1.00000000e+00,  2.00000000e+00]),
Tensor(shape=[2], dtype=Float32,
    value= [ 3.00000000e+00,  4.00000000e+00]),
Tensor(shape=[2], dtype=Float32,
    value= [ 5.00000000e+00,  6.00000000e+00]),
Tensor(shape=[2], dtype=Float32,
    value= [ 7.00000000e+00,  8.00000000e+00]))
```

13.2.6 mindspore.numpy.array_str

mindspore.numpy.**array_str**(*a*)

Returns a string representation of the data in an array.

The data in the array is returned as a single string. This function is similar to array_repr, the difference being that array_repr also returns information on the kind of array and its data type.

Note: Numpy argument *max_line_width*, *precision* and *suppress_small* are not supported. Graph mode does not support the function.

Parameters

a (Tensor) – Input data.

Returns

String.

Supported Platforms:

Ascend GPU CPU

Raises

TypeError – If input is not tensor.

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(5)
>>> np.array_str(x)
'[0 1 2 3 4]'
```

13.2.7 mindspore.numpy.atleast_1d

mindspore.numpy.**atleast_1d**(**arys*)

Converts inputs to arrays with at least one dimension.

Scalar inputs are converted to 1-dimensional arrays, whilst higher-dimensional inputs are preserved.

Note: In graph mode, returns a tuple of tensor instead of a list of tensors.

Parameters

***arys** (Tensor) – one or more input tensors.

Returns

Tensor, or list of tensors, each with `a.ndim >= 1`.

Raises

TypeError – If the input is not a tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.ones((2, 3))
>>> b = np.ones(())
>>> c = np.ones(5)
>>> output = np.atleast_1d(a, b, c)
>>> print(output)
    [Tensor(shape=[2, 3], dtype=Float32, value=
    [[1.00000000e+00, 1.00000000e+00, 1.00000000e+00],
    [1.00000000e+00, 1.00000000e+00, 1.00000000e+00]]),
    Tensor(shape=[1], dtype=Float32, value= [1.00000000e+00]),
    Tensor(shape=[5], dtype=Float32,
    value= [1.00000000e+00, 1.00000000e+00, 1.00000000e+00,
    1.00000000e+00, 1.00000000e+00])]
```

13.2.8 mindspore.numpy.atleast_2d

mindspore.numpy.**atleast_2d**(**arys*)

Reshapes inputs as arrays with at least two dimensions.

Note: In graph mode, returns a tuple of tensor instead of a list of tensors.

Parameters

***arys** (Tensor) – one or more input tensors.

Returns

Tensor, or list of tensors, each with `a.ndim >= 2`.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.ones((2, 3))
>>> b = np.ones(())
>>> c = np.ones(5)
>>> output = np.atleast_2d(a, b, c)
>>> print(output)
    [Tensor(shape=[2, 3], dtype=Float32, value=
    [[1.00000000e+00, 1.00000000e+00, 1.00000000e+00],
    [1.00000000e+00, 1.00000000e+00, 1.00000000e+00]]),
    Tensor(shape=[1, 1], dtype=Float32, value= [[1.00000000e+00]]),
    Tensor(shape=[1, 5], dtype=Float32,
    value= [[1.00000000e+00, 1.00000000e+00, 1.00000000e+00,
    1.00000000e+00, 1.00000000e+00]])]
```

13.2.9 mindspore.numpy.atleast_3d

mindspore.numpy.**atleast_3d**(**arys*)

Reshapes inputs as arrays with at least three dimensions.

Note: In graph mode, returns a tuple of tensor instead of a list of tensors.

Parameters

***arys** (Tensor) –one or more input tensors.

Returns

Tensor, or list of tensors, each with `a.ndim >= 3`. For example, a 1-D array of shape *(N,)* becomes a tensor of shape *(1, N, 1)*, and a 2-D array of shape *(M, N)* becomes a tensor of shape *(M, N, 1)*.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.ones((2, 3))
>>> b = np.ones(())
>>> c = np.ones(5)
>>> output = np.atleast_3d(a, b, c)
>>> print(output)
    [Tensor(shape=[2, 3, 1], dtype=Float32, value=
    [[[1.00000000e+00], [1.00000000e+00], [1.00000000e+00]],
    [[1.00000000e+00], [1.00000000e+00], [1.00000000e+00]]]),
    Tensor(shape=[1, 1, 1], dtype=Float32, value= [[[1.00000000e+00]]]),
    Tensor(shape=[1, 5, 1], dtype=Float32,
    value= [[[1.00000000e+00], [1.00000000e+00], [1.00000000e+00],
    [1.00000000e+00], [1.00000000e+00]]])]
```

13.2.10 mindspore.numpy.broadcast_arrays

mindspore.numpy.**broadcast_arrays**(**args*)

Broadcasts any number of arrays against each other.

Note: Numpy argument *subok* is not supported. In graph mode, returns a tuple of Tensor instead of a list of Tensor.

Parameters

***args** (Tensor) – The arrays to broadcast.

Returns

List of Tensor.

Raises

ValueError – If arrays cannot be broadcast.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([[1,2,3]])
>>> y = np.array([[4],[5]])
>>> output = np.broadcast_arrays(x, y)
>>> print(output)
[Tensor(shape=[2, 3], dtype=Int32, value=
[[1, 2, 3],
[1, 2, 3]]), Tensor(shape=[2, 3], dtype=Int32, value=
[[4, 4, 4],
[5, 5, 5]])]
```

13.2.11 mindspore.numpy.broadcast_to

mindspore.numpy.**broadcast_to**(*array*, *shape*)

Broadcasts an array to a new shape.

Parameters

- **array** (Tensor) –The array to broadcast.
- **shape** (*tuple*) –The shape of the desired array.

Returns

Tensor, original array broadcast to the given shape.

Raises

ValueError –If array cannot be broadcast to shape.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([1, 2, 3])
>>> output = np.broadcast_to(x, (3, 3))
>>> print(output)
[[1 2 3]
 [1 2 3]
 [1 2 3]]
```

13.2.12 mindspore.numpy.choose

mindspore.numpy.**choose**(*a*, *choices*, *mode='clip'*)

Construct an array from an index array and a list of arrays to choose from. Given an "index" array *a* of integers and a sequence of n arrays (choices), *a* and each choice array are first broadcast, as necessary, to arrays of a common shape; calling these *Ba* and *Bchoices[i], i = 0,⋯,n-1* we have that, necessarily, `Ba.shape == Bchoices[i].shape` for each *i*. Then, a new array with `shape Ba.shape` is created as follows:

- if `mode='raise'` (the default), then, first of all, each element of *a* (and thus *Ba*) must be in the range *[0, n-1]*; now, suppose that *i* (in that range) is the value at the *(j0, j1, ⋯, jm)* position in *Ba* - then the value at the same position in the new array is the value in `Bchoices[i]` at that same position;
- if `mode='wrap'`, values in *a* (and thus *Ba*) may be any (signed) integer; modular arithmetic is used to map integers outside the range `[0, n-1]` back into that range; and then the new array is constructed as above;
- if `mode='clip'`, values in *a* (and thus *Ba*) may be any (signed) integer; negative integers are mapped to 0; values greater than *n-1* are mapped to *n-1*; and then the new array is constructed as above.

Note: Numpy argument *out* is not supported. `mode = 'raise'` is not supported, and the default mode is 'clip' instead.

Parameters

- **a** (*int array*) –This array must contain integers in `[0, n-1]`, where *n* is the number of choices, unless `mode=wrap` or `mode=clip`, in which cases any integers are permissible.
- **choices** (*sequence of arrays*) –Choice arrays. *a* and all of the *choices* must be broadcastable to the same shape. If *choices* is itself an array, then its outermost dimension (i.e., the one corresponding to `choices.shape[0]`) is taken as defining the "sequence".
- **mode** (*'raise', 'wrap', 'clip', optional*) –Specifies how indices outside `[0, n-1]` will be treated:

  'raise' - raise an error;

  'wrap' - wrap around;

  'clip' - clip to the range. 'clip' mode means that all indices that are too large are replaced by the index that addresses the last element along that axis. Note that this disables indexing with negative numbers.

Returns

Tensor, the merged result.

Raises

ValueError –If *a* and any of the *choices* cannot be broadcast.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> choices = [[0, 1, 2, 3], [10, 11, 12, 13], [20, 21, 22, 23], [30, 31, 32, 33]]
>>> print(np.choose([2, 3, 1, 0], choices))
[20 31 12  3]
>>> print(np.choose([2, 4, 1, 0], choices, mode='clip'))
[20 31 12  3]
>>> print(np.choose([2, 4, 1, 0], choices, mode='wrap'))
[20  1 12  3]
>>> a = [[1, 0, 1], [0, 1, 0], [1, 0, 1]]
>>> choices = [-10, 10]
>>> print(np.choose(a, choices))
[[ 10 -10  10]
 [-10  10 -10]
 [ 10 -10  10]]
```

13.2.13 mindspore.numpy.column_stack

`mindspore.numpy.`**column_stack**(*tup*)

Stacks 1-D tensors as columns into a 2-D tensor. 2-D tensors are stacked as-is, like np.hstack.

Parameters

tup (*Union[Tensor, tuple, list]*) –A sequence of 1-D or 2-D tensors. All of them must have the same shape except the axis to be concatenated.

Returns

2-D Tensor, formed by stacking the given tensors.

Supported Platforms:

`Ascend` `GPU` `CPU`

Raises

- **TypeError** –If *tup* is not Tensor, list or tuple.
- **ValueError** –If *tup* is empty.

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.array([1, 2, 3]).astype('int32')
>>> x2 = np.array([4, 5, 6]).astype('int32')
>>> output = np.column_stack((x1, x2))
>>> print(output)
[[1 4]
 [2 5]
 [3 6]]
```

13.2.14 mindspore.numpy.concatenate

`mindspore.numpy.`**concatenate**(*arrays*, *axis=0*)

Joins a sequence of tensors along an existing axis.

Note: To match Numpy behaviour, *axis* >= 32 will not cause value error, the *axis* will be treated as `None` instead.

Parameters

- **arrays** (*Union[Tensor, tuple(Tensor), list(Tensor)]*) –a tensor or a list of tensors to be concatenated.
- **axis** (*Union[None, int], optional*) –The axis along which the tensors will be joined, if *axis* is `None`, tensors are flattened before use. Default: `0` .

Returns

A tensor concatenated from a tensor or a list of tensors.

Raises

- **TypeError** –If input arguments have types not specified above.
- **ValueError** –If *axis* is not in the range of $[-ndim, ndim - 1]$, and less than 32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.ones((1,2,3))
>>> x2 = np.ones((1,2,1))
>>> x = np.concatenate((x1, x2), axis=-1)
>>> print(x.shape)
(1, 2, 4)
```

13.2.15 mindspore.numpy.dsplit

mindspore.numpy.**dsplit**(*x*, *indices_or_sections*)

Splits a tensor into multiple sub-tensors along the 3rd axis (depth). It is equivalent to split with $axis = 2$ (default), the array is always split along the third axis regardless of the array dimension.

Parameters

- **x** (Tensor) –A Tensor to be divided.
- **indices_or_sections** (*Union[int, tuple(int), list(int)]*) –If integer, N, the tensor will be divided into N equal tensors along axis. If tuple(int), list(int) or of sorted integers, the entries indicate where along axis the array is split. For example, $[2, 3]$ would, for $axis = 0$, result in three sub-tensors $x[: 2]$, $x[2 : 3]$ and $x[3 :]$. If an index exceeds the dimension of the array along axis, an empty sub-array is returned correspondingly.

Returns

A list of sub-tensors.

Raises

TypeError –If argument *indices_or_sections* is not integer.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> input_x = np.arange(6).reshape((1, 2, 3)).astype('float32')
>>> output = np.dsplit(input_x, 3)
>>> print(output)
(Tensor(shape=[1, 2, 1], dtype=Float32,
value=[[[ 0.00000000e+00],
        [ 3.00000000e+00]]]),
Tensor(shape=[1, 2, 1], dtype=Float32,
value=[[[ 1.00000000e+00],
        [ 4.00000000e+00]]]),
Tensor(shape=[1, 2, 1], dtype=Float32,
value=[[[ 2.00000000e+00],
        [ 5.00000000e+00]]]))
```

13.2.16 mindspore.numpy.dstack

mindspore.numpy.**dstack**(*tup*)

Stacks tensors in sequence depth wise (along the third axis). This is equivalent to concatenation along the third axis. 1-D tensors $(N,)$ should be reshaped to $(1, N, 1)$. 2-D tensors (M, N) should be reshaped to $(M, N, 1)$ before concatenation.

Parameters

tup (*Union[Tensor, tuple, list]*) –A sequence of tensors. The tensors must have the same shape along all but the third axis. 1-D or 2-D tensors must have the same shape.

Returns

Stacked Tensor, formed by stacking the given tensors.

Supported Platforms:

Ascend GPU CPU

Raises

- **TypeError** –If *tup* is not Tensor, list or tuple.
- **ValueError** –If *tup* is empty.

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.array([1, 2, 3]).astype('float32')
>>> x2 = np.array([4, 5, 6]).astype('float32')
>>> output = np.dstack((x1, x2))
>>> print(output)
[[[1. 4.]
  [2. 5.]
  [3. 6.]]]
```

13.2.17 mindspore.numpy.expand_dims

mindspore.numpy.**expand_dims**(*a*, *axis*)

Expands the shape of a tensor.

Inserts a new axis that will appear at the axis position in the expanded tensor shape.

Parameters

- **a** (Tensor) –Input tensor array.
- **axis** (*Union[int, list(int), tuple(int)]*) –Position in the expanded axes where the new axis is placed,

Returns

Tensor, with the number of dimensions increased at specified axis.

Raises

- **TypeError** –If input arguments have types not specified above.
- **ValueError** –If axis exceeds a.ndim.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.ones((2,2))
>>> x = np.expand_dims(x,0)
>>> print(x.shape)
(1, 2, 2)
```

13.2.18 mindspore.numpy.flip

mindspore.numpy.**flip**(*m*, *axis=None*)

Reverses the order of elements in an array along the given axis.

The shape of the array is preserved, but the elements are reordered.

Parameters

- **m** (Tensor) –Input array.
- **axis** (*Union[int, tuple(int), None], optional*) –Axis or axes along which to flip over. The default, axis=None, will flip over all of the axes of the input array. If *axis* is negative it counts from the last to the first axis. If *axis* is a tuple of integers, flipping is performed on all of the axes specified in the tuple.

Returns

Tensor, with the entries of *axis* reversed.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> A = np.arange(8.0).reshape((2,2,2))
>>> output = np.flip(A)
>>> print(output)
[[[7. 6.]
  [5. 4.]]
 [[3. 2.]
  [1. 0.]]]
>>> output = np.flip(A, (0, 2))
>>> print(output)
[[[5. 4.]
  [7. 6.]]
 [[1. 0.]
  [3. 2.]]]
```

13.2.19 mindspore.numpy.fliplr

mindspore.numpy.**fliplr**(*m*)

Flips the entries in each row in the left/right direction. Columns are preserved, but appear in a different order than before.

Parameters

m (Tensor) –Input array.

Returns

Tensor.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> A = np.arange(8.0).reshape((2,2,2))
>>> output = np.fliplr(A)
>>> print(output)
[[[2. 3.]
  [0. 1.]]
 [[6. 7.]
  [4. 5.]]]
```

13.2.20 mindspore.numpy.flipud

mindspore.numpy.**flipud**(*m*)

Flips the entries in each column in the up/down direction. Rows are preserved, but appear in a different order than before.

Parameters

m (Tensor) –Input array.

Returns

Tensor.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> A = np.arange(8.0).reshape((2,2,2))
>>> output = np.flipud(A)
>>> print(output)
[[[4. 5.]
  [6. 7.]]
 [[0. 1.]
  [2. 3.]]]
```

13.2.21 mindspore.numpy.hsplit

mindspore.numpy.**hsplit**(*x*, *indices_or_sections*)

Splits a tensor into multiple sub-tensors horizontally (column-wise). It is equivalent to split with $axis = 1$ (default), the array is always split along the second axis regardless of the array dimension.

Parameters

- **x** (Tensor) –A Tensor to be divided.
- **indices_or_sections** (*Union[int, tuple(int), list(int)]*) –If integer, *N*, the tensor will be divided into *N* equal tensors along axis. If tuple(int), list(int) or of sorted integers, the entries indicate where along axis the array is split. For example, $[2, 3]$ would, for $axis = 0$, result in three sub-tensors $x[: 2]$, $x[2 : 3]$ and $x[3 :]$. If an index exceeds the dimension of the array along axis, an empty sub-array is returned correspondingly.

Returns

A list of sub-tensors.

Raises

TypeError –If argument *indices_or_sections* is not integer.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> input_x = np.arange(6).reshape((2, 3)).astype('float32')
>>> output = np.hsplit(input_x, 3)
>>> print(output)
(Tensor(shape=[2, 1], dtype=Float32,
value=[[ 0.00000000e+00],
       [ 3.00000000e+00]]),
Tensor(shape=[2, 1], dtype=Float32,
value=[[ 1.00000000e+00],
       [ 4.00000000e+00]]),
Tensor(shape=[2, 1], dtype=Float32,
value=[[ 2.00000000e+00],
       [ 5.00000000e+00]]))
```

13.2.22 mindspore.numpy.hstack

mindspore.numpy.**hstack**(*tup*)

Stacks tensors in sequence horizontally. This is equivalent to concatenation along the second axis, except for 1-D tensors where it concatenates along the first axis.

Parameters

tup (*Union[Tensor, tuple, list]*) – A sequence of 1-D or 2-D tensors. The tensors must have the same shape along all but the second axis, except 1-D tensors which can be any length.

Returns

Stacked Tensor, formed by stacking the given tensors.

Supported Platforms:

`Ascend` `GPU` `CPU`

Raises

- **TypeError** – If *tup* is not Tensor, list or tuple.
- **ValueError** – If *tup* is empty.

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.array([1, 2, 3]).astype('float32')
>>> x2 = np.array([4, 5, 6]).astype('float32')
>>> output = np.hstack((x1, x2))
>>> print(output)
[1. 2. 3. 4. 5. 6.]
```

13.2.23 mindspore.numpy.intersect1d

mindspore.numpy.**intersect1d**(*ar1*, *ar2*, *assume_unique=False*, *return_indices=False*)

Find the intersection of two Tensors. Return the sorted, unique values that are in both of the input Tensors.

Parameters

- **ar1** (*Union[int, float, bool, list, tuple, Tensor]*) – Input tensor.
- **ar2** (*Union[int, float, bool, list, tuple, Tensor]*) – Input tensor.
- **assume_unique** (*bool*) – If *True*, the input Tensors are assumed to be unique, which can speed up the calculation. If *True* but *ar1* or *ar2* are not unique, incorrect results and out-of-bounds indices could result. Default: `False`.
- **return_indices** (*bool*) – If *True*, the indices which correspond to the intersection of two Tensors are returned. The first instance of a value is used if there are multiple. Default: `False`.

Returns

Tensor or tuple of Tensors. If *return_indices* is `False`, return the intersection tensor, otherwise return tuple of tensors.

Raises

- **TypeError** – If input *ar1* or *ar2* is not array_like.
- **TypeError** – If *assume_unique* or *return_indices* is not bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> np.intersect1d([1, 3, 4, 3], [3, 1, 2, 1])
Tensor(shape=[2], dtype=Int32, value=[1, 3])
```

13.2.24 mindspore.numpy.moveaxis

`mindspore.numpy.`**`moveaxis`**(*a*, *source*, *destination*)

Moves axes of an array to new positions.

Other axes remain in their original order.

Parameters

- **a** (`Tensor`) –The array whose axes should be reordered.
- **source** (*int, sequence of ints*) –Original positions of the axes to move. These must be unique.
- **destination** (*int, sequence of ints*) –Destination positions for each of the original axes. These must also be unique.

Returns

Tensor, array with moved axes.

Raises

ValueError –If axes are out of the range of `[-a.ndim, a.ndim)`, or if the axes contain duplicates.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.zeros((3, 4, 5))
>>> output = np.moveaxis(x, 0, -1)
>>> print(output.shape)
(4, 5, 3)
>>> output = np.moveaxis(x, -1, 0)
>>> print(output.shape)
(5, 3, 4)
>>> output = np.moveaxis(x, [0, 1, 2], [-1, -2, -3])
>>> print(output.shape)
(5, 4, 3)
```

13.2.25 mindspore.numpy.piecewise

mindspore.numpy.**piecewise**(*x*, *condlist*, *funclist*, **args*, ***kw*)

Evaluates a piecewise-defined function. Given a set of conditions and corresponding functions, evaluate each function on the input data wherever its condition is true.

Parameters

- **x** (*Union[int, float, bool, list, tuple, Tensor]*) –The input domain.
- **condlist** (*Union[bool, list[Tensor, bool]]*) –Each boolean array corresponds to a function in *funclist*. Wherever *condlist[i]* is True, *funclist[i](x)* is used as the output value. Each boolean array in *condlist* selects a piece of *x*, and should therefore be of the same shape as *x*. The length of *condlist* must correspond to that of *funclist*. If one extra function is given, i.e. if `len(funclist) == len(condlist) + 1`, then that extra function is the default value, used wherever all conditions are false.
- **funclist** (*Union[list[callables], list[scalars]]*) –Each function is evaluated over *x* wherever its corresponding condition is True. It should take a 1d array as input and give an 1d array or a scalar value as output. If, instead of a callable, a scalar is provided then a constant function `(lambda x: scalar)` is assumed.
- **args** (*any*) –Any further arguments given to *piecewise* are passed to the functions upon execution, i.e., if called `piecewise(..., ..., 1, 'a')`, then each function is called as `f(x, 1, 'a')`.
- **kw** (*any*) –Keyword arguments used in calling *piecewise* are passed to the functions upon execution, i.e., if called `piecewise(..., ..., alpha=1)`, then each function is called as `f(x, alpha=1)`.

Returns

Tensor, the output is the same shape and type as *x* and is found by calling the functions in *funclist* on the appropriate portions of *x*, as defined by the boolean arrays in *condlist*. Portions not covered by any condition have a default value of 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Raises

ValueError –If length of *funclist* is not in `(len(condlist), len(condlist) + 1)`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.linspace(-2.5, 2.5, 6)
>>> print(np.piecewise(x, [x < 0, x >= 0], [-1, 1]))
[-1 -1 -1  1  1  1]
```

13.2.26 mindspore.numpy.ravel

mindspore.numpy.**ravel**(*x*)

Returns a contiguous flattened tensor.

A 1-D tensor, containing the elements of the input, is returned.

Parameters

x (`Tensor`) –A tensor to be flattened.

Returns

Flattened tensor, has the same data type as the original tensor *x*.

Raises

TypeError – If *x* is not tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.ones((2,3,4))
>>> output = np.ravel(x)
>>> print(output.shape)
(24,)
```

13.2.27 mindspore.numpy.repeat

`mindspore.numpy.repeat`(*a*, *repeats*, *axis=None*)

Repeats elements of an array.

Parameters

- **a** (`Tensor`) – Input array.
- **repeats** (*int, sequence of ints*) – The number of repetitions for each element. *repeats* is broadcasted to fit the shape of the given axis.
- **axis** (*int, optional*) – The axis along which to repeat values. By default, use the flattened input array, and return a flat output array. Default: `None` .

Returns

Tensor, output array which has the same shape as *a*, except along the given axis.

Raises

- **ValueError** – If axis is out of range.
- **TypeError** – If input *a* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.repeat(np.array(3), 4)
>>> print(output)
[3 3 3 3]
>>> x = np.array([[1,2],[3,4]])
>>> output = np.repeat(x, 2)
>>> print(output)
[1 1 2 2 3 3 4 4]
```

(continues on next page)

(continued from previous page)

```
>>> output = np.repeat(x, 3, axis=1)
>>> print(output)
[[1 1 1 2 2 2]
[3 3 3 4 4 4]]
>>> output = np.repeat(x, [1, 2], axis=0)
>>> print(output)
[[1 2]
[3 4]
[3 4]]
```

13.2.28 mindspore.numpy.reshape

mindspore.numpy.**reshape**(*x*, *new_shape*)

Reshapes a tensor without changing its data.

Parameters

- **x** (Tensor) – A tensor to be reshaped.
- **new_shape** (*Union[int, list(int), tuple(int)]*) – The new shape should be compatible with the original shape. If the tuple has only one element, the result will be a 1-D tensor of that length. One shape dimension can be –1. In this case, the value is inferred from the length of the tensor and remaining dimensions.

Returns

Reshaped Tensor. Has the same data type as the original tensor *x*.

Raises

- **TypeError** – If new_shape is not integer, list or tuple, or *x* is not tensor.
- **ValueError** – If new_shape is not compatible with the original shape.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.asarray([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]])
>>> output = np.reshape(x, (3, 2))
>>> print(output)
[[-0.1  0.3]
 [ 3.6  0.4]
 [ 0.5 -3.2]]
>>> output = np.reshape(x, (3, -1))
>>> print(output)
[[-0.1  0.3]
 [ 3.6  0.4]
 [ 0.5 -3.2]]
>>> output = np.reshape(x, (6, ))
>>> print(output)
[-0.1  0.3  3.6  0.4  0.5 -3.2]
```

13.2.29 mindspore.numpy.roll

mindspore.numpy.**roll**(*a*, *shift*, *axis=None*)

Rolls a tensor along given axes.

Elements that rolls beyond the last position are re-introduced at the first.

Parameters

- **a** (Tensor) – Input tensor.
- **shift** (*Union[int, tuple(int)]*) – The number of places by which elements are shifted. If a tuple, then axis must be a tuple of the same size, and each of the given axes is shifted by the corresponding number. If shift is an int while axis is a tuple of integers, then the same value is used for all given axes.
- **axis** (*Union[int, tuple(int)], optional*) – Axis or axes along which elements are shifted. By default, the array is flattened before shifting, after which the original shape is restored. Default: None .

Returns

Tensor, with the same shape as a.

Supported Platforms:

Ascend GPU CPU

Raises

- **TypeError** – If input arguments have types not specified above.
- **ValueError** – If axis exceeds *a.ndim*, or *shift* and *axis* cannot broadcast.

Examples

```
>>> import mindspore.numpy as np
>>> a = np.reshape(np.arange(12), (3, 4))
>>> print(np.roll(a, [2,-3], [0,-1]))
    [[ 7  4  5  6]
     [11  8  9 10]
     [ 3  0  1  2]]
```

13.2.30 mindspore.numpy.rollaxis

mindspore.numpy.**rollaxis**(*x*, *axis*, *start=0*)

Rolls the specified axis backwards, until it lies in the given position. The positions of the other axes do not change relative to one another.

Parameters

- **x** (Tensor) – A Tensor to be transposed.
- **axis** (*int*) – The axis to be rolled.
- **start** (*int*) – Default: 0 . If *start* <= *axis*, the axis is rolled back until it lies in this position (*start*). If *start* > *axis*: the axis is rolled until it lies before this position (*start*). If *start* < 0, the start will be normalized as a non-negative number (more details can be seen in the source code.)

Returns

Transposed Tensor. Has the same data type as the original tensor *x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Raises

- **TypeError** –If *axis* or *start* is not integer, or *x* is not tensor.
- **ValueError** –If *axis* is not in the range of $[-ndim, ndim-1]$ or *start* is not in the range of $[-ndim, ndim]$.

Examples

```
>>> import mindspore.numpy as np
>>> x = np.ones((2,3,4))
>>> output = np.rollaxis(x, 0, 2)
>>> print(output.shape)
(3, 2, 4)
```

13.2.31 mindspore.numpy.rot90

mindspore.numpy.**rot90**(*a*, *k=1*, *axes=(0, 1)*)

Rotates a tensor by 90 degrees in the plane specified by axes. Rotation direction is from the first towards the second axis.

Parameters

- **a** (`Tensor`) –Input tensor of two or more dimensions.
- **k** (*int*) –Number of times the tensor is rotated by 90 degrees. Default: `1` .
- **axes** (*Union[tuple(int), list(int)], optional*) –The tensor is rotated in the plane defined by the axes. Default: `(0, 1)` . Axes must be different and with the shape of *(2,)*.

Returns

Tensor.

Raises

- **TypeError** –If input *a* is not a Tensor or the argument *k* is not integer or the argument *axes* is not tuple of integers or list of ints.
- **ValueError** –If any axis is out of range or the length of *axes* is not *2*.

Supported Platforms:

`GPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.arange(24).reshape((2, 3, 4))
>>> output = np.rot90(a)
>>> print(output)
[[[ 8  9 10 11]
  [20 21 22 23]]
 [[ 4  5  6  7]
  [16 17 18 19]]
```

(continues on next page)

(continued from previous page)

```
 [[ 0  1  2  3]
  [12 13 14 15]]]
>>> output = np.rot90(a, 3, (1, 2))
>>> print(output)
[[[ 8  4  0]
  [ 9  5  1]
  [10  6  2]
  [11  7  3]]
 [[20 16 12]
  [21 17 13]
  [22 18 14]
  [23 19 15]]]
```

13.2.32 mindspore.numpy.select

mindspore.numpy.**select**(*condlist*, *choicelist*, *default=0*)

Returns an array drawn from elements in *choicelist*, depending on conditions.

Parameters

- **condlist** (*Union[int, float, bool, list, tuple, Tensor]*) – The list of conditions which determine from which array in *choicelist* the output elements are taken. When multiple conditions are satisfied, the first one encountered in *condlist* is used.
- **choicelist** (*Union[int, float, bool, list, tuple, Tensor]*) – The list of arrays from which the output elements are taken. It has to be of the same length as *condlist*.
- **default** (*scalar, optional*) – The element inserted in output when all conditions evaluate to *False*. Default: 0 .

Returns

Tensor, the output at position *m* is the *m-th* element of the array in *choicelist* where the *m-th* element of the corresponding array in *condlist* is *True*.

Raises

ValueError – If len(condlist) != len(choicelist).

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> condlist = [[True, True, True, False, False], [False, False, True, False, True]]
>>> choicelist = [[0, 1, 2, 3, 4], [0, 1, 4, 9, 16]]
>>> output = np.select(condlist, choicelist)
>>> print(output)
[ 0  1  2  0 16]
```

13.2.33 mindspore.numpy.setdiff1d

mindspore.numpy.**setdiff1d**(*ar1*, *ar2*, *assume_unique=False*)

Find the set difference of two Tensors. Return the unique values in *ar1* that are not in *ar2*.

Parameters

- **ar1** (*Union[int, float, bool, list, tuple, Tensor]*) –Input tensor.
- **ar2** (*Union[int, float, bool, list, tuple, Tensor]*) –Input tensor.
- **assume_unique** (*bool, optional*) –If *True*, the input Tensors are assumed to be unique, which can speed up the calculation. If *True* but *ar1* or *ar2* are not unique, incorrect results and out-of-bounds indices could result. Default: `False`.

Returns

1D Tensor of values in *ar1* that are not in *ar2*. The result is sorted when *assume_unique* = `False` , but otherwise only sorted if the input is sorted.

Raises

- **TypeError** –If input *ar1* or *ar2* is not array_like.
- **TypeError** –If *assume_unique* is not bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([1, 2, 3, 2, 4, 1])
>>> b = np.array([3, 4, 5, 6])
>>> np.setdiff1d(a, b)
Tensor(shape=[2], dtype=Int32, value=[1, 2])
```

13.2.34 mindspore.numpy.size

mindspore.numpy.**size**(*a*, *axis=None*)

Returns the number of elements along a given axis.

Parameters

- **a** (*Union[int, float, bool, list, tuple, Tensor]*) –Input data.
- **axis** (*int, optional*) –Axis along which the elements are counted. Default: `None`. If None, give the total number of elements.

Returns

Number of elements along the specified axis.

Supported Platforms:

`Ascend` `GPU` `CPU`

Raises

- **TypeError** –If input is not array_like or *axis* is not int.
- **ValueError** –If any axis is out of range or duplicate axes exist.

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(10).reshape(2, 5).astype('float32')
>>> print(np.size(x))
10
>>> print(np.size(x, axis=1))
5
```

13.2.35 mindspore.numpy.split

mindspore.numpy.**split**(*x*, *indices_or_sections*, *axis=0*)

Splits a tensor into multiple sub-tensors along the given axis.

Parameters

- **x** (Tensor) –A Tensor to be divided.
- **indices_or_sections** (*Union[int, tuple(int), list(int)]*) –If integer, N, the tensor will be divided into N equal tensors along axis. If tuple(int), list(int) or of sorted integers, the entries indicate where along axis the array is split. For example, $[2, 3]$ would, for $axis = 0$, result in three sub-tensors $x[: 2]$, $x[2 : 3]$ and $x[3 :]$. If an index exceeds the dimension of the array along axis, an empty sub-array is returned correspondingly.
- **axis** (*int, optional*) –The axis along which to split. Default: 0 .

Returns

A tuple of sub-tensors.

Raises

- **TypeError** –If argument *indices_or_sections* is not integer, tuple(int) or list(int) or argument *axis* is not integer.
- **ValueError** –If argument *axis* is out of range of $[-x.ndim, x.ndim)$.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> input_x = np.arange(9).astype("float32")
>>> output = np.split(input_x, 3)
>>> print(output)
(Tensor(shape=[3], dtype=Float32,
  value= [ 0.00000000e+00,  1.00000000e+00,  2.00000000e+00]),
 Tensor(shape=[3], dtype=Float32,
  value= [ 3.00000000e+00,  4.00000000e+00,  5.00000000e+00]),
 Tensor(shape=[3], dtype=Float32,
  value= [ 6.00000000e+00,  7.00000000e+00,  8.00000000e+00]))
```

13.2.36 mindspore.numpy.squeeze

mindspore.numpy.**squeeze**(*a*, *axis=None*)

Return the Tensor after deleting the dimension of size 1 in the specified *axis*.

If *axis* = *None*, it will remove all the dimensions of size 1. If *axis* is specified, it will remove the dimensions of size 1 in the given *axis*. For example, if the dimension is not specified *axis* = *None*, input shape is (A, 1, B, C, 1, D), then the shape of the output Tensor is (A, B, C, D). If the dimension is specified, the squeeze operation is only performed in the specified dimension. If input shape is (A, 1, B), when *axis* = 0 or *axis* = 2, the input tensor is not changed, while when *axis* = 1, the input tensor shape is changed to (A, B).

Parameters

- **a** (Tensor) –Input tensor array.
- **axis** (*Union[None, int, list(int), tuple(list)], optional*) –The axis(axes) to squeeze, default: None .

Returns

Tensor, with all or a subset of the dimensions of length 1 removed.

Raises

- **TypeError** –If input arguments have types not specified above.
- **ValueError** –If specified axis has shape entry > 1.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.ones((1,2,2,1))
>>> x = np.squeeze(x)
>>> print(x.shape)
(2, 2)
```

13.2.37 mindspore.numpy.stack

mindspore.numpy.**stack**(*arrays*, *axis=0*)

Joins a sequence of arrays along a new axis.

The *axis* parameter specifies the index of the new axis in the dimensions of the result. For example, if axis=0 it will be the first dimension and if axis=-1 it will be the last dimension.

Note: Numpy argument out is not supported.

Parameters

- **arrays** (*sequence of Tensor*) –Each array must have the same shape.
- **axis** (*int, optional*) –The axis in the result array along which the input arrays are stacked. Default: 0 .

Returns

Tensor, The stacked array has one more dimension than the input arrays.

Raises

ValueError –If input is not Tensor, tuple, or list.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> arrays = [np.ones((3, 4)) for _ in range(10)]
>>> output = np.stack(arrays, axis=0)
>>> print(output.shape)
(10, 3, 4)
>>> output = np.stack(arrays, axis=1)
>>> print(output.shape)
(3, 10, 4)
>>> output = np.stack(arrays, axis=2)
>>> print(output.shape)
(3, 4, 10)
```

13.2.38 mindspore.numpy.swapaxes

mindspore.numpy.**swapaxes**(*x*, *axis1*, *axis2*)

Interchanges two axes of a tensor.

Parameters

- **x** (Tensor) –A tensor to be transposed.
- **axis1** (*int*) –First axis.
- **axis2** (*int*) –Second axis.

Returns

Transposed tensor, has the same data type as the original tensor *x*.

Raises

- **TypeError** –If *axis1* or *axis2* is not integer, or *x* is not tensor.
- **ValueError** –If *axis1* or *axis2* is not in the range of $[-ndim, ndim - 1]$.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.ones((2,3,4))
>>> output = np.swapaxes(x, 0, 2)
>>> print(output.shape)
(4,3,2)
```

13.2.39 mindspore.numpy.take

mindspore.numpy.**take**(*a*, *indices*, *axis=None*, *mode='clip'*)

Takes elements from an array along an axis.

When axis is not None, this function does the same thing as "fancy" indexing (indexing arrays using arrays); however, it can be easier to use if you need elements along a given axis. A call such as `np.take(arr, indices, axis=3)` is equivalent to `arr[:,:,:,indices,...]`.

Note: Numpy argument out is not supported. `mode = 'raise'` is not supported, and the default mode is 'clip' instead.

Parameters

- **a** (Tensor) –Source array with shape *(Ni…, M, Nk…)*.
- **indices** (Tensor) –The indices with shape *(Nj…)* of the values to extract.
- **axis** (*int, optional*) –The axis over which to select values. By default, the flattened input array is used. Default: `None` .
- **mode** (*'raise', 'wrap', 'clip', optional*) –Specifies how out-of-bounds indices will behave. Default: `'clip'` .

  'raise' - raise an error;

  'wrap' - wrap around;

  'clip' - clip to the range. 'clip' mode means that all indices that are too large are replaced by the index that addresses the last element along that axis. Note that this disables indexing with negative numbers.

Returns

Tensor, the indexed result.

Raises

- **ValueError** –If axis is out of range.
- **TypeError** –If the input is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([4, 3, 5, 7, 6, 8])
>>> indices = np.array([0, 1, 4])
>>> output = np.take(a, indices)
>>> print(output)
[4 3 6]
>>> indices = np.array([[0, 1], [2, 3]])
>>> output = np.take(a, indices)
>>> print(output)
[[4 3]
[5 7]]
```

13.2.40 mindspore.numpy.take_along_axis

mindspore.numpy.**take_along_axis**(*arr*, *indices*, *axis*)

Takes values from the input array by matching 1d index and data slices.

This iterates over matching 1d slices oriented along the specified axis in the index and data arrays, and uses the former to look up values in the latter. These slices can be different lengths.

Parameters

- **arr** (Tensor) –Source array with shape *(Ni…, M, Nk…)*.
- **indices** (Tensor) –Indices with shape *(Ni…, J, Nk…)* to take along each 1d slice of *arr*. This must match the dimension of *arr*, but dimensions *Ni* and *Nj* only need to broadcast against *arr*.
- **axis** (*int*) –The axis to take 1d slices along. If *axis* is None, the input array is treated as if it had first been flattened to 1d.

Returns

Tensor, the indexed result, with shape *(Ni…, J, Nk…)*.

Raises

- **ValueError** –If input array and indices have different number of dimensions.
- **TypeError** –If the input is not a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(12).reshape(3, 4)
>>> indices = np.arange(3).reshape(1, 3)
>>> output = np.take_along_axis(x, indices, 1)
>>> print(output)
[[ 0  1  2]
 [ 4  5  6]
 [ 8  9 10]]
```

13.2.41 mindspore.numpy.tile

mindspore.numpy.**tile**(*a*, *reps*)

Constructs an array by repeating *a* the number of times given by *reps*.

If *reps* has length *d*, the result will have dimension of `max(d, a.ndim)`. If `a.ndim < d`, *a* is promoted to be d-dimensional by prepending new axes. So a shape (3,) array is promoted to (1, 3) for 2-D replication, or shape (1, 1, 3) for 3-D replication. If this is not the desired behavior, promote *a* to d-dimensions manually before calling this function. If `a.ndim > d`, *reps* is promoted to `a.ndim` by pre-pending 1's to it. Thus for an *a* of shape (2, 3, 4, 5), a *reps* of (2, 2) is treated as (1, 1, 2, 2).

Parameters

- **a** (Tensor) – The input array.
- **reps** (*int, sequence of ints*) – The number of repetitions of *a* along each axis.

Returns

Tensor, the tiled output array.

Raises

TypeError – If the input is not a tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([0, 1, 2])
>>> output = np.tile(a, 2)
>>> print(output)
[0 1 2 0 1 2]
>>> output = np.tile(a, (2, 2))
>>> print(output)
[[0 1 2 0 1 2]
[0 1 2 0 1 2]]
>>> output = np.tile(a, (2, 1, 2))
>>> print(output)
[[[0 1 2 0 1 2]]
[[0 1 2 0 1 2]]]
```

13.2.42 mindspore.numpy.transpose

mindspore.numpy.**transpose**(*a*, *axes=None*)

Reverses or permutes the axes of a tensor; returns the modified tensor.

Parameters

- **a** (Tensor) – a tensor to be transposed
- **axes** (*Union[None, tuple, list], optional*) – the axes order, if *axes* is *None*, transpose the entire tensor. Default: `None` .

Returns

Tensor, the transposed tensor array.

Raises

- **TypeError** –If input arguments have types not specified above.
- **ValueError** –If the number of *axes* is not equal to a.ndim.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.ones((1,2,3))
>>> x = np.transpose(x)
>>> print(x.shape)
(3, 2, 1)
```

13.2.43 mindspore.numpy.unique

`mindspore.numpy.`**unique**(*x*, *return_inverse=False*)

Finds the unique elements of a tensor. The input tensor will be flattened first when it has more than one dimension.

Note: Numpy arguments *axis*, *return_index* and *return_counts* are not supported. On CPU, this operator must be executed in graph mode.

Parameters

- **x** (`Tensor`) –The input tensor to be processed.
- **return_inverse** (*bool, optional*) –If *True*, also return the indices of the unique tensor. Default: `False` .

Returns

Tensor or tuple of Tensors. If *return_inverse* is *False*, return the unique tensor, otherwise return tuple of tensors.

Supported Platforms:

`Ascend` `GPU` `CPU`

Raises

TypeError –If *x* is not tensor.

Examples

```
>>> import mindspore.numpy as np
>>> import mindspore as ms
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> input_x = np.asarray([1, 2, 2, 2, 3, 4, 5]).astype('int32')
>>> output_x = np.unique(input_x)
>>> print(output_x)
[1 2 3 4 5]
```

(continues on next page)

(continued from previous page)

```
>>> output_x = np.unique(input_x, return_inverse=True)
>>> print(output_x)
(Tensor(shape=[5], dtype=Int32, value= [ 1, 2, 3, 4, 5]), Tensor(shape=[7], dtype=Int32,
    value= [0, 1, 1, 1, 2, 3, 4]))
```

13.2.44 mindspore.numpy.unravel_index

mindspore.numpy.**unravel_index**(*indices*, *shape*, *order='C'*)

Converts a flat index or array of flat indices into a tuple of coordinate arrays.

Note: Out-of-bound indices are clipped by the boundaries of *shape* instead of raising an error.

Parameters

- **indices** (*Union[int, float, bool, list, tuple, Tensor]*) – An integer array whose elements are indices into the flattened version of an array of dimensions shape.
- **shape** (*tuple(int)*) – The shape of the array to use for unraveling indices.
- **order** (*Union['C', 'F'], optional*) – Determines whether the indices should be viewed as indexing in row-major (C-style) or column-major (Fortran-style) order. Default: `'C'` .

Returns

Tensor, each array in the tuple has the same shape as the indices array.

Supported Platforms:

`Ascend` `GPU` `CPU`

Raises

ValueError – If *order* is not 'C' or 'F'.

Examples

```
>>> import mindspore.numpy as np
>>> print(np.unravel_index([22, 41, 37], (7,6)))
(Tensor(shape=[3], dtype=Int32, value= [3, 6, 6]),
Tensor(shape=[3], dtype=Int32, value= [4, 5, 1]))
>>> print(np.unravel_index([31, 41, 13], (7,6), order='F'))
(Tensor(shape=[3], dtype=Int32, value= [3, 6, 6]),
Tensor(shape=[3], dtype=Int32, value= [4, 5, 1]))
```

13.2.45 mindspore.numpy.vsplit

mindspore.numpy.**vsplit**(*x*, *indices_or_sections*)

Splits a tensor into multiple sub-tensors vertically (row-wise). It is equivalent to split with $axis = 0$ (default), the array is always split along the first axis regardless of the array dimension.

Parameters

- **x** (Tensor) – A Tensor to be divided.
- **indices_or_sections** (*Union[int, tuple(int), list(int)]*) – If integer, *N*, the tensor will be divided into *N* equal tensors along axis. If tuple(int), list(int) or of sorted integers, the entries indicate where along axis the array is split. For example, $[2, 3]$ would, for $axis = 0$, result in three sub-tensors $x[: 2]$, $x[2 : 3]$ and $x[3 :]$. If an index exceeds the dimension of the array along axis, an empty sub-array is returned correspondingly.

Returns

A list of sub-tensors.

Raises

TypeError – If argument *indices_or_sections* is not integer.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> input_x = np.arange(9).reshape((3, 3)).astype('float32')
>>> output = np.vsplit(input_x, 3)
>>> print(output)
(Tensor(shape=[1, 3], dtype=Float32,
  value=[[ 0.00000000e+00,  1.00000000e+00,  2.00000000e+00]]),
 Tensor(shape=[1, 3], dtype=Float32,
  value=[[ 3.00000000e+00,  4.00000000e+00,  5.00000000e+00]]),
 Tensor(shape=[1, 3], dtype=Float32,
  value=[[ 6.00000000e+00,  7.00000000e+00,  8.00000000e+00]]))
```

13.2.46 mindspore.numpy.vstack

mindspore.numpy.**vstack**(*tup*)

Stacks tensors in sequence vertically. This is equivalent to concatenation along the first axis. 1-D tensors should firstly be reshaped to *(1, N)*, and then be concatenated along the first axis.

Parameters

tup (*Union[Tensor, tuple, list]*) – A sequence of 1-D or 2-D tensors. The tensors must have the same shape along all but the first axis. 1-D tensors must have the same shape.

Returns

Stacked Tensor, formed by stacking the given tensors.

Supported Platforms:

Ascend GPU CPU

Raises

- **TypeError** –If *tup* is not Tensor, list or tuple.
- **ValueError** –If *tup* is empty.

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.array([1, 2, 3]).astype('int32')
>>> x2 = np.array([4, 5, 6]).astype('int32')
>>> output = np.vstack((x1, x2))
>>> print(output)
[[1 2 3]
 [4 5 6]]
```

13.2.47 mindspore.numpy.where

mindspore.numpy.**where**(*condition*, *x=None*, *y=None*)

Returns elements chosen from *x* or *y* depending on *condition*.

Note: As nonzero is not supported, both *x* and *y* must be provided Tensor input.

Parameters

- **condition** (Tensor) –where True, yield *x*, otherwise yield *y*.
- **x** (Tensor, *optional*) –Values from which to choose. Default: None .
- **y** (Tensor, *optional*) –Values from which to choose. *x*, *y* and *condition* need to be broadcastable to some shape. Default: None .

Returns

Tensor or scalar, with elements from *x* where *condition* is True, and elements from *y* elsewhere.

Raises

ValueError –If operands cannot be broadcast.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> condition = np.full((1, 1, 2), [False, True])
>>> x = np.full((1, 3, 2), 5)
>>> y = np.full((2, 1, 1), 7)
>>> output = np.where(condition, x, y)
>>> print(output)
[[[7 5]
[7 5]
```

13.3 Logic

Logic operations define computations related with boolean types. Examples of *equal* and *less* operations are as follows:

```
input_x = np.arange(0, 5)
input_y = np.arange(0, 10, 2)
output = np.equal(input_x, input_y)
print("output of equal:", output)
output = np.less(input_x, input_y)
print("output of less:", output)
```

The result is as follows:

```
output of equal: [ True False False False False]
output of less: [False  True  True  True  True]
```

API Name	Description	Supported Platforms
mindspore.numpy.array_equal	Returns *True* if input arrays have same shapes and all elements equal.	GPU CPU Ascend
mindspore.numpy.array_equiv	Returns *True* if input arrays are shape consistent and all elements equal.	Ascend GPU CPU
mindspore.numpy.equal	Returns the truth value of `(x1 == x2)` element-wise.	Ascend GPU CPU
mindspore.numpy.greater	Returns the truth value of `(x1 > x2)` element-wise.	Ascend GPU CPU
mindspore.numpy.greater_equal	Returns the truth value of `(x1 >= x2)` element-wise.	Ascend GPU CPU
mindspore.numpy.in1d	Tests whether each element of a 1-D array is also present in a second array.	Ascend GPU CPU
mindspore.numpy.isclose	Returns a boolean tensor where two tensors are element-wise equal within a tolerance.	Ascend GPU CPU
mindspore.numpy.isfinite	Tests element-wise for finiteness (not infinity or not Not a Number).	Ascend GPU CPU
mindspore.numpy.isin	Calculates element in *test_elements*, broadcasting over *element* only.	Ascend GPU CPU
mindspore.numpy.isinf	Tests element-wise for positive or negative infinity.	GPU CPU
mindspore.numpy.isnan	Tests element-wise for NaN and return result as a boolean array.	GPU CPU
mindspore.numpy.isneginf	Tests element-wise for negative infinity, returns result as bool array.	GPU CPU
mindspore.numpy.isposinf	Tests element-wise for positive infinity, returns result as bool array.	GPU CPU
mindspore.numpy.isscalar	Returns True if the type of element is a scalar type.	Ascend GPU CPU
mindspore.numpy.less	Returns the truth value of `(x1 < x2)` element-wise.	Ascend GPU CPU

continues on next page

Table 3 – continued from previous page

mindspore.numpy.less_equal	Returns the truth value of `(x1 <= x2)` element-wise.	`Ascend` `GPU` `CPU`
mindspore.numpy.logical_and	Computes the truth value of *x1* AND *x2* element-wise.	`Ascend` `GPU` `CPU`
mindspore.numpy.logical_not	Computes the truth value of NOT *a* element-wise.	`Ascend` `GPU` `CPU`
mindspore.numpy.logical_or	Computes the truth value of *x1* OR *x2* element-wise.	`Ascend` `GPU` `CPU`
mindspore.numpy.logical_xor	Computes the truth value of *x1* XOR *x2*, element-wise.	`Ascend` `GPU` `CPU`
mindspore.numpy.not_equal	Returns (x1 != x2) element-wise.	`Ascend` `GPU` `CPU`
mindspore.numpy.signbit	Returns element-wise True where signbit is set (less than zero).	`Ascend` `GPU` `CPU`
mindspore.numpy.sometrue	Tests whether any array element along a given axis evaluates to True.	`Ascend` `GPU` `CPU`

13.3.1 mindspore.numpy.array_equal

`mindspore.numpy.`**`array_equal`**(*a1*, *a2*, *equal_nan=False*)

Returns *True* if input arrays have same shapes and all elements equal.

Note: In mindspore, a bool tensor is returned instead, since in Graph mode, the value cannot be traced and computed at compile time.

Since on Ascend, `nan` is treated differently, currently the argument `equal_nan` is not supported on Ascend.

Parameters

- **a1/a2** (*Union[int, float, bool, list, tuple, Tensor]*) – Input arrays.
- **equal_nan** (*bool, optional*) – Whether to compare NaN's as equal. Default: `False` .

Returns

Scalar bool tensor, value is *True* if inputs are equal, *False* otherwise.

Raises

TypeError – If inputs have types not specified above.

Supported Platforms:

`GPU` `CPU` `Ascend`

Examples

```
>>> import mindspore.numpy as np
>>> a = [0,1,2]
>>> b = [[0,1,2], [0,1,2]]
>>> print(np.array_equal(a,b))
False
```

13.3.2 mindspore.numpy.array_equiv

mindspore.numpy.**array_equiv**(*a1*, *a2*)

Returns *True* if input arrays are shape consistent and all elements equal.

Shape consistent means they are either the same shape, or one input array can be broadcasted to create the same shape as the other one.

Note: In mindspore, a bool tensor is returned instead, since in Graph mode, the value cannot be traced and computed at compile time.

Parameters

a1/a2 (*Union[int, float, bool, list, tuple, Tensor]*) –Input arrays.

Returns

Scalar bool tensor, value is *True* if inputs are equivalent, *False* otherwise.

Raises

TypeError –If inputs have types not specified above.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = [0,1,2]
>>> b = [[0,1,2], [0,1,2]]
>>> print(np.array_equiv(a,b))
True
```

13.3.3 mindspore.numpy.equal

mindspore.numpy.**equal**(*x1*, *x2*, *dtype=None*)

Returns the truth value of `(x1 == x2)` element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (`Tensor`) –Input array.
- **x2** (`Tensor`) –Input array. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, element-wise comparison of *x1* and *x2*. Typically of type bool, unless *dtype* is passed. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.equal(np.array([0, 1, 3]), np.arange(3))
>>> print(output)
[ True  True False]
```

13.3.4 mindspore.numpy.greater

`mindspore.numpy.`**`greater`**(*x1*, *x2*, *dtype=None*)

Returns the truth value of `(x1 > x2)` element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (`Tensor`) –Input array.
- **x2** (`Tensor`) –Input array. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*`mindspore.dtype`*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, element-wise comparison of *x1* and *x2*. Typically of type bool, unless *dtype* is passed. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.greater(np.array([4, 2]), np.array([2, 2]))
>>> print(output)
[ True False]
```

13.3.5 mindspore.numpy.greater_equal

mindspore.numpy.**greater_equal**(*x1*, *x2*, *dtype=None*)

Returns the truth value of `(x1 >= x2)` element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) −Input array.
- **x2** (Tensor) −Input array. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) −Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, element-wise comparison of *x1* and *x2*. Typically of type bool, unless *dtype* is passed. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.greater_equal(np.array([4, 2, 1]), np.array([2, 2, 2]))
>>> print(output)
[ True  True False]
```

13.3.6 mindspore.numpy.in1d

mindspore.numpy.**in1d**(*ar1*, *ar2*, *invert=False*)

Tests whether each element of a 1-D array is also present in a second array.

Returns a boolean array the same length as *ar1* that is True where an element of *ar1* is in *ar2* and False otherwise.

Note: Numpy argument *assume_unique* is not supported since the implementation does not rely on the uniqueness of the input arrays.

Parameters

- **ar1** (*Union[int, float, bool, list, tuple, Tensor]*) −Input array with shape *(M,)*.
- **ar2** (*Union[int, float, bool, list, tuple, Tensor]*) −The values against which to test each value of *ar1*.
- **invert** (*boolean, optional*) −If True, the values in the returned array are inverted (that is, False where an element of *ar1* is in *ar2* and True otherwise). Default: `False` .

Returns

Tensor, with shape *(M,)*. The values `ar1[in1d]` are in *ar2*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> test = np.array([0, 1, 2, 5, 0])
>>> states = [0, 2]
>>> mask = np.in1d(test, states)
>>> print(mask)
[ True False  True False  True]
>>> mask = np.in1d(test, states, invert=True)
>>> print(mask)
[False  True False  True False]
```

13.3.7 mindspore.numpy.isclose

`mindspore.numpy.`**`isclose`**(*a*, *b*, *rtol=1e-05*, *atol=1e-08*, *equal_nan=False*)

Returns a boolean tensor where two tensors are element-wise equal within a tolerance.

The tolerance values are positive, typically very small numbers. The relative difference ($rtol * abs(b)$) and the absolute difference *atol* are added together to compare against the absolute difference between *a* and *b*.

Note: For finite values, isclose uses the following equation to test whether two floating point values are equivalent. $absolute(a - b)$ <= $(atol + rtol * absolute(b))$ On Ascend, input arrays containing inf or NaN are not supported.

Parameters

- **a** (*Union[Tensor, list, tuple]*) – Input first tensor to compare.
- **b** (*Union[Tensor, list, tuple]*) – Input second tensor to compare.
- **rtol** (*numbers.Number, optional*) – The relative tolerance parameter (see Note). Default: `1e-05` .
- **atol** (*numbers.Number, optional*) – The absolute tolerance parameter (see Note). Default: `1e-08` .
- **equal_nan** (*bool, optional*) – Whether to compare `NaN` as equal. If True, `NaN` in *a* will be considered equal to `NaN` in *b* in the output tensor. Default: `False` .

Returns

A `bool` tensor of where *a* and *b* are equal within the given tolerance.

Raises

`TypeError` – If inputs have types not specified above.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([0,1,2,float('inf'),float('inf'),float('nan')])
>>> b = np.array([0,1,-2,float('-inf'),float('inf'),float('nan')])
>>> print(np.isclose(a, b))
[ True  True False False  True False]
>>> print(np.isclose(a, b, equal_nan=True))
[ True  True False False  True  True]
```

13.3.8 mindspore.numpy.isfinite

mindspore.numpy.**isfinite**(*x*, *dtype=None*)

Tests element-wise for finiteness (not infinity or not Not a Number).

The result is returned as a boolean array.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On GPU, the supported dtypes are np.float16, and np.float32.

Parameters

- **x** (Tensor) – Input values.
- **dtype** (*mindspore.dtype*, optional) – Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, true where *x* is not positive infinity, negative infinity, or NaN; false otherwise. This is a scalar if *x* is a scalar.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.isfinite(np.array([np.inf, 1., np.nan]).astype('float32'))
>>> print(output)
[False  True False]
```

13.3.9 mindspore.numpy.isin

mindspore.numpy.**isin**(*element*, *test_elements*, *invert=False*)

Calculates element in *test_elements*, broadcasting over *element* only. Returns a boolean array of the same shape as *element* that is True where an element of *element* is in *test_elements* and False otherwise.

Note: Numpy argument *assume_unique* is not supported since the implementation does not rely on the uniqueness of the input arrays.

Parameters

- **element** (*Union[int, float, bool, list, tuple, Tensor]*) –Input array.
- **test_elements** (*Union[int, float, bool, list, tuple, Tensor]*) –The values against which to test each value of *element*.
- **invert** (*boolean, optional*) –If True, the values in the returned array are inverted, as if calculating *element* not in *test_elements*. Default: `False` .

Returns

Tensor, has the same shape as *element*. The values `element[isin]` are in *test_elements*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> element = 2*np.arange(4).reshape((2, 2))
>>> test_elements = [1, 2, 4, 8]
>>> mask = np.isin(element, test_elements)
>>> print(mask)
[[False  True]
 [ True False]]
>>> mask = np.isin(element, test_elements, invert=True)
>>> print(mask)
[[ True False]
 [False  True]]
```

13.3.10 mindspore.numpy.isinf

`mindspore.numpy.`**`isinf`**(*x*, *dtype=None*)

Tests element-wise for positive or negative infinity.

Returns a boolean array of the same shape as *x*, True where `x == +/-inf`, otherwise False.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. Only np.float32 is currently supported.

Parameters

- **x** (`Tensor`) –Input values.
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, true where *x* is positive or negative infinity, false otherwise. This is a scalar if *x* is a scalar.

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.isinf(np.array(np.inf, np.float32))
>>> print(output)
True
>>> output = np.isinf(np.array([np.inf, -np.inf, 1.0, np.nan], np.float32))
>>> print(output)
[ True  True False False]
```

13.3.11 mindspore.numpy.isnan

mindspore.numpy.**isnan**(*x*, *dtype=None*)

Tests element-wise for NaN and return result as a boolean array.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. Only np.float32 is currently supported.

Parameters

- **x** (Tensor) –Input values.
- **dtype** (*mindspore.dtype*, optional) –Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, true where *x* is NaN, false otherwise. This is a scalar if *x* is a scalar.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.isnan(np.array(np.nan, np.float32))
>>> print(output)
True
>>> output = np.isnan(np.array(np.inf, np.float32))
>>> print(output)
False
```

13.3.12 mindspore.numpy.isneginf

mindspore.numpy.**isneginf**(*x*)

Tests element-wise for negative infinity, returns result as bool array.

Note: Numpy argument *out* is not supported. Only np.float32 is currently supported.

Parameters

x (Tensor) –Input values.

Returns

Tensor or scalar, true where *x* is negative infinity, false otherwise. This is a scalar if *x* is a scalar.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.isneginf(np.array([-np.inf, 0., np.inf, np.nan], np.float32))
>>> print(output)
[ True False False False]
```

13.3.13 mindspore.numpy.isposinf

mindspore.numpy.**isposinf**(*x*)

Tests element-wise for positive infinity, returns result as bool array.

Note: Numpy argument *out* is not supported. Only np.float32 is currently supported.

Parameters

x (Tensor) –Input values.

Returns

Tensor or scalar, true where *x* is positive infinity, false otherwise. This is a scalar if *x* is a scalar.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.isposinf(np.array([-np.inf, 0., np.inf, np.nan], np.float32))
>>> print(output)
[False False  True False]
```

13.3.14 mindspore.numpy.isscalar

mindspore.numpy.**isscalar**(*element*)

Returns True if the type of element is a scalar type.

Note: Only object types recognized by the mindspore parser are supported, which includes objects, types, methods and functions defined within the scope of mindspore. Other built-in types are not supported.

Parameters

element (*any*) –Input argument, can be of any type and shape.

Returns

Boolean, True if *element* is a scalar type, False if it is not.

Raises

TypeError –If the type of *element* is not supported by mindspore parser.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.isscalar(3.1)
>>> print(output)
True
>>> output = np.isscalar(np.array(3.1))
>>> print(output)
False
>>> output = np.isscalar(False)
>>> print(output)
True
>>> output = np.isscalar('numpy')
>>> print(output)
True
```

13.3.15 mindspore.numpy.less

mindspore.numpy.**less**(*x1*, *x2*, *dtype=None*)

Returns the truth value of `(x1 < x2)` element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) –input array.
- **x2** (Tensor) –Input array. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).

- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, element-wise comparison of *x1* and *x2*. Typically of type bool, unless *dtype* is passed. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.less(np.array([1, 2]), np.array([2, 2]))
>>> print(output)
[ True False]
```

13.3.16 mindspore.numpy.less_equal

`mindspore.numpy.`**`less_equal`**(*x1*, *x2*, *dtype=None*)

Returns the truth value of `(x1 <= x2)` element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (`Tensor`) –Input array.
- **x2** (`Tensor`) –Input array. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, element-wise comparison of *x1* and *x2*. Typically of type bool, unless *dtype* is passed. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.less_equal(np.array([4, 2, 1]), np.array([2, 2, 2]))
>>> print(output)
[False  True  True]
```

13.3.17 mindspore.numpy.logical_and

mindspore.numpy.**logical_and**(*x1*, *x2*, *dtype=None*)

Computes the truth value of *x1* AND *x2* element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) – Input tensor.
- **x2** (Tensor) – Input tensor. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. Boolean result of the logical AND operation applied to the elements of *x1* and *x2*; the shape is determined by broadcasting. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.array([True, False])
>>> x2 = np.array([False, False])
>>> output = np.logical_and(x1, x2)
>>> print(output)
[False False]
```

13.3.18 mindspore.numpy.logical_not

mindspore.numpy.**logical_not**(*a*, *dtype=None*)

Computes the truth value of NOT *a* element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **a** (Tensor) – The input tensor whose dtype is bool.
- **dtype** (*mindspore.dtype*, optional) – Default: `None`. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. Boolean result with the same shape as *a* of the NOT operation on elements of *a*. This is a scalar if *a* is a scalar.

Raises

TypeError – If the input is not a tensor or its dtype is not bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([True, False])
>>> output = np.logical_not(a)
>>> print(output)
[False  True]
```

13.3.19 mindspore.numpy.logical_or

`mindspore.numpy.`**`logical_or`**(*x1*, *x2*, *dtype=None*)

Computes the truth value of *x1* OR *x2* element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (`Tensor`) – Input tensor.
- **x2** (`Tensor`) – Input tensor. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, logical OR operation of *x1* and *x2*. Typically of type bool, unless `dtype=object` is passed. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.array([True, False])
>>> x2 = np.array([False, True])
>>> output = np.logical_or(x1, x2)
>>> print(output)
[ True  True]
```

13.3.20 mindspore.numpy.logical_xor

mindspore.numpy.**logical_xor**(*x1*, *x2*, *dtype=None*)

Computes the truth value of *x1* XOR *x2*, element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) –Input tensor.
- **x2** (Tensor) –Input tensor. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. Boolean result of the logical XOR operation applied to the elements of *x1* and *x2*; the shape is determined by broadcasting. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.array([True, False])
>>> x2 = np.array([False, False])
>>> output = np.logical_xor(x1, x2)
>>> print(output)
[True False]
```

13.3.21 mindspore.numpy.not_equal

mindspore.numpy.**not_equal**(*x1*, *x2*, *dtype=None*)

Returns (x1 != x2) element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) –First input tensor to be compared.
- **x2** (Tensor) –Second input tensor to be compared.
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, element-wise comparison of *x1* and *x2*. Typically of type bool, unless *dtype* is passed. This is a scalar if both *x1* and *x2* are scalars.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.asarray([1, 2])
>>> b = np.asarray([[1, 3],[1, 4]])
>>> print(np.not_equal(a, b))
[[False  True]
[False  True]]
```

13.3.22 mindspore.numpy.signbit

mindspore.numpy.**signbit**(*x*, *dtype=None*)

Returns element-wise True where signbit is set (less than zero).

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (*Union[int, float, bool, list, tuple, Tensor]*) –The input value(s).
- **dtype** (*mindspore.dtype*, optional) –Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor.

Raises

TypeError –If input is not array_like or *dtype* is not *None* or *bool*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([1, -2.3, 2.1]).astype('float32')
>>> output = np.signbit(x)
>>> print(output)
[False  True False]
```

13.3.23 mindspore.numpy.sometrue

mindspore.numpy.**sometrue**(*a*, *axis=None*, *keepdims=False*)

Tests whether any array element along a given axis evaluates to True.

Returns single boolean unless axis is not None

Parameters

- **a** (*Union[int, float, bool, list, tuple, Tensor]*) –Input tensor or object that can be converted to an array.
- **axis** (*Union[None, int, tuple(int)]*) –Axis or axes along which a logical OR reduction is performed. Default: `None` . If None, perform a logical OR over all the dimensions of the input array. If negative, it counts from the last to the first axis. If tuple of integers, a reduction is performed on multiple axes, instead of a single axis or all the axes as before.
- **keepdims** (*bool*) –Default: `False` . If True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array. If the default value is passed, then keepdims will not be passed through to the any method of sub-classes of ndarray, however any non-default value will be. If the sub-class method does not implement keepdims any exceptions will be raised.

Returns

Returns single boolean unless axis is not None

Raises

- **TypeError** –If input is not array_like or *axis* is not int or tuple of integers or *keepdims* is not bool.
- **ValueError** –If any axis is out of range or duplicate axes exist.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([1, -2.3, 2.1]).astype('float32')
>>> output = np.sometrue(x)
>>> print(output)
True
```

13.4 Math

Math operations include basic and advanced math operations on tensors, and they have full support on Numpy broadcasting rules. Here are some examples:

- Sum two tensors

  The following code implements the operation of adding two tensors of *input_x* and *input_y*:

```
input_x = np.full((3, 2), [1, 2])
input_y = np.full((3, 2), [3, 4])
output = np.add(input_x, input_y)
print(output)
```

The result is as follows:

```
[[4 6]
 [4 6]
 [4 6]]
```

- Matrix multiplication

  The following code implements the operation of multiplying two matrices *input_x* and *input_y*:

```
input_x = np.arange(2*3).reshape(2, 3).astype('float32')
input_y = np.arange(3*4).reshape(3, 4).astype('float32')
output = np.matmul(input_x, input_y)
print(output)
```

  The result is as follows:

```
[[20. 23. 26. 29.]
 [56. 68. 80. 92.]]
```

- Take the average along a given axis

  The following code implements the operation of averaging all the elements of *input_x*:

```
input_x = np.arange(6).astype('float32')
output = np.mean(input_x)
print(output)
```

  The result is as follows:

```
2.5
```

- Exponential arithmetic

  The following code implements the operation of the natural constant *e* to the power of *input_x*:

```
input_x = np.arange(5).astype('float32')
output = np.exp(input_x)
print(output)
```

  The result is as follows:

```
[ 1.         2.7182817  7.389056  20.085537  54.59815  ]
```

API Name	Description	Supported Platforms
mindspore.numpy.absolute	Calculates the absolute value element-wise.	Ascend GPU CPU
mindspore.numpy.add	Adds arguments element-wise.	Ascend GPU CPU
mindspore.numpy.amax	Returns the maximum of an array or maximum along an axis.	Ascend GPU CPU
mindspore.numpy.amin	Returns the minimum of an array or minimum along an axis.	Ascend GPU CPU
mindspore.numpy.arccos	Trigonometric inverse cosine, element-wise.	Ascend GPU CPU
mindspore.numpy.arccosh	Inverse hyperbolic cosine, element-wise.	Ascend GPU CPU
mindspore.numpy.arcsin	Inverse sine, element-wise.	Ascend GPU CPU
mindspore.numpy.arcsinh	Inverse hyperbolic sine element-wise.	Ascend GPU CPU
mindspore.numpy.arctan	Trigonometric inverse tangent, element-wise.	Ascend GPU CPU

continues on next page

Table 4 – continued from previous page

mindspore.numpy.arctan2	Element-wise arc tangent of $x1/x2$ choosing the quadrant correctly.	Ascend GPU CPU
mindspore.numpy.arctanh	Inverse hyperbolic tangent element-wise.	Ascend CPU
mindspore.numpy.argmax	Returns the indices of the maximum values along an axis.	Ascend GPU CPU
mindspore.numpy.argmin	Returns the indices of the minimum values along an axis.	Ascend GPU CPU
mindspore.numpy.around	Evenly round to the given number of decimals.	Ascend GPU CPU
mindspore.numpy.average	Computes the weighted average along the specified axis.	Ascend GPU CPU
mindspore.numpy.bincount	Count number of occurrences of each value in array of non-negative ints.	Ascend GPU CPU
mindspore.numpy.bitwise_and	Computes the bit-wise AND of two arrays element-wise.	Ascend CPU
mindspore.numpy.bitwise_or	Computes the bit-wise OR of two arrays element-wise.	Ascend CPU
mindspore.numpy.bitwise_xor	Computes the bit-wise XOR of two arrays element-wise.	Ascend CPU
mindspore.numpy.cbrt	Returns the cube-root of a tensor, element-wise.	Ascend GPU CPU
mindspore.numpy.ceil	Returns the ceiling of the input, element-wise.	Ascend GPU CPU
mindspore.numpy.clip	Clips (limits) the values in an array.	Ascend GPU CPU
mindspore.numpy.convolve	Returns the discrete, linear convolution of two one-dimensional sequences.	GPU CPU
mindspore.numpy.copysign	Changes the sign of *x1* to that of *x2*, element-wise.	Ascend GPU CPU
mindspore.numpy.corrcoef	Returns Pearson product-moment correlation coefficients.	Ascend GPU CPU
mindspore.numpy.correlate	Cross-correlation of two 1-dimensional sequences.	Ascend GPU CPU
mindspore.numpy.cos	Cosine element-wise.	Ascend GPU CPU
mindspore.numpy.cosh	Hyperbolic cosine, element-wise.	Ascend CPU
mindspore.numpy.count_nonzero	Counts the number of non-zero values in the tensor *x*.	Ascend GPU CPU
mindspore.numpy.cov	Estimates a covariance matrix, given data and weights.	Ascend GPU CPU
mindspore.numpy.cross	Returns the cross product of two (arrays of) vectors.	Ascend GPU CPU
mindspore.numpy.cumprod	Returns the cumulative product of elements along a given axis.	Ascend GPU
mindspore.numpy.cumsum	Returns the cumulative sum of the elements along a given axis.	Ascend GPU CPU
mindspore.numpy.deg2rad	Converts angles from degrees to radians.	Ascend GPU CPU
mindspore.numpy.diff	Calculates the n-th discrete difference along the given axis.	Ascend GPU CPU
mindspore.numpy.digitize	Returns the indices of the bins to which each value in input array belongs.	Ascend GPU CPU
mindspore.numpy.divide	Returns a true division of the inputs, element-wise.	Ascend GPU CPU
mindspore.numpy.divmod	Returns element-wise quotient and remainder simultaneously.	Ascend GPU CPU
mindspore.numpy.dot	Returns the dot product of two arrays.	Ascend GPU CPU
mindspore.numpy.ediff1d	The differences between consecutive elements of a tensor.	Ascend GPU CPU
mindspore.numpy.exp	Calculates the exponential of all elements in the input array.	Ascend GPU CPU

continues on next page

Table 4 – continued from previous page

mindspore.numpy.exp2	Calculates 2**p for all p in the input array.	Ascend GPU CPU
mindspore.numpy.expm1	Calculates exp(x) - 1 for all elements in the array.	Ascend GPU CPU
mindspore.numpy.fix	Rounds to nearest integer towards zero.	Ascend GPU CPU
mindspore.numpy.float_power	First array elements raised to powers from second array, element-wise.	Ascend GPU CPU
mindspore.numpy.floor	Returns the floor of the input, element-wise.	Ascend GPU CPU
mindspore.numpy.floor_divide	Returns the largest integer smaller or equal to the division of the inputs.	Ascend GPU CPU
mindspore.numpy.fmod	Returns the element-wise remainder of division.	Ascend GPU CPU
mindspore.numpy.gcd	Returns the greatest common divisor of |x1| and |x2|.	Ascend GPU CPU
mindspore.numpy.gradient	Returns the gradient of a N-dimensional array.	Ascend GPU CPU
mindspore.numpy.heaviside	Computes the Heaviside step function.	Ascend GPU CPU
mindspore.numpy.histogram	Computes the histogram of a dataset.	Ascend GPU CPU
mindspore.numpy.histogram2d	Computes the multidimensional histogram of some data.	Ascend GPU CPU
mindspore.numpy.histogramdd	Computes the multidimensional histogram of some data.	Ascend GPU CPU
mindspore.numpy.hypot	Given the "legs" of a right triangle, returns its hypotenuse.	Ascend GPU CPU
mindspore.numpy.inner	Returns the inner product of two tensors.	Ascend GPU CPU
mindspore.numpy.interp	One-dimensional linear interpolation for monotonically increasing sample points.	Ascend GPU CPU
mindspore.numpy.invert	Computes bit-wise inversion, or bit-wise NOT, element-wise.	Ascend
mindspore.numpy.kron	Kronecker product of two arrays.	Ascend GPU CPU
mindspore.numpy.lcm	Returns the lowest common multiple of |x1| and |x2|.	Ascend GPU CPU
mindspore.numpy.log	Returns the natural logarithm, element-wise.	Ascend GPU CPU
mindspore.numpy.log10	Base-10 logarithm of *x*.	Ascend GPU CPU
mindspore.numpy.log1p	Returns the natural logarithm of one plus the input array, element-wise.	Ascend GPU CPU
mindspore.numpy.log2	Base-2 logarithm of *x*.	Ascend GPU CPU
mindspore.numpy.logaddexp	Logarithm of the sum of exponentiations of the inputs.	Ascend GPU CPU
mindspore.numpy.logaddexp2	Logarithm of the sum of exponentiations of the inputs in base of 2.	Ascend GPU CPU
mindspore.numpy.matmul	Returns the matrix product of two arrays.	Ascend GPU CPU
mindspore.numpy.matrix_power	Raises a square matrix to the (integer) power *n*.	Ascend GPU CPU
mindspore.numpy.maximum	Returns the element-wise maximum of array elements.	Ascend GPU CPU
mindspore.numpy.mean	Computes the arithmetic mean along the specified axis.	Ascend GPU CPU
mindspore.numpy.minimum	Element-wise minimum of tensor elements.	Ascend GPU CPU
mindspore.numpy.multi_dot	Computes the dot product of two or more arrays in a single function call, while automatically selecting the fastest evaluation order.	Ascend GPU CPU
mindspore.numpy.multiply	Multiplies arguments element-wise.	Ascend GPU CPU
mindspore.numpy.nancumsum	Return the cumulative sum of array elements over a given axis treating Not a Numbers (NaNs) as zero.	GPU CPU

continues on next page

Table 4 – continued from previous page

mindspore.numpy.nanmax	Return the maximum of an array or maximum along an axis, ignoring any NaNs.	GPU CPU
mindspore.numpy.nanmean	Computes the arithmetic mean along the specified axis, ignoring NaNs.	GPU CPU
mindspore.numpy.nanmin	Returns the minimum of array elements over a given axis, ignoring any NaNs.	GPU CPU
mindspore.numpy.nanstd	Computes the standard deviation along the specified axis, while ignoring NaNs.	GPU CPU
mindspore.numpy.nansum	Returns the sum of array elements over a given axis treating Not a Numbers (NaNs) as zero.	GPU CPU
mindspore.numpy.nanvar	Computes the variance along the specified axis, while ignoring NaNs.	GPU CPU
mindspore.numpy.negative	Numerical negative, element-wise.	Ascend GPU CPU
mindspore.numpy.norm	Matrix or vector norm.	Ascend GPU CPU
mindspore.numpy.outer	Computes the outer product of two vectors.	Ascend GPU CPU
mindspore.numpy.polyadd	Finds the sum of two polynomials.	Ascend GPU CPU
mindspore.numpy.polyder	Returns the derivative of the specified order of a polynomial.	Ascend GPU CPU
mindspore.numpy.polyint	Returns an antiderivative (indefinite integral) of a polynomial.	Ascend GPU CPU
mindspore.numpy.polymul	Finds the product of two polynomials.	GPU
mindspore.numpy.polysub	Difference (subtraction) of two polynomials.	Ascend GPU CPU
mindspore.numpy.polyval	Evaluates a polynomial at specific values.	Ascend GPU CPU
mindspore.numpy.positive	Numerical positive, element-wise.	Ascend GPU CPU
mindspore.numpy.power	First array elements raised to powers from second array, element-wise.	Ascend GPU CPU
mindspore.numpy.promote_types	Returns the data type with the smallest size and smallest scalar kind.	Ascend GPU CPU
mindspore.numpy.ptp	Range of values (maximum - minimum) along an axis.	Ascend GPU CPU
mindspore.numpy.rad2deg	Converts angles from radians to degrees.	Ascend GPU CPU
mindspore.numpy.radians	Converts angles from degrees to radians.	Ascend GPU CPU
mindspore.numpy.ravel_multi_index	Converts a tuple of index arrays into an array of flat indices, applying boundary modes to the multi-index.	GPU
mindspore.numpy.reciprocal	Returns the reciprocal of the argument, element-wise.	Ascend GPU CPU
mindspore.numpy.remainder	Returns element-wise remainder of division.	Ascend GPU CPU
mindspore.numpy.result_type	Returns the type that results from applying the type promotion rules to the arguments.	Ascend GPU CPU
mindspore.numpy.rint	Rounds elements of the array to the nearest integer.	Ascend GPU CPU
mindspore.numpy.searchsorted	Finds indices where elements should be inserted to maintain order.	Ascend GPU CPU
mindspore.numpy.sign	Returns an element-wise indication of the sign of a number.	Ascend GPU CPU
mindspore.numpy.sin	Trigonometric sine, element-wise.	Ascend GPU CPU
mindspore.numpy.sinh	Hyperbolic sine, element-wise.	Ascend CPU
mindspore.numpy.sqrt	Returns the non-negative square-root of an array, element-wise.	Ascend GPU CPU
mindspore.numpy.square	Returns the element-wise square of the input.	Ascend GPU CPU

continues on next page

Table 4 – continued from previous page

mindspore.numpy.std	Computes the standard deviation along the specified axis.	Ascend GPU CPU
mindspore.numpy.subtract	Subtracts arguments, element-wise.	Ascend GPU CPU
mindspore.numpy.sum	Returns sum of array elements over a given axis.	Ascend GPU CPU
mindspore.numpy.tan	Computes tangent element-wise.	Ascend CPU
mindspore.numpy.tanh	Computes hyperbolic tangent element-wise.	Ascend GPU CPU
mindspore.numpy.tensordot	Computes tensor dot product along specified axes.	Ascend GPU CPU
mindspore.numpy.trapz	Integrates along the given axis using the composite trapezoidal rule.	Ascend GPU CPU
mindspore.numpy.true_divide	Returns a true division of the inputs, element-wise.	Ascend GPU CPU
mindspore.numpy.trunc	Returns the truncated value of the input, element-wise.	Ascend GPU CPU
mindspore.numpy.unwrap	Unwraps by changing deltas between values to 2*pi complement.	Ascend GPU CPU
mindspore.numpy.var	Computes the variance along the specified axis.	Ascend GPU CPU

13.4.1 mindspore.numpy.absolute

mindspore.numpy.**absolute**(*x*, *dtype=None*)

Calculates the absolute value element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. Currently the backend kernel only supports float calculation, if the input is not a *float*, then it will be casted to mstype.float32 and casted back.

Parameters

- **x** (Tensor) –Tensor to be used for calculation.
- **dtype** (*mindspore.dtype*, optional) –Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor.

Raises

TypeError –If input arguments have types not specified above.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.asarray([1, 2, 3, -4, -5], np.float32)
>>> output = np.absolute(x)
>>> print(output)
[1. 2. 3. 4. 5.]
```

13.4.2 mindspore.numpy.add

mindspore.numpy.**add**(*x1*, *x2*, *dtype=None*)

Adds arguments element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) – input to be added.
- **x2** (Tensor) – input to be added.
- **dtype** (*mindspore.dtype*, optional) – Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the sum of *x1* and *x2*, element-wise. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.full((3, 2), [1, 2])
>>> x2 = np.full((3, 2), [3, 4])
>>> output = np.add(x1, x2)
>>> print(output)
[[4 6]
[4 6]
[4 6]]
```

13.4.3 mindspore.numpy.amax

mindspore.numpy.**amax**(*a*, *axis=None*, *keepdims=False*, *initial=None*, *where=True*)

Returns the maximum of an array or maximum along an axis.

Note: Numpy argument *out* is not supported. On GPU, the supported dtypes are np.float16, and np.float32.

Parameters

- **a** (Tensor) – Input data.
- **axis** (*Union[int, tuple(int), None], optional*) – Default: None . Axis or axes along which to operate. By default, flattened input is used. If this is a tuple of integers, the maximum is selected over multiple axes, instead of a single axis or all the axes as before.
- **keepdims** (*boolean, optional*) – Default: False . If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.
- **initial** (*scalar, optional*) – Default: None . The minimum value of an output element. Must be present to allow computation on empty slice.

- **where** (*boolean Tensor, optional*) –Default: `True` . A boolean array which is broadcasted to match the dimensions of array, and selects elements to include in the reduction. If non-default value is passed, initial must also be provided.

Returns

Tensor or scalar, maximum of *a*. If *axis* is None, the result is a scalar value. If *axis* is given, the result is an array of dimension `a.ndim - 1`.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.arange(4).reshape((2,2)).astype('float32')
>>> output = np.amax(a)
>>> print(output)
3.0
>>> output = np.amax(a, axis=0)
>>> print(output)
[2. 3.]
>>> output = np.amax(a, axis=1)
>>> print(output)
[1. 3.]
>>> output = np.amax(a, where=np.array([False, True]), initial=-1, axis=0)
>>> print(output)
[-1.  3.]
```

13.4.4 mindspore.numpy.amin

`mindspore.numpy.`**`amin`**(*a*, *axis=None*, *keepdims=False*, *initial=None*, *where=True*)

Returns the minimum of an array or minimum along an axis.

Note: Numpy argument *out* is not supported. On GPU, the supported dtypes are np.float16, and np.float32.

Parameters

- **a** (`Tensor`) –Input data.
- **axis** (*`Union[int, tuple(int), None], optional`*) –Default: `None` . Axis or axes along which to operate. By default, flattened input is used. If this is a tuple of integers, the minimum is selected over multiple axes, instead of a single axis or all the axes as before.
- **keepdims** (*`bool, optional`*) –Default: `False` . If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array.
- **initial** (*`Number, optional`*) –Default: `None` . The maximum value of an output element. Must be present to allow computation on empty slice.

- **where** (*bool Tensor, optional*) –Default: `True` . A boolean array which is broadcasted to match the dimensions of array, and selects elements to include in the reduction. If non-default value is passed, initial must also be provided.

Returns

Tensor or scalar, minimum of *a*. If axis is None, the result is a scalar value. If *axis* is given, the result is an array of dimension `a.ndim - 1`.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.arange(4).reshape((2,2)).astype('float32')
>>> output = np.amin(a)
>>> print(output)
0.0
>>> output = np.amin(a, axis=0)
>>> print(output)
[0. 1.]
>>> output = np.amin(a, axis=1)
>>> print(output)
[0. 2.]
>>> output = np.amin(a, where=np.array([False, True]), initial=10, axis=0)
>>> print(output)
[10.  1.]
```

13.4.5 mindspore.numpy.arccos

`mindspore.numpy.`**`arccos`**(*input*, *dtype=None*)

Trigonometric inverse cosine, element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **input** (`Tensor`) –Input tensor. x-coordinate on the unit circle. For real arguments, the domain is $[-1, 1]$.
- **dtype** (*mindspore.dtype*, optional) –Default: `None`. Overrides the dtype of the output Tensor.

Returns

Tensor.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> input = np.asarray([1, -1], np.float32)
>>> output = np.arccos(input)
>>> print(output)
[0.        3.1415927]
```

13.4.6 mindspore.numpy.arccosh

mindspore.numpy.**arccosh**(*x*, *dtype=None*)

Inverse hyperbolic cosine, element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) –Input tensor.
- **dtype** (*mindspore.dtype*, optional) –Default: None. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(1, 5).astype('float32')
>>> print(np.arccosh(x))
[0.        1.316958  1.7627472 2.063437 ]
```

13.4.7 mindspore.numpy.arcsin

mindspore.numpy.**arcsin**(*x*, *dtype=None*)

Inverse sine, element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) –Input tensor. y-coordinate on the unit circle.
- **dtype** (*mindspore.dtype*, optional) –Default: None. Overrides the dtype of the output Tensor.

Returns

Output Tensor.

Raises

TypeError –If the input is not a tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.asarray([1, -1], np.float32)
>>> output = np.arcsin(x)
>>> print(output)
[ 1.5707964 -1.5707964]
```

13.4.8 mindspore.numpy.arcsinh

`mindspore.numpy.`**`arcsinh`**(*x*, *dtype=None*)

Inverse hyperbolic sine element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (`Tensor`) –Input tensor.
- **dtype** (*mindspore.dtype*, optional) –Default: `None`. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([1., 2., 3., 4.], dtype=np.float32)
>>> print(np.arcsinh(x))
[0.8813736 1.4436355 1.8184465 2.0947125]
```

13.4.9 mindspore.numpy.arctan

mindspore.numpy.**arctan**(*x*, *dtype=None*)

Trigonometric inverse tangent, element-wise.

The inverse of tan, so that if $y = tan(x)$ then $x = arctan(y)$.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) – Input tensor.
- **dtype** (*mindspore.dtype*, optional) – Default: None. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(5).astype('float32')
>>> print(np.arctan(x))
[0.        0.7853982 1.1071488 1.2490457 1.3258177]
```

13.4.10 mindspore.numpy.arctan2

mindspore.numpy.**arctan2**(*x1*, *x2*, *dtype=None*)

Element-wise arc tangent of $x1/x2$ choosing the quadrant correctly.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) – input tensor.
- **x2** (Tensor) – input tensor.
- **dtype** (*mindspore.dtype*, optional) – Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the sum of *x1* and *x2*, element-wise. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.array([-1, +1, +1, -1])
>>> x2 = np.array([-1, -1, +1, +1])
>>> output = np.arctan2(x1, x2)
>>> print(output)
[-2.3561945   2.3561945   0.78539819 -0.78539819]
```

13.4.11 mindspore.numpy.arctanh

mindspore.numpy.**arctanh**(*x*, *dtype=None*)

Inverse hyperbolic tangent element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) – Input tensor.
- **dtype** (*mindspore.dtype*, optional) – Default: None. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Supported Platforms:

Ascend CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([-0.99, -0.75, -0.5, 0, 0.5]).astype('float32')
>>> print(np.arctanh(x))
[-2.646653   -0.97295505 -0.54930615  0.          0.54930615]
```

13.4.12 mindspore.numpy.argmax

mindspore.numpy.**argmax**(*a*, *axis=None*)

Returns the indices of the maximum values along an axis.

Note: Numpy argument *out* is not supported. On Ascend, in case of multiple occurrences of the maximum values, the return indices may not necessarily correspond to the first occurrence.

Parameters

- **a** (*Union[int, float, bool, list, tuple, Tensor]*) – Input array.
- **axis** (*int, optional*) – By default, the index is into the flattened array, otherwise along the specified axis. Default: None .

Returns

Tensor, array of indices into the array. It has the same shape as a.shape with the dimension along axis removed.

Raises

ValueError – If axis is out of range.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.arange(10, 16).reshape(2, 3)
>>> print(np.argmax(a))
5
>>> print(np.argmax(a, axis=0))
[1 1 1]
>>> print(np.argmax(a, axis=1))
[2 2]
```

13.4.13 mindspore.numpy.argmin

`mindspore.numpy.`**`argmin`**(*a*, *axis=None*)

Returns the indices of the minimum values along an axis.

Note: Numpy argument *out* is not supported.

Parameters

- **a** (*Union[int, float, bool, list, tuple, Tensor]*) – Input array.
- **axis** (*int, optional*) – By default, the index is into the flattened array, otherwise along the specified axis. Default: `None` .

Returns

Tensor, array of indices into the array. It has the same shape as a.shape with the dimension along axis removed.

Raises

ValueError – If axis is out of range.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.arange(10, 16).reshape(2, 3)
>>> print(np.argmin(a))
0
>>> print(np.argmin(a, axis=0))
[0 0 0]
>>> print(np.argmin(a, axis=1))
[0 0]
```

13.4.14 mindspore.numpy.around

mindspore.numpy.**around**(*a*, *decimals=0*)

Evenly round to the given number of decimals.

Note: Numpy argument *out* is not supported. Complex numbers are not supported.

Parameters

- **a** (*Union[int, float, list, tuple, Tensor]*) – Input data.
- **decimals** (*int*) – Number of decimal places to round to. Default: 0 .

Returns

Tensor. A tensor of the same type as a, containing the rounded values. The result of rounding a float is a float.

Raises

TypeError – If the input can not be converted to a tensor or the *decimals* argument is not integer.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([-1.3, 0.0, 0.5, 1.5, 2.5])
>>> print(np.around(a))
[-1. 0. 0. 2. 2.]
```

13.4.15 mindspore.numpy.average

mindspore.numpy.**average**(*x*, *axis=None*, *weights=None*, *returned=False*)

Computes the weighted average along the specified axis.

Parameters

- **x** (Tensor) – A Tensor to be averaged.

- **axis** (*Union[None, int, tuple(int)], optional*) –Axis along which to average *x*. Default: `None` . If the axis is *None*, it will average over all of the elements of the tensor *x*. If the axis is negative, it counts from the last to the first axis.
- **weights** (*Union[None, Tensor], optional*) –Weights associated with the values in *x*. Default: `None` . If *weights* is *None*, all the data in *x* are assumed to have a weight equal to one. If *weights* is 1-D tensor, the length must be the same as the given axis. Otherwise, *weights* should have the same shape as *x*.
- **returned** (*bool, optional*) –Default: `False` . If *True*, the tuple (average, sum_of_weights) is returned. If *False*, only the average is returned.

Returns

Averaged Tensor. If returned is *True*, return tuple.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> input_x = np.array([[1., 2.], [3., 4.]])
>>> output = np.average(input_x, axis=0, weights=input_x, returned=True)
>>> print(output)
(Tensor(shape=[2], dtype=Float32, value= [ 2.50000000e+00,  3.33333325e+00]),
 Tensor(shape=[2], dtype=Float32, value= [ 4.00000000e+00,  6.00000000e+00]))
```

13.4.16 mindspore.numpy.bincount

`mindspore.numpy.`**bincount**(*x*, *weights=None*, *minlength=0*, *length=None*)

Count number of occurrences of each value in array of non-negative ints. The number of bins (of size 1) is one larger than the largest value in *x*. If *minlength* is specified, there will be at least this number of bins in the output array (though it will be longer if necessary, depending on the contents of *x*). Each bin gives the number of occurrences of its index value in *x*. If *weights* is specified the input array is weighted by it, i.e. if a value *n* is found at position *i*, `out[n] += weight[i]` instead of `out[n] += 1`.

Note: The additional argument *length* specifies the number of bins (overriding `x.max() + 1`), which must be provided in graph mode. If *x* contains negative values, no error will be raised, and negative values are treated as zeros instead.

Parameters

- **x** (*Union[list, tuple, Tensor]*) –1-d input array.
- **weights** (*Union[int, float, bool, list, tuple, Tensor], optional*) –Weights, array of the same shape as *x*. Default: `None` .
- **minlength** (*int, optional*) –A minimum number of bins for the output array. Default: `0` .
- **length** (*int, optional*) –Number of bins. Default: `None` .

Returns

Tensor, the result of binning the input array. The length of out is equal to `np.amax(x)+1`.

Raises

ValueError –If *x* is not one-dimensional, or if *x* and *weights* do not have the same shape.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.bincount(np.arange(5)))
[1. 1. 1. 1. 1.]
>>> print(np.bincount(np.array([0, 1, 1, 3, 2, 1, 7])))
[1. 3. 1. 1. 0. 0. 0. 1.]
>>> w = np.array([0.3, 0.5, 0.2, 0.7, 1., -0.6]) # weights
>>> x = np.array([0, 1, 1, 2, 2, 2])
>>> print(np.bincount(x,  weights=w))
[0.3 0.7 1.1]
```

13.4.17 mindspore.numpy.bitwise_and

`mindspore.numpy.`**`bitwise_and`**(*x1*, *x2*, *dtype=None*)

Computes the bit-wise AND of two arrays element-wise. Computes the bit-wise AND of the underlying binary representation of the integers in the input arrays. This ufunc implements the C/Python operator &.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (`Tensor`) –Input array.
- **x2** (`Tensor`) –Input array. Only integer and boolean types are handled. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, this is a scalar if both x1 and x2 are scalars.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.bitwise_and(13, 17))
1
```

13.4.18 mindspore.numpy.bitwise_or

mindspore.numpy.**bitwise_or**(*x1*, *x2*, *dtype=None*)

Computes the bit-wise OR of two arrays element-wise. Computes the bit-wise OR of the underlying binary representation of the integers in the input arrays. This ufunc implements the C/Python operator |.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) –Input array.
- **x2** (Tensor) –Input array. Only integer and boolean types are handled. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, this is a scalar if both x1 and x2 are scalars.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.bitwise_or(13, 16))
29
```

13.4.19 mindspore.numpy.bitwise_xor

mindspore.numpy.**bitwise_xor**(*x1*, *x2*, *dtype=None*)

Computes the bit-wise XOR of two arrays element-wise. Computes the bit-wise XOR of the underlying binary representation of the integers in the input arrays. This ufunc implements the C/Python operator ^.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) –Input array.
- **x2** (Tensor) –Input array. Only integer and boolean types are handled. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, this is a scalar if both x1 and x2 are scalars.

Supported Platforms:

Ascend CPU

Examples

```
>>> import mindspore.numpy as np
>>> print(np.bitwise_xor(13, 17))
28
```

13.4.20 mindspore.numpy.cbrt

mindspore.numpy.**cbrt**(*x*, *dtype=None*)

Returns the cube-root of a tensor, element-wise.

Note: Numpy arguments *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) – Input tensor.
- **dtype** (*mindspore.dtype*, optional) – Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.asarray([1, -1, 3, -8, 64])
>>> output = np.cbrt(a)
>>> print(output)
[ 1.         -1.          1.4422495 -2.          4.        ]
```

13.4.21 mindspore.numpy.ceil

mindspore.numpy.**ceil**(*x*, *dtype=None*)

Returns the ceiling of the input, element-wise.

The ceil of the scalar *x* is the smallest integer *i*, such that i >= x.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On GPU, the supported dtypes are np.float16, and np.float32.

Parameters

- **x** (Tensor) – input values.

- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the floor of each element in *x*. This is a scalar if *x* is a scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([-1.7, -1.5, -0.2, 0.2, 1.5, 1.7, 2.0])
>>> output = np.ceil(a)
>>> print(output)
[-1. -1. -0.  1.  2.  2.  2.]
```

13.4.22 mindspore.numpy.clip

`mindspore.numpy.clip`(*x*, *xmin*, *xmax*, *dtype=None*)

Clips (limits) the values in an array.

Given an interval, values outside the interval are clipped to the interval edges. For example, if an interval of $[0, 1]$ is specified, values smaller than 0 become 0, and values larger than 1 become 1.

Parameters

- **x** (`Tensor`) –Tensor containing elements to clip.
- **xmin** (`Tensor, scalar, None`) –Minimum value. If None, clipping is not performed on lower interval edge. Not more than one of *xmin* and *xmax* may be None.
- **xmax** (`Tensor, scalar, None`) –Maximum value. If None, clipping is not performed on upper interval edge. Not more than one of *xmin* and *xmax* may be None. If *xmin* or *xmax* are tensors, then the three tensors will be broadcasted to match their shapes.
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor, a tensor with the elements of *x*, but where values < *xmin* are replaced with *xmin*, and those > *xmax* with *xmax*.

Raises

- **TypeError** –If inputs have types not specified above.
- **ValueError** –If the shapes of *x1* and *x2* cannot broadcast, or both *xmin* and *xmax* are *None*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.asarray([1, 2, 3, -4, 0, 3, 2, 0])
>>> output = np.clip(x, 0, 2)
>>> print(output)
[1 2 2 0 0 2 2 0]
```

13.4.23 mindspore.numpy.convolve

mindspore.numpy.**convolve**(*a*, *v*, *mode='full'*)

Returns the discrete, linear convolution of two one-dimensional sequences.

Note: If *v* is longer than *a*, the tensors are swapped before computation.

Parameters

- **a** (*Union[list, tuple, Tensor]*) – First one-dimensional input tensor.
- **v** (*Union[list, tuple, Tensor]*) – Second one-dimensional input tensor.
- **mode** (*str, optional*) – By default, mode is *'full'*. This returns the convolution at each point of overlap, with an output shape of $(N+M-1,)$. At the end-points of the convolution, the signals do not overlap completely, and boundary effects may be seen. If *mode* is *'same'*, it returns output of length $max(M, N)$. Boundary effects are still visible. If *mode* is *'valid'*, it returns output of length $max(M, N) - min(M, N) + 1$. The convolution product is only given for points where the signals overlap completely. Values outside the signal boundary have no effect.

Returns

Tensor, discrete, linear convolution of a and v.

Raises

- **TypeError** – If the inputs have types not specified above.
- **ValueError** – If a and v are empty or have wrong dimensions

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.convolve([1., 2., 3., 4., 5.], [2., 3.], mode="valid")
>>> print(output)
[ 7. 12. 17. 22.]
```

13.4.24 mindspore.numpy.copysign

mindspore.numpy.**copysign**(*x1*, *x2*, *dtype=None*)

Changes the sign of *x1* to that of *x2*, element-wise.

If *x2* is a scalar, its sign will be copied to all elements of *x1*.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. Complex inputs are not supported now.

Parameters

- **x1** (*Union[int, float, list, tuple, Tensor]*) – Values to change the sign of.
- **x2** (*Union[int, float, list, tuple, Tensor]*) – The sign of x2 is copied to x1. If *x1.shape != x2.shape*, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. The values of *x1* with the sign of *x2*. This is a scalar if both *x1* and *x2* are scalars.

Raises

TypeError – If dtype of the input is not in the given types or the input can not be converted to tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.copysign(np.array([1, -1, -1]), np.array([-1, 1, -1]))
>>> print(output)
[-1  1 -1]
```

13.4.25 mindspore.numpy.corrcoef

mindspore.numpy.**corrcoef**(*x*, *y=None*, *rowvar=True*, *dtype=None*)

Returns Pearson product-moment correlation coefficients.

Please refer to the documentation for cov for more detail. The relationship between the correlation coefficient matrix, R, and the covariance matrix, C, is $R_{ij} = \frac{C_{ij}}{\sqrt{C_{ii} * C_{jj}}}$ The values of R are between -1 and 1, inclusive.

Note: Currently, complex numbers are not supported.

Parameters

- **x** (*Union[int, float, bool, tuple, list, Tensor]*) – A 1-D or 2-D array containing multiple variables and observations. Each row of *x* represents a variable, and each column a single observation of all those variables. Also see rowvar below.

- **y** (*Union[int, float, bool, tuple, list, Tensor], optional*) –An additional set of variables and observations. Default: `None` .
- **rowvar** (*bool, optional*) –If rowvar is `True` (default), then each row represents a variable, with observations in the columns. Otherwise, the relationship is transposed: each column represents a variable, while the rows contain observations. Default: `True` .
- **dtype** (*mindspore.dtype*, optional) –Data-type of the result. By default, the return data-type will have at least float32 precision. Default: `None` .

Returns

Tensor, The correlation coefficient matrix of the variables.

Raises

- **TypeError** –If the inputs have types not specified above.
- **ValueError** –If *x* and *y* have wrong dimensions.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.corrcoef([[2., 3., 4., 5.], [0., 2., 3., 4.], [7., 8., 9., 10.]])
>>> print(output)
[[1.         0.9827076  1.        ]
[0.9827077  0.99999994 0.9827077 ]
[1.         0.9827076  1.        ]]
```

13.4.26 mindspore.numpy.correlate

`mindspore.numpy.`**correlate**(*a*, *v*, *mode='valid'*)

Cross-correlation of two 1-dimensional sequences.

This function computes the correlation as generally defined in signal processing texts:

$c_{av}[k] = \sum_n a[n+k] * conj(v[n])$

with *a* and *v* sequences being zero-padded where necessary and conj being the conjugate.

Note:

- *correlate* is currently only used in *mindscience* scientific computing scenarios and dose not support other usage scenarios.
- *correlate* is not supported on Windows platform yet.

Parameters

- **a** (*Union[list, tuple, Tensor]*) –First input sequence.
- **v** (*Union[list, tuple, Tensor]*) –Second input sequence.
- **mode** (*str, optional*) –Specifies padding mode. The optional values are `"same"` , `"valid"` and `"full"` . Default: `"valid"` .

- "same": it returns output of length $max(M, N)$. Boundary effects are still visible.
- "valid": it returns output of length $max(M, N) - min(M, N) + 1$. The convolution product is only given for points where the signals overlap completely. Values outside the signal boundary have no effect.
- "full": it returns the convolution at each point of overlap, with an output shape of $(N+M-1,)$.At the end-points of the convolution, the signals do not overlap completely, and boundary effects may be seen.

Returns

Tensor, Discrete cross-correlation of *a* and *v*.

Raises

- **TypeError** –If *a* or *v* is not a tensor.
- **TypeError** –If *a* and *v* is of different dtype.
- **ValueError** –If *a* and *v* are empty or have wrong dimensions

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as mnp
>>> from mindspore import Tensor
>>> output = mnp.correlate(Tensor([1., 2., 3.]), Tensor([0., 1., 0.5]))
>>> print(output)
[3.5]
>>> output = mnp.correlate(Tensor([1., 2., 3.]), Tensor([0., 1., 0.5]), mode="same")
>>> print(output)
[2.  3.5 3. ]
>>> output = mnp.correlate(Tensor([1., 2., 3., 4., 5.]), Tensor([1., 2.]), mode="full")
>>> print(output)
[ 2.  5.  8. 11. 14.  5.]
```

13.4.27 mindspore.numpy.cos

mindspore.numpy.**cos**(*x*, *dtype=None*)

Cosine element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) –Input tensor.
- **dtype** (*mindspore.dtype*, optional) –Default: None. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(5).astype('float32')
>>> print(np.cos(x))
[ 1.          0.5403023  -0.41614684 -0.9899925  -0.6536436 ]
```

13.4.28 mindspore.numpy.cosh

mindspore.numpy.**cosh**(*x*, *dtype=None*)

Hyperbolic cosine, element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) – Input tensor.
- **dtype** (*mindspore.dtype*, optional) – Default: None. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Supported Platforms:

Ascend CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(5).astype('float32')
>>> print(np.cosh(x))
[ 1.          1.5430807   3.7621956  10.067662   27.308233 ]
```

13.4.29 mindspore.numpy.count_nonzero

mindspore.numpy.**count_nonzero**(*x*, *axis=None*, *keepdims=False*)

Counts the number of non-zero values in the tensor *x*.

Parameters

- **x** (Tensor) – The tensor for which to count non-zeros.
- **axis** (*Union[int, tuple], optional*) – Axis or tuple of axes along which to count non-zeros. Default is None, meaning that non-zeros will be counted along a flattened version of *x*. Default: None .
- **keepdims** (*bool, optional*) – If this is set to True, the axes that are counted are left in the result as dimensions with size one. With this option, the result will broadcast correctly against *x*. Default: False .

Returns

Tensor, indicating number of non-zero values in the *x* along a given axis. Otherwise, the total number of non-zero values in *x* is returned.

Raises

- **TypeError** –If axis is not int or tuple.
- **ValueError** –If axis is not in range [-x.ndim, x.ndim).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.asarray([1, 2, 3, -4, 0, 3, 2, 0])
>>> output = np.count_nonzero(x)
>>> print(output)
6
```

13.4.30 mindspore.numpy.cov

`mindspore.numpy.`**cov**(*m*, *y=None*, *rowvar=True*, *bias=False*, *ddof=None*, *fweights=None*, *aweights=None*, *dtype=None*)

Estimates a covariance matrix, given data and weights.

Covariance indicates the level to which two variables vary together. If we examine N-dimensional samples, $X = [x_1, x_2, ..x_N]^T$, then the covariance matrix element C_{ij} is the covariance of x_i and x_j. The element C_{ii} is the variance of x_i.

Note: *fweights* and *aweights* must be all positive, in Numpy if negative values are detected, a value error will be raised, in MindSpore we converts all values to positive instead.

Parameters

- **m** (*Union[Tensor, list, tuple]*) –A 1-D or 2-D tensor containing multiple variables and observations. Each row of *m* represents a variable, and each column represents a single observation of all those variables. Also see *rowvar* below.
- **y** (*Union[Tensor, list, tuple], optional*) –An additional set of variables and observations. *y* has the same form as that of *m*, default is `None`.
- **rowvar** (*bool, optional*) –If *rowvar* is `True` (default), then each row represents a variable, with observations in the columns. Otherwise, the relationship is transposed: each column represents a variable, while the rows contain observations.
- **bias** (*bool, optional*) –Default Normalization (`False`) is by $(N - 1)$, where N is the number of observations given (unbiased estimate). If bias is `True`, then Normalization is by N. These values can be overridden by using the keyword *ddof*.
- **ddof** (*int, optional*) –If not `None`, the default value implied by *bias* is overridden. Note that $ddof = 1$ will return the unbiased estimate, even if both fweights and aweights are specified, and $ddof = 0$ will return the simple average. See the notes for the details. The default value is `None`.
- **fweights** (*Union[Tensor, list, tuple], optional*) –1-D tensor of integer frequency weights; the number of times each observation vector should be repeated. The default value is `None`.
- **aweights** (*Union[Tensor, list, tuple], optional*) –1-D tensor of observation vector weights. These relative weights are typically larger for observations considered more important and smaller for observations considered

less important. If $ddof = 0$ the tensor of weights can be used to assign probabilities to observation vectors. The default value is `None`.

- **dtype** (Union[*mindspore.dtype*, str], optional) −Data-type of the result. By default, the return data-type will have mstype.float32 precision. Default is `None`.

Returns

Tensor, the covariance matrix of the variables.

Raises

- **TypeError** −If the inputs have types not specified above.
- **ValueError** −If *m* and *y* have wrong dimensions.
- **RuntimeError** −If *aweights* and *fweights* have dimensions > 2.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.cov([[2., 3., 4., 5.], [0., 2., 3., 4.], [7., 8., 9., 10.]])
>>> print(output)
[[1.6666666 2.1666667 1.6666666]
[2.1666667 2.9166667 2.1666667]
[1.6666666 2.1666667 1.6666666]]
```

13.4.31 mindspore.numpy.cross

`mindspore.numpy.`**cross**(*a*, *b*, *axisa=- 1*, *axisb=- 1*, *axisc=- 1*, *axis=None*)

Returns the cross product of two (arrays of) vectors.

The cross product of a and b in R^3 is a vector perpendicular to both a and b. If a and b are arrays of vectors, the vectors are defined by the last axis of a and b by default, and these axes can have dimensions 2 or 3. Where the dimension of either a or b is 2, the third component of the input vector is assumed to be zero and the cross product calculated accordingly. In cases where both input vectors have dimension 2, the z-component of the cross product is returned.

Parameters

- **a** (*Union[list, tuple, Tensor]*) −Components of the first vector(s).
- **b** (*Union[list, tuple, Tensor]*) −Components of the second vector(s).
- **axisa** (*int, optional*) −Axis of *a* that defines the vector(s). By default, the last axis.
- **axisb** (*int, optional*) −Axis of *b* that defines the vector(s). By default, the last axis.
- **axisc** (*int, optional*) −Axis of *c* containing the cross product vector(s). Ignored if both input vectors have dimension 2, as the return is scalar. By default, the last axis.
- **axis** (*int, optional*) −If defined, the axis of *a*, *b* and *c* that defines the vector(s) and cross product(s). Overrides *axisa*, *axisb* and *axisc*. Default: `None` .

Returns

Tensor, vector cross product(s).

Raises

ValueError –when the dimensions of the vector(s) in *a* and/or *b* does not equal 2 or 3.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([[1,2,3], [4,5,6]])
>>> y = np.array([[4,5,6], [1,2,3]])
>>> output = np.cross(x, y)
>>> print(output)
[[-3  6 -3]
 [ 3 -6  3]]
>>> output = np.cross(x, y, axisc=0)
>>> print(output)
[[-3  3]
 [ 6 -6]
 [-3  3]]
```

13.4.32 mindspore.numpy.cumprod

mindspore.numpy.**cumprod**(*a*, *axis=None*, *dtype=None*)

Returns the cumulative product of elements along a given axis.

Note: Numpy argument *out* is not supported.

Parameters

- **a** (*Union[int, float, bool, list, tuple, Tensor]*) –Input tensor.
- **axis** (*int, optional*) –Axis along which the cumulative product is computed. By default the input is flattened. Default: `None` .
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor.

Raises

- **TypeError** –If the input can not be converted to tensor or *axis* is not integer.
- **ValueError** –If axis is out of range.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([1, 2, 3])
>>> print(np.cumprod(x))
[1 2 6]
```

13.4.33 mindspore.numpy.cumsum

mindspore.numpy.**cumsum**(*a*, *axis=None*, *dtype=None*)

Returns the cumulative sum of the elements along a given axis.

Note: If `a.dtype` is *int8*, *int16* or *bool*, the result *dtype* will be elevated to *int32*.

Parameters

- **a** (`Tensor`) –Input tensor.
- **axis** (*int, optional*) –Axis along which the cumulative sum is computed. The default (`None`) is to compute the cumsum over the flattened array.
- **dtype** (*mindspore.dtype*, optional) –If not specified, stay the same as *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used. Default: `None` .

Returns

Tensor.

Raises

- **TypeError** –If input arguments have types not specified above.
- **ValueError** –If axis is out of range.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.cumsum(np.ones((3,3)), axis=0)
>>> print(output)
[[1. 1. 1.]
 [2. 2. 2.]
 [3. 3. 3.]]
```

13.4.34 mindspore.numpy.deg2rad

mindspore.numpy.**deg2rad**(*x*, *dtype=None*)

Converts angles from degrees to radians.

Parameters

- **x** (Tensor) −Angles in degrees.
- **dtype** (*mindspore.dtype*, optional) −Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor, the corresponding angle in radians. This is a tensor scalar if *x* is a tensor scalar.

Raises

TypeError −If *x* is not a tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.asarray([1, 2, 3, -4, -5])
>>> output = np.deg2rad(x)
>>> print(output)
[ 0.01745329  0.03490658  0.05235988 -0.06981317 -0.08726647]
```

13.4.35 mindspore.numpy.diff

mindspore.numpy.**diff**(*a*, *n=1*, *axis=- 1*, *prepend=None*, *append=None*)

Calculates the n-th discrete difference along the given axis.

The first difference is given by $out[i] = a[i+1] - a[i]$ along the given axis, higher differences are calculated by using *diff* iteratively.

Note: Since zero-shaped Tensor is not supported in MindSpore, a value error is raised if an empty Tensor is encountered.

Parameters

- **a** (Tensor) −Input tensor.
- **n** (*int, optional*) −The number of times values are differenced. If zero, the input is returned as-is. Default: 1 .
- **axis** (*int, optional*) −The axis along which the difference is taken, default is the last axis. Default: -1 .
- **prepend/append** (Tensor, *optional*) −Values to prepend or append to a along *axis* prior to performing the difference. Scalar values are expanded to arrays with length 1 in the direction of *axis* and the shape of the input array in along all other axes. Otherwise the dimension and shape must match *a* except along axis. Default: None .

Returns

The n-th differences. The shape of the output is the same as a except along *axis* where the dimension is smaller by *n*. The type of the output is the same as the type of the difference between any two elements of *a*. This is the same as the type of *a* in most cases.

Raises

- **TypeError** –If inputs have types not specified above.
- **ValueError** –If `n < 0`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> arr = np.array([1, 3, -1, 0, 4])
>>> print(np.diff(arr, n=2))
[-6  5  3]
```

13.4.36 mindspore.numpy.digitize

`mindspore.numpy.`**digitize**(*x*, *bins*, *right=False*)

Returns the indices of the bins to which each value in input array belongs. If values in *x* are beyond the bounds of *bins*, 0 or `len(bins)` is returned as appropriate.

Parameters

- **x** (*Union[int, float, bool, list, tuple, Tensor]*) –Input array to be binned.
- **bins** (*Union[list, tuple, Tensor]*) –Array of bins. It has to be 1-dimensional and monotonic.
- **right** (*boolean, optional*) –Indicating whether the intervals include the right or the left bin edge. Default behavior is `(right==False)` indicating that the interval does not include the right edge. The left bin end is open in this case, i.e., `bins[i-1] <= x < bins[i]` is the default behavior for monotonically increasing bins.

Returns

Tensor of ints, output array of indices, of same shape as *x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([1.2, 10.0, 12.4, 15.5, 20.])
>>> bins = np.array([0, 5, 10, 15, 20])
>>> inds = np.digitize(x, bins)
>>> print(inds)
[1 3 3 4 5]
```

13.4.37 mindspore.numpy.divide

mindspore.numpy.**divide**(*x1*, *x2*, *dtype=None*)

Returns a true division of the inputs, element-wise.

Instead of the Python traditional "floor division", this returns a true division.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) –the divident.
- **x2** (Tensor) –the divisor.
- **dtype** (*mindspore.dtype*, optional) –Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, this is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.full((3, 2), [1, 2])
>>> x2 = np.full((3, 2), [3, 4])
>>> output = np.divide(x1, x2)
>>> print(output)
[[0.33333334 0.5       ]
[0.33333334 0.5       ]
[0.33333334 0.5       ]]
```

13.4.38 mindspore.numpy.divmod

mindspore.numpy.**divmod**(*x1*, *x2*, *dtype=None*)

Returns element-wise quotient and remainder simultaneously.

Parameters

- **x1** (*Union[Tensor]*) –Dividend tensor.
- **x2** (*Union[Tensor, int, float, bool]*) –Divisor. If x1.shape != x2.shape, they must be broadcastable to a common shape.
- **dtype** (*mindspore.dtype*, optional) –Default: None . Overrides the dtype of the output Tensor.

Returns

Element-wise quotient and remainder from floor division, in format of (quotient, remainder)

Raises

TypeError –If *x1* and *x2* are not Tensor or scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([1, 2, 3, 4, 5])
>>> print(np.divmod(a, 1.5))
(Tensor(shape=[5], dtype=Float32,
 value= [ 0.00000000e+00,  1.00000000e+00,  2.00000000e+00,  2.00000000e+00,  3.
↪00000000e+00]),
 Tensor(shape=[5], dtype=Float32,
 value= [ 1.00000000e+00,  5.00000000e-01,  0.00000000e+00,  1.00000000e+00,  5.00000000e-
↪01]))
```

13.4.39 mindspore.numpy.dot

`mindspore.numpy.`**`dot`**(*a*, *b*)

Returns the dot product of two arrays.

Specifically, If both *a* and *b* are 1-D arrays, it is inner product of vectors (without complex conjugation). If both *a* and *b* are 2-D arrays, it is matrix multiplication. If either *a* or *b* is 0-D (scalar), it is equivalent to multiply. If *a* is an *N-D* array and *b* is a 1-D array, it is a sum product over the last axis of *a* and *b*. If *a* is an *N-D* array and *b* is an *M-D* array (where `M>=2`), it is a sum product over the last axis of *a* and the second-to-last axis of *b*: `dot(a, b)[i,j,k,m] = sum(a[i,j,:] * b[k,:,m])`

Note: Numpy argument *out* is not supported. On GPU, the supported dtypes are np.float16, and np.float32. On CPU, the supported dtypes are np.float16, np.float32, and np.float64.

Parameters

- **a** (`Tensor`) – input tensor
- **b** (`Tensor`) – input tensor

Returns

Tensor or scalar, the dot product of *a* and *b*. If *a* and *b* are both scalars or both 1-D arrays then a scalar is returned; otherwise an array is returned

Raises

`ValueError` – If the last dimension of *a* is not the same size as the second-to-last dimension of *b*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.full((1, 3), 7).astype('float32')
>>> b = np.full((2, 3, 4), 5).astype('float32')
>>> output = np.dot(a, b)
>>> print(output)
[[[105. 105. 105. 105.]
[105. 105. 105. 105.]]]
```

13.4.40 mindspore.numpy.ediff1d

mindspore.numpy.**ediff1d**(*ary*, *to_end=None*, *to_begin=None*)

The differences between consecutive elements of a tensor.

Parameters

- **ary** (Tensor) –If necessary, will be flattened before the differences are taken.
- **to_end** (Tensor, *scalar, optional*) –Number(s) to append at the end of the returned differences. Default: None .
- **to_begin** (Tensor, *scalar, optional*) –Number(s) to prepend at the beginning of the returned differences. Default: None .

Returns

The differences.

Raises

TypeError –If inputs have types not specified above.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> arr = np.array([1, 3, -1, 0, 4])
>>> print(np.ediff1d(arr))
[ 2 -4  1  4]
```

13.4.41 mindspore.numpy.exp

mindspore.numpy.**exp**(*x*, *dtype=None*)

Calculates the exponential of all elements in the input array.

Note: Numpy arguments *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. When *where* is provided, *out* must have a tensor value. *out* is not supported for storing the result, however it can be used in combination with *where* to set the value at indices for which *where* is set to False. On GPU, the supported dtypes are np.float16, and np.float32. On CPU, the supported dtypes are np.float16, np.float32, np.float64.

Parameters

- **x** (Tensor) –input data.
- **dtype** (*mindspore.dtype*, optional) –Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, element-wise exponential of *x*. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.exp(np.arange(5).astype(np.float32))
>>> print(output)
[ 1.         2.718282   7.3890557 20.085537  54.598145 ]
```

13.4.42 mindspore.numpy.exp2

mindspore.numpy.**exp2**(*x*, *dtype=None*)

Calculates 2**p for all p in the input array.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On GPU, the supported dtypes are np.float16, and np.float32.

Parameters

- **x** (Tensor) –input values.
- **dtype** (*mindspore.dtype*, optional) –Defaults to None. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, element-wise 2 to the power *x*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([2, 3]).astype(np.float32)
>>> output = np.exp2(x)
>>> print(output)
[4. 8.]
```

13.4.43 mindspore.numpy.expm1

mindspore.numpy.**expm1**(*x*, *dtype=None*)

Calculates `exp(x) - 1` for all elements in the array.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On GPU, the supported dtypes are np.float16, and np.float32. On CPU, the supported dtypes are np.float16, and np.float32.

Parameters

- **x** (Tensor) – input data.
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, element-wise exponential minus one, `out = exp(x) - 1`. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.expm1(np.arange(5).astype(np.float32))
>>> print(output)
[ 0.         1.7182819  6.389056  19.085537  53.59815  ]
```

13.4.44 mindspore.numpy.fix

mindspore.numpy.**fix**(*x*)

Rounds to nearest integer towards zero.

Rounds an array of floats element-wise to nearest integer towards zero. The rounded values are returned as floats.

Note: Numpy argument *out* is not supported.

Parameters

x (Tensor) – An array of floats to be rounded.

Returns

Tensor.

Raises

TypeError – If the input is not a tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.fix(np.array([2.1, 2.9, -2.1, -2.9]))
>>> print(output)
[ 2.  2. -2. -2.]
```

13.4.45 mindspore.numpy.float_power

mindspore.numpy.**float_power**(*x1*, *x2*, *dtype=None*)

First array elements raised to powers from second array, element-wise.

Raise each base in *x1* to the positionally-corresponding power in *x2*. *x1* and *x2* must be broadcastable to the same shape. This differs from the power function in that integers, float16, and float64 are promoted to floats with a minimum precision of float32 so that the result is always inexact. The intent is that the function will return a usable result for negative powers and seldom overflow for positive powers.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. Integers and floats are promoted to float32 instead of float64.

Parameters

- **x1** (Tensor) –the bases.
- **x2** (Tensor) –the exponents.
- **dtype** (*mindspore.dtype*, optional) –Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the bases in *x1* raised to the exponents in *x2*. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.arange(6)
>>> x2 = np.array(3)
>>> output = np.float_power(x1, x2)
>>> print(output)
[  0.   1.   8.  27.  64. 125.]
```

13.4.46 mindspore.numpy.floor

mindspore.numpy.**floor**(*x*, *dtype=None*)

Returns the floor of the input, element-wise.

The floor of the scalar *x* is the largest integer *i*, such that `i <= x`.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On GPU, the supported dtypes are np.float16 and np.float32. On CPU, the supported dtypes are np.float16, np.float32, and np.float64.

Parameters

- **x** (Tensor) –input data.
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the floor of each element in *x*. This is a scalar if *x* is a scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.floor(np.array([-1.7, -1.5, -0.2, 0.2, 1.5, 1.7, 2.0]))
>>> print(output)
[-2. -2. -1.  0.  1.  1.  2.]
```

13.4.47 mindspore.numpy.floor_divide

mindspore.numpy.**floor_divide**(*x1*, *x2*, *dtype=None*)

Returns the largest integer smaller or equal to the division of the inputs. It is equivalent to the Python // operator and pairs with the Python % (remainder), function so that `a = a % b + b * (a // b)` up to roundoff.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) –Input array.
- **x2** (Tensor) –Input array.
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.floor_divide(np.array([1., 2., 3., 4.]), np.array(2.5))
>>> print(output)
[0. 0. 1. 1.]
```

13.4.48 mindspore.numpy.fmod

mindspore.numpy.**fmod**(*x1*, *x2*, *dtype=None*)

Returns the element-wise remainder of division.

This is the NumPy implementation of the C library function fmod, the remainder has the same sign as the dividend *x1*. It is equivalent to the Matlab(TM) rem function and should not be confused with the Python modulus operator `x1 % x2`.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) – the first input arrays.
- **x2** (Tensor) – the second input arrays.
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the remainder of the division of *x1* by *x2*. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.fmod(np.array([-3, -2, -1, 1, 2, 3]), np.array(2))
>>> print(output)
[-1  0 -1  1  0  1]
```

13.4.49 mindspore.numpy.gcd

mindspore.numpy.**gcd**(*x1*, *x2*, *dtype=None*)

Returns the greatest common divisor of `|x1|` and `|x2|`.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) – input data.
- **x2** (Tensor) – input data.

- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the greatest common divisor of the absolute value of the inputs. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.gcd(np.arange(6), np.array(20))
>>> print(output)
[20  1  2  1  4  5]
```

13.4.50 mindspore.numpy.gradient

`mindspore.numpy.`**`gradient`**(*f*, **varargs*, *axis=None*, *edge_order=1*)

Returns the gradient of a N-dimensional array. The gradient is computed using second order accurate central differences in the interior points and either first or second order accurate one-sides (forward or backwards) differences at the boundaries. The returned gradient hence has the same shape as the input array.

Note: Currently we only support *edge_order* =1 and uniform spacing of *varargs*.

Parameters

- **f** (*Union[tuple, list, Tensor]*) –An N-dimensional array containing samples of a scalar function.
- **varargs** (*Union[tuple[number], tuple[tensor scalar]], optional*) –Spacing between f values. Default unitary spacing for all dimensions. Spacing can be specified using: 1. single scalar to specify a sample distance for all dimensions. 2. N scalars to specify a constant sample distance for each dimension.
- **axis** (*Union[None, int, tuple(int), list(int)], optional*) –Gradient is calculated only along the given axis or axes. The default `(axis = None)` is to calculate the gradient for all the axes of the input tensor. *axis* may be negative, in which case it counts from the last to the first *axis*.
- **edge_order** (*int, optional*) –Gradient is calculated using N-th order accurate differences at the boundaries. Default: `1` .

Returns

gradient, a list of tensors (or a single tensor if there is only one dimension to be calculated). Each derivative has the same shape as f.

Raises

- **TypeError** –If the inputs have types not specified above.
- **ValueError** –If *axis* values out of bounds, or shape of *f* has entries < 1.
- **NotImplementedError** –If *edge_order* != 1, or *varargs* contains non-scalar entries.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.gradient([[1, 2, 6], [3, 4, 5]], axis=-1)
>>> print(output)
[[1.  2.5 4. ]
[1.  1.  1. ]]
```

13.4.51 mindspore.numpy.heaviside

mindspore.numpy.**heaviside**(*x1*, *x2*, *dtype=None*)

Computes the Heaviside step function.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) −Input values.
- **x2** (Tensor) −The value of the function when *x1* is 0. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) −Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the output array, element-wise Heaviside step function of *x1*. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.heaviside(np.array([-1.5, 0, 2.0]), np.array(0.5))
>>> print(output)
[0.  0.5 1. ]
>>> output = np.heaviside(np.array([-1.5, 0, 2.0]), np.array(1))
>>> print(output)
[0. 1. 1.]
```

13.4.52 mindspore.numpy.histogram

mindspore.numpy.**histogram**(*a*, *bins=10*, *range=None*, *weights=None*, *density=False*)

Computes the histogram of a dataset.

Note: String values for *bins* is not supported. Deprecated numpy argument *normed* is not supported.

Parameters

- **a** (*Union[int, float, bool, list, tuple, Tensor]*) – Input data. The histogram is computed over the flattened array.
- **bins** (*Union[int, tuple, list, Tensor], optional*) – If *bins* is an int, it defines the number of equal-width bins in the given range (10, by default). If *bins* is a sequence, it defines the bin edges, including the rightmost edge, allowing for non-uniform bin widths. Default: `10` .
- **range** (*(float, float), optional*) – The lower and upper range of the bins. If not provided, *range* is simply `(a.min(), a.max())`. Values outside the range are ignored. The first element of the range must be less than or equal to the second. Default: `None` .
- **weights** (*Union[int, float, bool, list, tuple, Tensor], optional*) – An array of weights, of the same shape as *a*. If density is True, the weights are normalized, so that the integral of the density over the range remains 1. Default: `None` .
- **density** (*boolean, optional*) – If False, the result will contain the number of samples in each bin. If True, the result is the value of the probability density function at the bin, normalized such that the integral over the range is 1. Note that the sum of the histogram values will not be equal to 1 unless bins of unity width are chosen; it is not a probability mass function. Default: `False` .

Returns

(Tensor, Tensor), the values of the histogram and the bin edges.

Raises

ValueError – If *x* and *weights* do not have the same size.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import numpy as np
>>> print(np.histogram([1, 2, 1], bins=[0, 1, 2, 3]))
(Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  2.00000000e+00,  1.
 ↪00000000e+00]),
Tensor(shape=[4], dtype=Int32, value= [0, 1, 2, 3]))
>>> print(np.histogram(np.arange(4), bins=np.arange(5), density=True))
(Tensor(shape=[4], dtype=Float32, value=
[ 2.50000000e-01,  2.50000000e-01,  2.50000000e-01,  2.50000000e-01]),
Tensor(shape=[5], dtype=Int32, value= [0, 1, 2, 3, 4]))
>>> print(np.histogram([[1, 2, 1], [1, 0, 1]], bins=[0,1,2,3]))
(Tensor(shape=[3], dtype=Float32, value= [ 1.00000000e+00,  4.00000000e+00,  1.
 ↪00000000e+00]),
Tensor(shape=[4], dtype=Int32, value= [0, 1, 2, 3]))
```

13.4.53 mindspore.numpy.histogram2d

mindspore.numpy.**histogram2d**(*x*, *y*, *bins=10*, *range=None*, *weights=None*, *density=False*)

Computes the multidimensional histogram of some data.

Note: Deprecated numpy argument *normed* is not supported.

Parameters

- **x** (*Union[list, tuple, Tensor]*) – An array with shape *(N,)* containing the x coordinates of the points to be histogrammed.
- **y** (*Union[list, tuple, Tensor]*) – An array with shape *(N,)* containing the y coordinates of the points to be histogrammed.
- **bins** (*Union[int, tuple, list], optional*) – Default: `10` . The bin specification:

  If int, the number of bins for the two dimensions `(nx=ny=bins)`.

  If array_like, the bin edges for the two dimensions `(x_edges=y_edges=bins)`.

  If [int, int], the number of bins in each dimension `(nx, ny = bins)`.

  If [array, array], the bin edges in each dimension `(x_edges, y_edges = bins)`.

  A combination [int, array] or [array, int], where int is the number of bins and array is the bin edges.
- **range** (*Union[list, tuple], optional*) – has shape (2, 2), the leftmost and rightmost edges of the bins along each dimension (if not specified explicitly in the bins parameters): `[[xmin, xmax], [ymin, ymax]]`. All values outside of this range will be considered outliers and not tallied in the histogram. Default: `None` .
- **weights** (*Union[list, tuple, Tensor], optional*) – An array with shape *(N,)* of values *w_i* weighing each sample *(x_i, y_i)*. Default: `None` .
- **density** (*boolean, optional*) – If False, the default, returns the number of samples in each bin. If True, returns the probability density function at the bin, `bin_count / sample_count / bin_volume`. Default: `False` .

Returns

(Tensor, Tensor, Tensor), the values of the bi-directional histogram and the bin edges along the first and second dimensions.

Raises

ValueError – If *range* does not have the same size as the number of samples.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import numpy as np
>>> x = np.arange(5)
>>> y = np.arange(2, 7)
>>> print(np.histogram2d(x, y, bins=(2, 3)))
(Tensor(shape=[2, 3], dtype=Float32, value=
[[ 2.00000000e+00,  0.00000000e+00,  0.00000000e+00],
[ 0.00000000e+00,  1.00000000e+00,  2.00000000e+00]]),
Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  2.00000000e+00,  4.00000000e+00]),
```

(continues on next page)

(continued from previous page)

```
Tensor(shape=[4], dtype=Float32, value=
[ 2.00000000e+00,  3.33333349e+00,  4.66666698e+00,  6.00000000e+00]))
```

13.4.54 mindspore.numpy.histogramdd

mindspore.numpy.**histogramdd**(*sample*, *bins=10*, *range=None*, *weights=None*, *density=False*)

Computes the multidimensional histogram of some data.

Note: Deprecated numpy argument *normed* is not supported.

Parameters

- **sample** (*Union[list, tuple, Tensor]*) – The data to be histogrammed, either *(N, D)* array, or *(D, N)* array_like. Note the unusual interpretation of sample when an array_like:

  When an array, each row is a coordinate in a *D-dimensional* space, such as `histogramdd(np.array([p1, p2, p3]))`.

  When an array_like, each element is the list of values for single coordinate, such as `histogramdd((X, Y, Z))`.

  The first form should be preferred.

- **bins** (*Union[int, tuple, list], optional*) – Default: `10` . The bin specification:

  A sequence of arrays describing the monotonically increasing bin edges along each dimension.

  The number of bins for each dimension `(nx, ny, ···=bins)`

  The number of bins for all dimensions `(nx=ny=···=bins)`.

- **range** (*Union[list, tuple], optional*) – A sequence of length *D*, each an optional `(lower, upper)` tuple giving the outer bin edges to be used if the edges are not given explicitly in bins. An entry of None in the sequence results in the minimum and maximum values being used for the corresponding dimension. The default, None, is equivalent to passing a tuple of *D* None values. Default: `None` .

- **weights** (*Union[list, tuple, Tensor], optional*) – An array with shape *(N,)* of values *w_i* weighing each sample `(x_i, y_i, z_i, ···)`. Default: `None` .

- **density** (*boolean, optional*) – If False, the default, returns the number of samples in each bin. If True, returns the probability density function at the bin, `bin_count / sample_count / bin_volume`. Default: `False` .

Returns

(Tensor, list of Tensor), the values of the histogram and the bin edges.

Raises

ValueError – If *range* does not have the same size as the number of samples.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import numpy as np
>>> sample = np.arange(15).reshape(5, 3)
>>> print(sample)
[[ 0  1  2]
[ 3  4  5]
[ 6  7  8]
[ 9 10 11]
[12 13 14]]
>>> print(np.histogramdd(sample, bins=(2, 3, 4)))
(Tensor(shape=[2, 3, 4], dtype=Float32, value=
[[[ 1.00000000e+00,  1.00000000e+00,  0.00000000e+00,  0.00000000e+00],
[ 0.00000000e+00,  0.00000000e+00,  0.00000000e+00,  0.00000000e+00],
[ 0.00000000e+00,  0.00000000e+00,  0.00000000e+00,  0.00000000e+00]],
[[ 0.00000000e+00,  0.00000000e+00,  0.00000000e+00,  0.00000000e+00],
[ 0.00000000e+00,  0.00000000e+00,  1.00000000e+00,  0.00000000e+00],
[ 0.00000000e+00,  0.00000000e+00,  0.00000000e+00,  2.00000000e+00]]]),
[Tensor(shape=[3], dtype=Float32, value= [ 0.00000000e+00,  6.00000000e+00,  1.
↪20000000e+01]),
Tensor(shape=[4], dtype=Float32, value=
[ 1.00000000e+00,  5.00000000e+00,  9.00000000e+00,  1.30000000e+01]),
Tensor(shape=[5], dtype=Float32, value=
[ 2.00000000e+00,  5.00000000e+00,  8.00000000e+00,  1.10000000e+01,  1.40000000e+01])])
```

13.4.55 mindspore.numpy.hypot

`mindspore.numpy.`**`hypot`**(*x1*, *x2*, *dtype=None*)

Given the "legs" of a right triangle, returns its hypotenuse.

Equivalent to `sqrt(x1**2 + x2**2)`, element-wise. If *x1* or *x2* is scalar_like (i.e., unambiguously cast-able to a scalar type), it is broadcast for use with each element of the other argument. (See Examples)

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On GPU, the supported dtypes are np.float16 and np.float32. On CPU, the supported dtypes are np.float16, np.float32, and np.float64.

Parameters

- **x1** (`Tensor`) –Leg of the triangle(s).
- **x2** (`Tensor`) –Leg of the triangle(s). If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the hypotenuse of the triangle(s). This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.hypot(3*np.ones((3, 3)), 4*np.ones((3, 3)))
>>> print(output)
[[5. 5. 5.]
[5. 5. 5.]
[5. 5. 5.]]
>>> output = np.hypot(3*np.ones((3, 3)), np.array([4.0]))
>>> print(output)
[[5. 5. 5.]
[5. 5. 5.]
[5. 5. 5.]]
```

13.4.56 mindspore.numpy.inner

mindspore.numpy.**inner**(*a*, *b*)

Returns the inner product of two tensors.

Ordinary inner product of vectors for 1-D tensors (without complex conjugation), in higher dimensions a sum product over the last axes.

Note: Numpy argument *out* is not supported. On GPU, the supported dtypes are np.float16, and np.float32. On CPU, the supported dtypes are np.float16, np.float32, and np.float64.

Parameters

- **a** (Tensor) – input tensor. If *a* and *b* are nonscalar, their last dimensions must match.
- **b** (Tensor) – input tensor. If *a* and *b* are nonscalar, their last dimensions must match.

Returns

Tensor or scalar.

Raises

ValueError – If `x1.shape[-1] != x2.shape[-1]`.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.ones((5, 3))
>>> b = np.ones((2, 7, 3))
>>> output = np.inner(a, b)
>>> print(output)
[[[3. 3. 3. 3. 3. 3. 3.]
[3. 3. 3. 3. 3. 3. 3.]]
[[3. 3. 3. 3. 3. 3. 3.]
[3. 3. 3. 3. 3. 3. 3.]]
```

(continues on next page)

(continued from previous page)

```
[[3. 3. 3. 3. 3. 3. 3.]
[3. 3. 3. 3. 3. 3. 3.]]
[[3. 3. 3. 3. 3. 3. 3.]
[3. 3. 3. 3. 3. 3. 3.]]
[[3. 3. 3. 3. 3. 3. 3.]
[3. 3. 3. 3. 3. 3. 3.]]]
```

13.4.57 mindspore.numpy.interp

mindspore.numpy.**interp**(*x*, *xp*, *fp*, *left=None*, *right=None*)

One-dimensional linear interpolation for monotonically increasing sample points. Returns the one-dimensional piecewise linear interpolant to a function with given discrete data points *(xp, fp)*, evaluated at *x*.

Note: Numpy argument *period* is not supported. Complex values are not supported.

Parameters

- **x** (*Union[int, float, bool, list, tuple, Tensor]*) – The x-coordinates at which to evaluate the interpolated values.
- **xp** (*Union[int, float, bool, list, tuple, Tensor]*) – 1-D sequence of floats, the x-coordinates of the data points, must be increasing.
- **fp** (*Union[int, float, bool, list, tuple, Tensor]*) – 1-D sequence of floats, the y-coordinates of the data points, same length as *xp*.
- **left** (*float, optional*) – Value to return for `x < xp[0]`, default is `fp[0]` once obtained. Default: `None` .
- **right** (*float, optional*) – Value to return for `x > xp[-1]`, default is `fp[-1]` once obtained. Default: `None` .

Returns

Tensor, the interpolated values, same shape as *x*.

Raises

ValueError – If *xp* or *fp* is not one-dimensional, or if *xp* and *fp* do not have the same length.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> xp = [1, 2, 3]
>>> fp = [3, 2, 0]
>>> print(np.interp([0, 1, 1.5, 2.72, 3.14], xp, fp))
[3.         3.         2.5        0.55999994 0.        ]
>>> UNDEF = -99.0
>>> print(np.interp(3.14, xp, fp, right=UNDEF))
-99.0
```

13.4.58 mindspore.numpy.invert

mindspore.numpy.**invert**(*x*, *dtype=None*)

Computes bit-wise inversion, or bit-wise NOT, element-wise. Computes the bit-wise NOT of the underlying binary representation of the integers in the input arrays. This ufunc implements the C/Python operator ~. For signed integer inputs, the two's complement is returned. In a two's-complement system negative numbers are represented by the two's complement of the absolute value. This is the most common method of representing signed integers on computers [1]. A N-bit two's-complement system can represent every integer in the range -2^{N-1} to +2^{N-1}-1.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. Supported dtypes on Ascend: np.int16, np.uint16.

Parameters

- **x** (Tensor) –Only integer and boolean types are handled.
- **dtype** (*mindspore.dtype*, optional) –Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore.numpy as np
>>> print(np.invert(np.array(13, dtype=np.uint16)))
65522
```

13.4.59 mindspore.numpy.kron

mindspore.numpy.**kron**(*a*, *b*)

Kronecker product of two arrays.

Computes the Kronecker product, a composite array made of blocks of the second array scaled by the first.

Note: Booleans are not supported.

Parameters

- **a** (*Union[int, float, list, tuple, Tensor]*) –input values.
- **b** (*Union[int, float, list, tuple, Tensor]*) –input values.

Returns

Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.kron([1,10,100], [5,6,7])
>>> print(output)
[  5   6   7  50  60  70 500 600 700]
>>> output = np.kron([5,6,7], [1,10,100])
>>> print(output)
[  5  50 500   6  60 600   7  70 700]
>>> output = np.kron(np.eye(2), np.ones((2,2)))
>>> print(output)
[[1. 1. 0. 0.]
[1. 1. 0. 0.]
[0. 0. 1. 1.]
[0. 0. 1. 1.]]
```

13.4.60 mindspore.numpy.lcm

mindspore.numpy.**lcm**(*x1*, *x2*, *dtype=None*)

Returns the lowest common multiple of |x1| and |x2|.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) – input data.
- **x2** (Tensor) – input data.
- **dtype** (*mindspore.dtype*, optional) – Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the lowest common multiple of the absolute value of the inputs. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.lcm(np.arange(6), np.array(20))
>>> print(output)
[ 0 20 20 60 20 20]
```

13.4.61 mindspore.numpy.log

mindspore.numpy.**log**(*x*, *dtype=None*)

Returns the natural logarithm, element-wise.

The natural logarithm log is the inverse of the exponential function, so that `log(exp(x)) = x`. The natural logarithm is logarithm in base e.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On GPU, the supported dtypes are np.float16, and np.float32. On CPU, the supported dtypes are np.float16, np.float32, and np.float64.

Parameters

- **x** (Tensor) –Input array.
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the natural logarithm of *x*, element-wise. This is a scalar if *x* is a scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([2, 3, 4]).astype('float32')
>>> output = np.log(x)
>>> print(output)
[0.69314575 1.09861    1.3862929 ]
```

13.4.62 mindspore.numpy.log10

mindspore.numpy.**log10**(*x*, *dtype=None*)

Base-10 logarithm of *x*.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) –Input tensor.
- **dtype** (*mindspore.dtype*, optional) –Default: `None`. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([10, 100, 1000]).astype('float16')
>>> output = np.log10(x)
>>> print(output)
[1. 2. 3.]
```

13.4.63 mindspore.numpy.log1p

mindspore.numpy.**log1p**(*x*, *dtype=None*)

Returns the natural logarithm of one plus the input array, element-wise.

Calculates `log(1 + x)`.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) –Input array.
- **dtype** (*mindspore.dtype*) –Default: `None`. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([1, 2, 3]).astype('float16')
>>> output = np.log1p(x)
>>> print(output)
[0.6934 1.099 1.387 ]
```

13.4.64 mindspore.numpy.log2

mindspore.numpy.**log2**(*x*, *dtype=None*)

Base-2 logarithm of *x*.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) –Input tensor.
- **dtype** (*mindspore.dtype*, optional) –Default: `None`. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([2, 4, 8]).astype('float16')
>>> output = np.log2(x)
>>> print(output)
[1. 2. 3.]
```

13.4.65 mindspore.numpy.logaddexp

`mindspore.numpy.`**`logaddexp`**(*x1*, *x2*, *dtype=None*)

Logarithm of the sum of exponentiations of the inputs. Calculates `log(exp(x1) + exp(x2))`.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (`Tensor`) –Input array.
- **x2** (`Tensor`) –Input array. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*) –Default: `None`. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.array([1, 2, 3]).astype('float16')
>>> x2 = np.array(2).astype('float16')
>>> output = np.logaddexp(x1, x2)
>>> print(output)
[2.312 2.693 3.312]
```

13.4.66 mindspore.numpy.logaddexp2

mindspore.numpy.**logaddexp2**(*x1*, *x2*, *dtype=None*)

Logarithm of the sum of exponentiations of the inputs in base of 2.

Calculates `log2(2**x1 + 2**x2)`. This function is useful in machine learning when the calculated probabilities of events may be so small as to exceed the range of normal floating point numbers. In such cases the base-2 logarithm of the calculated probability can be used instead. This function allows adding probabilities stored in such a fashion.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) –Input tensor.
- **x2** (Tensor) –Input tensor. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*) –Default: `None`. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.array([2, 4, 8]).astype('float16')
>>> x2 = np.array(2).astype('float16')
>>> output = np.logaddexp2(x1, x2)
>>> print(output)
[3. 4.32 8.02]
```

13.4.67 mindspore.numpy.matmul

mindspore.numpy.**matmul**(*x1*, *x2*, *dtype=None*)

Returns the matrix product of two arrays.

Note: Numpy arguments *out*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On GPU, the supported dtypes are np.float16 and np.float32. On CPU, the supported dtypes are np.float16 and np.float32.

Parameters

- **x1** (Tensor) –Input tensor, scalar not allowed.
- **x2** (Tensor) –Input tensor, scalar not allowed.
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the matrix product of the inputs. This is a scalar only when both *x1*, *x2* are 1-d vectors.

Raises

ValueError – If the last dimension of *x1* is not the same size as the second-to-last dimension of *x2*, or if a scalar value is passed in.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.arange(2*3*4).reshape(2, 3, 4).astype('float32')
>>> x2 = np.arange(4*5).reshape(4, 5).astype('float32')
>>> output = np.matmul(x1, x2)
>>> print(output)
[[[  70.   76.   82.   88.   94.]
[ 190.  212.  234.  256.  278.]
[ 310.  348.  386.  424.  462.]]
[[ 430.  484.  538.  592.  646.]
[ 550.  620.  690.  760.  830.]
[ 670.  756.  842.  928. 1014.]]]
```

13.4.68 mindspore.numpy.matrix_power

mindspore.numpy.**matrix_power**(*a*, *n*)

Raises a square matrix to the (integer) power *n*.

For positive integers *n*, the power is computed by repeated matrix squarings and matrix multiplications. If $n == 0$, the identity matrix of the same shape as *M* is returned.

Note: Stacks of object matrices are not currently supported and $n < 0$ is not supported.

Parameters

- **a** (*Union[int, float, bool, list, tuple, Tensor]*) – Input matrix.
- **n** (*int*) – The exponent can be any integer or long integer, positive or zero.

Returns

Tensor.

Raises

- **TypeError** – If the input can not be converted to a tensor or the exponent is not integer.
- **ValueError** – If the input includes less than 2 dimensions or the last 2 dimensions are not square.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import numpy as np
>>> a = np.arange(16).reshape(4, 4).astype('float32')
>>> print(np.matrix_power(a, 2))
[[ 56.  62.  68.  74.]
 [152. 174. 196. 218.]
 [248. 286. 324. 362.]
 [344. 398. 452. 506.]]
```

13.4.69 mindspore.numpy.maximum

mindspore.numpy.**maximum**(*x1*, *x2*, *dtype=None*)

Returns the element-wise maximum of array elements.

Compares two arrays and returns a new array containing the element-wise maxima.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On Ascend, input arrays containing inf or NaN are not supported.

Parameters

- **x1** (Tensor) – Input array
- **x2** (Tensor) – The array holding the elements to be compared. If `x1.shape != x2.shape`, they must be broadcastable to a common shape (which becomes the shape of the output).
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the maximum of *x1* and *x2*, element-wise. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.maximum(np.array([2, 3, 4]), np.array([1, 5, 2]))
>>> print(output)
[2 5 4]
```

13.4.70 mindspore.numpy.mean

mindspore.numpy.**mean**(*a*, *axis=None*, *keepdims=False*, *dtype=None*)

Computes the arithmetic mean along the specified axis.

Returns the average of the array elements. The average is taken over the flattened array by default, otherwise over the specified axis.

Note: Numpy arguments *out* is not supported. On GPU, the supported dtypes are np.float16, and np.float32.

Parameters

- **a** (Tensor) – input tensor containing numbers whose mean is desired. If a is not an array, a conversion is attempted.
- **axis** (*Union[int, tuple(int), None], optional*) – Axis or axes along which the means are computed. The default is to compute the mean of the flattened array. If this is a tuple of ints, a mean is performed over multiple axes. Default: None .
- **keepdims** (*bool, optional*) – If this is set to True , the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input tensor. Default: False .
- **dtype** (*mindspore.dtype*, optional) – Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, an array containing the mean values.

Raises

ValueError – If axes are out of the range of [-a.ndim, a.ndim), or if the axes contain duplicates.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.arange(6, dtype='float32')
>>> output = np.mean(a, 0)
>>> print(output)
2.5
```

13.4.71 mindspore.numpy.minimum

mindspore.numpy.**minimum**(*x1*, *x2*, *dtype=None*)

Element-wise minimum of tensor elements.

Compares two tensors and returns a new tensor containing the element-wise minima.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On Ascend, input arrays containing inf or NaN are not supported.

Parameters

- **x1** (Tensor) –first input tensor to be compared.
- **x2** (Tensor) –second input tensor to be compared.
- **dtype** (*mindspore.dtype*, optional) –Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor, element-wise minimum of *x1* and *x2*.

Raises

- **TypeError** –If inputs have types not specified above.
- **ValueError** –If the shapes of *x1* and *x2* cannot be broadcast.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.asarray([1, 2])
>>> b = np.asarray([[1, 3],[1, 4]])
>>> print(np.minimum(a, b))
[[1 2]
[1 2]]
```

13.4.72 mindspore.numpy.multi_dot

mindspore.numpy.**multi_dot**(*arrays*)

Computes the dot product of two or more arrays in a single function call, while automatically selecting the fastest evaluation order. multi_dot chains numpy.dot and uses optimal parenthesization of the matrices. For more information, refer to the wiki page. Depending on the shapes of the matrices, this can speed up the multiplication a lot. If the first argument is 1-D, it is treated as a row vector. If the last argument is 1-D, it is treated as a column vector. The other arguments must be 2-D.

Note: Numpy argument *out* is not supported.

Parameters

arrays (*sequence of array_like*) –If the first argument is 1-D, it is treated as row vector. If the last argument is 1-D, it is treated as column vector. The other arguments must be 2-D.

Returns

Tensor, the dot product of the supplied arrays.

Raises

ValueError –arrays are not 2-D.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> A = np.ones((10000, 100))
>>> B = np.ones((100, 100))
>>> C = np.ones((100, 5))
>>> D = np.ones((5, 333))
>>> output = np.multi_dot([A, B, C, D])
>>> print(output)
[[50000. 50000. 50000. ... 50000. 50000. 50000.]
[50000. 50000. 50000. ... 50000. 50000. 50000.]
[50000. 50000. 50000. ... 50000. 50000. 50000.]
...
[50000. 50000. 50000. ... 50000. 50000. 50000.]
[50000. 50000. 50000. ... 50000. 50000. 50000.]
[50000. 50000. 50000. ... 50000. 50000. 50000.]]
```

13.4.73 mindspore.numpy.multiply

mindspore.numpy.**multiply**(*x1*, *x2*, *dtype=None*)

Multiplies arguments element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) – input tensor to be multiplied.
- **x2** (Tensor) – input tensor to be multiplied.
- **dtype** (*mindspore.dtype*, optional) – Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the product of *x1* and *x2*, element-wise. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.full((3, 2), [1, 2])
>>> x2 = np.full((3, 2), [3, 4])
>>> output = np.multiply(x1, x2)
>>> print(output)
[[3 8]
[3 8]
[3 8]]
```

13.4.74 mindspore.numpy.nancumsum

mindspore.numpy.**nancumsum**(*a*, *axis=None*, *dtype=None*)

Return the cumulative sum of array elements over a given axis treating Not a Numbers (NaNs) as zero. The cumulative sum does not change when NaNs are encountered and leading NaNs are replaced by zeros.

Zeros are returned for slices that are all-NaN or empty.

Note: If `a.dtype` is *int8*, *int16* or *bool*, the result *dtype* will be elevated to *int32*.

Parameters

- **a** (`Tensor`) – Input tensor.
- **axis** (*int, optional*) – Axis along which the cumulative sum is computed. The default (None) is to compute the cumsum over the flattened array.
- **dtype** (*mindspore.dtype*, optional) – If not specified, stay the same as *a*, unless *a* has an integer dtype with a precision less than that of the default platform integer. In that case, the default platform integer is used. Default: `None`.

Returns

Tensor.

Raises

- **TypeError** – If input arguments have types not specified above.
- **ValueError** – If axis is out of range.

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([[1, 2], [3, np.nan]])
>>> output = np.nancumsum(a)
>>> print(output)
[1. 3. 6. 6.]
>>> output = np.nancumsum(a, axis=0)
>>> print(output)
[[1. 2.]
[4. 2.]]
>>> output = np.nancumsum(a, axis=1)
>>> print(output)
[[1. 3.]
[3. 3.]]
```

13.4.75 mindspore.numpy.nanmax

mindspore.numpy.**nanmax**(*a*, *axis=None*, *dtype=None*, *keepdims=False*)

Return the maximum of an array or maximum along an axis, ignoring any NaNs.

Note: Numpy arguments *out* is not supported. For all NaN slices, a very small negative number is returned instead of NaN.

Parameters

- **a** (*Union[int, float, list, tuple, Tensor]*) – Array containing numbers whose maximum is desired. If *a* is not an array, a conversion is attempted.
- **axis** (*Union[int, tuple(int), None], optional*) – Axis or axes along which the maximum is computed. The default is to compute the maximum of the flattened array. Default: `None` .
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.
- **keepdims** (*boolean, optional*) – Default: `False` . If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original *a*.

Returns

Tensor.

Raises

ValueError – If axes are out of the range of `[-a.ndim, a.ndim)` , or if the axes contain duplicates.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([[1, 2], [3, np.nan]])
>>> output = np.nanmax(a)
>>> print(output)
3.0
>>> output = np.nanmax(a, axis=0)
>>> print(output)
[3. 2.]
```

13.4.76 mindspore.numpy.nanmean

mindspore.numpy.**nanmean**(*a*, *axis=None*, *dtype=None*, *keepdims=False*)

Computes the arithmetic mean along the specified axis, ignoring NaNs.

Returns the average of the array elements. The average is taken over the flattened array by default, otherwise over the specified axis. float32 intermediate and return values are used for integer inputs.

Note: Numpy arguments *out* is not supported.

Parameters

- **a** (*Union[int, float, list, tuple, Tensor]*) –Array containing numbers whose mean is desired. If *a* is not an array, a conversion is attempted.
- **axis** (*Union[int, tuple of int, None], optional*) –Axis or axes along which the mean is computed. The default is to compute the mean of the flattened array. Default: `None` .
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.
- **keepdims** (*boolean, optional*) –Default: `False` . If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original *a*.

Returns

Tensor.

Raises

ValueError –If axes are out of the range of `[-a.ndim, a.ndim)` , or if the axes contain duplicates.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([[1, np.nan], [3, 4]])
>>> output = np.nanmean(a)
>>> print(output)
2.6666667
>>> output = np.nanmean(a, axis=0)
>>> print(output)
[2. 4.]
>>> output = np.nanmean(a, axis=1)
>>> print(output)
[1.  3.5]
```

13.4.77 mindspore.numpy.nanmin

mindspore.numpy.**nanmin**(*a*, *axis=None*, *dtype=None*, *keepdims=False*)

Returns the minimum of array elements over a given axis, ignoring any NaNs.

Note: Numpy arguments *out* is not supported. For all-NaN slices, a very large number is returned instead of NaN. On Ascend, since checking for NaN is currently not supported, it is not recommended to use np.nanmin. If the array does not contain NaN, np.min should be used instead.

Parameters

- **a** (*Union[int, float, list, tuple, Tensor]*) –Array containing numbers whose minimum is desired. If *a* is not an array, a conversion is attempted.
- **axis** (*Union[int, tuple(int), None], optional*) –Axis or axes along which the minimum is computed. The default is to compute the minimum of the flattened array. Default: `None` .
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

- **keepdims** (*boolean, optional*) –Default: `False` . If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original *a*.

Returns

Tensor.

Raises

ValueError –If axes are out of the range of `[-a.ndim, a.ndim)` , or if the axes contain duplicates.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([[1, 2], [3, np.nan]])
>>> output = np.nanmin(a)
>>> print(output)
1.0
>>> output = np.nanmin(a, axis=0)
>>> print(output)
[1. 2.]
```

13.4.78 mindspore.numpy.nanstd

`mindspore.numpy.`**nanstd**(*a*, *axis=None*, *dtype=None*, *ddof=0*, *keepdims=False*)

Computes the standard deviation along the specified axis, while ignoring NaNs.

Returns the standard deviation, a measure of the spread of a distribution, of the non-NaN array elements. The standard deviation is computed for the flattened array by default, otherwise over the specified axis.

Note: Numpy arguments *out* is not supported. On GPU, the supported dtypes are np.float16, and np.float32.

Parameters

- **a** (*Union[int, float, list, tuple, Tensor]*) –Calculates the standard deviation of the non-NaN values.
- **axis** (*Union[int, tuple of int, None], optional*) –Axis or axes along which the standard deviation is computed. The default is to compute the standard deviation of the flattened array. Default: `None` .
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.
- **ddof** (*int, optional*) –"Delta Degrees of Freedom": the divisor used in the calculation is `N - ddof`, where *N* represents the number of non-NaN elements. By default *ddof* is zero.
- **keepdims** (*boolean, optional*) –Default: `False` . If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original *a*.

Returns

Tensor.

Raises

ValueError –If axes are out of the range of `[-a.ndim, a.ndim)` , or if the axes contain duplicates.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([[1, np.nan], [3, 4]])
>>> output = np.nanstd(a)
>>> print(output)
1.2472192
>>> output = np.nanstd(a, axis=0)
>>> print(output)
[1. 0.]
>>> output = np.nanstd(a, axis=1)
>>> print(output)
[0.  0.5]
```

13.4.79 mindspore.numpy.nansum

mindspore.numpy.**nansum**(*a*, *axis=None*, *dtype=None*, *keepdims=False*)

Returns the sum of array elements over a given axis treating Not a Numbers (NaNs) as zero.

Note: Numpy arguments *out* is not supported.

Parameters

- **a** (*Union[int, float, list, tuple, Tensor]*) – Array containing numbers whose sum is desired. If *a* is not an array, a conversion is attempted.
- **axis** (*Union[int, tuple of int, None], optional*) – Axis or axes along which the sum is computed. The default is to compute the sum of the flattened array. Default: `None` .
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.
- **keepdims** (*boolean, optional*) – Default: `False` . If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original *a*.

Returns

Tensor.

Raises

ValueError – If axes are out of the range of `[-a.ndim, a.ndim)` , or if the axes contain duplicates.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([[1, 1], [1, np.nan]])
>>> output = np.nansum(a)
>>> print(output)
3.0
>>> output = np.nansum(a, axis=0)
>>> print(output)
[2. 1.]
```

13.4.80 mindspore.numpy.nanvar

mindspore.numpy.**nanvar**(*a*, *axis=None*, *dtype=None*, *ddof=0*, *keepdims=False*)

Computes the variance along the specified axis, while ignoring NaNs.

Returns the variance of the array elements, a measure of the spread of a distribution. The variance is computed for the flattened array by default, otherwise over the specified axis.

Note: Numpy arguments *out* is not supported. On GPU, the supported dtypes are np.float16, and np.float32.

Parameters

- **a** (*Union[int, float, list, tuple, Tensor]*) – Array containing numbers whose variance is desired. If *a* is not an array, a conversion is attempted.
- **axis** (*Union[int, tuple of int, None], optional*) – Axis or axes along which the variance is computed. The default is to compute the variance of the flattened array. Default: `None` .
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.
- **ddof** (*int, optional*) – "Delta Degrees of Freedom": the divisor used in the calculation is `N - ddof`, where *N* represents the number of non-NaN elements. By default *ddof* is zero.
- **keepdims** (*boolean, optional*) – Default: `False` . If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the original *a*.

Returns

Tensor.

Raises

ValueError – If axes are out of the range of `[-a.ndim, a.ndim)`, or if the axes contain duplicates.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.array([[1, np.nan], [3, 4]])
>>> output = np.nanvar(a)
>>> print(output)
1.5555557
>>> output = np.nanvar(a, axis=0)
>>> print(output)
[1. 0.]
>>> output = np.nanvar(a, axis=1)
>>> print(output)
[0.   0.25]
```

13.4.81 mindspore.numpy.negative

mindspore.numpy.**negative**(*a*, *dtype=None*)

Numerical negative, element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **a** (Tensor) −Input tensor.
- **dtype** (*mindspore.dtype*, optional) −Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.asarray([1, -1]).astype('float32')
>>> output = np.negative(a)
>>> print(output)
[-1. 1.]
```

13.4.82 mindspore.numpy.norm

mindspore.numpy.**norm**(*x*, *ord=None*, *axis=None*, *keepdims=False*)

Matrix or vector norm. This function is able to return one of eight different matrix norms, or one of an infinite number of vector norms (described below), depending on the value of the ord parameter.

Note: Nuclear norm and 2-norm are not supported for matrices.

Parameters

- **x** (*Union[int, float, bool, list, tuple, Tensor]*) – Input array. If *axis* is None, *x* must be 1-D or 2-D, unless *ord* is None. If both *axis* and *ord* are None, the 2-norm of `x.ravel` will be returned.
- **ord** (*Union[None, 'fro', 'nuc', inf, -inf, int, float], optional*) – Order of the norm. inf means numpy's inf object. Default: `None` .
- **axis** (*Union[int, 2-tuple(int), None], optional*) – If *axis* is an integer, it specifies the axis of *x* along which to compute the vector norms. If *axis* is a 2-tuple, it specifies the axes that hold 2-D matrices, and the matrix norms of these matrices are computed. If *axis* is None then either a vector norm (when x is 1-D) or a matrix norm (when *x* is 2-D) is returned. The default is None.
- **keepdims** (*boolean, optional*) – If this is set to True, the axes which are normed over are left in the result as dimensions with size one. With this option the result will broadcast correctly against the original *x*.

Returns

Tensor, norm of the matrix or vector(s).

Raises

ValueError – If the norm order is not defined.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.norm(np.arange(9).astype(np.float32)))
14.282857
```

13.4.83 mindspore.numpy.outer

mindspore.numpy.**outer**(*a*, *b*)

Computes the outer product of two vectors.

Given two vectors, `a = [a0, a1, ..., aM]` and `b = [b0, b1, ..., bN]`, the outer product is:

```
[[a0*b0 a0*b1 ... a0*bN ]
[a1*b0 . ]
[ ... . ]
[aM*b0 aM*bN ]]
```

Note: Numpy argument `out` is not supported. On GPU, the supported dtypes are np.float16, and np.float32. On CPU, the supported dtypes are np.float16, np.float32, and np.float64.

Parameters

- **a** (Tensor) – first input vector. Input is flattened if not already 1-dimensional.
- **b** (Tensor) – second input vector. Input is flattened if not already 1-dimensional.

Returns

Tensor or scalar, `out[i, j] = a[i] * b[j]`.

Raises

TypeError – If the input is not a tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.full(7, 2).astype('float32')
>>> b = np.full(4, 3).astype('float32')
>>> output = np.outer(a, b)
>>> print(output)
[[6. 6. 6. 6.]
[6. 6. 6. 6.]
[6. 6. 6. 6.]
[6. 6. 6. 6.]
[6. 6. 6. 6.]
[6. 6. 6. 6.]
[6. 6. 6. 6.]]
```

13.4.84 mindspore.numpy.polyadd

mindspore.numpy.**polyadd**(*a1*, *a2*)

Finds the sum of two polynomials. Returns the polynomial resulting from the sum of two input polynomials.

Note: Numpy object poly1d is currently not supported.

Parameters

- **a1** (*Union[int, float, list, tuple, Tensor]*) – Input polynomial.
- **a2** (*Union[int, float, list, tuple, Tensor]*) – Input polynomial.

Returns

Tensor, the sum of the inputs.

Raises

ValueError –If the input array has more than 1 dimensions.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.polyadd([1, 2], [9, 5, 4]))
[9 6 6]
```

13.4.85 mindspore.numpy.polyder

mindspore.numpy.**polyder**(*p*, *m=1*)

Returns the derivative of the specified order of a polynomial.

Note: Numpy object poly1d is currently not supported.

Parameters

- **p** (*Union[int, float, bool, list, tuple, Tensor]*) –Polynomial to differentiate. A sequence is interpreted as polynomial coefficients.
- **m** (*int, optional*) –Default: `1` , order of differentiation.

Returns

Tensor, a new polynomial representing the derivative.

Raises

ValueError –If *p* has more than 1 dimensions.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.polyder([1, 1, 1, 1]))
[3 2 1]
```

13.4.86 mindspore.numpy.polyint

mindspore.numpy.**polyint**(*p*, *m=1*, *k=None*)

Returns an antiderivative (indefinite integral) of a polynomial.

Note: Numpy object poly1d is currently not supported.

Parameters

- **p** (*Union[int, float, bool, list, tuple, Tensor]*) –Polynomial to integrate. A sequence is interpreted as polynomial coefficients.
- **m** (*int, optional*) –Defaults to 1, Order of the antiderivative.
- **k** (*Union[int, list[int]], optional*) –Integration constants. They are given in the order of integration: those corresponding to highest-order terms come first. If None (default), all constants are assumed to be zero. If `m = 1`, a single scalar can be given instead of a list.

Returns

Tensor, a new polynomial representing the antiderivative.

Raises

ValueError –If *p* has more than 1 dimensions.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.polyint([1, 1, 1]))
[0.33333334 0.5        1.         0.        ]
```

13.4.87 mindspore.numpy.polymul

mindspore.numpy.**polymul**(*a1*, *a2*)

Finds the product of two polynomials.

Note: Numpy object poly1d is currently not supported.

Parameters

- **a1** (*Union[int, float, bool, list, tuple, Tensor]*) –Input polynomial.
- **a2** (*Union[int, float, bool, list, tuple, Tensor]*) –Input polynomial.

Returns

Tensor, a new polynomial representing the derivative.

Raises

ValueError –If the input array has more than 1 dimensions.

Supported Platforms:

GPU

Examples

```
>>> import mindspore.numpy as np
>>> print(np.polymul([3, 1, 2], [2, 5]))
[ 6 17  9 10]
```

13.4.88 mindspore.numpy.polysub

mindspore.numpy.**polysub**(*a1*, *a2*)

Difference (subtraction) of two polynomials. Given two polynomials *a1* and *a2*, returns `a1 - a2`.

Note: Numpy object poly1d is currently not supported.

Parameters

- **a1** (*Union[int, float, list, tuple, Tensor]*) –Minuend polynomial.
- **a2** (*Union[int, float, list, tuple, Tensor]*) –Subtrahend polynomial.

Returns

Tensor, the difference of the inputs.

Raises

ValueError –If the input array has more than 1 dimensions.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> print(np.polysub([2, 10, -2], [3, 10, -4]))
[-1  0  2]
```

13.4.89 mindspore.numpy.polyval

mindspore.numpy.**polyval**(*p*, *x*)

Evaluates a polynomial at specific values. If *p* is of length *N*, this function returns the value: `p[0]*x**(N-1) + p[1]*x**(N-2) + ... + p[N-2]*x + p[N-1]` If *x* is a sequence, then `p(x)` is returned for each element of *x*. If *x* is another polynomial then the composite polynomial `p(x(t))` is returned.

Note: Numpy object poly1d is currently not supported.

Parameters

- **p** (*Union[int, float, bool, list, tuple, Tensor]*) – 1D array of polynomial coefficients (including coefficients equal to zero) from highest degree to the constant term.
- **x** (*Union[int, float, bool, list, tuple, Tensor]*) – A number, an array of numbers, at which to evaluate *p*.

Returns

Tensor.

Raises

ValueError – If *p* has more than 1 dimensions.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.polyval([3.,0.,1.], 5.))
76.0
```

13.4.90 mindspore.numpy.positive

mindspore.numpy.**positive**(*a*, *dtype=None*)

Numerical positive, element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **a** (`Tensor`) – Input tensor.
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> a = np.asarray([1, -1]).astype('float32')
>>> output = np.positive(a)
>>> print(output)
[1. -1.]
```

13.4.91 mindspore.numpy.power

mindspore.numpy.**power**(*x1*, *x2*, *dtype=None*)

First array elements raised to powers from second array, element-wise.

Raises each base in *x1* to the positionally-corresponding power in *x2*.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On GPU, the supported dtypes are np.float16, and np.float32.

Parameters

- **x1** (Tensor) – The bases.
- **x2** (Tensor) – The exponents.
- **dtype** (*mindspore.dtype*, optional) – Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the bases in *x1* raised to the exponents in *x2*. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.full((3, 2), [1, 2]).astype('float32')
>>> x2 = np.full((3, 2), [3, 4]).astype('float32')
>>> output = np.power(x1, x2)
>>> print(output)
[[ 1. 16.]
 [ 1. 16.]
 [ 1. 16.]]
```

13.4.92 mindspore.numpy.promote_types

mindspore.numpy.**promote_types**(*type1*, *type2*)

Returns the data type with the smallest size and smallest scalar kind.

Note: The promotion rule is slightly different from original Numpy, but more like jax, due to the preference on `32-bit` over `64-bit` data types.

Parameters

- **type1** (Union[*mindspore.dtype*, str]) –First data type.
- **type2** (Union[*mindspore.dtype*, str]) –Second data type.

Returns

The promoted data type.

Raises

TypeError –If the input are not valid *mindspore.dtype* input.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.promote_types(np.float32, np.float64)
>>> print(output)
Float64
```

13.4.93 mindspore.numpy.ptp

mindspore.numpy.**ptp**(*x*, *axis=None*, *keepdims=False*)

Range of values (maximum - minimum) along an axis. The name of the function comes from the acronym for "peak to peak".

Note: Numpy arguments *dtype* and *out* are not supported.

Parameters

- **x** (`Tensor`) –Input tensor.
- **axis** (*Union[None, int, tuple(int)]*) –Axis or axes along which the range is computed. The default is to compute the variance of the flattened array. Default: `None`.
- **keepdims** (*bool*) –If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input tensor. If the default value is passed, then keepdims will not be passed through to the ptp method of sub-classes of tensor, however any non-default value will be. Default: `False`.

Returns

Tensor.

Raises

TypeError –If inputs have types not specified above.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([[4.0, 9.0, 2.0, 10.0], [6.0, 9.0, 7.0, 12.0]])
>>> print(np.ptp(x, axis=1))
[8. 6.]
>>> print(np.ptp(x, axis=0))
[2. 0. 5. 2.]
```

13.4.94 mindspore.numpy.rad2deg

mindspore.numpy.**rad2deg**(*x*, *dtype=None*)

Converts angles from radians to degrees.

Parameters

- **x** (Tensor) –Angles in radians.
- **dtype** (*mindspore.dtype*, optional) –Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor, the corresponding angle in degrees. This is a tensor scalar if *x* is a tensor scalar.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.asarray([1, 2, 3, -4, -5])
>>> output = np.rad2deg(x)
>>> print(output)
[  57.295776  114.59155   171.88733  -229.1831   -286.47888 ]
```

13.4.95 mindspore.numpy.radians

mindspore.numpy.**radians**(*x*, *dtype=None*)

Converts angles from degrees to radians.

Parameters

- **x** (Tensor) −Angles in degrees.
- **dtype** (*mindspore.dtype*, optional) −Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor, the corresponding radian values. This is a tensor scalar if *x* is a tensor scalar.

Raises

TypeError −If *x* is not a tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.asarray([1, 2, 3, -4, -5])
>>> output = np.radians(x)
>>> print(output)
[ 0.01745329  0.03490658  0.05235988 -0.06981317 -0.08726647]
```

13.4.96 mindspore.numpy.ravel_multi_index

mindspore.numpy.**ravel_multi_index**(*multi_index*, *dims*, *mode='clip'*, *order='C'*)

Converts a tuple of index arrays into an array of flat indices, applying boundary modes to the multi-index.

Note: *raise* mode is not supported. Default mode is *clip*.

Parameters

- **multi_index** (*tuple of array_like*) −A tuple of integer arrays, one array for each dimension.
- **dims** (*Union[int, tuple(int)]*) −The shape of array into which the indices from multi_index apply.
- **mode** ({*wrap*, *clip*}, optional) −Specifies how out-of-bounds indices are handled. Default: 'clip'.
  - *wrap*: wrap around
  - *clip*: clip to the range

  In *clip* mode, a negative index which would normally wrap will clip to 0 instead.
- **order** ({*C*, *F*}, optional) −Determines whether the multi-index should be viewed as indexing in row-major (C-style) or column-major (Fortran-style) order.

Returns

Raveled_indices array. An array of indices into the flattened version of an array of dimensions dims.

Raises

- **TypeError** –If *multi_index* or *dims* can not be converted to tensor or *dims* is not a sequence of integer values.
- **ValueError** –If the length of *multi_index* and that of *dims* are not equal.

Supported Platforms:

`GPU`

Examples

```
>>> import mindspore.numpy as np
>>> arr = np.array([[3, 6, 6], [4, 5, 1]])
>>> output = np.ravel_multi_index(arr, (7, 6))
>>> print(output)
[22. 41. 37.]
>>> output = np.ravel_multi_index((3, 1, 4, 1), (6, 7, 8, 9))
>>> print(output)
1621.0
```

13.4.97 mindspore.numpy.reciprocal

`mindspore.numpy.`**`reciprocal`**(*x*, *dtype=None*)

Returns the reciprocal of the argument, element-wise.

Calculates `1/x`.

Note: Numpy arguments *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. When *where* is provided, *out* must have a tensor value. *out* is not supported for storing the result, however it can be used in combination with *where* to set the value at indices for which *where* is set to False.

Parameters

- **x** (`Tensor`) –Input array. For integer arguments with absolute value larger than 1 the result is always zero because of the way Python handles integer division. For integer zero the result is an overflow.
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, this is a scalar if *x* is a scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(1, 7).reshape(2, 3).astype('float32')
>>> output = np.reciprocal(x)
>>> print(output)
[[1.         0.5        0.33333334]
[0.25       0.2        0.16666667]]
```

13.4.98 mindspore.numpy.remainder

mindspore.numpy.**remainder**(*x1*, *x2*, *dtype=None*)

Returns element-wise remainder of division.

Computes the remainder complementary to the floor_divide function. It is equivalent to the Python modulus operator `x1 % x2` and has the same sign as the divisor *x2*. The MATLAB function equivalent to np.remainder is mod.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) – input array.
- **x2** (Tensor) – input array.
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the element-wise remainder of the quotient `floor_divide(x1, x2)`. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.remainder(np.array([4, 7]), np.array([2, 3]))
>>> print(output)
[0 1]
>>> output = np.remainder(np.arange(7), np.array(5))
>>> print(output)
[0 1 2 3 4 0 1]
```

13.4.99 mindspore.numpy.result_type

mindspore.numpy.**result_type**(**arrays_and_dtypes*)

Returns the type that results from applying the type promotion rules to the arguments.

Note: The promotion rule is slightly different from original Numpy, but more like jax, due to the preference on `32-bit` over `64-bit` data types. Complex dtypes are not supported.

Parameters

***arrays_and_dtypes** (Union[int, float, bool, list, tuple, Tensor, *mindspore.dtype*, str]) –The operands of some operation whose result type is needed.

Returns

mindspore.dtype, the result type.

Raises

TypeError –If the input is not a valid data type.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.result_type('i2', np.float32, True))
Float32
```

13.4.100 mindspore.numpy.rint

mindspore.numpy.**rint**(*x*, *dtype=None*)

Rounds elements of the array to the nearest integer.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (*Union[float, list, tuple, Tensor]*) –Input tensor of any dimension.
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Output tensor is same shape and type as x. This is a scalar if x is a scalar.

Raises

TypeError –If *x* can not be converted to tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([-1.7, -1.5, 0.2, 1.5, 1.7, 2.0])
>>> print(np.rint(x))
[-2. -2. 0. 2. 2. 2.]
```

13.4.101 mindspore.numpy.searchsorted

mindspore.numpy.**searchsorted**(*a*, *v*, *side='left'*, *sorter=None*)

Finds indices where elements should be inserted to maintain order. Finds the indices into a sorted array *a* such that, if the corresponding elements in *v* were inserted before the indices, the order of *a* would be preserved.

Parameters

- **a** (*Union[list, tuple, Tensor]*) – 1-D input array. If *sorter* is None, then it must be sorted in ascending order, otherwise *sorter* must be an array of indices that sort it.
- **v** (*Union[int, float, bool, list, tuple, Tensor]*) – Values to insert into *a*.
- **side** (*'left', 'right', optional*) – If `'left'` (default value), the index of the first suitable location found is given. If `'right'` , return the last such index. If there is no suitable index, return either 0 or N (where N is the length of *a*).
- **sorter** (*Union[int, float, bool, list, tuple, Tensor]*) – 1-D optional array of integer indices that sort array *a* into ascending order. They are typically the result of argsort. Default: `None` .

Returns

Tensor, array of insertion points with the same shape as *v*.

Raises

ValueError – If argument for *side* or *sorter* is invalid.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import numpy as np
>>> print(np.searchsorted([1,2,3,4,5], 3))
2
>>> print(np.searchsorted([1,2,3,4,5], 3, side='right'))
3
>>> print(np.searchsorted([1,2,3,4,5], [-10, 10, 2, 3]))
[0 5 1 2]
```

13.4.102 mindspore.numpy.sign

mindspore.numpy.**sign**(*x*, *dtype=None*)

Returns an element-wise indication of the sign of a number.

The sign function returns *-1 if x < 0, 0 if x == 0, 1 if x > 0*. nan is returned for nan inputs.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. Complex inputs are not supported now. On Ascend, integer inputs are not supported.

Parameters

- **x** (*Union[int, float, list, tuple, Tensor]*) –Input values.
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

The sign of x. This is a tensor or a scalar when x is a scalar.

Raises

TypeError –If dtype of the input is not in the given types or the input can not be converted to tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> output = np.sign(np.array([-1., 0., 1., 1.2]))
>>> print(output)
[-1.  0.  1.  1.]
```

13.4.103 mindspore.numpy.sin

mindspore.numpy.**sin**(*x*, *dtype=None*)

Trigonometric sine, element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (`Tensor`) –Input tensor.
- **dtype** (*mindspore.dtype*, optional) –Default: `None`. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([-5, -1, 0, 2, 4, 100]).astype('float32')
>>> output = np.sin(x)
>>> print(output)
[ 0.9589243  -0.84147096  0.   0.9092974  -0.7568025  -0.50636566]
```

13.4.104 mindspore.numpy.sinh

mindspore.numpy.**sinh**(*x*, *dtype=None*)

Hyperbolic sine, element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) –Input tensor.
- **dtype** (*mindspore.dtype*, optional) –Default: None. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Supported Platforms:

Ascend CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(5).astype('float32')
>>> print(np.sinh(x))
[ 0.         1.1752012  3.6268604 10.017875  27.289917 ]
```

13.4.105 mindspore.numpy.sqrt

mindspore.numpy.**sqrt**(*x*, *dtype=None*)

Returns the non-negative square-root of an array, element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On GPU, the supported dtypes are np.float16 and np.float32.

Parameters

- **x** (Tensor) –The values whose square-roots are required.
- **dtype** (*mindspore.dtype*, optional) –Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, an array of the same shape as *x*, containing the positive square-root of each element in *x*. For negative elements, nan is returned. This is a scalar if *x* is a scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(6).reshape(2, 3).astype('float32')
>>> x_squared = np.square(x)
>>> output = np.sqrt(x_squared)
>>> print(output)
[[ 0. 1. 2.]
 [ 3. 4. 5.]]
```

13.4.106 mindspore.numpy.square

`mindspore.numpy.`**`square`**(*x*, *dtype=None*)

Returns the element-wise square of the input.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported. On GPU, the supported dtypes are np.float16 and np.float32.

Parameters

- **x** (`Tensor`) – Input data.
- **dtype** (*mindspore.dtype*, optional) – Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, element-wise `x*x`, of the same shape and dtype as *x*. This is a scalar if *x* is a scalar.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.square(np.arange(6).reshape(2, 3).astype('float32'))
>>> print(x)
[[ 0.  1.  4.]
 [ 9. 16. 25.]]
```

13.4.107 mindspore.numpy.std

mindspore.numpy.**std**(*x*, *axis=None*, *ddof=0*, *keepdims=False*)

Computes the standard deviation along the specified axis. The standard deviation is the square root of the average of the squared deviations from the mean, i.e., $std = sqrt(mean(abs(x - x.mean()) **2))$.

Returns the standard deviation, which is computed for the flattened array by default, otherwise over the specified axis.

Note: Numpy arguments *dtype*, *out* and *where* are not supported.

Parameters

- **x** (Tensor) −A Tensor to be calculated.
- **axis** (*Union[None, int, tuple(int)]*) −Axis or axes along which the standard deviation is computed. Default: None .

  If None , compute the standard deviation of the flattened array.
- **ddof** (*int*) −Means Delta Degrees of Freedom. The divisor used in calculations is $N - ddof$, where N represents the number of elements. Default: 0.
- **keepdims** −If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input tensor. If the default value is passed, then keepdims will not be passed through to the std method of sub-classes of tensor, however any non-default value will be. If the sub-class' method does not implement keepdims any exceptions will be raised. Default: False .

Returns

Standard deviation tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> input_x = np.array([1., 2., 3., 4.])
>>> output = np.std(input_x)
>>> print(output)
1.118034
```

13.4.108 mindspore.numpy.subtract

mindspore.numpy.**subtract**(*x1*, *x2*, *dtype=None*)

Subtracts arguments, element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (Tensor) −The input to be subtracted from.

- **x2** (Tensor) –The input to be subtracted by.
- **dtype** (*mindspore.dtype*, optional) –Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the difference of *x1* and *x2*, element-wise. This is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.full((3, 2), [1, 2])
>>> x2 = np.full((3, 2), [3, 4])
>>> output = np.subtract(x1, x2)
>>> print(output)
[[-2 -2]
[-2 -2]
[-2 -2]]
```

13.4.109 mindspore.numpy.sum

mindspore.numpy.**sum**(*a*, *axis=None*, *dtype=None*, *keepdims=False*, *initial=None*)

Returns sum of array elements over a given axis.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **a** (*Union[int, float, bool, list, tuple, Tensor]*) –Elements to sum.
- **axis** (*Union[None, int, tuple(int)], optional*) –Axis or axes along which a sum is performed. Default: None. If *None*, sum all of the elements of the input array. If axis is negative it counts from the last to the first axis. If axis is a tuple of integers, a sum is performed on all of the axes specified in the tuple instead of a single axis or all the axes as before.
- **dtype** (*mindspore.dtype*, optional) –Defaults to *None*. Overrides the dtype of the output Tensor.
- **keepdims** (*bool, optional*) –If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input array. If the default value is passed, then keepdims will not be passed through to the sum method of sub-classes of ndarray, however any non-default value will be. If the sub-class method does not implement keepdims any exceptions will be raised. Default: False.
- **initial** (*scalar, optional*) –Starting value for the sum, if *None*, which refers to the first element of the reduction. Default: None.

Returns

Tensor. An array with the same shape as a, with the specified axis removed. If a is a 0-d array, or if axis is *None*, a scalar is returned. If an output array is specified, a reference to out is returned.

Raises

- **TypeError** –If input is not array_like or *axis* is not int or tuple of integers or *keepdims* is not integer or *initial* is not scalar.
- **ValueError** –If any axis is out of range or duplicate axes exist.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> print(np.sum([0.5, 1.5]))
2.0
>>> x = np.arange(10).reshape(2, 5).astype('float32')
>>> print(np.sum(x, axis=1))
[10. 35.]
```

13.4.110 mindspore.numpy.tan

`mindspore.numpy.`**`tan`**(*x*, *dtype=None*)

Computes tangent element-wise.

Equivalent to $np.sin(x)/np.cos(x)$ element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (`Tensor`) –Input tensor.
- **dtype** (*mindspore.dtype*, optional) –Default: `None`. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Raises

TypeError –If the input is not a tensor or the dtype of tensor is mindspore.float64.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x = np.array([-5, -1, 0, 2, 4, 100]).astype('float32')
>>> print(np.tan(x))
[ 3.380515   -1.5574077   0.         -2.1850398   1.1578213  -0.58721393]
```

13.4.111 mindspore.numpy.tanh

mindspore.numpy.**tanh**(*x*, *dtype=None*)

Computes hyperbolic tangent element-wise.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) – Input tensor.
- **dtype** (*mindspore.dtype*, optional) – Default: None. Overrides the dtype of the output Tensor.

Returns

Tensor or scalar. This is a scalar if *x* is a scalar.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> x = np.arange(5).astype('float32')
>>> print(np.tanh(x))
[0.        0.7615942 0.9640276 0.9950548 0.9993293]
```

13.4.112 mindspore.numpy.tensordot

mindspore.numpy.**tensordot**(*a*, *b*, *axes=2*)

Computes tensor dot product along specified axes.

Given two tensors, *a* and *b*, and an array_like object containing two array_like objects, *(a_axes, b_axes)*, sum the products of *a*'s and *b*'s elements (components) over the axes specified by *a_axes* and *b_axes*. The third argument can be a single non-negative integer_like scalar, *N*; if it is such, then the last *N* dimensions of *a* and the first *N* dimensions of *b* are summed over. Three common use cases are:

- axes = 0 : tensor product
- axes = 1 : tensor dot product
- axes = 2 : (default) tensor double contraction

When axes is integer_like, the sequence for evaluation will be: first the -*Nth* axis in *a* and 0th axis in *b*, and the -1th axis in *a* and *Nth* axis in *b* last. When there is more than one axis to sum over - and they are not the last (first) axes of *a (b)* - the argument axes should consist of two sequences of the same length, with the first axis to sum over given first in both sequences, the second axis second, and so forth. The shape of the result consists of the non-contracted axes of the first tensor, followed by the non-contracted axes of the second.

Note: On CPU, the supported dypes are np.float16 and np.float32. On GPU, the supported dypes are np.float16 and np.float32.

Parameters

- **a** (Tensor) –Tensor to "dot".
- **b** (Tensor) –Tensor to "dot".
- **axes** (*int or sequence of ints*) –integer_like: If an int *N*, sum over the last *N* axes of *a* and the first *N* axes of *b* in order. The sizes of the corresponding axes must match.

  sequence of ints: Or, a list of axes to be summed over, first sequence applying to *a*, second to *b*. Both elements *array_like* must be of the same length.

Returns

Tensor, or list of tensors, the tensor dot product of the input.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.ones((3, 4, 5))
>>> b = np.ones((4, 3, 2))
>>> output = np.tensordot(a, b, axes=([1,0],[0,1]))
>>> print(output.shape)
(5, 2)
```

13.4.113 mindspore.numpy.trapz

mindspore.numpy.**trapz**(*y*, *x=None*, *dx=1.0*, *axis=- 1*)

Integrates along the given axis using the composite trapezoidal rule.

Integrates *y* (x) along given axis.

Parameters

- **y** (Tensor) –Input array to integrate.
- **x** (*Union[int, float, bool, list, tuple, Tensor], optional*) –The sample points corresponding to the *y* values. If *x* is None, the sample points are assumed to be evenly spaced *dx* apart. Default: `None` .
- **dx** (*scalar, optional*) –The spacing between sample points when *x* is None. Default: `1.0` .
- **axis** (*int, optional*) –The axis along which to integrate. Default: `-1` .

Returns

Tensor of float, definite integral as approximated by trapezoidal rule.

Raises

ValueError –If axis is out of range of `[-y.ndim, y.ndim)`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> a = np.arange(6).reshape(2, 3)
>>> output = np.trapz(a,  x=[-2, 1, 2], axis=1)
>>> print(output)
[ 3. 15.]
>>> output = np.trapz(a,  dx=3, axis=0)
>>> print(output)
[ 4.5  7.5 10.5]
```

13.4.114 mindspore.numpy.true_divide

`mindspore.numpy.`**`true_divide`**(*x1*, *x2*, *dtype=None*)

Returns a true division of the inputs, element-wise.

Instead of the Python traditional "floor division", this returns a true division.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x1** (`Tensor`) –the dividend.
- **x2** (`Tensor`) –the divisor.
- **dtype** (*mindspore.dtype*, optional) –Default: `None` . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, this is a scalar if both *x1* and *x2* are scalars.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> x1 = np.full((3, 2), [1, 2])
>>> x2 = np.full((3, 2), [3, 4])
>>> output = np.true_divide(x1, x2)
>>> print(output)
[[0.33333334 0.5       ]
[0.33333334 0.5       ]
[0.33333334 0.5       ]]
```

13.4.115 mindspore.numpy.trunc

mindspore.numpy.**trunc**(*x*, *dtype=None*)

Returns the truncated value of the input, element-wise.

The truncated value of the scalar *x* is the nearest integer *i* which is closer to zero than *x* is. In short, the fractional part of the signed number *x* is discarded.

Note: Numpy arguments *out*, *where*, *casting*, *order*, *subok*, *signature*, and *extobj* are not supported.

Parameters

- **x** (Tensor) – input data.
- **dtype** (*mindspore.dtype*, optional) – Default: None . Overrides the dtype of the output Tensor.

Returns

Tensor or scalar, the truncated value of each element in *x*. This is a scalar if *x* is a scalar.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.numpy as np
>>> output = np.trunc(np.array([-1.7, -1.5, -0.2, 0.2, 1.5, 1.7, 2.0]))
>>> print(output)
[-1. -1. -0.  0.  1.  1.  2.]
```

13.4.116 mindspore.numpy.unwrap

mindspore.numpy.**unwrap**(*p*, *discont=3.141592653589793*, *axis=- 1*)

Unwraps by changing deltas between values to 2*pi complement. Unwraps radian phase *p* by changing absolute jumps greater than *discont* to their 2*pi complement along the given axis.

Note: For absolute jumps that are within a very close range to pi, unwrapping may be done differently than numpy due to differences in round-off.

Parameters

- **p** (*Union[int, float, bool, list, tuple, Tensor]*) – Input array.
- **discont** (*float, optional*) – Maximum discontinuity between values, default: pi .
- **axis** (*int, optional*) – Axis along which unwrap will operate, default: -1 .

Returns

Tensor.

Raises

ValueError – If the axis is out of range.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore.numpy as np
>>> phase = np.add(np.linspace(0, np.pi, num=5), [0, 0, 0, np.pi, np.pi])
>>> print(phase)
[0.        0.7853982 1.5707964 5.4977875 6.2831855]
>>> print(np.unwrap(phase))
[ 0.0000000e+00  7.8539819e-01  1.5707964e+00 -7.8539848e-01 -4.7683716e-07]
```

13.4.117 mindspore.numpy.var

`mindspore.numpy.`**`var`**(*x*, *axis=None*, *ddof=0*, *keepdims=False*)

Computes the variance along the specified axis. The variance is the average of the squared deviations from the mean, i.e., $var = mean(abs(x - x.mean()) **2)$.

Returns the variance, which is computed for the flattened array by default, otherwise over the specified axis.

Note: Numpy arguments *dtype*, *out* and *where* are not supported.

Parameters

- **`x`** (`Tensor`) −A Tensor to be calculated.
- **`axis`** (*`Union[None, int, tuple(int)]`*) −Axis or axes along which the variance is computed. The default is to compute the variance of the flattened array. Default: `None` .
- **`ddof`** (*`int`*) −Means Delta Degrees of Freedom. Default: `0` . The divisor used in calculations is $N - ddof$, where N represents the number of elements.
- **`keepdims`** (*`bool`*) −If this is set to True, the axes which are reduced are left in the result as dimensions with size one. With this option, the result will broadcast correctly against the input tensor. If the default value is passed, then keepdims will not be passed through to the var method of sub-classes of tensor, however any non-default value will be. If the sub-class method does not implement keepdims any exceptions will be raised. Default: `False` .

Supported Platforms:

`Ascend` `GPU` `CPU`

Returns

Standard deviation tensor.

Examples

```
>>> import mindspore.numpy as np
>>> input_x = np.array([1., 2., 3., 4.])
>>> output = np.var(input_x)
>>> print(output)
1.25
```

13.5 Interact With MindSpore Functions

Since *mindspore.numpy* directly wraps MindSpore tensors and operators, it has all the advantages and properties of MindSpore. In this section, we will briefly introduce how to employ MindSpore execution management and automatic differentiation in *mindspore.numpy* coding scenarios. These include:

- *jit* decorator: for running codes in static graph mode for better efficiency.
- *GradOperation*: for automatic gradient computation.
- *mindspore.set_context*: for *mindspore.numpy* execution management.
- *mindspore.nn.Cell*: for using *mindspore.numpy* interfaces in MindSpore Deep Learning Models.

The following are examples:

- Use *jit* decorator to run code in static graph mode

  Let's first see an example consisted of matrix multiplication and bias add, which is a typical process in Neural Networks:

```
import mindspore.numpy as np

x = np.arange(8).reshape(2, 4).astype('float32')
w1 = np.ones((4, 8))
b1 = np.zeros((8,))
w2 = np.ones((8, 16))
b2 = np.zeros((16,))
w3 = np.ones((16, 4))
b3 = np.zeros((4,))

def forward(x, w1, b1, w2, b2, w3, b3):
    x = np.dot(x, w1) + b1
    x = np.dot(x, w2) + b2
    x = np.dot(x, w3) + b3
return x

print(forward(x, w1, b1, w2, b2, w3, b3))
```

  The result is as follows:

```
[[ 768.  768.  768.  768.]
 [2816. 2816. 2816. 2816.]]
```

  In this function, MindSpore dispatches each computing kernel to device separately. However, with the help of *jit* decorator, we can compile all operations into a single static computing graph.

```
from mindspore import jit
```

(continues on next page)

(continued from previous page)

```
forward_compiled = jit(forward)
print(forward(x, w1, b1, w2, b2, w3, b3))
```

The result is as follows:

```
[[ 768.  768.  768.  768.]
 [2816. 2816. 2816. 2816.]]
```

Note: Currently, static graph cannot run in Python interactive mode and not all python types can be passed into functions decorated with *jit*.

- Use GradOperation to compute deratives

  GradOperation can be used to take deratives from normal functions and functions decorated with *jit*. Take the previous example:

```
from mindspore import ops

grad_all = ops.GradOperation(get_all=True)
print(grad_all(forward)(x, w1, b1, w2, b2, w3, b3))
```

The result is as follows:

```
(Tensor(shape=[2, 4], dtype=Float32, value=
 [[ 5.12000000e+02,  5.12000000e+02,  5.12000000e+02,  5.12000000e+02],
  [ 5.12000000e+02,  5.12000000e+02,  5.12000000e+02,  5.12000000e+02]]),
 Tensor(shape=[4, 8], dtype=Float32, value=
 [[ 2.56000000e+02,  2.56000000e+02,  2.56000000e+02 ...  2.56000000e+02,  2.56000000e+02, ␣
↪2.56000000e+02],
  [ 3.84000000e+02,  3.84000000e+02,  3.84000000e+02 ...  3.84000000e+02,  3.84000000e+02, ␣
↪3.84000000e+02],
  [ 5.12000000e+02,  5.12000000e+02,  5.12000000e+02 ...  5.12000000e+02,  5.12000000e+02, ␣
↪5.12000000e+02]
  [ 6.40000000e+02,  6.40000000e+02,  6.40000000e+02 ...  6.40000000e+02,  6.40000000e+02, ␣
↪6.40000000e+02]]),
  ...
 Tensor(shape=[4], dtype=Float32, value= [ 2.00000000e+00,  2.00000000e+00,  2.00000000e+00,␣
↪ 2.00000000e+00]))
```

To take the gradient of *jit* compiled functions, first we need to set the execution mode to static graph mode.

```
from mindspore import jit, set_context, GRAPH_MODE, ops

set_context(mode=GRAPH_MODE)
grad_all = ops.GradOperation(get_all=True)
print(grad_all(jit(forward))(x, w1, b1, w2, b2, w3, b3))
```

The result is as follows:

```
(Tensor(shape=[2, 4], dtype=Float32, value=
 [[ 5.12000000e+02,  5.12000000e+02,  5.12000000e+02,  5.12000000e+02],
  [ 5.12000000e+02,  5.12000000e+02,  5.12000000e+02,  5.12000000e+02]]),
 Tensor(shape=[4, 8], dtype=Float32, value=
 [[ 2.56000000e+02,  2.56000000e+02,  2.56000000e+02 ...  2.56000000e+02,  2.56000000e+02, ␣
↪2.56000000e+02],
  [ 3.84000000e+02,  3.84000000e+02,  3.84000000e+02 ...  3.84000000e+02,  3.84000000e+02, ␣
↪3.84000000e+02],
```

(continues on next page)

(continued from previous page)

```
  [ 5.12000000e+02,  5.12000000e+02,  5.12000000e+02 ...  5.12000000e+02,  5.12000000e+02, ␣
↪5.12000000e+02]
  [ 6.40000000e+02,  6.40000000e+02,  6.40000000e+02 ...  6.40000000e+02,  6.40000000e+02, ␣
↪6.40000000e+02]]),
  ...
 Tensor(shape=[4], dtype=Float32, value= [ 2.00000000e+00,  2.00000000e+00,  2.00000000e+00,␣
↪ 2.00000000e+00]))
```

For more details, see API GradOperation .

- Use mindspore.set_context to control execution mode

  Most functions in *mindspore.numpy* can run in Graph Mode and PyNative Mode, and can run on CPU, GPU and Ascend. Like MindSpore, users can manage the execution mode using *mindspore.set_context* :

```
from mindspore import set_context, GRAPH_MODE, PYNATIVE_MODE

# Execution in static graph mode
set_context(mode=GRAPH_MODE)

# Execution in PyNative mode
set_context(mode=PYNATIVE_MODE)

# Execution on CPU backend
set_context(device_target="CPU")

# Execution on GPU backend
set_context(device_target="GPU")

# Execution on Ascend backend
set_context(device_target="Ascend")
...
```

  For more details, see API mindspore.set_context .

- Use mindspore.numpy in MindSpore Deep Learning Models

  mindspore.numpy interfaces can be used inside *nn.cell* blocks as well. For example, the above code can be modified to:

```
import mindspore.numpy as np
from mindspore import set_context, GRAPH_MODE
from mindspore.nn import Cell

set_context(mode=GRAPH_MODE)

x = np.arange(8).reshape(2, 4).astype('float32')
w1 = np.ones((4, 8))
b1 = np.zeros((8,))
w2 = np.ones((8, 16))
b2 = np.zeros((16,))
w3 = np.ones((16, 4))
b3 = np.zeros((4,))

class NeuralNetwork(Cell):
    def construct(self, x, w1, b1, w2, b2, w3, b3):
        x = np.dot(x, w1) + b1
        x = np.dot(x, w2) + b2
        x = np.dot(x, w3) + b3
```

(continues on next page)

(continued from previous page)

```
        return x

net = NeuralNetwork()

print(net(x, w1, b1, w2, b2, w3, b3))
```

The result is as follows:

```
[[ 768.  768.  768.  768.]
 [2816. 2816. 2816. 2816.]]
```

CHAPTER

FOURTEEN

MINDSPORE.SCIPY

Warning: These are experimental APIs that are subject to change or deletion. Only support Linux.

Scipy-like interfaces in mindspore.

14.1 mindspore.scipy.linalg

Linear algebra submodule

API Name	Description	Supported Platforms
mindspore.scipy.linalg.block_diag	Create a block diagonal matrix from provided arrays.	GPU CPU
mindspore.scipy.linalg.cho_factor	Compute the cholesky decomposition of a matrix, to use in *mindspore.scipy.linalg.cho_solve()*.	GPU CPU
mindspore.scipy.linalg.cho_solve	Given the cholesky factorization of A, solve the linear equation.	GPU CPU
mindspore.scipy.linalg.cholesky	Compute the cholesky decomposition of a matrix.	GPU CPU
mindspore.scipy.linalg.eigh	Solve a standard or generalized eigenvalue problem for a complex Hermitian or real symmetric matrix.	GPU CPU
mindspore.scipy.linalg.inv	Compute the inverse of a matrix.	GPU CPU
mindspore.scipy.linalg.lstsq	Computes a solution to the least squares problem of a system of linear equations $AX = B$.	Ascend CPU
mindspore.scipy.linalg.lu	Compute pivoted LU decomposition of a general matrix.	GPU CPU
mindspore.scipy.linalg.lu_factor	Compute pivoted LU decomposition of a square matrix, and its outputs can be directly used as the inputs of *lu_solve*.	GPU CPU
mindspore.scipy.linalg.solve_triangular	Solve the linear system $ax = b$ for x, Assuming a is a triangular matrix.	Ascend CPU

14.1.1 mindspore.scipy.linalg.block_diag

mindspore.scipy.linalg.**block_diag**(**arrs*)

Create a block diagonal matrix from provided arrays.

Given the list of Tensors *A*, *B*, and *C*, the output will have these Tensors arranged on the diagonal:

```
[[A, 0, 0],
 [0, B, 0],
 [0, 0, C]]
```

Note: *block_diag* is not supported on Windows platform yet.

Parameters

arrs (*list*) – up to 2-D Input Tensors. One or more Tensors, the dimension of Tensors should be 0-D, 1-D or 2-D.

Returns

Tensor with *A*, *B*, *C*, ··· on the diagonal which has the same dtype as *A*.

Raises

ValueError – If there are Tensors with dimensions higher than 2 in all arguments.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as onp
>>> from mindspore import Tensor
>>> from mindspore.scipy.linalg import block_diag
>>> A = Tensor(onp.array([[1, 0], [0, 1]]))
>>> B = Tensor(onp.array([[3, 4, 5], [6, 7, 8]]))
>>> C = Tensor(onp.array([[7]]))
>>> P = Tensor(onp.zeros((2, ), dtype='int32'))
>>> print(block_diag(A, B, C))
[[1 0 0 0 0 0]
 [0 1 0 0 0 0]
 [0 0 3 4 5 0]
 [0 0 6 7 8 0]
 [0 0 0 0 0 7]]
>>> print(block_diag(A, P, B, C))
[[1 0 0 0 0 0 0 0]
 [0 1 0 0 0 0 0 0]
 [0 0 0 0 0 0 0 0]
 [0 0 0 0 3 4 5 0]
 [0 0 0 0 6 7 8 0]
 [0 0 0 0 0 0 0 7]]
```

14.1.2 mindspore.scipy.linalg.cho_factor

mindspore.scipy.linalg.**cho_factor**(*a*, *lower=False*, *overwrite_a=False*, *check_finite=True*)

Compute the cholesky decomposition of a matrix, to use in *mindspore.scipy.linalg.cho_solve()*.

Returns the cholesky decomposition of a Hermitian positive-definite matrix A. Base on the value of *lower*, perform the following decomposition:

- when *lower* is True: $A = LL^*$
- when *lower* is False: $A = U^*U$

L^* is a conjugate transpose matrix of L. U^* is a conjugate transpose matrix of U.

The return value can be directly used as the first parameter to *mindspore.scipy.linalg.cho_solve()*.

Note:

- *cho_factor* is not supported on Windows platform yet.
- Only float32, float64, int32, int64 are supported Tensor dtypes.
- If Tensor with dtype int32 or int64 is passed, it will be cast to mstype.float64.

Warning: The returned matrix also contains random data in the entries not used by the cholesky decomposition. If you need to zero these entries, use the function *cholesky* instead.

Parameters

- **a** (Tensor) −square Matrix of (M, M) to be decomposed.
- **lower** (*bool, optional*) −Whether to compute the upper or lower triangular cholesky factorization. Default: `False`.
- **overwrite_a** (*bool, optional*) −Whether to overwrite data in a (may improve performance). Default: `False`. in mindspore, this arg does not work right now.
- **check_finite** (*bool, optional*) −Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default: `True`. in mindspore, this arg does not work right now.

Returns

- Tensor, matrix whose upper or lower triangle contains the cholesky factor of a. Other parts of the matrix contain random data.
- bool, flag indicating whether the factor is in the lower or upper triangle

Raises

ValueError −If input a tensor is not a square matrix or it's dims not equal to 2D.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as onp
>>> from mindspore import Tensor
>>> from mindspore.scipy.linalg import cho_factor
>>> a = Tensor(onp.array([[9, 3, 1, 5], [3, 7, 5, 1], [1, 5, 9, 2], [5, 1, 2, 6]]).
↪astype(onp.float32))
>>> c, low = cho_factor(a)
>>> print(c)
[[ 3.          1.          0.33333334  1.6666666 ]
 [ 3.          2.4494898   1.9051585  -0.2721655 ]
 [ 1.          5.          2.2933078   0.8559526 ]
 [ 5.          1.          2.          1.5541857 ]]
```

14.1.3 mindspore.scipy.linalg.cho_solve

mindspore.scipy.linalg.**cho_solve**(*c_and_lower*, *b*, *overwrite_b=False*, *check_finite=True*)

Given the cholesky factorization of A, solve the linear equation.

$$Ax = b$$

Note:

- *cho_solve* is not supported on Windows platform yet.
- Only float32, float64, int32, int64 are supported Tensor dtypes.
- If Tensor with dtype int32 or int64 is passed, it will be cast to mstype.float64.

Parameters

- **c_and_lower** (*(Tensor, bool)*) – cholesky factorization of a, as given by *mindspore.scipy.linalg.cho_factor()*.
- **b** (Tensor) – Right-hand side.
- **overwrite_b** (*bool, optional*) – Whether to overwrite data in b (may improve performance). Default: `False`.
- **check_finite** (*bool, optional*) – Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default: `True`.

Returns

Tensor, the solution to the system $Ax = b$.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as onp
>>> import mindspore as ms
>>> a = ms.Tensor(onp.array([[9, 3, 1, 5], [3, 7, 5, 1], [1, 5, 9, 2], [5, 1, 2, 6]]).
↪astype(onp.float32))
>>> b = ms.Tensor(onp.array([1, 1, 1, 1]).astype(onp.float32))
>>> c, low = ms.scipy.linalg.cho_factor(a)
>>> x = ms.scipy.linalg.cho_solve((c, low), b)
>>> print(x)
[-0.01749266  0.11953348  0.01166185  0.15743434]
```

14.1.4 mindspore.scipy.linalg.cholesky

mindspore.scipy.linalg.**cholesky**(*a*, *lower=False*, *overwrite_a=False*, *check_finite=True*)

Compute the cholesky decomposition of a matrix.

Returns the cholesky decomposition of a Hermitian positive-definite matrix A. Base on the value of *lower*, perform the following decomposition:

- when *lower* is True: $A = LL^*$
- when *lower* is False: $A = U^*U$

L^* is a conjugate transpose matrix of L. U^* is a conjugate transpose matrix of U.

Note:

- *cholesky* is not supported on Windows platform yet.
- Only float32, float64, int32, int64 are supported Tensor dtypes.
- If Tensor with dtype int32 or int64 is passed, it will be cast to mstype.float64.

Parameters

- **a** (Tensor) –square Matrix of (M, M) to be decomposed.
- **lower** (*bool, optional*) –Whether to compute the upper- or lower-triangular cholesky factorization. Default: False.
- **overwrite_a** (*bool, optional*) –Whether to overwrite data in *a* (may improve performance). Default: False . in mindspore, this arg does not work right now.
- **check_finite** (*bool, optional*) –Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default: True . in mindspore, this arg does not work right now.

Returns

Tensor, upper- or lower-triangular cholesky factor of *a*.

Raises

ValueError –If input a tensor is not a square matrix or it's dims not equal to 2D.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as onp
>>> from mindspore import Tensor
>>> from mindspore.scipy.linalg import cholesky
>>> a = Tensor(onp.array([[1, 2],[2, 5]]).astype(onp.float32))
>>> L = cholesky(a, lower=True)
>>> print(L)
[[1. 0.]
 [2. 1.]]
```

14.1.5 mindspore.scipy.linalg.eigh

mindspore.scipy.linalg.**eigh**(*a*, *b=None*, *lower=True*, *eigvals_only=False*, *overwrite_a=False*, *overwrite_b=False*, *turbo=True*, *eigvals=None*, *type=1*, *check_finite=True*)

Solve a standard or generalized eigenvalue problem for a complex Hermitian or real symmetric matrix.

Find eigenvalues Tensor *w* and optionally eigenvectors Tensor *v* of Tensor *a*, where *b* is positive definite such that for every eigenvalue λ (i-th entry of w) and its eigenvector *vi* (i-th column of *v*) satisfies:

```
                a @ vi = λ * b @ vi
vi.conj().T @ a @ vi = λ
vi.conj().T @ b @ vi = 1
```

In the standard problem, *b* is assumed to be the identity matrix.

Note:

- *eigh* is not supported on Windows platform yet.
- Only float32, float64, int32, int64 are supported Tensor dtypes.
- If Tensor with dtype int32 or int64 is passed, it will be cast to mstype.float64.

Parameters

- **a** (Tensor) – A (M, M) complex Hermitian or real symmetric matrix whose eigenvalues and eigenvectors will be computed.
- **b** (Tensor, *optional*) – A (M, M) complex Hermitian or real symmetric definite positive matrix in. If omitted, identity matrix is assumed. Default: None.
- **lower** (*bool*, *optional*) – Whether the pertinent Tensor data is taken from the lower or upper triangle of *a* and, if applicable, *b*. Default: True.
- **eigvals_only** (*bool*, *optional*) – Whether to calculate only eigenvalues and no eigenvectors. Default: False.
- **overwrite_a** (*bool*, *optional*) – Whether to overwrite data in *a* (may improve performance). Default: False.
- **overwrite_b** (*bool*, *optional*) – Whether to overwrite data in *b* (may improve performance). Default: False.
- **turbo** (*bool*, *optional*) – use divide and conquer algorithm (faster but expensive in memory, only for generalized eigenvalue problem and if full set of eigenvalues are requested.). Has no significant effect if eigenvectors are not requested. Default: True .

- **eigvals** (*tuple, optional*) –Indexes of the smallest and largest (in ascending order) eigenvalues and corresponding eigenvectors to be returned: $0 <= lo <= hi <= M - 1$. If omitted, all eigenvalues and eigenvectors are returned. Default: `None` .
- **type** (*int, optional*) –For the generalized problems, this keyword specifies the problem type to be solved for w and v (only takes 1, 2, 3 as possible inputs):

```
1 =>     a @ v = w @ b @ v
2 => a @ b @ v = w @ v
3 => b @ a @ v = w @ v
```

  This keyword is ignored for standard problems. Default: `1` .
- **check_finite** (*bool, optional*) –Whether to check that the input matrices contain only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default: `True` .

Returns

- Tensor with shape $(N,)$, the $N(1 <= N <= M)$ selected eigenvalues, in ascending order, each repeated according to its multiplicity.
- Tensor with shape (M, N), if *eigvals_only* == *False*.

Raises

- **RuntimeError** –If eigenvalue computation does not converge, an error occurred, or b matrix is not definite positive. Note that if input matrices are not symmetric or Hermitian, no error will be reported but results will be wrong.
- **TypeError** –If *a* is not Tensor.
- **TypeError** –If *lower* is not bool.
- **TypeError** –If *eigvals_only* is not bool.
- **TypeError** –If *overwrite_a* is not bool.
- **TypeError** –If *overwrite_b* is not bool.
- **TypeError** –If *turbo* is not bool.
- **TypeError** –If *check_finite* is not bool.
- **ValueError** –If *a* is not 2D square matrix.
- **ValueError** –If *b* is not None.
- **ValueError** –If *eigvals* is not None.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as onp
>>> import mindspore.numpy as mnp
>>> from mindspore import Tensor, dtype
>>> from mindspore.scipy.linalg import eigh
>>> a = Tensor([[6, 3, 1, 5], [3, 0, 5, 1], [1, 5, 6, 2], [5, 1, 2, 2]], dtype.float64)
>>> w, v = eigh(a)
>>> print(onp.allclose(mnp.dot(a, v).asnumpy(), mnp.dot(v, mnp.diag(w)).asnumpy(), 1e-5, 1e-
↪8))
True
```

14.1.6 mindspore.scipy.linalg.inv

mindspore.scipy.linalg.**inv**(*a*, *overwrite_a=False*, *check_finite=True*)

Compute the inverse of a matrix.

Note:

- *inv* is not supported on Windows platform yet.
- Only float32, float64, int32, int64 are supported Tensor dtypes.
- If Tensor with dtype int32 or int64 is passed, it will be cast to mstype.float64.

Parameters

- **a** (Tensor) –Square matrix to be inverted.
- **overwrite_a** (*bool, optional*) –Discard data in *a* (may improve performance). Default: False .
- **check_finite** (*bool, optional*) –Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default: True .

Returns

Tensor, inverse of the matrix *a*.

Raises

- **LinAlgError** –If *a* is singular.
- **ValueError** –If *a* is not square, or not 2D.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as onp
>>> from mindspore import Tensor
>>> import mindspore.numpy as mnp
>>> from mindspore.scipy.linalg import inv
>>> a = Tensor(onp.array([[1., 2.], [3., 4.]]))
>>> print(inv(a))
[[-2.   1. ]
 [ 1.5 -0.5]]
>>> print(mnp.dot(a, inv(a)))
[[1.0000000e+00 0.0000000e+00]
 [8.8817842e-16 1.0000000e+00]]
```

14.1.7 mindspore.scipy.linalg.lstsq

mindspore.scipy.linalg.**lstsq**(*A*, *B*, *rcond=None*, *driver=None*)

Computes a solution to the least squares problem of a system of linear equations $AX = B$.

Note:

- *lstsq* is currently only used in *mindscience* scientific computing scenarios and dose not support other usage scenarios.
- *lstsq* is not supported on Windows platform yet.

Parameters

- **A** (Tensor) –LHS input tensor of shape $(*, M, N)$, where $*$ is zero or more batch dimensions.
- **B** (Tensor) –RHS input tensor of shape $(*, M, K)$, where $*$ is zero or more batch dimensions.
- **rcond** (*number.Number, optional*) –Not implemented now, Default is None.
- **driver** (*string, optional*) –Which LAPACK driver is used to solve the least-squares problem. Options are "gels", "gelsy", "gelss", "gelsd". Default is None ("gelsy"). if A is well-conditioned, "gels" is a good choice for full-rank matrix, and "gelsy" for a general matrix. if A is not well-conditioned, "gelsd" works good, "gelss" was used historically. It is generally slow but uses less memory.

Returns

- **solution** (Tensor), Least-squares solution. It has shape $(*, N, K)$, where $*$ is same as broadcast batch dimensions.
- **residual** (Tensor), Square of the 2-norm for each column in $AX - B$, It has shape $(*, K)$, where $*$ is same as broadcast batch dimensions. It is computed when *driver* is one of ("gels", "gelss", "gelsd") and $M > N$, otherwise, it is an empty tensor.
- **rank** (Tensor), Effective rank of A. It has shape $(*)$, where $*$ is same as batch dimensions of A. It is computed when *driver* is one of ("gelsy", "gelss", "gelsd"), otherwise it is an empty tensor.
- **singular_value** (Tensor), Singular values of A. It has shape $(*, min(M, N))$, where $*$ is same as batch dimensions of A. It is computed when *driver* is one of ("gelss", "gelsd"), otherwise it is an empty tensor.

Raises

- **TypeError** –If dtype of A and B are not the same.
- **ValueError** –If A is less than 2 dimension.
- **ValueError** –If the shape of A and B are not matched.

- **ValueError** –If *driver* is not in set {None, "gels", "gelsy", "gelss", "gelsd"}.

Supported Platforms:

Ascend CPU

Examples

```
>>> import numpy as onp
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore.scipy.linalg import lstsq
>>> a = Tensor(onp.array([[3, 0, 0, 0], [2, 1, 0, 0], [1, 0, 1, 0], [1, 1, 1, 1]], onp.
↪float32))
>>> b = Tensor(onp.array([3, 1, 3, 4], onp.float32))
>>> solution, residual, rank, singular_value = lstsq(a, b)
>>> print(solution)
[ 1. -1.  2.  2.]
>>> print(a @ solution)  # Check the result
[3. 1. 3. 4.]
```

14.1.8 mindspore.scipy.linalg.lu

mindspore.scipy.linalg.**lu**(*a*, *permute_l=False*, *overwrite_a=False*, *check_finite=True*)

Compute pivoted LU decomposition of a general matrix.

The decomposition is:

$$A = PLU$$

where P is a permutation matrix, L lower triangular with unit diagonal elements, and U upper triangular.

Note:

- *lu* is not supported on Windows platform yet.
- Only float32, float64, int32, int64 are supported Tensor dtypes.
- If Tensor with dtype int32 or int64 is passed, it will be cast to mstype.float64.

Parameters

- **a** (Tensor) –a (M, N) matrix to decompose. Note that if the input tensor is not a float, then it will be cast to mstype.float32.
- **permute_l** (*bool, optional*) –Perform the multiplication PL (Default: do not permute). Default: False .
- **overwrite_a** (*bool, optional*) –Whether to overwrite data in *a* (may improve performance). Default: False .
- **check_finite** (*bool, optional*) –Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default: True .

Returns

If permute_l == False

- Tensor, (M, M) permutation matrix.
- Tensor, (M, K) lower triangular or trapezoidal matrix with unit diagonal. $K = min(M, N)$.
- Tensor, (K, N) upper triangular or trapezoidal matrix.

If permute_l == True

- Tensor, (M, K) permuted L matrix. $K = min(M, N)$.
- Tensor, (K, N) upper triangular or trapezoidal matrix.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as onp
>>> from mindspore import Tensor
>>> from mindspore.scipy.linalg import lu
>>> a = Tensor(onp.array([[2, 5, 8, 7], [5, 2, 2, 8], [7, 5, 6, 6], [5, 4, 4, 8]]).
↪astype(onp.float64))
>>> p, l, u = lu(a)
>>> print(p)
[[0 1 0 0]
 [0 0 0 1]
 [1 0 0 0]
 [0 0 1 0]]
>>> print(l)
[[ 1.          0.          0.          0.        ]
 [ 0.2857143   1.          0.          0.        ]
 [ 0.71428573  0.12        1.          0.        ]
 [ 0.71428573 -0.44       -0.46153846  1.        ]]
>>> print(u)
[[ 7.          5.          6.          6.        ]
 [ 0.          3.57142854  6.28571415  5.28571415]
 [ 0.          0.         -1.03999996  3.07999992]
 [ 0.         -0.         -0.          7.46153831]]
```

14.1.9 mindspore.scipy.linalg.lu_factor

mindspore.scipy.linalg.**lu_factor**(*a*, *overwrite_a=False*, *check_finite=True*)

Compute pivoted LU decomposition of a square matrix, and its outputs can be directly used as the inputs of *lu_solve*. The decomposition is:

$$a = PLU$$

where P is a permutation matrix, L lower triangular with unit diagonal elements, and U upper triangular.

Note:

- *lu_factor* is not supported on Windows platform yet.

- Only float32, float64, int32, int64 are supported Tensor dtypes.
- If Tensor with dtype int32 or int64 is passed, it will be cast to mstype.float64.

Parameters

- **a** (`Tensor`) –square matrix of (M, M) to decompose. Note that if the input tensor is not a float, then it will be cast to mstype.float32.
- **overwrite_a** (*bool, optional*) –Whether to overwrite data in a (may increase performance). Default: `False` .
- **check_finite** (*bool, optional*) –Whether to check that the input matrix contains only finite numbers. Disabling may give a performance gain, but may result in problems (crashes, non-termination) if the inputs do contain infinities or NaNs. Default: `True` .

Returns

- Tensor, a square matrix of (M, M) containing U in its upper triangle, and L in its lower triangle. The unit diagonal elements of L are not stored.
- Tensor, $(M,)$ pivot indices representing the permutation matrix P: the i-th element value j in the indices indicates that row i of matrix was interchanged with row j.

Raises

ValueError –If a is not 2D square.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as onp
>>> from mindspore import Tensor
>>> from mindspore.scipy.linalg import lu_factor
>>> a = Tensor(onp.array([[2, 5, 8, 7], [5, 2, 2, 8], [7, 5, 6, 6], [5, 4, 4, 8]]).
↪astype(onp.float64))
>>> lu, piv = lu_factor(a)
>>> print(lu)
[[ 7.          5.          6.          6.        ]
 [ 0.28571429  3.57142857  6.28571429  5.28571429]
 [ 0.71428571  0.12       -1.04        3.08      ]
 [ 0.71428571 -0.44       -0.46153846  7.46153846]]
>>> print(piv)
[2 2 3 3]
```

14.1.10 mindspore.scipy.linalg.solve_triangular

mindspore.scipy.linalg.**solve_triangular**(*a*, *b*, *trans=0*, *lower=False*, *unit_diagonal=False*, *overwrite_b=False*, *debug=None*, *check_finite=True*)

Solve the linear system $ax = b$ for x, Assuming a is a triangular matrix.

Note:

- *solve_triangular* is currently only used in *mindscience* scientific computing scenarios and dose not support other usage scenarios.
- *solve_triangular* is not supported on Windows platform yet.

Parameters

- **a** (Tensor) −A triangular matrix of shape $(*, M, M)$ where $*$ is zero or more batch dimensions.
- **b** (Tensor) −A Tensor of shape $(*, M)$ or $(*, M, N)$. Right-hand side matrix in $ax = b$.
- **trans** (*Union[int, str], optional*) −Type of system to solve. Default: 0.

trans	system
0 or 'N'	a x = b
1 or 'T'	a^T x = b
2 or 'C'	a^H x = b

- **lower** (*bool, optional*) −Use only data contained in the lower triangle of a. Default: False.
- **unit_diagonal** (*bool, optional*) −If True, diagonal elements of a are assumed to be 1 and will not be referenced. Default: False.
- **overwrite_b** (*bool, optional*) −Not implemented now. Default: False.
- **debug** (*Any, optional*) −Not implemented now. Default: None.
- **check_finite** (*bool, optional*) −Not implemented now. Default: True.

Returns

Tensor of shape $(*, M)$ or $(*, M, N)$, which is the solution to the system $ax = b$. Shape of x matches b.

Raises

- **ValueError** −If a is less than 2 dimension.
- **ValueError** −if a is not square matrix.
- **TypeError** −If dtype of a and b are not the same.
- **ValueError** −If the shape of a and b are not matched.
- **ValueError** −If *trans* is not in set {0, 1, 2, 'N', 'T', 'C'}.

Supported Platforms:

Ascend CPU

Examples

```
>>> import numpy as onp
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore.scipy.linalg import solve_triangular
>>> a = Tensor(onp.array([[3, 0, 0, 0], [2, 1, 0, 0], [1, 0, 1, 0], [1, 1, 1, 1]], onp.
↪float32))
>>> b = Tensor(onp.array([3, 1, 3, 4], onp.float32))
>>> x = solve_triangular(a, b, lower=True, unit_diagonal=False, trans='N')
>>> print(x)
[ 1. -1.  2.  2.]
>>> print(a @ x)  # Check the result
[3. 1. 3. 4.]
```

14.2 mindspore.scipy.optimize

Optimize submodule

API Name	Description	Supported Platforms
mindspore.scipy.optimize.line_search	Inexact line search that satisfies strong Wolfe conditions.	GPU CPU
mindspore.scipy.optimize.linear_sum_assignment	Solve the linear sum assignment problem.	Ascend CPU
mindspore.scipy.optimize.minimize	Minimization of scalar function of one or more variables.	GPU CPU

14.2.1 mindspore.scipy.optimize.line_search

mindspore.scipy.optimize.**line_search**(*f*, *xk*, *pk*, *jac=None*, *gfk=None*, *old_fval=None*, *old_old_fval=None*, *c1=1e-4*, *c2=0.9*, *maxiter=20*)

Inexact line search that satisfies strong Wolfe conditions.

Algorithm 3.5 from Wright and Nocedal, 'Numerical Optimization', 1999, pg. 59-61

Note: *line_search* is not supported on Windows platform yet.

Parameters

- **f** (*function*) –function of the form f(x) where x is a flat Tensor and returns a real scalar. The function should be composed of operations with vjp defined.
- **xk** (Tensor) –initial guess.
- **pk** (Tensor) –direction to search in. Assumes the direction is a descent direction.
- **jac** (*function*) –the gradient function at x where x is a flat Tensor and returns a Tensor. The function can be None if you want to use automatic credits.
- **gfk** (Tensor) –initial value of value_and_gradient as position. Default: None .
- **old_fval** (Tensor) –The same as *gfk*. Default: None .

- **old_old_fval** (Tensor) −unused argument, only for scipy API compliance. Default: None .
- **c1** (*float*) −Wolfe criteria constant, see ref. Default: 1e-4 .
- **c2** (*float*) −The same as *c1*. Default: 0.9 .
- **maxiter** (*int*) −maximum number of iterations to search. Default: 20 .

Returns

LineSearchResults, results of line search results.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as onp
>>> from mindspore.scipy.optimize import line_search
>>> from mindspore import Tensor
>>> x0 = Tensor(onp.ones(2).astype(onp.float32))
>>> p0 = Tensor(onp.array([-1, -1]).astype(onp.float32))
>>> def func(x):
...     return x[0] ** 2 - x[1] ** 3
>>> res = line_search(func, x0, p0)
>>> print(res.a_k)
1.0
```

14.2.2 mindspore.scipy.optimize.linear_sum_assignment

mindspore.scipy.optimize.**linear_sum_assignment**(*cost_matrix*, *maximize*, *dimension_limit=Tensor(sys.maxsize)*)

Solve the linear sum assignment problem.

The assignment problem is represented as follows:

$$min \sum_i \sum_j C_{i,j} X_{i,j}$$

where C is cost matrix, $X_{i,j} = 1$ means column j is assigned to row i .

Parameters

- **cost_matrix** (Tensor) −2-D cost matrix. Tensor of shape (M, N) .
- **maximize** (*bool*) −Calculate a maximum weight matching if true, otherwise calculate a minimum weight matching.
- **dimension_limit** (Tensor, *optional*) −A scalar used to limit the actual size of the 2nd dimension of cost_matrix. Default is Tensor(sys.maxsize), which means no limitation. The type is 0-D int64 Tensor.

Returns

A tuple of tensors containing 'row_idx' and 'col_idx'.

- **row_idx** (Tensor) - Row indices of the problem. If *dimension_limit* is given, -1 would be padded at the end. The shape is $(N,)$, where N is the minimum value of *cost_matrix* dimension.
- **col_idx** (Tensor) - Column indices of the problem. If *dimension_limit* is given, -1 would be padded at the end. The shape is $(N,)$, where N is the minimum value of *cost_matrix* dimension.

Raises

- **TypeError** – If the data type of *cost_matrix* is not the type in [float16, float32, float64, int8, int16, int32, int64, uint8, uint16, uint32, uint64, bool]
- **TypeError** – If the type of *maximize* is not bool.
- **TypeError** – If the data type of *dimension_limit* is not int64.
- **ValueError** – If the rank of *cost_matrix* is not 2.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor
>>> import mindspore.scipy.optimize.linear_sum_assignment as lsap
>>> cost_matrix = Tensor(np.array([[2, 3, 3], [3, 2, 3], [3, 3, 2]])).astype(ms.float64)
>>> dimension_limit = Tensor(2)
>>> maximize = False
>>> a, b = lsap(cost_matrix, maximize, dimension_limit)
>>> print(a)
[0 1 -1]
>>> print(b)
[0 1 -1]
>>> a, b = lsap(cost_matrix, maximize)
>>> print(a)
[0 1 2]
>>> print(b)
[0 1 2]
```

14.2.3 mindspore.scipy.optimize.minimize

mindspore.scipy.optimize.**minimize**(*func*, *x0*, *args=()*, *method=None*, *jac=None*, *hess=None*, *hessp=None*, *bounds=None*, *constraints=()*, *tol=None*, *callback=None*, *options=None*)

Minimization of scalar function of one or more variables.

This API for this function matches SciPy with some minor deviations:

- Gradients of `func` are calculated automatically using MindSpore's autodiff support when the value of jac is None.
- The `method` argument is required. A exception will be thrown if you don't specify a solver.
- Various optional arguments *"hess"*, *"hessp"*, *"bounds"*, *"constraints"*, *"tol"*, *"callback"* in the SciPy interface have not yet been implemented.
- Optimization results may differ from SciPy due to differences in the line search implementation.

Note:

- *minimize* does not yet support differentiation or arguments in the form of multi-dimensional Tensor, but support for both is planned.
- *minimize* is not supported on Windows platform yet.

- *LAGRANGE* method is only supported on "GPU".

Parameters

- **func** (*Callable*) −the objective function to be minimized, $fun(x, *args) -> float$, where x is a 1-D array with shape $(n,)$ and *args* is a tuple of the fixed parameters needed to completely specify the function. *fun* must support differentiation if jac is None.
- **x0** (Tensor) −initial guess. Array of real elements of size $(n,)$, where n is the number of independent variables.
- **args** (*Tuple*) −extra arguments passed to the objective function. Default: `()` .
- **method** (*str*) −solver type. Should be one of *"BFGS"* and *"LBFGS"*, *"LAGRANGE"*.
- **jac** (*Callable, optional*) −method for computing the gradient vector. Only for *"BFGS"* and *"LBFGS"*. if it is None, the gradient will be estimated with gradient of `func`. if it is a callable, it should be a function that returns the gradient vector: $jac(x, *args) -> array\_like, shape(n,)$ where x is an array with shape $(n,)$ and args is a tuple with the fixed parameters.
- **hess** (*Callable, optional*) −Method for calculating the Hessian Matrix. Not implemented yet.
- **hessp** (*Callable, optional*) −Hessian of objective function times an arbitrary vector p. Not implemented yet.
- **bounds** (*Sequence, optional*) −Sequence of *(min, max)* pairs for each element in x. Not implemented yet.
- **constraints** (*Callable, optional*) −representing the inequality constrains, each function in constrains indicates the function < 0 as an inequality constrain.
- **tol** (*float, optional*) −tolerance for termination. For detailed control, use solver-specific options. Default: `None` .
- **callback** (*Callable, optional*) −A callable called after each iteration. Not implemented yet.
- **options** (*Mapping[str, Any], optional*) −a dictionary of solver options. All methods accept the following generic options. Default: `None` .
  - history_size (int): size of buffer used to help to update inv hessian, only used with method="LBFGS". Default: `20` .
  - maxiter (int): Maximum number of iterations to perform. Depending on the method each iteration may use several function evaluations.

  The follow options are exclusive to Lagrange method:
  - save_tol (list): list of saving tolerance, with the same length with 'constrains'.
  - obj_weight (float): weight for objective function, usually between 1.0 - 100000.0.
  - lower (Tensor): lower bound constrain for variables, must have same shape with x0.
  - upper (Tensor): upper bound constrain for variables, must have same shape with x0.
  - learning_rate (float): learning rate for each Adam step.
  - coincide_func (Callable): sub-function representing the common parts between objective function and constrains to avoid redundant computation.
  - rounds (int): times to update Lagrange multipliers.
  - steps (int): steps to apply Adam per round.
  - log_sw (bool): whether to print the loss at each step.

Returns

OptimizeResults, object holding optimization results.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as onp
>>> from mindspore.scipy.optimize import minimize
>>> from mindspore import Tensor
>>> x0 = Tensor(onp.zeros(2).astype(onp.float32))
>>> def func(p):
...     x, y = p
...     return (x ** 2 + y - 11.) ** 2 + (x + y ** 2 - 7.) ** 2
>>> res = minimize(func, x0, method='BFGS', options=dict(maxiter=None, gtol=1e-6))
>>> print(res.x)
[3. 2.]
>>> l_res = minimize(func, x0, method='LBFGS', options=dict(maxiter=None, gtol=1e-6))
>>> print(l_res.x)
[3. 2.]
```

CHAPTER

FIFTEEN

MINDSPORE.MULTIPROCESSING

15.1 Overview

mindspore.multiprocessing provides the ability to create multiple processes. Its internal implementation inherits from Python native multiprocessing module and overloads some of the interfaces to ensure that the MindSpore framework works properly when creating multiple processes by fork.

When using mindspore.multiprocessing and creating multiprocesses by fork, the framework internally cleans up and resets threads, locks, and other resources to ensure that the framework functions properly.

- When fork occurs, the parent process waits for the internal thread task to finish executing before the fork, and actively holds the GIL lock in the current thread to avoid the child process after the fork from being unable to hold the GIL lock.
- After fork occurs, the parent process releases the actively held GIL lock.
- After fork occurs, the child process releases the actively held GIL lock, then restores and cleans up resources such as threads within the framework, and resets the backend to `CPU`.

The above process is not triggered when creating a multiprocess without using fork. At this point, the process of creating a multiprocess using mindspore.multiprocessing is exactly the same as that of using Python native multiprocessing module.

Since mindspore.multiprocessing inherits from Python native multiprocessing module, its interface usage is fully compatible with the native module, so users can directly change `import multiprocessing` to `import mindspore.multiprocessing`. Therefore, the description of the native interfaces is not repeated here. For a detailed description and the usage description of the interface, please refer to multiprocessing.

> Only Tensors with `CPU` backend can be shared between processes now.

15.2 Usage Description

A sample of creating multiple processes using mindspore.multiprocessing is shown below:

```
from mindspore import Tensor, ops
import mindspore.multiprocessing as multiprocessing

def child_process():
    y = ops.log(Tensor(2.0))
    print("ops.log(Tensor(2.0))=", y)

if __name__ == '__main__':
    p = multiprocessing.Process(target=child_process)
    p.start()
    p.join()
```

The result is shown below:

```
ops.log(Tensor(2.0))= 0.6931472
```

A sample of creating a process pool using mindspore.multiprocessing is shown below:

```
from mindspore import Tensor, ops
import mindspore.multiprocessing as multiprocessing

def child_process(x):
    return ops.log(x)

if __name__ == '__main__':
    with multiprocessing.Pool(processes=2) as pool:
        inputs = [Tensor(2.0), Tensor(2.0)]
        outputs = pool.map(child_process, inputs)
        print("ops.log(Tensor(2.0))=", outputs)
```

The result is shown below:

```
ops.log(Tensor(2.0))= [Tensor(shape=[], dtype=Float32, value= 0.693147), Tensor(shape=[],␣
↪dtype=Float32, value= 0.693147)]
```

When the user creates a multiprocess by fork after executing a computing task, if the module used is not mindspore.multiprocessing, there may be a problem that the child process is stuck due to the loss of the frame thread. Changing to use the fork of the mindspore.multiprocessing module to create multiprocesses can solve this problem.

The fork of creating child processes is only supported on POSIX systems (e.g. Linux and macOS), but not on Windows.

```
from mindspore import Tensor, ops
# Child process may be stuck when using 'import multiprocessing' .
import mindspore.multiprocessing as multiprocessing

def child_process(q):
    y = ops.log(Tensor(2.0))
    q.put(y)
    return

if __name__ == '__main__':
    multiprocessing.set_start_method("fork", force=True)
    print("parent process:ops.log(Tensor(2.0))=", ops.log(Tensor(2.0)))
    q = multiprocessing.Queue()
    p = multiprocessing.Process(target=child_process, args=(q,))
    p.start()
    print("child process:ops.log(Tensor(2.0))=", q.get())
    p.join()
```

The result is shown below:

```
parent process:ops.log(Tensor(2.0))= 0.6931472
child process:ops.log(Tensor(2.0))= 0.6931472
```

When the backend is `Ascend`, the process has exclusive access to the card resources. If a user creates a child process after performing a computation task, and the child process uses the resources of the parent process to perform another computation task, it may report an error due to resource inaccessibility. After modifying the child process creation method to fork, the framework will reset the backend of the child process to `CPU` to avoid resource conflicts.

```
from mindspore import Tensor, ops, context
import mindspore.multiprocessing as multiprocessing

def child_process(q):
    y = ops.log(Tensor(2.0))
    q.put(y)
    return

if __name__ == '__main__':
    context.set_context(device_target="Ascend")
    # Child process may not be able to acquire resources when start_method is set to 'spawn' .
    multiprocessing.set_start_method("fork", force=True)
    print("parent process:ops.log(Tensor(2.0))=", ops.log(Tensor(2.0)))
    q = multiprocessing.Queue()
    p = multiprocessing.Process(target=child_process, args=(q,))
    p.start()
    print("child process:ops.log(Tensor(2.0))=", q.get())
    p.join()
```

The result is shown below:

```
parent process:ops.log(Tensor(2.0))= 0.6931472
child process:ops.log(Tensor(2.0))= 0.6931472
```

The action of creating a multiprocess can be placed in front of executing any computational tasks an the backend is modified manually in a child process.

```
from mindspore import Tensor, ops, context
import mindspore.multiprocessing as multiprocessing

def child_process(q):
    # Child process may not be able to acquire resources when using the same resources as parent␣
↪process.
    context.set_context(device_target="CPU")
    y = ops.log(Tensor(2.0))
    q.put(y)
    return

if __name__ == '__main__':
    context.set_context(device_target="Ascend")
    multiprocessing.set_start_method("spawn", force=True)
    q = multiprocessing.Queue()
    p = multiprocessing.Process(target=child_process, args=(q,))
    p.start()
    print("child process:ops.log(Tensor(2.0))=", q.get())
    p.join()
    # Child process may not be able to acquire resources when this compute task is executed␣
↪before the child process is created.
    print("parent process:ops.log(Tensor(2.0))=", ops.log(Tensor(2.0)))
```

The result is shown below:

```
child process:ops.log(Tensor(2.0))= 0.6931472
parent process:ops.log(Tensor(2.0))= 0.6931472
```

CHAPTER

SIXTEEN

MINDSPORE.UTILS

mindspore.utils.**stress_detect**()

Inspect the hardware to determine if there are any faults affecting its accuracy and precision.Common use cases include invoking this interface at each step or when saving checkpoints, allowing users to check if any hardware issues could impact precision.

Returns

int, the return value represents the error type: zero indicates normal operation; non-zero values indicate a hardware failure.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore.utils import stress_detect
>>> ret = stress_detect()
>>> print(ret)
0
```

mindspore.utils.dryrun.**set_simulation**()

This interface is used to enable the dryrun function. The dryrun function is mainly used to simulate the actual operation of the large model. After it is enabled, the memory usage, compilation information, etc. can be simulated without occupying device card. In the PyNative mode, once it is enabled, if values are fetched from the device to the host, the Python call stack log will be printed to inform users that these values are inaccurate.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore as ms
>>> from mindspore.utils import dryrun
>>> import numpy as np
>>> dryrun.set_simulation()
>>> print(os.environ.get('MS_SIMULATION_LEVEL'))
1
```

mindspore.utils.dryrun.**mock**(*mock_val*, **args*)

In the network, if some *if* branch need to use the actual execution values and the virtual execution cannot obtain them, this interface can be used to return simulated values. During actual execution, the correct results can be obtained and the execution values can be returned.

Parameters

- **mock_val** (*Union[Value, Tensor]*) – The value you want to return.
- **args** (*Union[Value, function]*) – The content you want to mock, it can be values, function and so on.

Returns

If dryrun is enabled, mock_val will be returned; otherwise, the actual execution value of args will be returned.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore.utils import dryrun
>>> import numpy as np
>>> dryrun.set_simulation()
>>> a = ms.Tensor(np.random.rand(3, 3).astype(np.float32))
>>> if dryrun.mock(True, a[0, 0] > 0.5):
...     print("return mock_val: True.")
return mock_val: True
>>>
>>> import mindspore as ms
>>> from mindspore.utils import dryrun
>>> import numpy as np
>>> a = ms.Tensor(np.ones((3, 3)).astype(np.float32))
>>> if dryrun.mock(False, a[0, 0] > 0.5):
...     print("return real execution: True.")
return real execution: True.
>>>
>>> import mindspore as ms
>>> from mindspore.utils import dryrun
>>> import numpy as np
>>> a = ms.Tensor(np.ones((3, 3)).astype(np.float32))
>>> if dryrun.mock(False, (a > 0.5).any):
...     print("return real execution: True.")
return real execution: True.
```

CHAPTER

SEVENTEEN

MINDSPORE.EXPERIMENTAL

The experimental modules.

17.1 Experimental Optimizer

API Name	Description	Supported Platforms
mindspore.experimental.optim.Optimizer	Base class for all optimizers.	Ascend GPU CPU
mindspore.experimental.optim.Adadelta	Implements Adadelta algorithm.	Ascend GPU CPU
mindspore.experimental.optim.Adagrad	Implements Adagrad algorithm.	Ascend GPU CPU
mindspore.experimental.optim.Adam	Implements Adam algorithm.	Ascend GPU CPU
mindspore.experimental.optim.Adamax	Implements Adamax algorithm (a variant of Adam based on infinity norm).	Ascend GPU CPU
mindspore.experimental.optim.AdamW	Implements Adam Weight Decay algorithm.	Ascend GPU CPU
mindspore.experimental.optim.ASGD	Implements Averaged Stochastic Gradient Descent algorithm.	Ascend GPU CPU
mindspore.experimental.optim.NAdam	Implements NAdam algorithm.	Ascend GPU CPU
mindspore.experimental.optim.RAdam	Implements RAdam algorithm.	Ascend GPU CPU
mindspore.experimental.optim.RMSprop	Implements RMSprop algorithm.	Ascend GPU CPU
mindspore.experimental.optim.Rprop	Implements Rprop algorithm.	Ascend GPU CPU
mindspore.experimental.optim.SGD	Stochastic Gradient Descent optimizer.	Ascend GPU CPU

17.1.1 mindspore.experimental.optim.Optimizer

class mindspore.experimental.optim.**Optimizer**(*params*, *defaults*)

Base class for all optimizers.

> **Warning:** This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) – an iterable of *mindspore.Parameter* or dict. Specifies what Tensors should be optimized.
- **defaults** (*dict*) – a dict containing default values of optimization options (used when a parameter group doesn't specify them).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import nn, Tensor, Parameter
>>> from mindspore import ops
>>> from mindspore.experimental import optim
>>>
>>> class MySGD(optim.Optimizer):
...     def __init__(self, params, lr):
...         defaults = dict(lr=lr)
...         super(MySGD, self).__init__(params, defaults)
...
...     def construct(self, gradients):
...          for group_id, group in enumerate(self.param_groups):
...             id = self.group_start_id[group_id]
...             for i, param in enumerate(group["params"]):
...                 next_param = param + gradients[id+i] * group["lr"]
...                 ops.assign(param, next_param)
>>>
>>> net = nn.Dense(8, 2)
>>> data = Tensor(np.random.rand(20, 8).astype(np.float32))
>>> label = Tensor(np.random.rand(20, 2).astype(np.float32))
>>>
>>> optimizer = MySGD(net.trainable_params(), 0.01)
>>> optimizer.add_param_group({"params": Parameter([0.01, 0.02])})
>>>
>>> criterion = nn.MAELoss(reduction="mean")
>>>
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = criterion(logits, label)
...     return loss, logits
>>>
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
```

(continues on next page)

(continued from previous page)

```
>>>
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     print(loss)
>>>
>>> train_step(data, label)
```

add_param_group(*param_group*)

Add a param group to the *Optimizer.param_groups*.

Parameters

param_group (*dict*) – Specifies what Parameters should be optimized along with group specific optimization options.

17.1.2 mindspore.experimental.optim.Adadelta

class mindspore.experimental.optim.**Adadelta**(*params*, *lr=1.0*, *rho=0.9*, *eps=1e-6*, *weight_decay=0.0*, ***, *maximize=False*)

Implements Adadelta algorithm.

---

input : γ (lr), θ_0 (params), $f(\theta)$ (objective), ρ (decay), λ (weight decay)
initialize : $v_0 \leftarrow 0$ (square avg), $u_0 \leftarrow 0$ (accumulate variables)

---

for $t = 1$ **to** ... **do**

$g_t \leftarrow \nabla_\theta f_t(\theta_{t-1})$
$if\ \lambda \neq 0$
$\quad g_t \leftarrow g_t + \lambda\theta_{t-1}$
$v_t \leftarrow v_{t-1}\rho + g_t^2(1-\rho)$
$\Delta x_t \leftarrow \frac{\sqrt{u_{t-1}+\epsilon}}{\sqrt{v_t+\epsilon}} g_t$
$u_t \leftarrow u_{t-1}\rho + \Delta x_t^2(1-\rho)$
$\theta_t \leftarrow \theta_{t-1} - \gamma\Delta x_t$

---

return θ_t

Warning: This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) – list of parameters to optimize or dicts defining parameter groups.
- **lr** (*Union[int, float, Tensor], optional*) – learning rate. Default: `1.0`.
- **rho** (*float, optional*) – coefficient used for computing a running average of squared gradients. ρ in the formula above. Default: `0.9`.
- **eps** (*float, optional*) – term added to the denominator to improve numerical stability. ϵ in the formula above. Default: `1e-6`.
- **weight_decay** (*float, optional*) – weight decay (L2 penalty). Default: `0.`.

Keyword Arguments

maximize (bool, *optional*) – maximize the params based on the objective, instead of minimizing. Default: False.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** – If the learning rate is not int, float or Tensor.
- **ValueError** – If the learning rate is less than 0.
- **ValueError** – If the *eps* is less than or equal to 0.0.
- **ValueError** – If the *rho* is not in the range of [0, 1].
- **ValueError** – If the *weight_decay* is less than 0.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.Adadelta(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

17.1.3 mindspore.experimental.optim.Adagrad

class mindspore.experimental.optim.**Adagrad**(*params*, *lr=1e-2*, *lr_decay=0.0*, *weight_decay=0.0*, *initial_accumulator_value=0.0*, *eps=1e-10*, ***, *maximize=False*)

Implements Adagrad algorithm.

$$
\begin{aligned}
&\textbf{input} : \gamma \text{ (lr)},\ \theta_0 \text{ (params)},\ f(\theta) \text{ (objective)},\ \lambda \text{ (weight decay)},\\
&\qquad \tau \text{ (initial accumulator value)},\ \eta \text{ (lr decay)}\\
&\textbf{initialize} : state\_sum_0 \leftarrow 0\\
&\textbf{for } t = 1 \textbf{ to } \ldots \textbf{ do}\\
&\quad g_t \leftarrow \nabla_\theta f_t(\theta_{t-1})\\
&\quad \tilde{\gamma} \leftarrow \gamma / (1 + (t-1)\eta)\\
&\quad \textbf{if } \lambda \neq 0\\
&\quad\quad g_t \leftarrow g_t + \lambda \theta_{t-1}\\
&\quad state\_sum_t \leftarrow state\_sum_{t-1} + g_t^2\\
&\quad \theta_t \leftarrow \theta_{t-1} - \tilde{\gamma} \frac{g_t}{\sqrt{state\_sum_t} + \epsilon}\\
&\textbf{return } \theta_t
\end{aligned}
$$

Warning: This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) – list of parameters to optimize or dicts defining parameter groups.
- **lr** (*Union[int, float, Tensor], optional*) – learning rate. Default: `1e-2`.
- **lr_decay** (*float, optional*) – learning rate decay. Default: `0.`.
- **weight_decay** (*float, optional*) – weight decay (L2 penalty). Default: `0.`.
- **initial_accumulator_value** (*float, optional*) – the initial accumulator value. Default: `0.`.
- **eps** (*float, optional*) – term added to the denominator to improve numerical stability. Default: `1e-10`.

Keyword Arguments

maximize (*bool, optional*) – maximize the params based on the objective, instead of minimizing. Default: `False`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** – If the learning rate is not int, float or Tensor.
- **ValueError** – If the learning rate is less than 0.
- **ValueError** – If the learning rate decay is less than 0.
- **ValueError** – If the *weight_decay* is less than 0.
- **ValueError** – If the *initial_accumulator_value* is less than 0.0.
- **ValueError** – If the *eps* is less than 0.0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.Adagrad(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

17.1.4 mindspore.experimental.optim.Adam

class mindspore.experimental.optim.**Adam**(*params*, *lr=1e-3*, *betas=(0.9, 0.999)*, *eps=1e-8*, *weight_decay=0.0*, *amsgrad=False*, ***, *maximize=False*)

Implements Adam algorithm.

The updating formulas are as follows:

---

input : γ (lr), β_1, β_2 (betas), θ_0 (params), $f(\theta)$ (objective)
λ (weight decay), *amsgrad*, *maximize*
initialize : $m_0 \leftarrow 0$ (first moment), $v_0 \leftarrow 0$ (second moment), $\widehat{v_0}^{max} \leftarrow 0$

---

for $t = 1$ **to** ... **do**
  if *maximize* :
    $g_t \leftarrow -\nabla_\theta f_t(\theta_{t-1})$
  else
    $g_t \leftarrow \nabla_\theta f_t(\theta_{t-1})$
  if $\lambda \neq 0$
    $g_t \leftarrow g_t + \lambda\theta_{t-1}$
  $m_t \leftarrow \beta_1 m_{t-1} + (1-\beta_1) g_t$
  $v_t \leftarrow \beta_2 v_{t-1} + (1-\beta_2) g_t^2$
  $\widehat{m_t} \leftarrow m_t / \left(1-\beta_1^t\right)$
  $\widehat{v_t} \leftarrow v_t / \left(1-\beta_2^t\right)$
  if *amsgrad*
    $\widehat{v_t}^{max} \leftarrow \max(\widehat{v_t}^{max}, \widehat{v_t})$
    $\theta_t \leftarrow \theta_{t-1} - \gamma\widehat{m_t} / \left(\sqrt{\widehat{v_t}^{max}} + \epsilon\right)$
  else
    $\theta_t \leftarrow \theta_{t-1} - \gamma\widehat{m_t} / \left(\sqrt{\widehat{v_t}} + \epsilon\right)$

---

return θ_t

Warning: The implementation formula of this optimizer interface is not completely consistent with that in the paper. If you want to use an interface that is completely consistent, it is recommended to use *mindspore.mint.optim.Adam*, which currently only supports Ascend. This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) –list of parameters to optimize or dicts defining parameter groups
- **lr** (*Union[int, float, Tensor], optional*) –learning rate. Default: `1e-3`.
- **betas** (*Tuple[float, float], optional*) –The exponential decay rate for the moment estimations. Default: `(0.9, 0.999)`.
- **eps** (*float, optional*) –term added to the denominator to improve numerical stability. Default: `1e-8`.
- **weight_decay** (*float, optional*) –weight decay (L2 penalty). Default: `0.`.
- **amsgrad** (*bool, optional*) –whether to use the AMSGrad algorithm. Default: `False`.

Keyword Arguments

maximize (`bool, optional`) –maximize the params based on the objective, instead of minimizing. Default: `False`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** –If the *lr* is not int, float or Tensor.
- **ValueError** –If the *lr* is less than 0.
- **ValueError** –If the *eps* is less than 0.0.
- **ValueError** –If the *betas* not in the range of [0, 1).
- **ValueError** –If the *weight_decay* is less than 0.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.Adam(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
```

(continues on next page)

(continued from previous page)

```
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

17.1.5 mindspore.experimental.optim.Adamax

class mindspore.experimental.optim.**Adamax**(*params*, *lr=2e-3*, *betas=(0.9, 0.999)*, *eps=1e-8*, *weight_decay=0.0*, ***, *maximize=False*)

Implements Adamax algorithm (a variant of Adam based on infinity norm).

---

input : γ (lr), β_1, β_2 (betas), θ_0 (params), $f(\theta)$ (objective), λ (weight decay),
ϵ (epsilon)
initialize : $m_0 \leftarrow 0$ (first moment), $u_0 \leftarrow 0$ (infinity norm)

---

for $t = 1$ **to** ... **do**
$g_t \leftarrow \nabla_\theta f_t(\theta_{t-1})$
$if\ \lambda \neq 0$
$g_t \leftarrow g_t + \lambda\theta_{t-1}$
$m_t \leftarrow \beta_1 m_{t-1} + (1-\beta_1) g_t$
$u_t \leftarrow \max(\beta_2 u_{t-1}, |g_t| + \epsilon)$
$\theta_t \leftarrow \theta_{t-1} - \frac{\gamma m_t}{(1-\beta_1^t) u_t}$

---

return θ_t

Warning: This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) – list of parameters to optimize or dicts defining parameter groups.
- **lr** (*Union[int, float, Tensor], optional*) – learning rate. Default: `2e-3`.
- **betas** (*Tuple[float, float], optional*) – coefficients used for computing running averages of gradient and its square. Default: `(0.9, 0.999)`.
- **eps** (*float, optional*) – term added to the denominator to improve numerical stability. Default: `1e-8`.
- **weight_decay** (*float, optional*) – weight decay (L2 penalty). Default: `0.`.

Keyword Arguments

maximize (*bool, optional*) – maximize the params based on the objective, instead of minimizing. Default: `False`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** – If the learning rate is not int, float or Tensor.

- **ValueError** – If the learning rate is less than 0.
- **ValueError** – If the *eps* is less than 0.0.
- **ValueError** – If the *weight_decay* is less than 0.
- **ValueError** – If elements of the *betas* not in the range of [0,1).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.Adamax(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

17.1.6 mindspore.experimental.optim.AdamW

class mindspore.experimental.optim.**AdamW**(*params*, *lr=1e-3*, *betas=(0.9, 0.999)*, *eps=1e-8*, *weight_decay=1e-2*, *amsgrad=False*, ***, *maximize=False*)

Implements Adam Weight Decay algorithm.

---

input : γ(lr), β_1, β_2(betas), θ_0(params), $f(\theta)$(objective), ϵ (epsilon)
λ(weight decay), *amsgrad*, *maximize*
initialize : $m_0 \leftarrow 0$ (first moment), $v_0 \leftarrow 0$ (second moment), $\widehat{v_0}^{max} \leftarrow 0$

---

for $t = 1$ **to** ... **do**
  if *maximize* :
    $g_t \leftarrow -\nabla_\theta f_t(\theta_{t-1})$
  else
    $g_t \leftarrow \nabla_\theta f_t(\theta_{t-1})$
  $\theta_t \leftarrow \theta_{t-1} - \gamma\lambda\theta_{t-1}$
  $m_t \leftarrow \beta_1 m_{t-1} + (1-\beta_1) g_t$
  $v_t \leftarrow \beta_2 v_{t-1} + (1-\beta_2) g_t^2$
  $\widehat{m_t} \leftarrow m_t / \left(1-\beta_1^t\right)$
  $\widehat{v_t} \leftarrow v_t / \left(1-\beta_2^t\right)$
  if $amsgrad$
    $\widehat{v_t}^{max} \leftarrow \max(\widehat{v_t}^{max}, \widehat{v_t})$
    $\theta_t \leftarrow \theta_t - \gamma\widehat{m_t} / \left(\sqrt{\widehat{v_t}^{max}} + \epsilon\right)$
  else
    $\theta_t \leftarrow \theta_t - \gamma\widehat{m_t} / \left(\sqrt{\widehat{v_t}} + \epsilon\right)$

---

return θ_t

Warning: This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) – list of parameters to optimize or dicts defining parameter groups
- **lr** (*Union[int, float, Tensor], optional*) – learning rate. Default: `1e-3`.
- **betas** (*Tuple[float, float], optional*) – The exponential decay rate for the moment estimations. Default: `(0.9, 0.999)`.
- **eps** (*float, optional*) – term added to the denominator to improve numerical stability. Default: `1e-8`.
- **weight_decay** (*float, optional*) – weight decay (L2 penalty). Default: `0.`.
- **amsgrad** (*bool, optional*) – whether to use the AMSGrad algorithm. Default: `False`.

Keyword Arguments

maximize (*bool, optional*) – maximize the params based on the objective, instead of minimizing. Default: `False`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** –If the learning rate is not int, float or Tensor.
- **ValueError** –If the learning rate is less than 0.
- **ValueError** –If the *eps* is less than 0.0.
- **ValueError** –If the *betas* not in the range of [0, 1).
- **ValueError** –If the *weight_decay* is less than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.AdamW(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

17.1.7 mindspore.experimental.optim.ASGD

class mindspore.experimental.optim.**ASGD**(*params*, *lr=1e-2*, *lambd=1e-4*, *alpha=0.75*, *t0=1e6*, *weight_decay=0.0*, *maximize=False*)

Implements Averaged Stochastic Gradient Descent algorithm.

> **Warning:** This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) –list of parameters to optimize or dicts defining parameter groups.
- **lr** (*Union[int, float, Tensor], optional*) –learning rate. Default: `1e-2`.
- **lambd** (*float, optional*) –decay term. Default: `1e-4`.
- **alpha** (*float, optional*) –power for eta update. Default: `0.75`.
- **t0** (*float, optional*) –point at which to start averaging. Default: `1e6`.
- **weight_decay** (*float, optional*) –weight decay (L2 penalty). Default: `0.`.

- **maximize** (*bool, optional*) –maximize the params based on the objective, instead of minimizing. Default: `False`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** –If the learning rate is not int, float or Tensor.
- **ValueError** –If the learning rate is less than 0.
- **ValueError** –If the *weight_decay* is less than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.ASGD(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

17.1.8 mindspore.experimental.optim.NAdam

class mindspore.experimental.optim.**NAdam**(*params*, *lr=2e-3*, *betas=(0.9, 0.999)*, *eps=1e-8*, *weight_decay=0.0*, *momentum_decay=4e-3*)

Implements NAdam algorithm.

> **Warning:** This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) –list of parameters to optimize or dicts defining parameter groups.
- **lr** (*Union[int, float, Tensor], optional*) –learning rate. Default: `2e-3`.

- **betas** (*Tuple[float, float], optional*) –coefficients used for computing running averages of gradient and its square. Default: `(0.9, 0.999)`.
- **eps** (*float, optional*) –term added to the denominator to improve numerical stability. Default: `1e-8`.
- **weight_decay** (*float, optional*) –weight decay (L2 penalty). Default: `0.`.
- **momentum_decay** (*float, optional*) –momentum momentum_decay. Default: `4e-3`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** –If the learning rate is not int, float or Tensor.
- **ValueError** –If the learning rate is less than 0.
- **ValueError** –If the *eps* is less than 0.0.
- **ValueError** –If the *weight_decay* is less than 0.
- **ValueError** –If the *momentum_decay* is less than 0.
- **ValueError** –If elements of *betas* not in the range of [0, 1).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.NAdam(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

17.1.9 mindspore.experimental.optim.RAdam

class mindspore.experimental.optim.**RAdam**(*params*, *lr=1e-3*, *betas=(0.9, 0.999)*, *eps=1e-8*, *weight_decay=0.0*)

Implements RAdam algorithm.

Input : γ (lr), β_1, β_2 (betas), θ_0 (params), $f(\theta)$ (objective), λ (weightdecay), ϵ (epsilon)

Initialize : $\begin{cases} m_0 \leftarrow 0 \text{ (first moment)} \\ v_0 \leftarrow 0 \text{ (second moment)} \\ \rho_\infty \xleftarrow{\text{def}} \dfrac{2}{1-\beta_2} - 1 \end{cases}$

For $t = 1$ to $\ldots$ do :

$g_t \leftarrow \nabla_\theta f_t(\theta_{t-1})$

If $\lambda \neq 0$:

$g_t \leftarrow g_t + \lambda\theta_{t-1}$

$m_t \leftarrow \beta_1 m_{t-1} + (1-\beta_1) g_t$

$v_t \leftarrow \beta_2 v_{t-1} + (1-\beta_2) g_t^2$

$\widehat{m_t} \leftarrow \dfrac{m_t}{1-\beta_1^t}$

Let $\rho_t' = 2t\beta_2^t/(1-\beta_2^t)$ (auxiliary variable)

$\rho_t \leftarrow \rho_\infty - \rho_t'$

If $\rho_t > 5$:

$l_t \leftarrow \dfrac{\sqrt{1-\beta_2^t}}{\sqrt{v_t}+\epsilon}$

$r_t \leftarrow \sqrt{\dfrac{(\rho_t-4)(\rho_t-2)\rho_\infty}{(\rho_\infty-4)(\rho_\infty-2)\rho_t}}$

$\theta_t \leftarrow \theta_{t-1} - \gamma\widehat{m_t} r_t l_t$

Else :

$\theta_t \leftarrow \theta_{t-1} - \gamma\widehat{m_t}$

Return : θ_t

Warning: This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) – list of parameters to optimize or dicts defining parameter groups.
- **lr** (*Union[int, float, Tensor], optional*) – learning rate. Default: 1e-3.
- **betas** (*Tuple[float, float], optional*) – coefficients used for computing running averages of gradient and its square. Default: (0.9, 0.999).

- **eps** (*float, optional*) – term added to the denominator to improve numerical stability. Default: `1e-8`.
- **weight_decay** (*float, optional*) – weight decay (L2 penalty). Default: `0.0`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** – If the learning rate is not int, float or Tensor.
- **ValueError** – If the learning rate is less than 0.
- **ValueError** – If the *eps* is less than 0.0.
- **ValueError** – If the *weight_decay* is less than 0.
- **ValueError** – If elements of *betas* not in the range of [0, 1).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.RAdam(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

17.1.10 mindspore.experimental.optim.RMSprop

class mindspore.experimental.optim.**RMSprop**(*params*, *lr=1e-2*, *alpha=0.99*, *eps=1e-8*, *weight_decay=0.0*, *momentum=0.0*, *centered=False*, *maximize=False*)

Implements RMSprop algorithm.

> **Warning:** This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) – list of parameters to optimize or dicts defining parameter groups.
- **lr** (*Union[int, float, Tensor], optional*) – learning rate. Default: `1e-2`.
- **alpha** (*float, optional*) – smoothing constant. Default: `0.99`.
- **eps** (*float, optional*) – term added to the denominator to improve numerical stability. Default: `1e-8`.
- **weight_decay** (*float, optional*) – weight decay (L2 penalty). Default: `0.`.
- **momentum** (*float, optional*) – momentum factor. Default: `0.`.
- **centered** (*bool, optional*) – if `True`, compute the centered RMSProp, the gradient is normalized by an estimation of its variance. Default: `False`.
- **maximize** (*bool, optional*) – maximize the params based on the objective, instead of minimizing. Default: `False`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** – If the learning rate is not int, float or Tensor.
- **ValueError** – If the learning rate is less than 0.
- **ValueError** – If the *momentum* is less than 0.0.
- **ValueError** – If the *alpha* is less than 0.0.
- **ValueError** – If the *eps* is less than 0.0.
- **ValueError** – If the *weight_decay* is less than 0.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.RMSprop(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

17.1.11 mindspore.experimental.optim.Rprop

class mindspore.experimental.optim.**Rprop**(*params*, *lr=1e-2*, *etas=(0.5, 1.2)*, *step_sizes=(1e-6, 50)*, ***, *maximize=False*)

Implements Rprop algorithm.

> **Warning:** This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) – list of parameters to optimize or dicts defining parameter groups.
- **lr** (*Union[int, float, Tensor], optional*) – learning rate. Default: `1e-2`.
- **etas** (*Tuple[float, float], optional*) – pair of (etaminus, etaplus), that are multiplicative increase and decrease factors. Default: `(0.5, 1.2)`
- **step_sizes** (*Tuple[float, float], optional*) – a pair of minimal and maximal allowed step sizes. Default: `(1e-6, 50)`

Keyword Arguments

maximize (`bool, optional`) – maximize the params based on the objective, instead of minimizing. Default: `False`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** – If the learning rate is not int, float or Tensor.
- **ValueError** – If the learning rate is less than 0.
- **ValueError** – If the *etas[1]* is less than or equal to 1.0.
- **ValueError** – If the *etas[0]* not in the range of 0-1.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.Rprop(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
```

(continues on next page)

(continued from previous page)

```
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

17.1.12 mindspore.experimental.optim.SGD

class mindspore.experimental.optim.**SGD**(*params*, *lr*, *momentum=0*, *dampening=0*, *weight_decay=0.0*, *nesterov=False*, ***, *maximize=False*)

Stochastic Gradient Descent optimizer.

$$v_{t+1} = u * v_t + gradient * (1 - dampening)$$

If nesterov is True:

$$p_{t+1} = p_t - lr * (gradient + u * v_{t+1})$$

If nesterov is False:

$$p_{t+1} = p_t - lr * v_{t+1}$$

To be noticed, for the first step, $v_{t+1} = gradient$.

Here: where p, v and u denote the parameters, accum, and momentum respectively.

Warning: This is an experimental optimizer API that is subject to change. This module must be used with lr scheduler module in LRScheduler Class .

Parameters

- **params** (*Union[list(Parameter), list(dict)]*) –list of parameters to optimize or dicts defining parameter groups.
- **lr** (*Union[int, float, Tensor]*) –learning rate.
- **momentum** (*Union[int, float], optional*) –momentum factor. Default: `0`.
- **weight_decay** (*float, optional*) –weight decay (L2 penalty). Default: `0`..
- **dampening** (*Union[int, float], optional*) –dampening for momentum. Default: `0`.
- **nesterov** (*bool, optional*) –enables Nesterov momentum. Default: `False`.

Keyword Arguments

maximize (*bool, optional*) –maximize the params based on the objective, instead of minimizing. Default: `False`.

Inputs:

- **gradients** (tuple[Tensor]) - The gradients of *params*.

Raises

- **ValueError** –If the learning rate is not int, float or Tensor.

- **ValueError** – If the learning rate is less than 0.
- **ValueError** – If the *momentum* or *weight_decay* value is less than 0.0.
- **ValueError** – If the *momentum*, *dampening* or *weight_decay* value is not int or float.
- **ValueError** – If the *nesterov* and *maximize* is not bool.
- **ValueError** – If the *nesterov* is true, *momentum* is not positive or *dampening* is not 0.0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.SGD(net.trainable_params(), lr=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
```

17.1.13 LRScheduler Class

The dynamic learning rates in this module are all subclasses of LRScheduler, this module should be used with optimizers in mindspore.experimental.optim, pass the optimizer instance to a LRScheduler when used. During the training process, the LRScheduler subclass dynamically changes the learning rate by calling the *step* method.

```
import mindspore
from mindspore import nn
from mindspore.experimental import optim

# Define the network structure of LeNet5. Refer to
# https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py

net = LeNet5()
loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
optimizer = optim.Adam(net.trainable_params(), lr=0.05)
scheduler = optim.lr_scheduler.StepLR(optimizer, step_size=2, gamma=0.1)
def forward_fn(data, label):
    logits = net(data)
    loss = loss_fn(logits, label)
    return loss, logits
grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
```

(continues on next page)

(continued from previous page)

```
def train_step(data, label):
    (loss, _), grads = grad_fn(data, label)
    optimizer(grads)
    return loss
for epoch in range(6):
    # Create the dataset taking MNIST as an example. Refer to
    # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py

    for data, label in create_dataset(need_download=False):
        train_step(data, label)
    scheduler.step()
```

API Name	Description	Supported Platforms
mindspore.experimental.optim.lr_scheduler.LRScheduler	Basic class of learning rate schedule.	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.ConstantLR	Decays the learning rate of each parameter group by a small constant factor until the number of epoch reaches a pre-defined milestone: total_iters.	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.CosineAnnealingLR	Set the learning rate of each parameter group using a cosine annealing lr schedule.	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.CosineAnnealingWarmRestarts	Set the learning rate of each parameter group using a cosine annealing warm restarts schedule.	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.CyclicLR	Sets the learning rate of each parameter group according to cyclical learning rate policy (CLR).	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.ExponentialLR	For each epoch, the learning rate decays exponentially, multiplied by gamma.	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.LambdaLR	Sets the learning rate of each parameter group to the initial lr times a given function.	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.LinearLR	Decays the learning rate of each parameter group by linearly changing small multiplicative factor until the number of epoch reaches a pre-defined milestone: total_iters.	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.MultiplicativeLR	Multiply the learning rate of each parameter group by the factor given in the specified function.	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.MultiStepLR	Multiply the learning rate of each parameter group by gamma once the number of epoch reaches one of the milestones.	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.PolynomialLR	For each epoch, the learning rate is adjusted by polynomial fitting.	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.ReduceLROnPlateau	Reduce learning rate when a metric has stopped improving.	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.SequentialLR	Concatenate multiple learning rate adjustment strategies in *schedulers* in sequence, switching to the next learning rate adjustment strategy at *milestone*.	Ascend GPU CPU
mindspore.experimental.optim.lr_scheduler.StepLR	Decays the learning rate of each parameter group by gamma every step_size epochs.	Ascend GPU CPU

mindspore.experimental.optim.lr_scheduler.LRScheduler

class mindspore.experimental.optim.lr_scheduler.**LRScheduler**(*optimizer*, *last_epoch=- 1*)

Basic class of learning rate schedule.

> **Warning:** This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) –The optimizer instance.
- **last_epoch** (*int, optional*) –The number of times the *step()* method of the current learning rate adjustment strategy has been executed. Default: `-1`.

Raises

- **TypeError** –If *optimizer* does not satisfy the type requirement.
- **KeyError** –If *last_epoch* != -1 and `'initial_lr'` not in param groups.
- **ValueError** –if *last_epoch* is not int.
- **ValueError** –If *last_epoch* is not greater than -1.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>>
>>> class ConstantLR(optim.lr_scheduler.LRScheduler):
...     def __init__(self, optimizer, factor=0.5, total_iters=3, last_epoch=-1):
...         self.factor = factor
...         self.total_iters = total_iters
...         super(ConstantLR, self).__init__(optimizer, last_epoch)
...
...     def get_lr(self):
...         if self.last_epoch == 0:
...             return [lr * self.factor for lr in self._last_lr]
...         if self.last_epoch != self.total_iters:
...             return [lr * 1. for lr in self._last_lr]
...         return [lr / self.factor for lr in self._last_lr]
>>>
>>> net = nn.Dense(8, 2)
>>> optimizer = optim.SGD(net.trainable_params(), 0.01)
>>> scheduler = ConstantLR(optimizer)
>>> for i in range(4):
...     scheduler.step()
...     current_lr = scheduler.get_last_lr()
...     print(current_lr)
[Tensor(shape=[], dtype=Float32, value= 0.005)]
[Tensor(shape=[], dtype=Float32, value= 0.005)]
```

(continues on next page)

(continued from previous page)

```
[Tensor(shape=[], dtype=Float32, value= 0.01)]
[Tensor(shape=[], dtype=Float32, value= 0.01)]
```

get_last_lr()
Return last computed learning rate by current scheduler.

step(*epoch=None*)
Get the current learning rate and change the learning rate.

Parameters

epoch (*int, optional*) –The index of the last epoch. Default: None.

mindspore.experimental.optim.lr_scheduler.ConstantLR

class mindspore.experimental.optim.lr_scheduler.**ConstantLR**(*optimizer*, *factor=1.0 / 3*, *total_iters=5*, *last_epoch=- 1*)

Decays the learning rate of each parameter group by a small constant factor until the number of epoch reaches a pre-defined milestone: total_iters. Notice that such decay can happen simultaneously with other changes to the learning rate from outside this scheduler.

Warning: This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) –Wrapped optimizer.
- **factor** (*float, optional*) –The factor number multiplied learning rate. Default: 1./3.
- **total_iters** (*int, optional*) –The number of steps that the scheduler decays the learning rate, when the *last_epoch* reach *total_iters*, restore the learning rate. Default: 5.
- **last_epoch** (*int, optional*) –The index of the last epoch. Default: -1.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> net = nn.Dense(2, 3)
>>> optimizer = optim.Adam(net.trainable_params(), 0.05)
>>> # Assuming optimizer uses lr = 0.05 for all groups
>>> # lr = 0.025   if epoch <4
>>> # lr = 0.05    if epoch >= 4
>>> scheduler = optim.lr_scheduler.ConstantLR(optimizer, factor=0.5, total_iters=4)
>>> for i in range(6):
...     scheduler.step()
...     current_lr = scheduler.get_last_lr()
...     print(current_lr)
[Tensor(shape=[], dtype=Float32, value= 0.025)]
```

(continues on next page)

(continued from previous page)

```
[Tensor(shape=[], dtype=Float32, value= 0.025)]
[Tensor(shape=[], dtype=Float32, value= 0.025)]
[Tensor(shape=[], dtype=Float32, value= 0.05)]
[Tensor(shape=[], dtype=Float32, value= 0.05)]
[Tensor(shape=[], dtype=Float32, value= 0.05)]
```

mindspore.experimental.optim.lr_scheduler.CosineAnnealingLR

class mindspore.experimental.optim.lr_scheduler.**CosineAnnealingLR**(*optimizer*, *T_max*, *eta_min=0.0*, *last_epoch=- 1*)

Set the learning rate of each parameter group using a cosine annealing lr schedule. Where η_{max} is set to the initial lr, η_{min} is the minimum value for learning rate, η_t is the current learning rate, T_{max} is iteration number of cosine function, and T_{cur} is the number of epochs since the last restart in SGDR.

$$
\begin{aligned}
&\eta_t && = \eta_{min} + \tfrac{1}{2}(\eta_{max} - \eta_{min})\left(1 + \cos\left(\tfrac{T_{cur}}{T_{max}}\pi\right)\right), \\
&T_{cur} \neq (2k+1)T_{max}; && \\
&\eta_{t+1} && = \eta_t + \tfrac{1}{2}(\eta_{max} - \eta_{min})\left(1 - \cos\left(\tfrac{1}{T_{max}}\pi\right)\right), \\
&T_{cur} = (2k+1)T_{max}. &&
\end{aligned}
$$

For more details, please refer to: SGDR: Stochastic Gradient Descent with Warm Restarts .

Warning: This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) –Wrapped optimizer.
- **T_max** (*int*) –Maximum number of iterations.
- **eta_min** (*float, optional*) –Minimum learning rate. Default: `0.0`.
- **last_epoch** (*int, optional*) –The index of the last epoch. Default: `-1`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore.experimental import optim
>>> from mindspore import nn
>>> net = nn.Dense(3, 2)
>>> optimizer = optim.SGD(net.trainable_params(), lr=0.1, momentum=0.9)
>>> scheduler = optim.lr_scheduler.CosineAnnealingLR(optimizer, T_max=2)
>>>
>>> for i in range(6):
...     scheduler.step()
...     current_lr = scheduler.get_last_lr()
...     print(current_lr)
[Tensor(shape=[], dtype=Float32, value= 0.05)]
```

(continues on next page)

(continued from previous page)

```
[Tensor(shape=[], dtype=Float32, value= 0)]
[Tensor(shape=[], dtype=Float32, value= 0.05)]
[Tensor(shape=[], dtype=Float32, value= 0.1)]
[Tensor(shape=[], dtype=Float32, value= 0.05)]
[Tensor(shape=[], dtype=Float32, value= 0)]
```

mindspore.experimental.optim.lr_scheduler.CosineAnnealingWarmRestarts

class mindspore.experimental.optim.lr_scheduler.**CosineAnnealingWarmRestarts**(*optimizer*, *T_0*, *T_mult=1*, *eta_min=0*, *last_epoch=- 1*)

Set the learning rate of each parameter group using a cosine annealing warm restarts schedule.

$$\eta_t = \eta_{min} + \frac{1}{2}(\eta_{max} - \eta_{min})\left(1 + \cos\left(\frac{T_{cur}}{T_i}\pi\right)\right)$$

Where η_{max} is set to the initial lr, η_{min} is the minimum value for learning rate, η_t is the current learning rate, T_0 is the number of iterations for the first restar, T_i is the current number of iterations between two warm restarts in SGDR, T_{cur} is the number of epochs since the last restart in SGDR.

When $T_{cur} = T_i$, set $\eta_t = \eta_{min}$. When $T_{cur} = 0$ after restart, set $\eta_t = \eta_{max}$.

For more details, please refer to: SGDR: Stochastic Gradient Descent with Warm Restarts.

Warning: This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) –Wrapped optimizer.
- **T_0** (*int*) –Number of iterations for the first restart.
- **T_mult** (*int, optional*) –A factor increases T_i after a restart. Default: `1`.
- **eta_min** (*Union(float, int), optional*) –Minimum learning rate. Default: `0`.
- **last_epoch** (*int, optional*) –The number of times the *step()* method of the current learning rate adjustment strategy has been executed. Default: `-1`.

Raises

- **ValueError** –*T_0* is less than or equal than 0 or not an int.
- **ValueError** –*T_mult* is less than or equal than 1 or not an int.
- **ValueError** –*eta_min* is not int or float.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore.experimental import optim
>>> from mindspore import nn
>>> net = nn.Dense(3, 2)
>>> optimizer = optim.SGD(net.trainable_params(), lr=0.1, momentum=0.9)
>>> scheduler = optim.lr_scheduler.CosineAnnealingWarmRestarts(optimizer, 2)
>>> iters = 3
>>> for epoch in range(2):
...     for i in range(iters):
...         scheduler.step(epoch + i / iters)
...         current_lr = scheduler.get_last_lr()
...         print(current_lr)
[Tensor(shape=[], dtype=Float32, value= 0.1)]
[Tensor(shape=[], dtype=Float32, value= 0.0933013)]
[Tensor(shape=[], dtype=Float32, value= 0.075)]
[Tensor(shape=[], dtype=Float32, value= 0.05)]
[Tensor(shape=[], dtype=Float32, value= 0.025)]
[Tensor(shape=[], dtype=Float32, value= 0.00669873)]
```

step(*epoch=None*)

Get the current learning rate and change the learning rate.

Parameters

epoch (*int, optional*) – The index of the last epoch. Default: `None`.

mindspore.experimental.optim.lr_scheduler.CyclicLR

class mindspore.experimental.optim.lr_scheduler.**CyclicLR**(*optimizer*, *base_lr*, *max_lr*, *step_size_up=2000*, *step_size_down=None*, *mode='triangular'*, *gamma=1.*, *scale_fn=None*, *scale_mode='cycle'*, *last_epoch=- 1*)

Sets the learning rate of each parameter group according to cyclical learning rate policy (CLR). The policy cycles the learning rate between two boundaries with a constant frequency, as detailed in the paper Cyclical Learning Rates for Training Neural Networks. The distance between the two boundaries can be scaled on a per-iteration or per-cycle basis.

This class has three built-in policies, as put forth in the paper:

- "triangular": A basic triangular cycle without amplitude scaling.
- "triangular2": A basic triangular cycle that scales initial amplitude by half each cycle.
- "exp_range": A cycle that scales initial amplitude by $\text{gamma}^{\text{cycle iterations}}$ at each cycle iteration.

Warning: This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) – Wrapped optimizer.
- **base_lr** (*Union(float, list)*) – Initial learning rate which is the lower boundary in the cycle for each parameter group.

- **max_lr** (*Union(float, list)*) –Upper learning rate boundaries in the cycle for each parameter group. Functionally, it defines the cycle amplitude (max_lr - base_lr). The lr at any cycle is the sum of base_lr and some scaling of the amplitude.
- **step_size_up** (*int, optional*) –Number of training iterations in the increasing half of a cycle. Default: `2000`.
- **step_size_down** (*int, optional*) –Number of training iterations in the decreasing half of a cycle. If step_size_down is None, it is set to step_size_up. Default: `None`.
- **mode** (*str, optional*) –One of {triangular, triangular2, exp_range}. Values correspond to policies detailed above. If scale_fn is not None, this argument is ignored. Default: `'triangular'`.
- **gamma** (*float, optional*) –Constant in 'exp_range' scaling function: gamma**(cycle iterations). Default: `1.0`.
- **scale_fn** (*function, optional*) –Custom scaling policy defined by a single argument lambda function, where 0 <= scale_fn(x) <= 1 for all x >= 0. If specified, then 'mode' is ignored. Default: `None`.
- **scale_mode** (*str, optional*) –{'cycle', 'iterations'}. Defines whether scale_fn is evaluated on cycle number or cycle iterations (training iterations since start of cycle). Illegal inputs will use `'iterations'` by defaults. Default: `'cycle'`.
- **last_epoch** (*int, optional*) –The index of the last epoch. Default: `-1`.

Raises

- **ValueError** –When *base_lr* is list or tuple, the length of it is not equal to the number of param groups.
- **ValueError** –When *max_lr* is list or tuple, the length of it is not equal to the number of param groups.
- **ValueError** –*mode* is not in [`'triangular'`, `'triangular2'`, `'exp_range'`] and *scale_fn* is None.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore.experimental import optim
>>> from mindspore import nn
>>> net = nn.Dense(3, 2)
>>> optimizer = optim.SGD(net.trainable_params(), lr=0.1, momentum=0.9)
>>> scheduler = optim.lr_scheduler.CyclicLR(optimizer, base_lr=0.01, max_lr=0.1)
>>> expect_list = [[0.010045], [0.01009], [0.010135], [0.01018], [0.010225]]
>>>
>>> for i in range(5):
...     scheduler.step()
...     current_lr = scheduler.get_last_lr()
...     print(current_lr)
[Tensor(shape=[], dtype=Float32, value= 0.010045)]
[Tensor(shape=[], dtype=Float32, value= 0.01009)]
[Tensor(shape=[], dtype=Float32, value= 0.010135)]
[Tensor(shape=[], dtype=Float32, value= 0.01018)]
[Tensor(shape=[], dtype=Float32, value= 0.010225)]
```

mindspore.experimental.optim.lr_scheduler.ExponentialLR

class mindspore.experimental.optim.lr_scheduler.**ExponentialLR**(*optimizer*, *gamma*, *last_epoch=- 1*)

For each epoch, the learning rate decays exponentially, multiplied by gamma. Notice that such decay can happen simultaneously with other changes to the learning rate from outside this scheduler.

> **Warning:** This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) –Wrapped optimizer.
- **gamma** (*float*) –Learning rate scaling factor.
- **last_epoch** (*int, optional*) –The index of the last epoch. Default: -1.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.fc = nn.Dense(16 * 5 * 5, 120)
...     def construct(self, x):
...         return self.fc(x)
>>> net = Net()
>>> optimizer = optim.Adam(net.trainable_params(), 0.01)
>>> scheduler = optim.lr_scheduler.ExponentialLR(optimizer, gamma=0.5)
>>> for i in range(3):
...     scheduler.step()
...     current_lr = scheduler.get_last_lr()
...     print(current_lr)
[Tensor(shape=[], dtype=Float32, value= 0.005)]
[Tensor(shape=[], dtype=Float32, value= 0.0025)]
[Tensor(shape=[], dtype=Float32, value= 0.00125)]
```

mindspore.experimental.optim.lr_scheduler.LambdaLR

class mindspore.experimental.optim.lr_scheduler.**LambdaLR**(*optimizer*, *lr_lambda*, *last_epoch=- 1*)

Sets the learning rate of each parameter group to the initial lr times a given function. When last_epoch=-1, sets initial lr as lr.

> **Warning:** This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) –Wrapped optimizer.

- **lr_lambda** (*Union(function, list)*) –A function which computes a multiplicative factor given a parameter *last_epoch*, or a list of such functions, one for each group in *optimizer.param_groups*.
- **last_epoch** (*int, optional*) –The index of the last epoch. Default: -1.

Raises

ValueError –If the length of *lr_lambda* is not equal to the number of param groups.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> net = nn.Dense(2, 3)
>>> optimizer = optim.Adam(net.trainable_params(), 0.01)
>>> lmbda = lambda epoch: 0.9 ** epoch
>>> scheduler = optim.lr_scheduler.LambdaLR(optimizer, lr_lambda=[lmbda])
>>> for i in range(3):
...     scheduler.step()
...     current_lr = scheduler.get_last_lr()
...     print(current_lr)
[Tensor(shape=[], dtype=Float32, value= 0.009)]
[Tensor(shape=[], dtype=Float32, value= 0.0081)]
[Tensor(shape=[], dtype=Float32, value= 0.00729)]
```

mindspore.experimental.optim.lr_scheduler.LinearLR

class mindspore.experimental.optim.lr_scheduler.**LinearLR**(*optimizer*, *start_factor=1.0 / 3*, *end_factor=1.0*, *total_iters=5*, *last_epoch=- 1*)

Decays the learning rate of each parameter group by linearly changing small multiplicative factor until the number of epoch reaches a pre-defined milestone: total_iters. Notice that such decay can happen simultaneously with other changes to the learning rate from outside this scheduler.

Warning: This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) –Wrapped optimizer.
- **start_factor** (*float, optional*) –The number we multiply learning rate in the first epoch. The multiplication factor changes towards *end_factor* in the following epochs. Default: 1.0 /3.
- **end_factor** (*float, optional*) –The number we multiply learning rate at the end of linear changing process. Default: 1.0.
- **total_iters** (*int, optional*) –The number of iterations that multiplicative factor reaches to 1. Default: 5.
- **last_epoch** (*int, optional*) –The index of the last epoch. Default: -1.

Raises

- **ValueError** –If *start_factor* is not in the range of (0, 1].

- **ValueError** – If *end_factor* is not in the range of [0, 1].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.Adam(net.trainable_params(), lr=0.05)
>>> # Assuming optimizer uses lr = 0.05 for all groups
>>> # lr = 0.025    if epoch == 0
>>> # lr = 0.03125  if epoch == 1
>>> # lr = 0.0375   if epoch == 2
>>> # lr = 0.04375  if epoch == 3
>>> # lr = 0.05    if epoch >= 4
>>> scheduler = optim.lr_scheduler.LinearLR(optimizer, start_factor=0.5, total_iters=4)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
>>> for epoch in range(5):
...     # Create the dataset taking MNIST as an example. Refer to
...     # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
...     for data, label in create_dataset():
...         train_step(data, label)
...     scheduler.step()
...     current_lr = scheduler.get_last_lr()
```

mindspore.experimental.optim.lr_scheduler.MultiplicativeLR

class mindspore.experimental.optim.lr_scheduler.**MultiplicativeLR**(*optimizer*, *lr_lambda*, *last_epoch=-1*)

Multiply the learning rate of each parameter group by the factor given in the specified function. When last_epoch=-1, sets initial lr as lr.

> **Warning:** This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) – Wrapped optimizer.

- **lr_lambda** (*Union(function, list)*) –A function which computes a multiplicative factor given an integer parameter epoch, or a list of such functions, one for each group in optimizer.param_groups.
- **last_epoch** (*int, optional*) –The index of the last epoch. Default: `-1`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> net = nn.Dense(2, 3)
>>> optimizer = optim.Adam(net.trainable_params(), 0.01)
>>> lmbda = lambda epoch: 0.95
>>> scheduler = optim.lr_scheduler.MultiplicativeLR(optimizer, lr_lambda=lmbda)
>>> for i in range(3):
...     scheduler.step()
...     current_lr = scheduler.get_last_lr()
...     print(current_lr)
[Tensor(shape=[], dtype=Float32, value= 0.0095)]
[Tensor(shape=[], dtype=Float32, value= 0.009025)]
[Tensor(shape=[], dtype=Float32, value= 0.00857375)]
```

mindspore.experimental.optim.lr_scheduler.MultiStepLR

class mindspore.experimental.optim.lr_scheduler.**MultiStepLR**(*optimizer*, *milestones*, *gamma=0.1*, *last_epoch=- 1*)

Multiply the learning rate of each parameter group by gamma once the number of epoch reaches one of the milestones. Notice that such change can happen simultaneously with other changes to the learning rate from outside this scheduler. When last_epoch=-1, sets initial lr as lr.

> **Warning:** This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) –Wrapped optimizer.
- **milestones** (*list*) –List of epoch indices. When *last_epoch* reach the milestone, multiply the learning rate of each parameter group by *gamma*.
- **gamma** (*float, optional*) –Multiplicative factor of learning rate decay. Default: `0.1`.
- **last_epoch** (*int, optional*) –The index of the last epoch. Default: `-1`.

Raises

- **TypeError** –If the *milestones* is not list.
- **TypeError** –If elements of the *milestones* are not int.
- **TypeError** –If the *gamma* is not float.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> net = nn.Dense(2, 3)
>>> optimizer = optim.Adam(net.trainable_params(), 0.05)
>>> # Assuming optimizer uses lr = 0.05 for all groups
>>> # lr = 0.05     if epoch < 2
>>> # lr = 0.005    if 2 <= epoch < 4
>>> # lr = 0.0005   if epoch >= 4
>>> scheduler = optim.lr_scheduler.MultiStepLR(optimizer, milestones=[2,4], gamma=0.1)
>>> for i in range(6):
...     scheduler.step()
...     current_lr = scheduler.get_last_lr()
...     print(current_lr)
[Tensor(shape=[], dtype=Float32, value= 0.05)]
[Tensor(shape=[], dtype=Float32, value= 0.005)]
[Tensor(shape=[], dtype=Float32, value= 0.005)]
[Tensor(shape=[], dtype=Float32, value= 0.0005)]
[Tensor(shape=[], dtype=Float32, value= 0.0005)]
[Tensor(shape=[], dtype=Float32, value= 0.0005)]
```

mindspore.experimental.optim.lr_scheduler.PolynomialLR

class mindspore.experimental.optim.lr_scheduler.**PolynomialLR**(*optimizer*, *total_iters=5*, *power=1.0*, *last_epoch=- 1*)

For each epoch, the learning rate is adjusted by polynomial fitting. When the epoch is greater than or equal to *total_iters* , the learning rate is `0` . Notice that such decay can happen simultaneously with other changes to the learning rate from outside this scheduler.

The polynomial formula for learning rate calculation is as follows:

$$factor = (\frac{1.0 - \frac{last\_epoch}{total\_iters}}{1.0 - \frac{last\_epoch - 1.0}{total\_iters}})^{power}$$
$$lr = lr \times factor$$

Warning: This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) –Wrapped optimizer.
- **total_iters** (*int, optional*) –The number of iterations adjusting learning rate by polynomial fitting. Default: `5`.
- **power** (*float, optional*) –Power of polynomial. Default: `1.0`.
- **last_epoch** (*int, optional*) –The index of the last epoch. Default: `-1`.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.fc = nn.Dense(16 * 5 * 5, 120)
...     def construct(self, x):
...         return self.fc(x)
>>> net = Net()
>>> optimizer = optim.Adam(net.trainable_params(), 0.01)
>>> scheduler = optim.lr_scheduler.PolynomialLR(optimizer)
>>> for i in range(6):
...     scheduler.step()
...     current_lr = scheduler.get_last_lr()
...     print(current_lr)
[Tensor(shape=[], dtype=Float32, value= 0.008)]
[Tensor(shape=[], dtype=Float32, value= 0.006)]
[Tensor(shape=[], dtype=Float32, value= 0.004)]
[Tensor(shape=[], dtype=Float32, value= 0.002)]
[Tensor(shape=[], dtype=Float32, value= 0)]
[Tensor(shape=[], dtype=Float32, value= 0)]
```

mindspore.experimental.optim.lr_scheduler.ReduceLROnPlateau

class mindspore.experimental.optim.lr_scheduler.**ReduceLROnPlateau**(*optimizer*, *mode='min'*, *factor=0.1*, *patience=10*, *threshold=1e-4*, *threshold_mode='rel'*, *cooldown=0*, *min_lr=0*, *eps=1e-8*)

Reduce learning rate when a metric has stopped improving. Models often benefit from reducing the learning rate by a factor of 2-10 once learning stagnates. The scheduler reads the metrics *metrics* during execution and adjusts the learning rate via the *step* method if the metrics do not improve within *patience* cycles.

> **Warning:** This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) –Wrapped optimizer.
- **mode** (*str, optional*) –Trigger mode that triggers a reduction in learning rate when the monitoring metrics are at their *min* / *max* point. In *min* mode, lr will be reduced when the quantity monitored has stopped decreasing; in *max* mode it will be reduced when the quantity monitored has stopped increasing. Default: `'min'`.
- **factor** (*float, optional*) –Factor by which the learning rate will be reduced. Default: `0.1`.
- **patience** (*int, optional*) –Number of epochs with no improvement after which learning rate will be reduced. For example, if *patience* = 2, then we will ignore the first 2 epochs with no improvement, and will only decrease the LR after the 3rd epoch if the loss still hasn't improved then. Default: `10`.

- **threshold** (*float, optional*) – Threshold for measuring the new optimum, to only focus on significant changes. Default: `1e-4`.
- **threshold_mode** (*str, optional*) – A mode for measuring indicators of change for the better. One of *rel*, *abs*. Default: `'rel'`.

  Assume that *best* represents the best value of the current performance metric.

  - In `'rel'` mode, the indicator is compared to a *threshold* in proportional form:
    - When *mode* is `'max'`, the indicator is considered better if it exceeds best * (1 + threshold).
    - When *mode* is `'min'`, the indicator is considered better if it is lower than best * (1 - threshold).
  - In `'abs'` mode, the indicator is compared to *threshold* in absolute value form:
    - When *mode* is `'max'`, the indicator is considered better if it exceeds best + threshold.
    - When *mode* is `'min'`, the indicator is considered better if it is lower than best - threshold.
- **cooldown** (*int, optional*) – Number of epochs to wait before resuming normal operation after lr has been reduced. Default: `0`.
- **min_lr** (*Union(float, list), optional*) – A scalar or a list of scalars. A lower bound on the learning rate of all param groups or each group respectively. Default: `0`.
- **eps** (*float, optional*) – Minimal decay applied to lr. If the difference between new and old lr is smaller than eps, the update is ignored. Default: `1e-8`.

Raises

- **ValueError** – *factor* is greater than or equal to 1.0.
- **TypeError** – *optimizer* is not an *Optimizer*.
- **ValueError** – When *min_lr* is a list or tuple, the length of it is not equal to the number of param groups.
- **ValueError** – *mode* is neither `'min'` nor `'max'`.
- **ValueError** – *threshold_mode* is neither `'rel'` nor `'abs'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore.experimental import optim
>>> from mindspore import nn
>>> net = nn.Dense(3, 2)
>>> optimizer = optim.Adam(net.trainable_params(), 0.1)
>>> scheduler = optim.lr_scheduler.ReduceLROnPlateau(optimizer, 'min', patience=0)
>>> metrics = [1, 1.5, 1.8, 0.4, 0.5]
>>> for i in range(5):
...     scheduler.step(metrics[i])
...     current_lr = scheduler.get_last_lr()
...     print(current_lr)
[Tensor(shape=[], dtype=Float32, value= 0.1)]
[Tensor(shape=[], dtype=Float32, value= 0.01)]
[Tensor(shape=[], dtype=Float32, value= 0.001)]
[Tensor(shape=[], dtype=Float32, value= 0.001)]
[Tensor(shape=[], dtype=Float32, value= 0.0001)]
```

get_last_lr()
Return last computed learning rate by current scheduler.

in_cooldown()
Whether in cooldown period.

step(*metrics*)
Get the current learning rate and change the learning rate.

Parameters

metrics (*Union(int, float)*) –the evaluation metrics.

mindspore.experimental.optim.lr_scheduler.SequentialLR

class mindspore.experimental.optim.lr_scheduler.**SequentialLR**(*optimizer*, *schedulers*, *milestones*, *last_epoch=- 1*)

Concatenate multiple learning rate adjustment strategies in *schedulers* in sequence, switching to the next learning rate adjustment strategy at *milestone*.

> **Warning:** This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) –Wrapped optimizer.
- **schedulers** (list[*mindspore.experimental.optim.lr_scheduler.LRScheduler*]) –List of learning rate schedulers.
- **milestones** (*list*) –List of integers of milestone points, sets which learning rate adjustment strategy is invoked for each epoch.
- **last_epoch** (*int, optional*) –The number of times the *step()* method of the current learning rate adjustment strategy has been executed. Default: `-1`.

Raises

- **ValueError** –The optimizer in *schedulers* is different from the *optimizer* passed in.
- **ValueError** –The optimizer in *schedulers* is different from the optimizer of *schedulers[0]*.
- **ValueError** –Length of *milestones* is not equal to length of *schedulers* minus 1.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore.experimental import optim
>>> from mindspore import nn
>>> net = nn.Dense(3, 2)
>>> optimizer = optim.Adam(net.trainable_params(), 0.1)
>>> scheduler1 = optim.lr_scheduler.ConstantLR(optimizer, factor=0.1, total_iters=2)
>>> scheduler2 = optim.lr_scheduler.ExponentialLR(optimizer, gamma=0.9)
>>> scheduler = optim.lr_scheduler.SequentialLR(optimizer, schedulers=[scheduler1,␣
↪scheduler2], milestones=[2])
>>> for i in range(6):
...     scheduler.step()
...     current_lr = scheduler.get_last_lr()
...     print(current_lr)
[Tensor(shape=[], dtype=Float32, value= 0.01)]
[Tensor(shape=[], dtype=Float32, value= 0.1)]
[Tensor(shape=[], dtype=Float32, value= 0.09)]
[Tensor(shape=[], dtype=Float32, value= 0.081)]
[Tensor(shape=[], dtype=Float32, value= 0.0729)]
[Tensor(shape=[], dtype=Float32, value= 0.06561)]
```

get_last_lr()
Return last computed learning rate by current scheduler.

step()
Get the current learning rate and change the learning rate.

mindspore.experimental.optim.lr_scheduler.StepLR

class mindspore.experimental.optim.lr_scheduler.**StepLR**(*optimizer*, *step_size*, *gamma=0.1*, *last_epoch=- 1*)
Decays the learning rate of each parameter group by gamma every step_size epochs. Notice that such decay can happen simultaneously with other changes to the learning rate from outside this scheduler.

> **Warning:** This is an experimental lr scheduler module that is subject to change. This module must be used with optimizers in Experimental Optimizer .

Parameters

- **optimizer** (*mindspore.experimental.optim.Optimizer*) –Wrapped optimizer.
- **step_size** (*int*) –Period of learning rate decay.
- **gamma** (*float, optional*) –Multiplicative factor of learning rate decay. Default: `0.5`.
- **last_epoch** (*int, optional*) –The index of the last epoch. Default: `-1`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import nn
>>> from mindspore.experimental import optim
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits(sparse=True)
>>> optimizer = optim.Adam(net.trainable_params(), lr=0.05)
>>> # Assuming optimizer uses lr = 0.05 for all groups
>>> # lr = 0.05     if epoch < 2
>>> # lr = 0.005    if 2 <= epoch < 4
>>> # lr = 0.0005   if 4 <= epoch < 6
>>> scheduler = optim.lr_scheduler.StepLR(optimizer, step_size=2, gamma=0.1)
>>> def forward_fn(data, label):
...     logits = net(data)
...     loss = loss_fn(logits, label)
...     return loss, logits
>>> grad_fn = mindspore.value_and_grad(forward_fn, None, optimizer.parameters, has_aux=True)
>>> def train_step(data, label):
...     (loss, _), grads = grad_fn(data, label)
...     optimizer(grads)
...     return loss
>>> for epoch in range(6):
...     # Create the dataset taking MNIST as an example. Refer to
...     # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/mnist.py
...     for data, label in create_dataset():
...         train_step(data, label)
...     scheduler.step()
...     current_lr = scheduler.get_last_lr()
```

17.2 Experimental EmbeddingService

mindspore.experimental.es.EmbeddingService	ES(EmbeddingService) feature can support model training and inference for PS embedding and data_parallel embedding, and provide unified embedding management, storage, and computing capabilities for training and inference.
mindspore.experimental.es.EsEmbeddingLookup	Look up a PS embedding.
mindspore.experimental.es.ESEmbeddingSmallTableLookup	Look up a data_parallel embedding.

17.2.1 mindspore.experimental.es.EmbeddingService

class mindspore.experimental.es.**EmbeddingService**

ES(EmbeddingService) feature can support model training and inference for PS embedding and data_parallel embedding, and provide unified embedding management, storage, and computing capabilities for training and inference. PS embedding refer to tables that vocab_size more than 100,000, and recommended to store them on the Parameter Server (PS). Data_parallel embedding refer to tables that vocab_size less than 100,000, and recommended to store them on device.

Currently, ES feature can only create one instance of EmbeddingService object.

Warning: This is an experimental EmbeddingService API that is subject to change.

Note: This API needs to call *mindspore.communication.init()* before, and it can take effect after the dynamic networking is completed.

Raises

- **ValueError** –If the ESCLUSTER_CONFIG_PATH environment variable is not set during object instantiation.
- **ValueError** –If the number of each server ParameterServer configured in ESCLUSTER_CONFIG_PATH configuration file exceeds four.
- **ValueError** –If the number of ParameterServer configured in ESCLUSTER_CONFIG_PATH configuration file exceeds four.

Supported Platforms:

`Atlas A2 training series products`

completion_key(*completion_key*, *mask=True*)

Init completion key option for each PS embedding.

Parameters

- **completion_key** (*int*) –The value for completion key.
- **mask** (*bool, optional*) –Whether to update completion key. If set to false, it will not be updated, and default is `True`.

Returns

CompletionKeyOption object.

Raises

- **TypeError** –If the type of "completion_key" is not int.
- **TypeError** –If the type of "mask" is not bool.

counter_filter(*filter_freq*, *default_key=None*, *default_value=None*)

Init counter filter option for each PS embedding.

Note: This feature only supports training mode. When user set counter filter option in train mode and then eval, the default value can be used for the key that cannot be look up in eval.

Parameters

- **filter_freq** (*int*) –The frequency threshold value for feature admission.
- **default_key** (*int, optional*) –The key that number of occurrences does not reach the threshold, return value of *default_key* as the corresponding value when look up embedding, and default is `None`.
- **default_value** (*Union[int, float], optional*) –The key that number of occurrences does not reach the threshold, return default value which length value is embedding dim, and default is `None`.

Returns

CounterFilter object.

Raises

- **TypeError** –If the type of "filter_freq" is not int.
- **ValueError** –If the value of "filter_freq" is less than 0.
- **ValueError** –If the values of "default_key" and "default_value" are None.
- **ValueError** –If neither of the values of "default_key" and "default_value" are None.
- **TypeError** –If the value of "default_key" is None and the type of "default_value" is neither int nor float.
- **TypeError** –If the value of "default_value" is None and the type of "default_key" is not int.

embedding_ckpt_export(*file_path*, *trainable_var*)

Export the embedding table and optimizer parameters of each PS embedding, and export embedding of a data_parallel embedding.

Note: This function can only be executed by rank 0. Need to call *mindspore.experimental.es.EmbeddingService.embedding_variable_option()* to set evict_option for each PS embedding before export.

Parameters

- **file_path** (*str*) –The path to export embedding ckpt, and the last character cannot be `"/"`.
- **trainable_var** (*list[parameter]*) –The list of data_parallel embedding parameter.

Returns

The output of EmbeddingComputeVarExport operator and data_parallel embedding export result.

embedding_ckpt_import(*file_path*)

Import embedding and ckpt file from file path.

Parameters

file_path (*str*) –The path to import embedding and ckpt, and the last character cannot be `"/"`.

Returns

The output of EmbeddingComputeVarImport operator and data_parallel embedding import result.

embedding_evict(*steps_to_live*)

Embedding evict for all PS embedding.

Parameters

steps_to_live (*int*) –The steps set for evict key.

Returns

The output of ESEmbeddingTableEvict op.

Raises

- **TypeError** –If the type of "steps_to_live" is not int.
- **ValueError** –If the value of "steps_to_live" is not greater than 0.

embedding_init(*name*, *init_vocabulary_size*, *embedding_dim*, *max_feature_count=None*, *initializer=Uniform(scale=0.01)*, *embedding_type='PS'*, *ev_option=None*, *multihot_lens=None*, *optimizer=None*, *allow_merge=False*, *optimizer_param=None*, *mode='train'*)

Init for PS embedding and data_parallel embedding.

Parameters

- **name** (*str*) –The embedding table name.
- **init_vocabulary_size** (*int*) –The size of embedding table.
- **embedding_dim** (*int*) –The embedding dim of data in embedding table.
- **max_feature_count** (*int, optional*) –The count of keys when look up for PS. Default: `None`.
- **initializer** (`Initializer`, *optional*) –The initialization strategy for the PS embedding, default is `Uniform(scale=0.01)`.
- **embedding_type** (*str, optional*) –The embedding type, configurable parameters ["PS", "data_parallel"], `"PS"` means initializing PS embedding, `"data_parallel"` means initializing data_parallel embedding, and default is `"PS"`.
- **ev_option** (*EmbeddingVariableOption, optional*) –Properties of the PS embedding, is a EmbeddingVariableOption obj which returned by embedding_variable_option function. Default is `None`.
- **multihot_lens** (*int, optional*) –The param only use when *allow_merge* is enabled, and not support now. Default is `None`.
- **optimizer** (*str, optional*) –The type of optimizer in the train mode for PS embedding, cannot be shared among each PS embedding, and currently only `"Adam"`, `"Ftrl"`, `"SGD"` and `"RMSProp"` are supported, and default is `None`.
- **allow_merge** (*bool, optional*) –Whether to enable merge data_parallel embeddings, currently only be False, and default is `False`.
- **optimizer_param** (*float, optional*) –The "initialize accumulator value" param of optimizer which configured by user, representing the init value of moment accumulator, and default is `None`.
- **mode** (*str, optional*) –Run mode, configurable parameters ["train", "predict", "export"], `"train"` means train mode, `"predict"` means predict mode, `"export"` mean export mode, and default is `"train"`.

Returns

- data_parallel embedding - a dict that contain data_parallel embedding information.
- PS embedding - EmbeddingServiceOut, the embedding init object that contains PS embedding information, which contain five parameters: table_id_dict, es_initializer, es_counter_filter, es_padding_keys, es_completion_keys.
  - table_id_dict (dict): key is PS embedding and value is table_id.
  - es_initializer (dict): key is table_id and value is EsInitializer obj which means PS embedding parameters.
  - es_counter_filter (dict): key is table_id and value is filter option.
  - es_padding_keys (dict): key is table_id and value is padding key.
  - es_completion_keys (dict): key is table_id amd value is completion key.

Raises

- **ValueError** –If "name", "init_vocabulary_size", "embedding_dim", "max_feature_count" are not set.
- **ValueError** –If the types of "name", "init_vocabulary_size", "embedding_dim", and "max_feature_count" do not match.
- **ValueError** –If the value of "init_vocabulary_size", "embedding_dim" and "max_feature_count" is less than or equal to 0, or the value of "init_vocabulary_size" is bigger than 2147483647.
- **ValueError** –If the number of PS embedding exceeds 1024.
- **ValueError** –If the value of "optimizer" not in ["adam", "adagrad", "adamw", "ftrl", "sgd", "rmsprop"].
- **TypeError** –If the type of "initializer" is not EsInitializer obj or not in ["TruncatedNormal", "Uniform", "Constant"].

embedding_table_export(*file_path*, *trainable_var*)

Export Embedding table for each PS embedding and data_parallel embedding.

Note: This function can only be executed by rank 0.

Parameters

- **file_path** (*str*) –The path to export embedding table, and the last character cannot be `"/"`.
- **trainable_var** (*list[parameter]*) –The list of data_parallel embedding parameter.

Returns

The output of EmbeddingTableExport operator and data_parallel embedding export result.

embedding_table_import(*file_path*)

Import embedding file from file path.

Parameters

file_path (*str*) –The path to import embedding table, and the last character cannot be `"/"`.

Returns

The output of EmbeddingTableImport operator and data_parallel embedding import result.

embedding_variable_option(*filter_option=None*, *padding_option=None*, *evict_option=None*, *completion_option=None*, *storage_option=None*, *feature_freezing_option=None*, *communication_option=None*)

Set variable option for PS embedding.

Parameters

- **filter_option** (*CounterFilter, optional*) –The option of counter filter. Default is `None`.
- **padding_option** (*PaddingParamsOption, optional*) –The option of padding key. Default is `None`.
- **evict_option** (*EvictOption, optional*) –The option evict. Default is `None`.
- **completion_option** (*CompletionKeyOption, optional*) –The option of completion key. Default is `None`.
- **storage_option** (*None, optional*) –Reserved option, currently not supported. Default is `None`.
- **feature_freezing_option** (*None, optional*) –Reserved option, currently not supported. Default is `None`.
- **communication_option** (*None, optional*) –Reserved option, currently not supported. Default is `None`.

Returns

EmbeddingVariableOption object, used as the ev_option parameter for *mindspore.experimental.es.EmbeddingService.embedding_init()*.

Raises

- **TypeError** –If value of "filter_option" is not None and the type of "filter_option" is not CounterFilter.
- **TypeError** –If value of "padding_option" is not None and the type of "padding_option" is not PaddingParamsOption.
- **TypeError** –If value of "completion_option" is not None and the type of "completion_option" is not CompletionKeyOption.
- **TypeError** –If value of "evict_option" is not None and the type of "evict_option" is not EvictOption.

evict_option(*steps_to_live*)

Set evict option for each PS embedding.

Parameters

steps_to_live (*int*) –The steps set for evict key.

Returns

EvictOption object.

Raises

- **TypeError** –If the type of "steps_to_live" is not int.
- **ValueError** –If the value of "steps_to_live" is not greater than 0.

incremental_embedding_table_export(*file_path*)

Incremental export embedding table for each PS embedding.

Note: This function can only be executed by rank 0.

Parameters

file_path (*str*) –The path to incremental export embedding table, and the last character cannot be `"/"`.

Returns

The output of EmbeddingTableExport op.

init_table()

Init table for data_parallel embedding.

Returns

A dict of data_parallel embedding parameter, that key is data_parallel embedding name, value is data_parallel embedding parameter.

padding_param(*padding_key*, *mask=True*, *mask_zero=False*)

Init padding key option for each PS embedding.

Parameters

- **padding_key** (*int*) –The value for padding key, must be a genuine and legal hash key.
- **mask** (*bool, optional*) –Whether to update padding key. If set to false, it will not be updated. Default is `True`.

- **mask_zero** (*bool, optional*) –Whether to update padding key when key is 0. Default is `False`.

Returns

PaddingParamsOption object.

Raises

- **TypeError** –If the type of "padding_key" is not int.
- **TypeError** –If the type of "mask" is not bool.

17.2.2 mindspore.experimental.es.EsEmbeddingLookup

class mindspore.experimental.es.**EsEmbeddingLookup**(*table_id*, *es_initializer*, *embedding_dim*, *max_key_num*, *optimizer_mode=None*, *optimizer_params=None*, *es_filter=None*, *es_padding_key=None*, *es_completion_key=None*)

Look up a PS embedding.

Warning: This is an experimental EmbeddingService API that is subject to change.

Parameters

- **table_id** (*int*) –The table id.
- **es_initializer** (*EsInitializer*) –The EsInitialize object for PS embedding with table_id, which can be None when the inference is performed.
- **embedding_dim** (*int*) –The embedding dim of keys for PS embedding with table_id.
- **max_key_num** (*int*) –The num of keys when lookup.
- **optimizer_mode** (*str*) –The type of optimizer. Default is `None`.
- **optimizer_params** (*tuple[float]*) –The parameters of optimizer. Default is `None`.
- **es_filter** (*CounterFilter*) –The option of counter filter for PS embedding with table_id. Default is `None`.
- **es_padding_key** (*PaddingParamsOption*) –The option of padding key for PS embedding with table_id. Default is `None`.
- **es_completion_key** (*CompletionKeyOption*) –The option of completion key for PS embedding with table_id. Default is `None`.

Inputs:

- **keys** (Tensor): The keys of each feature in PS embedding.
- **actual_keys_input** (Tensor): Tensor composed of all unique elements of keys.
- **unique_indices** (Tensor): The index value of each element in keys to actual_keys_input .
- **key_count** (Tensor): The count of each element in the actual_keys_input to keys.

Supported Platforms:

`Atlas A2 training series products`

17.2.3 mindspore.experimental.es.ESEmbeddingSmallTableLookup

class mindspore.experimental.es.**ESEmbeddingSmallTableLookup**(*name*, *rank_id*, *rank_size*, *small_table_to_variable*)

Look up a data_parallel embedding.

> **Warning:** This is an experimental EmbeddingService API that is subject to change.

Parameters

- **name** (*str*) –The data_parallel embedding name.
- **rank_id** (*int*) –The rank id when look up data_parallel embedding key.
- **rank_size** (*int*) –The rank size when look up data_parallel embedding key.
- **small_table_to_variable** (*dict[str, parameter]*) –The dict to restore data_parallel embedding information: key is table name, value is parameter.

Inputs:

- **ids_list** (Tensor) - The keys of each feature in data_parallel embedding.

Supported Platforms:

`Atlas A2 training series products`

CHAPTER

EIGHTEEN

MINDSPORE.OPS.PRIMITIVE

operators that can be used for constructor function of Cell

For more information about dynamic shape support status, please refer to Dynamic Shape Support Status of primitive Interface .

For more information about the support for the bfloat16 data type, please refer to Support List .

For the details about the usage constraints of each operator in the operator parallel process, refer to Usage Constraints During Operator Parallel .

The module import method is as follows:

```
import mindspore.ops as ops
```

Compared with the previous version, the added, deleted and supported platforms change information of *mindspore.ops.primitive* operators in MindSpore, please refer to the link mindspore.ops.primitive API Interface Change .

18.1 Operator Primitives

mindspore.ops.Primitive	Primitive is the base class of operator primitives in python.
mindspore.ops.PrimitiveWithCheck	PrimitiveWithCheck is the base class of primitives in python, which defines functions to check the input arguments of operators, but uses the infer method registered in c++ source codes.
mindspore.ops.PrimitiveWithInfer	PrimitiveWithInfer is the base class of primitives in python and defines functions for tracking inference in python.

18.1.1 mindspore.ops.Primitive

class mindspore.ops.**Primitive**(*name*)

Primitive is the base class of operator primitives in python.

Parameters

name (*str*) – Name for the current Primitive.

Examples

```
>>> from mindspore.ops import prim_attr_register, Primitive
>>> add = Primitive('add')
>>>
>>> # or work with prim_attr_register:
>>> # init a Primitive class with attr1 and attr2
>>> class Add(Primitive):
...     @prim_attr_register
...     def __init__(self, attr1, attr2):
...         '''init for add'''
...     # check attr1 and attr2 or do some initializations
...     # init a Primitive obj with attr1=1 and attr2=2
>>> add = Add(attr1=1, attr2=2)
```

add_prim_attr(*name*, *value*)

Add primitive attribute.

Parameters

- **name** (*str*) –Attribute Name.
- **value** (*Any*) –Attribute value.

Examples

```
>>> from mindspore import ops
>>> a = ops.Add()
>>> a = a.add_prim_attr("attr",1)
>>> out = a.attrs["attr"]
>>> print(out)
1
```

check_elim(**args*)

Check if the primitive can be eliminated. Subclass in need should override this method.

Parameters

args (*Primitive args*) –Same as arguments of current Primitive.

Returns

A tuple consisting of two elements. The first element means if the primitive can be calculated in compiling stage, the second element is calculated result.

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore.ops import prim_attr_register, Primitive
>>> class AddN(Primitive):
...     @prim_attr_register
...     def __init__(self):
...         self.init_prim_io_names(inputs=["inputs"], outputs=["sum"])
...     def check_elim(self, inputs):
```

(continues on next page)

(continued from previous page)

```
...         if len(inputs) != 1:
...             return (False, None)
...         if isinstance(inputs[0], Tensor):
...             return (True, inputs[0])
...
>>> addn = AddN()
>>> input_x = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> output = addn.check_elim((input_x,))
>>> print(output)
(True, Tensor(shape=[3], dtype=Float32, value= [ 1.00000000e+00,  2.00000000e+00,  3.
↪00000000e+00]))
```

del_prim_attr(*name*)

Delete primitive attribute.

Parameters

name (*str*) – Attribute Name.

Examples

```
>>> from mindspore import ops
>>> a = ops.Add()
>>> a = a.add_prim_attr("attr",1)
>>> a = a.del_prim_attr("attr")
>>> print(a.attrs)
{}
```

init_prim_io_names(*inputs*, *outputs*)

Initialize the name of inputs and outputs of Tensor or attributes.

Parameters

- **inputs** (*list[str]*) – list of inputs names.
- **outputs** (*list[str]*) – list of outputs names.

Examples

```
>>> from mindspore import ops
>>> a = ops.Add()
>>> a.init_prim_io_names(["x","y"],["sum"])
>>> print(a.input_names)
['x','y']
>>> print(a.output_names)
['sum']
```

place(*role*, *rank_id*)

Set the label for this primitive. This label tells MindSpore compiler on which process this operator should be launched. And each process's identical label consists of input 'role' and 'rank_id'. So by setting different operators with different labels, which will be launched on different processes, users can launch a distributed training job.

Note:

- This method is effective only after "mindspore.communication.init()" is called for dynamic cluster building.

Parameters

- **role** (*str*) –The role of the process on which this operator will be launched. Only 'MS_WORKER' is supported for now.
- **rank_id** (*int*) –The rank id of the process on which this operator will be launched. The rank_id is unique in processes with the same role.

Examples

```
>>> from mindspore import context
>>> from mindspore import ops
>>> context.set_context(mode=context.GRAPH_MODE)
>>> matmul = ops.MatMul()
>>> matmul.place('MS_WORKER', 0)
```

recompute(*mode=True*)

Set the primitive recomputed. If a primitive set recomputed feeds into some backward nodes for computing gradient, rather than storing the intermediate activation computed in forward pass, we will recompute it in backward pass.

Note:

- If the computation involves something like randomization or global variable, the equivalence is not guaranteed currently.
- Not supported in pynative mode

Parameters

mode (*bool*) –Specifies whether the primitive is recomputed. Default: `True` .

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor, ops, nn
>>> class NetRecompute(nn.Cell):
...     def __init__(self):
...         super(NetRecompute,self).__init__()
...         self.relu = ops.ReLU().recompute()
...         self.sqrt = ops.Sqrt()
...     def construct(self, x):
...         out = self.relu(x)
...         return self.sqrt(out)
...
>>> class GradNet(nn.Cell):
...     def __init__(self, network):
...         super(GradNet,self).__init__()
...         self.network = network
...         self.grad = ops.GradOperation()
...     def construct(self, x):
...         g_out = self.grad(self.network)(x)
...         return g_out
```

(continues on next page)

(continued from previous page)

```
...
>>> x = Tensor(np.array([-1,1]).astype(np.float32))
>>> net = NetRecompute()
>>> grad = GradNet(net)
>>> a = grad(x)
>>> print(a)
[0. 0.5]
```

set_device(*device_target*)

Set primitive been executed device.

Parameters

device_target (*str*) – The target device to run, support "Ascend", "GPU", and "CPU".

Examples

```
>>> from mindspore import ops
>>> a = ops.Add()
>>> a = a.set_device("GPU")
>>> print(a.primitive_target)
GPU
```

set_prim_instance_name(*instance_name*)

Set instance name to primitive operator.

Note: It will be called by default when user defines primitive operator.

Parameters

instance_name (*str*) – Instance name of primitive operator set by user.

Examples

```
>>> from mindspore import ops
>>> a = ops.Add()
>>> a = a.set_prim_instance_name("add")
>>> print(a.instance_name)
add
```

set_stage(*stage*)

Add stage id to primitive attribute.

Note: It is valid only in semi auto parallel. In other parallel modes, please set it to be 0.

Parameters

stage (*int*) – The stage id for the current operation.

Examples

```
>>> from mindspore import ops
>>> add = ops.Add()
>>> print(add.set_stage(0))
Prim[Add]<stage=0>
```

shard(*in_strategy=None*, *out_strategy=None*)
Add strategies to primitive attribute.

Note: It is valid only in semi auto parallel or auto parallel mode. In other parallel modes, strategies set here will be ignored.

Parameters

- **in_strategy** (*tuple*) –Describe the split strategy of operator input. Default: `None` .
- **out_strategy** (*tuple*) –Describe the split strategy of operator output, it is only for certain operators, such as MatMul. Default: `None` .

Examples

```
>>> from mindspore import ops
>>> add = ops.Add()
>>> print(add.shard(((1, 1), (1, 1))))
Prim[Add]<in_strategy=((1, 1), (1, 1)), out_strategy=None>
>>> # using layout
>>> from mindspore import Layout
>>> layout = Layout((2, 2, 2), ("dp", "sp", "mp"))
>>> layout_tuple = (layout("dp", "sp"), layout("sp", "mp"))
>>> from mindspore import ops
>>> matmul = ops.MatMul()
>>> print(matmul.shard(layout_tuple))
Prim[MatMul]<in_layout=({'device_matrix': (2, 2, 2), 'tensor_map': (2, 1)},
{'device_matrix': (2, 2, 2), 'tensor_map': (1, 0)})>
>>> # using layout with None
>>> from mindspore import Layout
>>> layout = Layout((2, 2, 2), ("dp", "sp", "mp"))
>>> layout_tuple = (layout("dp", "sp"), layout("sp", "None")) # "None" means the axis␣
↪would not be split
>>> from mindspore import ops
>>> matmul = ops.MatMul()
>>> print(matmul.shard(layout_tuple))
Prim[MatMul]<in_layout=({'device_matrix': (2, 2, 2), 'tensor_map': (2, 1)},
{'device_matrix': (2, 2, 2), 'tensor_map': (1, -1)})>
```

property update_parameter
Return whether the primitive will update the value of parameter.

18.1.2 mindspore.ops.PrimitiveWithCheck

class mindspore.ops.**PrimitiveWithCheck**(*name*)

PrimitiveWithCheck is the base class of primitives in python, which defines functions to check the input arguments of operators, but uses the infer method registered in c++ source codes.

There are three methods can be overridden to define the check logic of the primitive: __check__(), check_shape(), check_dtype(). If __check__() is defined in primitive, the __check__() has the highest priority to be called. If __check__() is not defined, check_shape() and check_dtype() can be defined to describe the check logic of the shape and type. Method infer_value() can also be defined (such as PrimitiveWithInfer) for constant propagation.

More on how to customize a Op, please refer to Custom Operators.

Parameters

name (*str*) – Name of the current Primitive.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore.ops import prim_attr_register, PrimitiveWithCheck
>>> # init a Primitive class with check
>>> class Flatten(PrimitiveWithCheck):
...     @prim_attr_register
...     def __init__(self):
...         pass
...     def check_shape(self, input_x):
...         Validator.check_int(len(input_x), 1, validator.GE, 'input_x rank', self.name)
...
...     def check_dtype(self, input_x):
...         Validator.check_subclass("input_x", input_x, mstype.tensor_type, self.name)
...
>>> # init a Primitive obj
>>> add = Flatten()
```

check_dtype(**args*)

Check data types of input args.

Parameters

args (*mindspore.dtype*) – data type of inputs.

Returns

None.

check_shape(**args*)

Check shapes of input args.

Note: The shape of scalar is an empty tuple.

Parameters

args (*tuple(int)*) – shapes of input tensors.

Returns

None.

18.1.3 mindspore.ops.PrimitiveWithInfer

class mindspore.ops.**PrimitiveWithInfer**(*name*)

PrimitiveWithInfer is the base class of primitives in python and defines functions for tracking inference in python.

There are four method can be overridden to define the infer logic of the primitive: __infer__(), infer_shape(), infer_dtype(), and infer_value(). If __infer__() is defined in primitive, the __infer__() has the highest priority to be called. If __infer__() is not defined, infer_shape() and infer_dtype() can be defined to describe the infer logic of the shape and type. The infer_value() is used for constant propagation.

More on how to customize a Op, please refer to Custom Operators.

Parameters

name (*str*) – Name of the current Primitive.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore.ops import prim_attr_register, PrimitiveWithInfer
>>> # init a Primitive class with infer
>>> class Add(PrimitiveWithInfer):
...     @prim_attr_register
...     def __init__(self):
...         pass
...
...     def infer_shape(self, x, y):
...         return x # output shape same as first input 'x'
...
...     def infer_dtype(self, x, y):
...         return x # output type same as first input 'x'
...
>>> # init a Primitive obj
>>> add = Add()
```

18.2 Neural Network Layer Operators

18.2.1 Neural Network

API Name	Description	Supported Platforms
mindspore.ops.AvgPool	Average pooling operation.	Ascend GPU CPU
mindspore.ops.AvgPool3D	3D Average pooling operation.	Ascend GPU CPU
mindspore.ops.BatchNorm	Batch Normalization for input data and updated parameters.	Ascend GPU CPU

continues on next page

Table 2 – continued from previous page

mindspore.ops.Conv2D	2D convolution layer.	Ascend GPU CPU
mindspore.ops.Conv2DTranspose	Calculates a 2D transposed convolution, which can be regarded as Conv2d for the gradient of the input, also called deconvolution, although it is not an actual deconvolution.	Ascend GPU CPU
mindspore.ops.Conv3D	3D convolution layer.	Ascend GPU CPU
mindspore.ops.Conv3DTranspose	Computes a 3D transposed convolution, which is also known as a deconvolution (although it is not an actual deconvolution).	Ascend GPU CPU
mindspore.ops.CTCGreedyDecoder	Performs greedy decoding on the logits given in inputs.	Ascend GPU CPU
mindspore.ops.Dense	Refer to mindspore.ops.dense() for more details.	Ascend GPU CPU
mindspore.ops.Dropout	During training, randomly zeroes some of the elements of the input tensor with probability $1 - keep\_prob$ from a Bernoulli distribution.	Ascend GPU CPU
mindspore.ops.Dropout2D	During training, randomly zeroes some channels of the input tensor with probability $1 - keep\_prob$ from a Bernoulli distribution(For a 4-dimensional tensor with a shape of (N, C, H, W), the channel feature map refers to a 2-dimensional feature map with the shape of (H, W)).	Ascend GPU CPU
mindspore.ops.Dropout3D	During training, randomly zeroes some channels of the input tensor with probability $1 - keep\_prob$ from a Bernoulli distribution(For a 5-dimensional tensor with a shape of NCDHW, the channel feature map refers to a 3-dimensional feature map with a shape of DHW).	Ascend GPU CPU
mindspore.ops.DynamicGRUV2	Applies a single-layer gated recurrent unit (GRU) to an input sequence.	Ascend
mindspore.ops.DynamicRNN	Applies a recurrent neural network to the input.	Ascend
mindspore.ops.Flatten	Flattens a tensor without changing its batch size on the 0-th axis.	Ascend GPU CPU
mindspore.ops.FractionalMaxPool3DWithFixedKsize	Applies a 3D fractional max pooling to an input signal composed of multiple input planes.	Ascend GPU CPU
mindspore.ops.GridSampler2D	This operation samples 2d *input_x* by using interpolation based on flow field grid, which is usually gennerated by mindspore.ops.affine_grid().	Ascend GPU CPU
mindspore.ops.GridSampler3D	Given an input and a grid, the output is calculated using the input values and pixel positions in the grid.	Ascend GPU CPU
mindspore.ops.LayerNorm	Applies the Layer Normalization to the input tensor.	Ascend GPU CPU
mindspore.ops.LRN	Local Response Normalization.	GPU CPU
mindspore.ops.LSTM	Performs the Long Short-Term Memory (LSTM) on the input.	GPU CPU
mindspore.ops.MaxPool	Max pooling operation.	Ascend GPU CPU
mindspore.ops.MaxPool3D	Applies a 3D max pooling over an input Tensor which can be regarded as a composition of 3D planes.	Ascend GPU CPU

continues on next page

Table 2 – continued from previous page

mindspore.ops.MaxPool3DWithArgmax	Performs a 3D max pooling on the input Tensor and returns both max values and indices.	Ascend GPU CPU
mindspore.ops.MaxUnpool2D	Calculates the partial inverse of MaxPool2D operation.	Ascend GPU CPU
mindspore.ops.MaxUnpool3D	Computes the inverse of *mindspore.ops.MaxPool3D*.	Ascend GPU CPU
mindspore.ops.MirrorPad	Pads the input tensor according to the paddings and mode.	Ascend GPU CPU
mindspore.ops.Pad	Pads the input tensor according to the paddings.	Ascend GPU CPU
mindspore.ops.EmbeddingLookup	Returns a slice of input tensor based on the specified indices.	Ascend GPU CPU
mindspore.ops.Padding	Extends the last dimension of the input tensor from 1 to pad_dim_size, by filling with 0.	Ascend GPU CPU
mindspore.ops.ResizeBicubic	Resize images to size using bicubic interpolation.	Ascend GPU CPU
mindspore.ops.ResizeNearestNeighbor	Resizes the input tensor to a given size by using the nearest neighbor algorithm.	Ascend GPU CPU

mindspore.ops.AvgPool

class mindspore.ops.**AvgPool**(*kernel_size=1*, *strides=1*, *pad_mode='VALID'*, *data_format='NCHW'*)

Average pooling operation.

Refer to *mindspore.ops.avg_pool2d()* for more details.

Parameters

- **kernel_size** (*Union[int, tuple[int]], optional*) – The size of kernel used to take the average value, is an int number that represents height and width of the kernel, or a tuple of two int numbers that represent height and width respectively. Default: `1` .
- **strides** (*Union[int, tuple[int]], optional*) – The distance of kernel moving, an int number that represents the height and width of movement are both strides, or a tuple of two int numbers that represent height and width of movement respectively. Default: `1` .
- **pad_mode** (*str, optional*) – Specifies the padding mode with a padding value of 0. It can be set to: `"SAME"` or `"VALID"` . Default: `"VALID"` .
  - `"SAME"`: Pad the input around its edges so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally, If the amount is even, it is uniformly distributed around the input, if it is odd, the excess amount goes to the right/bottom side.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible height and width. Extra pixels that could not complete a full stride will be discarded.
- **data_format** (*str, optional*) – The format of input and output data. It should be `'NHWC'` or `'NCHW'` . Default: `'NCHW'` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, H_{in}, W_{in})$. Supported dtypes: float16, float32, float64.

Outputs:

Tensor, with shape $(N, C_{out}, H_{out}, W_{out})$.

Raises

- **TypeError** – If *kernel_size* or *strides* is neither int nor tuple.

- **TypeError** – If dtype of *x* is not float16, float32 or float64.
- **ValueError** – If *kernel_size* or *strides* is less than 1.
- **ValueError** – If *pad_mode* is neither 'valid' nor 'same' with not case sensitive.
- **ValueError** – If *data_format* is neither 'NCHW' nor 'NHWC'.
- **ValueError** – If length of shape of *x* is not equal to 4.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, nn
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.avgpool_op = ops.AvgPool(pad_mode='VALID', kernel_size=2, strides=1)
...
...     def construct(self, x):
...         result = self.avgpool_op(x)
...         return result
...
>>> x = Tensor(np.arange(1 * 3 * 3 * 4).reshape(1, 3, 3, 4), mindspore.float32)
>>> net = Net()
>>> output = net(x)
>>> print(output)
[[[[ 2.5   3.5   4.5]
   [ 6.5   7.5   8.5]]
  [[14.5  15.5  16.5]
   [18.5  19.5  20.5]]
  [[26.5  27.5  28.5]
   [30.5  31.5  32.5]]]]
```

mindspore.ops.AvgPool3D

class mindspore.ops.**AvgPool3D**(*kernel_size=1*, *strides=1*, *pad_mode='valid'*, *pad=0*, *ceil_mode=False*, *count_include_pad=True*, *divisor_override=0*, *data_format='NCDHW'*)

3D Average pooling operation.

Typically the input is of shape $(N, C, D_{in}, H_{in}, W_{in})$, AvgPool3D outputs regional average in the (D_{in}, H_{in}, W_{in})-dimension. Given kernel size $ks = (d_{ker}, h_{ker}, w_{ker})$ and stride $s = (s_0, s_1, s_2)$, the operation is as follows:

$$\text{output}(N_i, C_j, d, h, w) = \frac{1}{d_{ker} * h_{ker} * w_{ker}} \sum_{l=0}^{d_{ker}-1} \sum_{m=0}^{h_{ker}-1} \sum_{n=0}^{w_{ker}-1} \text{input}(N_i, C_j, s_0 \times d + l, s_1 \times h + m, s_2 \times w + n)$$

Note: This interface currently does not support Atlas A2 training series products.

Parameters

- **kernel_size** (*Union[int, tuple[int]], optional*) – The size of kernel used to take the average value, is an int number that represents depth, height and width are both kernel_size, or a tuple of three int numbers that represent depth, height and width respectively. Default: `1` . The value range is: [1, 255].
- **strides** (*Union[int, tuple[int]], optional*) – The distance of kernel moving, an int number that represents the depth, height and width of movement are both strides, or a tuple of three int numbers that represent depth, height and width of movement respectively. Default: `1` . The value range is: [1, 63].
- **pad_mode** (*str, optional*) – Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"valid"` .
  - `"same"`: Pad the input around its depth/height/width dimension so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally. If the amount is even, it isuniformly distributed around the input, if it is odd, the excess amount goes to the front/right/bottom side. If this mode is set, *pad* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible depth, height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *pad* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the depth, height and width dimension is determined by the *pad* parameter. If this mode is set, *pad* must be greater than or equal to 0.
- **pad** (*Union(int, tuple[int], list[int]), optional*) – The pad value to be filled. Default: `0` . If *pad* is an integer, the paddings of head, tail, top, bottom, left and right are the same, equal to pad. If *pad* is a tuple of six integers, the padding of head, tail, top, bottom, left and right equal to pad[0], pad[1], pad[2], pad[3], pad[4] and pad[5] correspondingly.
- **ceil_mode** (*bool, optional*) – If `True` , ceil instead of floor to compute the output shape. Default: `False` .
- **count_include_pad** (*bool, optional*) – If `True` , averaging calculation will include the zero-padding. Default: `True` .
- **divisor_override** (*int, optional*) – If specified, it will be used as divisor in the averaging calculation, otherwise kernel_size will be used. Default: `0` .
- **data_format** (*str, optional*) – The optional value for data format. Currently only support `'NCDHW'` . Default: `'NCDHW'` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C, D_{in}, H_{in}, W_{in})$. Currently support float16, float32 and float64 data type.

Outputs:

Tensor, with shape $(N, C, D_{out}, H_{out}, W_{out})$. Has the same data type with *x*.

Raises

- **TypeError** – If *kernel_size*, *strides* or *pad* is neither an int not a tuple.
- **TypeError** – If *ceil_mode* or *count_include_pad* is not a bool.
- **TypeError** – If *pad_mode* or *data_format* is not a string.
- **TypeError** – If *divisor_override* is not an int.
- **ValueError** – If numbers in *kernel_size* or *strides* are not positive.
- **ValueError** – If *kernel_size* or *strides* is a tuple whose length is not equal to 3.
- **ValueError** – If *pad_mode* is not one of 'same', 'valid' or 'pad'.
- **ValueError** – If *pad* is a tuple whose length is not equal to 6.
- **ValueError** – If element of *pad* is less than 0.

- **ValueError** – If *pad_mode* is not equal to 'pad' and *pad* is not equal to 0 or (0, 0, 0, 0, 0, 0).
- **ValueError** – If *data_format* is not 'NCDHW'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> import numpy as np
>>> x = Tensor(np.arange(1 * 2 * 2 * 2 * 3).reshape((1, 2, 2, 2, 3)), mindspore.float16)
>>> avg_pool3d = ops.AvgPool3D(kernel_size=2, strides=1, pad_mode="valid")
>>> output = avg_pool3d(x)
>>> print(output)
[[[[[ 5.  6.]]]
  [[[17. 18.]]]]]
```

mindspore.ops.BatchNorm

class mindspore.ops.**BatchNorm**(*is_training=False*, *epsilon=1e-5*, *momentum=0.1*, *data_format='NCHW'*)

Batch Normalization for input data and updated parameters.

Batch Normalization is widely used in convolutional neural networks. This operation applies Batch Normalization over inputs to avoid internal covariate shift as described in the paper Batch Normalization: Accelerating Deep Network Training by Reducing Internal Covariate Shift. It rescales and recenters the features using a mini-batch of data and the learned parameters can be described in the following formula,

$$y = \frac{x - mean}{\sqrt{variance + \epsilon}} * \gamma + \beta$$

where γ is scale, β is bias, ϵ is epsilon, $mean$ is the mean of x, $variance$ is the variance of x.

Warning:

- If the operation is used for inference, and outputs "reserve_space_1" and "reserve_space_2" are available, then "reserve_space_1" has the same value as "mean" and "reserve_space_2" has the same value as "variance".
- For Ascend 310, the result accuracy fails to reach 1‰ due to the square root instruction.

Parameters

- **is_training** (*bool, optional*) – If *is_training* is `True` , *mean* and *variance* are computed during training. If *is_training* is `False` , they're loaded from checkpoint during inference. Default: `False` .
- **epsilon** (*float, optional*) – A small value added for numerical stability. Default: `1e-5`, value must be (0, 1] .
- **momentum** (*float, optional*) – The hyper parameter to compute moving average for running_mean and running_var (e.g. $new\_running\_mean = (1 - momentum) * running\_mean + momentum * current\_mean$). Momentum value must be [0, 1]. Default: `0.1` .
- **data_format** (*str, optional*) – The optional value for data format, is `'NHWC'` or `'NCHW'`, and the `'NHWC'` format is only supported in GPU target. Default: `"NCHW"` .

Inputs:

- **input_x** (Tensor) - Tensor of shape (N, C), with float16 or float32 data type.
- **scale** (Union[Parameter, Tensor]) - Tensor or Parameter of shape $(C,)$, with float16 or float32 data type.
- **bias** (Union[Parameter, Tensor]) - Tensor or Parameter of shape $(C,)$, has the same data type with *scale*.
- **mean** (Union[Parameter, Tensor]) - Tensor or Parameter of shape $(C,)$, has the same data type with *scale*.
- **variance** (Union[Parameter, Tensor]) - Tensor or Parameter of shape $(C,)$, has the same data type with *scale*.

Outputs:

Tuple of 5 Tensors, the normalized inputs and the updated parameters.

- **output_x** (Tensor) - The same type and shape as the input_x. The shape is (N, C).
- **batch_mean** (Tensor) - The mean calculated per-dimension over the mini-batches, shape is $(C,)$.
- **batch_variance** (Tensor) - The variance calculated per-dimension over the mini-batches, shape is $(C,)$.
- **reserve_space_1** (Tensor) - The mean that needs to be reused when calculating gradients, one-dimensional Tensor. The shape is $(C,)$.
- **reserve_space_2** (Tensor) - The variance that needs to be reused when calculating gradients, one-dimensional Tensor. The shape is $(C,)$.

Raises

- **TypeError** –If *is_training* is not a bool.
- **TypeError** –If dtype of *epsilon* or *momentum* is not float.
- **TypeError** –If *data_format* is not a str.
- **TypeError** –If *input_x*, *scale*, *bias*, *mean* or *variance* is not a Tensor.
- **TypeError** –If dtype of *input_x*, *scale* is neither float16 nor float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.ones([2, 2]), mindspore.float32)
>>> scale = Tensor(np.ones([2]), mindspore.float32)
>>> bias = Tensor(np.ones([2]), mindspore.float32)
>>> mean = Tensor(np.ones([2]), mindspore.float32)
>>> variance = Tensor(np.ones([2]), mindspore.float32)
>>> batch_norm = ops.BatchNorm()
>>> output = batch_norm(input_x, scale, bias, mean, variance)
>>> print(output[0])
[[1. 1.]
 [1. 1.]]
```

mindspore.ops.Conv2D

class mindspore.ops.**Conv2D**(*out_channel*, *kernel_size*, *mode=1*, *pad_mode='valid'*, *pad=0*, *stride=1*, *dilation=1*, *group=1*, *data_format='NCHW'*)

2D convolution layer.

Applies a 2D convolution over an input tensor which is typically of shape $(N, C_{in}, H_{in}, W_{in})$, where N is batch size, C is channel number, H is feature height, W is feature width.

The output is calculated based on formula:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{in}-1} \text{ccor}(\text{weight}(C_{\text{out}_j}, k), \text{X}(N_i, k))$$

where $bias$ is the output channel bias, $ccor$ is the cross-correlation, , $weight$ is the convolution kernel value and X represents the input feature map.

Here are the indices' meanings:

- i corresponds to the batch number, the range is $[0, N-1]$, where N is the batch size of the input.
- j corresponds to the output channel, the range is $[0, C_{out}-1]$, where C_{out} is the number of output channels, which is also equal to the number of kernels.
- k corresponds to the input channel, the range is $[0, C_{in}-1]$, where C_{in} is the number of input channels, which is also equal to the number of channels in the convolutional kernels.

Therefore, in the above formula, $bias(C_{\text{out}_j})$ represents the bias of the j-th output channel, $weight(C_{\text{out}_j}, k)$ represents the slice of the j-th convolutional kernel in the k-th channel, and $X(N_i, k)$ represents the slice of the k-th input channel in the i-th batch of the input feature map.

The shape of the convolutional kernel is given by (kernel_size[0], kernel_size[1]), where kernel_size[0] and kernel_size[1] are the height and width of the kernel, respectively. If we consider the input and output channels as well as the *group* parameter, the complete kernel shape will be $(C_{out}, C_{in}/\text{group}, \text{kernel\_size}[0], \text{kernel\_size}[1])$, where *group* is the number of groups dividing *x*'s input channel when applying group convolution.

For more details about convolution layer, please refer to Gradient Based Learning Applied to Document Recognition.

Note: On Ascend platform, only group convolution in depthwise convolution scenarios is supported. That is, when *group>1*, condition *in_channels* = *out_channels* = *group* must be satisfied.

Parameters

- **out_channel** (*int*) –Specifies output channel C_{out}.
- **kernel_size** (*Union[int, tuple[int]]*) –Specifies the height and width of the 2D convolution kernel. It can be a single int or a tuple of 2 integers. A single int means the value is for both the height and the width. A tuple of 2 ints means the first value is for the height and the other is for the width.
- **mode** (*int, optional*) –Modes for different convolutions. The value is currently not used. Default: `1` .
- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"valid"` .
  - `"same"`: Pad the input around its edges so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally, If the amount is even, it is uniformly distributed around the input, if it is odd, the excess amount goes to the right/bottom side. If this mode is set, *pad* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *pad* must be 0.

  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the height and width directions is determined by the *pad* parameter. If this mode is set, *pad* must be greater than or equal to 0.

- **pad** (*Union(int, tuple[int]), optional*) – Specifies the amount of padding to apply on input when *pad_mode* is set to `"pad"`. It can be a single int or a tuple of 4 ints. If *pad* is one integer, the paddings of top, bottom, left and right are the same, equal to *pad*. If *pad* is a tuple with four integers, the paddings of top, bottom, left and right will be equal to pad[0], pad[1], pad[2], and pad[3] accordingly. Default: `0` .
- **stride** (*Union(int, tuple[int]), optional*) – Specifies the stride of the convolution kernel's movement. It can be a single int or a tuple of two or four ints. A single int means the stride is the same in both the height and width directions. A tuple of two ints indicates the strides in the height and width directions, respectively. For a tuple of four ints, the two ints correspond to (N, C) dimension are treated as 1, and the two correspond to (H, W) dimensions is the step size in the height and width directions respectively. Default: `1` .
- **dilation** (*Union(int, tuple[int]), optional*) – Specifies the dilation rate to use for dilated convolution. It can be a single int or a tuple of 2 or 4 integers. A single int means the dilation size is the same in both the height and width directions. A tuple of two ints represents the dilation size in the height and width directions, respectively. For a tuple of four ints, the two ints correspond to (N, C) dimension are treated as 1, and the two correspond to (H, W) dimensions is the dilation size in the height and width directions respectively. Assuming $dilation = (d0, d1)$, the convolutional kernel samples the input with a spacing of $d0 - 1$ elements in the height direction and $d1 - 1$ elements in the width direction. The values in the height and width dimensions are in the ranges [1, H] and [1, W], respectively. Default: `1` .
- **group** (*int, optional*) – Specifies the number of groups dividing *x*'s input channel when applying group convolution. Default: `1` .
- **data_format** (*str, optional*) – The optional value for data format, is `'NHWC'` or `'NCHW'` . Default: `"NCHW"`. (NHWC is only supported in GPU now.)

Inputs:

- **x** (Tensor) - Input tensor of shape $(N, C_{in}, H_{in}, W_{in})$ or $(N, H_{in}, W_{in}, C_{in})$ depending on *data_format* .
- **weight** (Tensor) - The convolutional kernel value, it should has shape $(C_{out}, C_{in}/\text{group}, \text{kernel\_size}[0], \text{kernel\_size}[1])$.

Outputs:

Tensor, the value that applied 2D convolution. The shape is $(N, C_{out}, H_{out}, W_{out})$ or $(N, H_{out}, W_{out}, C_{out})$. To see how different pad modes affect the output shape, please refer to *mindspore.nn.Conv2d* for more details.

Raises

- **TypeError** – If *kernel_size*, *stride*, *pad* or *dilation* is neither an int nor a tuple.
- **TypeError** – If *out_channel* or *group* is not an int.
- **ValueError** – If *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** – If *pad_mode* is not one of `'same'`, `'valid'` or `'pad'`.
- **ValueError** – If *pad* is a tuple whose length is not equal to 4.
- **ValueError** – If *pad_mode* it not equal to `'pad'` and *pad* is not equal to `(0, 0, 0, 0)`.
- **ValueError** – If *data_format* is neither `'NHWC'` nor `'NCHW'` .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> # case 1: All parameters use default values.
>>> x = Tensor(np.ones([10, 32, 32, 32]), mindspore.float32)

...                     pad=(4, 10, 4, 10), stride=(2, 4), dilation=2,  group=2)
>>> output = conv2d(x, weight)
>>> print(output.shape)
(10, 32, 21, 11)
```

mindspore.ops.Conv2DTranspose

class mindspore.ops.**Conv2DTranspose**(*out_channel*, *kernel_size*, *pad_mode='valid'*, *pad=0*, *pad_list=None*, *mode=1*, *stride=1*, *dilation=1*, *group=1*, *data_format='NCHW'*)

Calculates a 2D transposed convolution, which can be regarded as Conv2d for the gradient of the input, also called deconvolution, although it is not an actual deconvolution. Because it cannot restore the original input data completely, but it can restore the shape of the original input.

Parameters

- **out_channel** (*int*) –The dimensionality of the output space.
- **kernel_size** (*Union[int, tuple[int]]*) –The size of the convolution window.
- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"valid"` .
  - `"same"`: Pad the input around its edges so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally, If the amount is even, it is uniformly distributed around the input, if it is odd, the excess amount goes to the right/bottom side. If this mode is set, *pad* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *pad* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the height and width directions is determined by the *pad* parameter. If this mode is set, *pad* must be greater than or equal to 0.

  Please refer to *mindspore.nn.Conv2dTranspose* for more specifications about *pad_mode*.
- **pad** (*Union[int, tuple[int]], optional*) –The pad value to be filled. Default: `0` . If *pad* is an integer, the paddings of top, bottom, left and right are the same, equal to pad. If *pad* is a tuple of four integers, the padding of top, bottom, left and right equal to pad[0], pad[1], pad[2], and pad[3] correspondingly.
- **pad_list** (*Union[str, None], optional*) –The pad list like (top, bottom, left, right). Default: `None` .
- **mode** (*int, optional*) –Modes for different convolutions. The value is currently not used. Default: `1` .
- **stride** (*Union[int, tuple[int]], optional*) –The stride to be applied to the convolution filter. Default: `1` .
- **dilation** (*Union[int, tuple[int]], optional*) –Specifies the dilation rate to be used for the dilated convolution. Default: `1` .
- **group** (*int, optional*) –Splits input into groups. Default: `1` .
- **data_format** (*str, optional*) –The format of input and output data. It should be `'NHWC'` or `'NCHW'` . Default is `'NCHW'` .

Inputs:

- **dout** (Tensor) - the gradients with respect to the output of the convolution. The shape conforms to the default data_format $(N, C_{out}, H_{out}, W_{out})$.
- **weight** (Tensor) - Set size of kernel is (K_1, K_2), then the shape is $(C_{out}, C_{in}, K_1, K_2)$.
- **input_size** (Tensor) - A tuple describes the shape of the input which conforms to the format $(N, C_{in}, H_{in}, W_{in})$.

Outputs:

Tensor, the gradients with respect to the input of convolution. It has the same shape as the input.

Raises

- **TypeError** –If *kernel_size*, *stride*, *pad* or *dilation* is neither an int nor a tuple.

- **TypeError** – If *out_channel* or *group* is not an int.
- **ValueError** – If *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** – If *pad_mode* is not one of `'same'`, `'valid'` or `'pad'`.
- **ValueError** – If *padding* is a tuple whose length is not equal to 4.
- **ValueError** – If *pad_mode* it not equal to `'pad'` and *pad* is not equal to (0, 0, 0, 0).
- **ValueError** – If *data_format* is neither `'NCHW'` nor `'NHWC'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> dout = Tensor(np.ones([10, 32, 30, 30]), mindspore.float32)
>>> weight = Tensor(np.ones([32, 32, 3, 3]), mindspore.float32)
>>> x = Tensor(np.ones([10, 32, 32, 32]))
>>> conv2d_transpose_input = ops.Conv2DTranspose(out_channel=32, kernel_size=3)
>>> output = conv2d_transpose_input(dout, weight, ops.shape(x))
>>> print(output.shape)
(10, 32, 32, 32)
```

mindspore.ops.Conv3D

class mindspore.ops.**Conv3D**(*out_channel*, *kernel_size*, *mode=1*, *pad_mode='valid'*, *pad=0*, *stride=1*, *dilation=1*, *group=1*, *data_format='NCDHW'*)

3D convolution layer.

Applies a 3D convolution over an input tensor which is typically of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$, where N is batch size, C is channel number, D, H, W are the depth, height and width of the feature map, respectively.

The output is calculated based on formula:

$$\text{out}(N_i, C_{\text{out}_j}) = \text{bias}(C_{\text{out}_j}) + \sum_{k=0}^{C_{in}-1} \text{ccor}(\text{weight}(C_{\text{out}_j}, k), \text{X}(N_i, k))$$

where *bias* is the output channel bias, $ccor$ is the cross-correlation, $weight$ is the convolution kernel value and X represents the input feature map.

Here are the indices' meanings:

- i corresponds to the batch number, the range is $[0, N-1]$, where N is the batch size of the input.
- j corresponds to the output channel, the range is $[0, C_{out}-1]$, where C_{out} is the number of output channels, which is also equal to the number of kernels.
- k corresponds to the input channel, the range is $[0, C_{in}-1]$, where C_{in} is the number of input channels, which is also equal to the number of channels in the convolutional kernels.

Therefore, in the above formula, $bias(C_{\text{out}_j})$ represents the bias of the j-th output channel, $weight(C_{\text{out}_j}, k)$-th convolutional kernel in the k-th channel, and $X(N_i, k)$ represents the slice of the k-th input channel in the i-th batch of the input feature map.

The shape of the convolutional kernel is given by (kernel_size[0], kernel_size[1], kernel_size[2]) where kernel_size[0], kernel_size[1] and kernel_size[2] are the depth, height and width of the kernel, respectively. If we consider the input and output channels as well as the *group* parameter, the complete kernel shape will be $(C_{out}, C_{in}/\text{group}, \text{kernel\_size}[0], \text{kernel\_size}[1], \text{kernel\_size}[2])$, where *group* is the number of groups dividing *x*'s input channel when applying group convolution.

For more details about convolution layer, please refer to Gradient Based Learning Applied to Document Recognition.

Note:

1. On Ascend platform, $groups = 1$ must be satisfied.
2. On Ascend $dilation$ on depth only supports the case of 1.

Parameters

- **out_channel** (*int*) −Specifies output channel C_{out}.
- **kernel_size** (*Union[int, tuple[int]]*) −Specifies the depth, height and width of the 3D convolution kernel. It can be a single int or a tuple of 3 integers. A single int means the value is for depth, height and the width. A tuple of 3 ints means the first value is for depth and the rest is for the height and width.
- **mode** (*int, optional*) −Modes for different convolutions. It is currently not used. Default: `1` .
- **stride** (*Union[int, tuple[int]], optional*) −The distance of kernel moving, it can be an int number that represents the depth, height and width of movement or a tuple of three int numbers that represent depth, height and width movement respectively. Default: `1` .
- **pad_mode** (*str, optional*) −Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"valid"` .
  - `"same"`: Pad the input around its depth/height/width dimension so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally. If the amount is even, it isuniformly distributed around the input, if it is odd, the excess amount goes to the front/right/bottom side. If this mode is set, *pad* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible depth, height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *pad* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the depth, height and width dimension is determined by the *pad* parameter. If this mode is set, *pad* must be greater than or equal to 0.
- **pad** (*Union(int, tuple[int]), optional*) −Specifies the amount of padding to apply on input when *pad_mode* is set to `"pad"`. It can be a single int or a tuple of 6 ints. If *pad* is one integer, the paddings of head, tail, top, bottom, left and right are the same, equal to *pad*. If *pad* is a tuple with 6 integers, the paddings of head, tail, top, bottom, left and right is equal to pad[0], pad[1], pad[2], pad[3], pad[4] and pad[5] accordingly. Default: `0` .
- **dilation** (*Union[int, tuple[int]], optional*) −Specifies the dilation rate to use for dilated convolution. It can be a single int or a tuple of 3 integers. A single int means the dilation size is the same in the depth, height and width directions. A tuple of 3 ints represents the dilation size in the depth, height and width directions, respectively. Assuming $dilation = (d0, d1, d2)$, the convolutional kernel samples the input with a spacing of $d0 - 1$ elements in the depth direction, $d1 - 1$ elements in the height direction, $d2 - 1$ elements in the width direction respectively. The values in the depth, height and width dimensions are in the ranges [1, D], [1, H] and [1, W], respectively. Default: `1` .
- **group** (*int, optional*) −The number of groups into which the filter is divided. *in_channels* and *out_channels* must be divisible by *group*. Default: `1` .
- **data_format** (*str, optional*) −The optional value for data format. Currently only support `"NCDHW"` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, D_{in}, H_{in}, W_{in})$. Currently input data type only support float16 and float32.
- **weight** (Tensor) - Set size of kernel is (k_d, K_h, K_w), then the shape is $(C_{out}, C_{in}/groups, k_d, K_h, K_w)$. Currently weight data type only support float16 and float32.
- **bias** (Tensor) - Tensor of shape (C_{out}). When bias is None, zeros will be used. Default: `None` .

Outputs:

Tensor, the value that applied 3D convolution. The shape is $(N, C_{out}, D_{out}, H_{out}, W_{out})$. To see how different pad modes affect the output shape, please refer to *mindspore.nn.Conv3d* for more details.

Raises

- **TypeError** –If *out_channel* or *group* is not an int.
- **TypeError** –If *kernel_size*, *stride*, *pad* or *dilation* is neither an int nor a tuple.
- **ValueError** –If *out_channel*, *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** –If *pad* is less than 0.
- **ValueError** –If *pad_mode* is not one of 'same', 'valid' or 'pad'.
- **ValueError** –If *pad* is a tuple whose length is not equal to 6.
- **ValueError** –If *pad_mode* is not equal to 'pad' and *pad* is not equal to (0, 0, 0, 0, 0, 0).
- **ValueError** –If *data_format* is not 'NCDHW'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> # case 1: specify kernel_size with tuple, all parameters use default values.
>>> x = Tensor(np.ones([16, 3, 10, 32, 32]), mindspore.float16)
>>> weight = Tensor(np.ones([32, 3, 4, 3, 3]), mindspore.float16)
>>> conv3d = ops.Conv3D(out_channel=32, kernel_size=(4, 3, 3))
>>> output = conv3d(x, weight)
>>> print(output.shape)
(16, 32, 7, 30, 30)

mindspore.ops.Conv3DTranspose

class mindspore.ops.**Conv3DTranspose**(*in_channel*, *out_channel*, *kernel_size*, *mode=1*, *pad_mode='valid'*, *pad=0*, *stride=1*, *dilation=1*, *group=1*, *output_padding=0*, *data_format='NCDHW'*)

Computes a 3D transposed convolution, which is also known as a deconvolution (although it is not an actual deconvolution).

Input is typically of shape (N, C, D, H, W), where N is batch size, C is channel number, D is depth, H is height, W is width.

If the 'pad_mode' is set to be "pad", the depth, height and width of output are defined as:

$$D_{out} = (D_{in} - 1) \times \text{stride}[0] - 2 \times \text{pad}[0] + \text{dilation}[0] \times (\text{kernel\_size}[0] - 1) + \text{output\_padding}[0] + 1$$
$$H_{out} = (H_{in} - 1) \times \text{stride}[1] - 2 \times \text{pad}[1] + \text{dilation}[1] \times (\text{kernel\_size}[1] - 1) + \text{output\_padding}[1] + 1$$
$$W_{out} = (W_{in} - 1) \times \text{stride}[2] - 2 \times \text{pad}[2] + \text{dilation}[2] \times (\text{kernel\_size}[2] - 1) + \text{output\_padding}[2] + 1$$

Note:

- In Ascend, only support $group = 1$.
- For Atlas A2 training series products, *output_padding* is currently not supported.

Parameters

- **in_channel** (*int*) −The channel of the input x.
- **out_channel** (*int*) −The channel of the weight x.

- **kernel_size** (*Union[int, tuple[int]]*) –The data type is int or a tuple of 3 integers. Specifies the depth, height and width of the 3D convolution window. Single int means the value is for the depth, height and width of the kernel. A tuple of 3 ints means the first value is for the depth, the second value is for the height and the other is for the width of the kernel.
- **mode** (*int, optional*) –Modes for different convolutions. Default is `1` . It is currently not used.
- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"same"` , `"valid"` or `"pad"` . Default: `"valid"` .
  - `"same"`: Pad the input around its depth/height/width dimension so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally. If the amount is even, it isuniformly distributed around the input, if it is odd, the excess amount goes to the front/right/bottom side. If this mode is set, *pad* must be 0.
  - `"valid"`: No padding is applied to the input, and the output returns the maximum possible depth, height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *pad* must be 0.
  - `"pad"`: Pad the input with a specified amount. In this mode, the amount of padding in the depth, height and width dimension is determined by the *pad* parameter. If this mode is set, *pad* must be greater than or equal to 0.
- **pad** (*Union(int, tuple[int]), optional*) –The pad value to be filled. Default: `0` . If *pad* is an integer, the paddings of head, tail, top, bottom, left and right are the same, equal to pad. If *pad* is a tuple of six integers, the padding of head, tail, top, bottom, left and right equal to pad[0], pad[1], pad[2], pad[3], pad[4] and pad[5] correspondingly.
- **stride** (*Union(int, tuple[int]), optional*) –The distance of kernel moving, an int number that represents the depth, height and width of movement are both strides, or a tuple of three int numbers that represent depth, height and width of movement respectively. Default: `1` .
- **dilation** (*Union(int, tuple[int]), optional*) –Specifies the space to use between kernel elements. Default: `1` .
- **group** (*int, optional*) –The number of groups into which the filter is divided. *in_channels* and *out_channels* must be divisible by *group*. Default: `1` .
- **output_padding** (*Union(int, tuple[int]), optional*) –Add extra size to each dimension of the output. Default: `0` .
- **data_format** (*str, optional*) –The optional value for data format. Currently only `'NCDHW'` is supported. Default: `'NCDHW'`.

Inputs:

- **dout** (Tensor) - The gradients with respect to the output of the convolution. The shape conforms to the default. data_format $(N, C_{in}, D_{out}, H_{out}, W_{out})$. Supported dtypes:
  - Ascend: float16.
  - GPU/CPU: float16, float32.
- **weight** (Tensor) - Set size of kernel is (K_d, K_h, K_w), then the shape is $(C_{in}, C_{out}//group, K_d, K_h, K_w)$. Where $group$ is the Args parameter, // is the symbol for integer division. It has the same dtype as *dout*.
- **bias** (Tensor) - Tensor of shape C_{out}. Currently, only support none. Default: `None` .

Outputs:

Tensor, the gradients with respect to the input of convolution 3D. Tensor of shape $(N, C_{out}//group, D_{out}, H_{out}, W_{out})$, where $group$ is the Args parameter.

Raises

- **TypeError** –If *in_channel*, *out_channel* or *group* is not an int.

- **TypeError** – If *kernel_size*, *stride*, *pad* , *dilation* or *output_padding* is neither an int not a tuple.
- **ValueError** – If *in_channel*, *out_channel*, *kernel_size*, *stride* or *dilation* is less than 1.
- **ValueError** – If *pad* is less than 0.
- **ValueError** – If *pad_mode* is not one of 'same', 'valid' nor 'pad'.
- **ValueError** – If *pad* is a tuple whose length is not equal to 6.
- **ValueError** – If *pad_mode* is not equal to 'pad' and *pad* is not equal to (0, 0, 0, 0, 0, 0).
- **ValueError** – If *data_format* is not 'NCDHW'.
- **TypeError** – If data type of dout and weight is neither float16 nor float32.
- **ValueError** – If bias is not none. The rank of dout and weight is not 5.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> dout = Tensor(np.ones([32, 16, 10, 32, 32]), mindspore.float16)
>>> weight = Tensor(np.ones([16, 3, 4, 6, 2]), mindspore.float16)
>>> conv3d_transpose = ops.Conv3DTranspose(in_channel=16, out_channel=3, kernel_size=(4, 6,␣
↪2))
>>> output = conv3d_transpose(dout, weight)
>>> print(output.shape)
(32, 3, 13, 37, 33)
```

mindspore.ops.CTCGreedyDecoder

class mindspore.ops.**CTCGreedyDecoder**(*merge_repeated=True*)

Performs greedy decoding on the logits given in inputs.

Refer to *mindspore.ops.ctc_greedy_decoder()* for more details.

Note: On Ascend, 'merge_repeated' can not be set to false.

Parameters

merge_repeated (*bool, optional*) – If `True` , merge repeated classes in output. Default: `True` .

Inputs:

- **inputs** (Tensor) - The input Tensor must be a 3-D tensor whose shape is $(max\_time, batch\_size, num\_classes)$. *num_classes* must be *num_labels* + *1* classes, *num_labels* indicates the number of actual labels. Blank labels are reserved. Default blank label is *num_classes* - *1*. Data type must be float32 or float64.
- **sequence_length** (Tensor) - A tensor containing sequence lengths with the shape of $(batch\_size,)$. The type must be int32. Each value in the tensor must be equal to or less than *max_time*.

Outputs:

- **decoded_indices** (Tensor) - A tensor with shape of $(total\_decoded\_outputs, 2)$. Data type is int64.
- **decoded_values** (Tensor) - A tensor with shape of $(total\_decoded\_outputs,)$, it stores the decoded classes. Data type is int64.
- **decoded_shape** (Tensor) - A tensor with shape of $(batch\_size, max\_decoded\_length)$. Data type is int64.
- **log_probability** (Tensor) - A tensor with shape of $(batch\_size, 1)$, containing sequence log-probability, has the same type as *inputs*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> inputs = Tensor(np.array([[[0.6, 0.4, 0.2], [0.8, 0.6, 0.3]],
...                           [[0.0, 0.6, 0.0], [0.5, 0.4, 0.5]]]), mindspore.float32)
>>> sequence_length = Tensor(np.array([2, 2]), mindspore.int32)
>>> decoded_indices, decoded_values, decoded_shape, log_probability = ops.
 ↪CTCGreedyDecoder()(inputs,
...
 ↪sequence_length)
>>> print(decoded_indices)
[[0 0]
 [0 1]
 [1 0]]
>>> print(decoded_values)
[0 1 0]
>>> print(decoded_shape)
[2 2]
>>> print(log_probability)
[[-1.2]
 [-1.3]]
```

mindspore.ops.Dense

class mindspore.ops.**Dense**

```
prim = ops.Dense()
out = prim(input, weight, bias)
```

is equivalent to

```
ops.dense(input, weight, bias)
```

Refer to *mindspore.ops.dense()* for more details.

mindspore.ops.Dropout

class mindspore.ops.**Dropout**(*keep_prob=0.5*, *Seed0=0*, *Seed1=0*)

During training, randomly zeroes some of the elements of the input tensor with probability $1 - keep\_prob$ from a Bernoulli distribution. It plays the role of reducing neuron correlation and avoid overfitting.

Refer to *mindspore.ops.dropout()* for more details.

> **Warning:** The Ascend backend does not support the reproducibility of random numbers, so the *Seed0* and *Seed1* parameter have no effect.

Parameters

- **keep_prob** (*float, optional*) – The keep rate, between 0 and 1, e.g. keep_prob = 0.9, means dropping out 10% of input units. Default: `0.5`.
- **Seed0** (*int, optional*) – Seed0 value for random generating. Default: `0`.
- **Seed1** (*int, optional*) – Seed1 value for random generating. Default: `0`.

Inputs:

- **x** (Tensor) - The input Tensor of shape $(*, N)$, with data type of float16, float32 or float64.

Outputs:

- **output** (Tensor) - With the same shape and data type as *x*.
- **mask** (Tensor) - The mask applied to *x*.
  - On GPU and CPU, *mask* has the same shape and data type as *x*.
  - On Ascend, to achieve a better performance, it is denoted as a 1-D Tensor with Uint8 data type. It has shape $(byte\_counts,)$ where $byte\_counts$ is the number of bytes needed to mask the input *x*, $byte\_counts$ is calculated using the following formula:

    $$byte\_counts = \text{ceil}(\text{cumprod}(x.shape)/128) * 16$$

    If shape of *x* is $(2, 3, 4, 5, 6)$, the shape of *mask* will be $(96,)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> dropout = ops.Dropout(keep_prob=0.5)
>>> x = Tensor(np.ones([1, 2, 3, 4, 5]), mindspore.float32)
>>> output, mask = dropout(x)
>>> print(output.shape, mask.shape, mask.dtype)
(1, 2, 3, 4, 5) (16,) UInt8
```

mindspore.ops.Dropout2D

class mindspore.ops.**Dropout2D**(*keep_prob=0.5*)

During training, randomly zeroes some channels of the input tensor with probability $1 - keep\_prob$ from a Bernoulli distribution(For a 4-dimensional tensor with a shape of (N, C, H, W), the channel feature map refers to a 2-dimensional feature map with the shape of (H, W)).

Dropout2D can improve the independence between channel feature maps.

Note: The keep probability $keep\_prob$ is equal to $1 - p$ in *mindspore.ops.dropout2d()*.

Parameters

keep_prob (*float, optional*) – The keep probability of a channel, between 0 and 1, e.g. *keep_prob* = 0.8, means dropping out 20% of channels. Default: `0.5` .

Inputs:

- **x** (Tensor) - A 4-D tensor with shape (N, C, H, W), where N is the batch size, C is the number of channels, H is the feature height, and W is the feature width.

Outputs:

- **output** (Tensor) - With the same shape and data type as *x*.
- **mask** (Tensor) - With the same shape as *x* and the data type is bool.

Raises

- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If the data type of *keep_prob* is not float.
- **ValueError** – If *keep_prob* is out of the range *[0.0, 1.0]*.
- **ValueError** – If *x* shape is not *4D*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> dropout = ops.Dropout2D(keep_prob=0.5)
>>> x = Tensor(np.ones([2, 1, 2, 3]), mindspore.float32)
>>> output, mask = dropout(x)
>>> print(output.shape)
(2, 1, 2, 3)
```

mindspore.ops.Dropout3D

class mindspore.ops.**Dropout3D**(*keep_prob=0.5*)

During training, randomly zeroes some channels of the input tensor with probability $1 - keep\_prob$ from a Bernoulli distribution(For a 5-dimensional tensor with a shape of NCDHW, the channel feature map refers to a 3-dimensional feature map with a shape of DHW).

Note: The keep probability $keep\_prob$ is equal to $1 - p$ in *mindspore.ops.dropout3d()*.

Dropout3D can improve the independence between channel feature maps.

Parameters

keep_prob (*float, optional*) – The keep probability of a channel, between 0 and 1, e.g. *keep_prob* = 0.8, means dropping out 20% of channels. Default: `0.5` .

Inputs:

- **x** (Tensor) - A 5-D tensor with shape (N, C, D, H, W), where N is the batch size, C is the number of channels, D is the feature depth, H is the feature height, and W is the feature width.

Outputs:

- **output** (Tensor) - With the same shape and data type as *x*.
- **mask** (Tensor) - With the same shape as *x* and the data type is bool.

Raises

- **TypeError** – If the data type of *keep_prob* is not float.
- **ValueError** – If *keep_prob* is out of the range [0.0, 1.0]; or if the dim of input is not 5-D.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> dropout = ops.Dropout3D(keep_prob=0.5)
>>> x = Tensor(np.ones([2, 1, 2, 1, 2]), mindspore.float32)
>>> output, mask = dropout(x)
>>> print(output.shape)
(2, 1, 2, 1, 2)
```

mindspore.ops.DynamicGRUV2

class mindspore.ops.**DynamicGRUV2**(*direction='UNIDIRECTIONAL'*, *cell_depth=1*, *keep_prob=1.0*, *cell_clip=- 1.0*, *num_proj=0*, *time_major=True*, *activation='tanh'*, *gate_order='rzh'*, *reset_after=True*, *is_training=True*)

Applies a single-layer gated recurrent unit (GRU) to an input sequence.

$$
\begin{aligned}
r_{t+1} &= \sigma(W_{ir}x_{t+1} + b_{ir} + W_{hr}h_{(t)} + b_{hr}) \\
z_{t+1} &= \sigma(W_{iz}x_{t+1} + b_{iz} + W_{hz}h_{(t)} + b_{hz}) \\
n_{t+1} &= \tanh(W_{in}x_{t+1} + b_{in} + r_{t+1} * (W_{hn}h_{(t)} + b_{hn})) \\
h_{t+1} &= (1 - z_{t+1}) * n_{t+1} + z_{t+1} * h_{(t)}
\end{aligned}
$$

where h_{t+1} is the hidden state at time *t+1*, x_{t+1} is the input at time *t+1*, h_t is the hidden state of the layer at time *t* or the initial hidden state at time *0*. r_{t+1}, z_{t+1}, n_{t+1} are the reset, update, and new gates, respectively. W, b are the weight parameter and the deviation parameter respectively. σ is the sigmoid function, and $*$ is the Hadamard product.

Parameters

- **direction** (*str, optional*) – A string identifying the direction in the operator. Default: `'UNIDIRECTIONAL'`. Only `'UNIDIRECTIONAL'` is currently supported.
- **cell_depth** (*int, optional*) – An integer identifying the cell depth in the operator. Default: `1`.
- **keep_prob** (*float, optional*) – A float identifying the keep prob in the operator. Default: `1.0`.
- **cell_clip** (*float, optional*) – A float identifying the cell clip in the operator. Default: `-1.0`.
- **num_proj** (*int, optional*) – An integer identifying the number projection in the operator. Default: `0`.
- **time_major** (*bool, optional*) – A bool identifying the time major in the operator. Default: `True`.
- **activation** (*str, optional*) – A string identifying the type of activation function in the operator. Default: `'tanh'`. Only `'tanh'` is currently supported.
- **gate_order** (*str, optional*) – A string identifying the gate order in weight and bias. Default: `'rzh'`. `'zrh'` is another option. Here, `'rzh'` means the gate order is: reset gate, update gate, hidden gate. `'zrh'` means the gate order is: update gate, reset gate, hidden gate.
- **reset_after** (*bool, optional*) – A bool identifying whether to apply reset gate after matrix multiplication. Default: `True`.
- **is_training** (*bool, optional*) – A bool identifying is training in the operator. Default: `True`.

Inputs:

- **x** (Tensor) - Current words. Tensor of shape (num_step, batch_size, input_size). The data type must be float16.
- **weight_input** (Tensor) - Input-hidden weight $W_{\{ir,iz,in\}}$. Tensor of shape (input_size, $3 \times$ hidden_size). The data type must be float16.
- **weight_hidden** (Tensor) - Hidden-hidden weight $W_{\{hr,hz,hn\}}$. Tensor of shape (hidden_size, $3 \times$ hidden_size). The data type must be float16.
- **bias_input** (Tensor) - Input-hidden bias $b_{\{ir,iz,in\}}$. Tensor of shape ($3 \times$ hidden_size), or None. Has the same data type with input *init_h*.
- **bias_hidden** (Tensor) - Hidden-hidden bias $b_{\{hr,hz,hn\}}$. Tensor of shape ($3 \times$ hidden_size), or None. Has the same data type with input *init_h*.
- **seq_length** (Tensor) - The length of each batch. Tensor of shape (batch_size). Only *None* is currently supported.
- **init_h** (Tensor) - Hidden state of initial time. Tensor of shape (batch_size, hidden_size). The data type must be float16 or float32.

Outputs:

- **y** (Tensor) - A Tensor of shape:
  - y_shape = $(num\_step, batch\_size, min(hidden\_size, num\_proj))$: *If num_proj > 0*,
  - y_shape = $(num\_step, batch\_size, hidden\_size)$: *If num_proj = 0*.

  Has the same data type with input *bias_type*.
- **output_h** (Tensor) - A Tensor of shape (num_step, batch_size, hidden_size). Has the same data type with input *bias_type*.
- **update** (Tensor) - A Tensor of shape (num_step, batch_size, hidden_size). Has the same data type with input *bias_type*.
- **reset** (Tensor) - A Tensor of shape (num_step, batch_size, hidden_size). Has the same data type with input *bias_type*.
- **new** (Tensor) - A Tensor of shape (num_step, batch_size, hidden_size). Has the same data type with input *bias_type*.
- **hidden_new** (Tensor) - A Tensor of shape (num_step, batch_size, hidden_size). Has the same data type with input *bias_type*.

A note about the bias_type:

- If *bias_input* and *bias_hidden* both are *None*, *bias_type* is the data type of *init_h*.
- If *bias_input* is not *None*, *bias_type* is the data type of *bias_input*.
- If *bias_input* is *None* and *bias_hidden* is not *None*, *bias_type* is the data type of *bias_hidden*.

Raises

- **TypeError** –If *direction*, *activation* or *gate_order* is not a str.
- **TypeError** –If *cell_depth* or *num_proj* is not an int.
- **TypeError** –If *keep_prob* or *cell_clip* is not a float.
- **TypeError** –If *time_major*, *reset_after* or *is_training* is not a bool.
- **TypeError** –If *x*, *weight_input*, *weight_hidden*, *bias_input*, *bias_hidden*, *seq_length* or *ini_h* is not a Tensor.
- **TypeError** –If dtype of *x*, *weight_input* or *weight_hidden* is not float16.
- **TypeError** –If dtype of *init_h* is neither float16 nor float32.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.random.rand(2, 8, 64).astype(np.float16))
>>> weight_i = Tensor(np.random.rand(64, 48).astype(np.float16))
>>> weight_h = Tensor(np.random.rand(16, 48).astype(np.float16))
>>> bias_i = Tensor(np.random.rand(48).astype(np.float16))
>>> bias_h = Tensor(np.random.rand(48).astype(np.float16))
>>> init_h = Tensor(np.random.rand(8, 16).astype(np.float16))
>>> dynamic_gru_v2 = ops.DynamicGRUV2()
>>> output = dynamic_gru_v2(x, weight_i, weight_h, bias_i, bias_h, None, init_h)
>>> print(output[0].shape)
(2, 8, 16)
```

mindspore.ops.DynamicRNN

class mindspore.ops.**DynamicRNN**(*cell_type='LSTM'*, *direction='UNIDIRECTIONAL'*, *cell_depth=1*, *use_peephole=False*, *keep_prob=1.0*, *cell_clip=- 1.0*, *num_proj=0*, *time_major=True*, *activation='tanh'*, *forget_bias=0.0*, *is_training=True*)

Applies a recurrent neural network to the input. Only long short-term memory (LSTM) is supported currently.

$$
\begin{aligned}
i_{t+1} &= \sigma(W_{ix}x_{t+1} + b_{ix} + W_{ih}h_{(t)} + b_{ih}) \\
f_{t+1} &= \sigma(W_{fx}x_{t+1} + b_{fx} + W_{fh}h_{(t)} + b_{fh}) \\
\tilde{c}_{t+1} &= \tanh(W_{cx}x_{t+1} + b_{cx} + W_{ch}h_{(t)} + b_{ch}) \\
o_{t+1} &= \sigma(W_{ox}x_{t+1} + b_{ox} + W_{oh}h_{(t)} + b_{oh}) \\
c_{t+1} &= f_{t+1} * c_{(t)} + i_t * \tilde{c}_{t+1} \\
h_{t+1} &= o_{t+1} * \tanh(c_{t+1})
\end{aligned}
$$

h_{t+1} is the hidden state at time *t+1*. x_{t+1} is the input at time *t+1*. h_t is the hidden state of the layer at time *t* or the initial hidden state at time *0*. σ is the sigmoid function, and $*$ is the Hadamard product. W, b are learnable weights between the output and the input in the formula. For instance, W_{ix}, b_{ix} are the weight and bias used to transform from input x to i.

Parameters

- **cell_type** (*str, optional*) – A string identifying the cell type in the operator. Default: `'LSTM'`. Only 'LSTM' is currently supported.
- **direction** (*str, optional*) – A string identifying the direction in the operator. Default: `'UNIDIRECTIONAL'`. Only 'UNIDIRECTIONAL' is currently supported.
- **cell_depth** (*int, optional*) – An integer identifying the cell depth in the operator. Default: `1`.
- **use_peephole** (*bool, optional*) – A bool identifying if use peephole in the operator. Default: `False`.
- **keep_prob** (*float, optional*) – A float identifying the keep prob in the operator. Default: `1.0`.
- **cell_clip** (*float, optional*) – A float identifying the cell clip in the operator. Default: `-1.0`.
- **num_proj** (*int, optional*) – An integer identifying the number projection in the operator. Default: `0`.
- **time_major** (*bool, optional*) – A bool specify the data format of *x*. If it is set to `True`, the format is ($num\_step, batch\_size, input\_size$), if it is set to False, the format is ($batch\_size, num\_step, input\_size$). Default: `True`. Only supports `True` at present.
- **activation** (*str, optional*) – A string identifying the type of activation function in the operator. Default: `'tanh'`. Only 'tanh' is currently supported.
- **forget_bias** (*float, optional*) – A float identifying the forget bias in the operator. Default: `0.0`.
- **is_training** (*bool, optional*) – A bool identifying is training in the operator. Default: `True`.

Inputs:

- **x** (Tensor) - Current words. Tensor of shape ($num\_step, batch\_size, input\_size$). The data type must be float16.
- **w** (Tensor) - Weight. Tensor of shape ($input\_size + hidden\_size, 4 * hidden\_size$). The data type must be float16.
- **b** (Tensor) - Bias. Tensor of shape ($4 * hidden\_size$). The data type must be float16.
- **seq_length** (Tensor) - The length of each batch. Tensor of shape ($batch\_size,$). Only *None* is currently supported.
- **init_h** (Tensor) - Hidden state of initial time. Tensor of shape ($1, batch\_size, hidden\_size$). The data type must be float16.
- **init_c** (Tensor) - Cell state of initial time. Tensor of shape ($1, batch\_size, hidden\_size$). The data type must be float16.

Outputs:

- **y** (Tensor) - A Tensor of shape ($num\_step, batch\_size, hidden\_size$). Has the same type with input *b*.
- **output_h** (Tensor) - A Tensor of shape ($num\_step, batch\_size, hidden\_size$). With data type of float16.
- **output_c** (Tensor) - A Tensor of shape ($num\_step, batch\_size, hidden\_size$). Has the same type with input *b*.
- **i** (Tensor) - A Tensor of shape ($num\_step, batch\_size, hidden\_size$). Has the same type with input *b*.
- **j** (Tensor) - A Tensor of shape ($num\_step, batch\_size, hidden\_size$). Has the same type with input *b*.
- **f** (Tensor) - A Tensor of shape ($num\_step, batch\_size, hidden\_size$). Has the same type with input *b*.
- **o** (Tensor) - A Tensor of shape ($num\_step, batch\_size, hidden\_size$). Has the same type with input *b*.
- **tanhct** (Tensor) - A Tensor of shape ($num\_step, batch\_size, hidden\_size$). Has the same type with input *b*.

Raises

- **TypeError** – If *cell_type*, *direction* or *activation* is not a str.
- **TypeError** – If *cell_depth* or *num_proj* is not an int.
- **TypeError** – If *keep_prob*, *cell_clip* or *forget_bias* is not a float.
- **TypeError** – If *use_peehpole*, *time_major* or *is_training* is not a bool.
- **TypeError** – If *x*, *w*, *b*, *seq_length*, *init_h* or *init_c* is not a Tensor.
- **TypeError** – If dtype of *x*, *w*, *init_h* or *init_c* is not float16.
- **TypeError** – If dtype of *b* is neither float16 nor float32.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.random.rand(2, 16, 64).astype(np.float16))
>>> w = Tensor(np.random.rand(96, 128).astype(np.float16))
>>> b = Tensor(np.random.rand(128).astype(np.float16))
>>> init_h = Tensor(np.random.rand(1, 16, 32).astype(np.float16))
>>> init_c = Tensor(np.random.rand(1, 16, 32).astype(np.float16))
>>> dynamic_rnn = ops.DynamicRNN()
>>> output = dynamic_rnn(x, w, b, None, init_h, init_c)
>>> print(output[0].shape)
(2, 16, 32)
```

mindspore.ops.Flatten

class mindspore.ops.**Flatten**

Flattens a tensor without changing its batch size on the 0-th axis.

Refer to *mindspore.ops.flatten()* for more details.

Inputs:

- **input_x** (Tensor) - Tensor of shape $(N, \ldots)$ to be flattened, where N is batch size.

Outputs:

Tensor, the shape of the output tensor is (N, X), where X is the product of the remaining dimension.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.ones(shape=[1, 2, 3, 4]), mindspore.float32)
>>> flatten = ops.Flatten()
>>> output = flatten(input_x)
>>> print(output.shape)
(1, 24)
```

mindspore.ops.FractionalMaxPool3DWithFixedKsize

class mindspore.ops.**FractionalMaxPool3DWithFixedKsize**(*ksize*, *output_shape*, *data_format='NCDHW'*)

Applies a 3D fractional max pooling to an input signal composed of multiple input planes. The max-pooling operation is applied in (kD, kH, kW) regions by a stochastic step size determined by the target output size *output_shape*.

The number of output features is equal to the number of input planes.

Refer to the paper Fractional MaxPooling by Ben Graham for more details.

The input and output data format can be "NCDHW" and "NDHWC". N is the batch size, C is the number of channels, D the feature depth, H is the feature height, and W is the feature width.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **ksize** (*Union[float, tuple]*) –Size of the pooling window. *ksize* can be a tuple of three values specify a shape (k_D, k_H, k_W), or a single int K for (K, K, K).
- **output_shape** (*Union[int, tuple]*) –The target output shape. *output_shape* can be a tuple of three values specify a shape $(D_{out}, H_{out}, W_{out})$, or a single float S for (S, S, S).
- **data_format** (*str, optional*) –The optional value for data format. Currently support `'NCDHW'` and `'NHDWC'` . Default: `'NCDHW'` .

Inputs:

- **x** (Tensor) - The input of FractionalMaxPool3DWithFixedKsize, which is a 4D or 5D tensor. Tensor of data type : float16, float32, double, int32, int64. Supported shape $(N, C, D_{in}, H_{in}, W_{in})$ or $(N, D_{in}, H_{in}, W_{in}, C)$.
- **random_samples** (Tensor) - The random step of FractionalMaxPool3DWithFixedKsize, which is a 3D tensor. Tensor of data type : float16, float32, double, and value is between (0, 1). Supported shape $(N, C, 3)$

Outputs:

- **y** (Tensor) - A tensor, the output of FractionalMaxPool3DWithFixedKsize. Has the same data type with *x*. Tensor of shape $(N, C, D_{out}, H_{out}, W_{out})$ or $(N, D_{out}, H_{out}, W_{out}, C)$.
- **argmax** (Tensor) - A tensor, the indices along with the outputs. Has the same shape as the *y* and int32 or int64 data type.

Raises

- **TypeError** –If *input_x* is not a 4D or 5D tensor.
- **TypeError** –If *random_samples* is not a 3D tensor.
- **TypeError** –If data type of *x* is not float16, float32, double, int32, int64.
- **TypeError** –If dtype of *random_samples* is not float16, float32, double.
- **TypeError** –If dtype of *argmax* is not int32, int64.
- **ValueError** –If *output_shape* is a tuple and if *output_shape* length is not 3.
- **ValueError** –If *ksize* is a tuple and if *ksize* length is not 3.
- **ValueError** –If numbers in *output_shape* or *ksize* is not positive.
- **ValueError** –If *data_format* is neither 'NCDHW' nor 'NDHWC'.
- **ValueError** –If the first dimension size of *input_x* and *random_samples* is not equal.
- **ValueError** –If the second dimension size of *input_x* and *random_samples* is not equal.
- **ValueError** –If the third dimension size of *random_samples* is not 3.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor(np.array([1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16])
...       .reshape([1, 1, 2, 2, 4]), mstype.float32)
>>> random_samples = Tensor(np.array([0.7, 0.7, 0.7]).reshape([1, 1, 3]), mstype.float32)
>>> ksize = (1, 1, 1)
>>> output_shape = (1, 1, 2)
>>> net = ops.FractionalMaxPool3DWithFixedKsize(ksize = ksize, output_shape = output_shape)
>>> output, argmax = net(x, random_samples)
>>> print(output)
[[[[[13. 16.]]]]]
>>> print(argmax)
[[[[[12 15]]]]]
```

mindspore.ops.GridSampler2D

class mindspore.ops.**GridSampler2D**(*interpolation_mode='bilinear'*, *padding_mode='zeros'*, *align_corners=False*)

This operation samples 2d *input_x* by using interpolation based on flow field grid, which is usually gennerated by *mindspore.ops.affine_grid()*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.grid_sample()* for more details.

Parameters

- **interpolation_mode** (*str, optional*) – An optional string specifying the interpolation method. The optional values are "bilinear" or "nearest" . Default: "bilinear" .
  - "nearest": Nearest neighbor interpolation. Each output pixel is assigned the value of the nearest input pixel. This method is simple and fast but can result in blocky or pixelated outputs.
  - "bilinear": Bilinear interpolation. Each output pixel is a weighted average of the four nearest input pixels, computed using bilinear interpolation. This method produces smoother results compared to nearest neighbor interpolation.
- **padding_mode** (*str, optional*) – An optional string specifying the pad method. The optional values are "zeros" , "border" or "reflection" . Default: "zeros" . When the sampling grid is outside input's bounds, effects of various padding modes are as follows:
  - "zeros": Pads the input tensor with zeros.
  - "border": Pads the input tensor with the values of the pixels on the border of the tensor.
  - "reflection": Pads the input tensor by reflecting the values of the pixels at the boundary of the tensor.
- **align_corners** (*bool, optional*) – An optional bool. When set to True , the centers of the corner pixels of the input and output tensors are aligned. When set to False , it is not aligned. Default: False .

Inputs:

- **input_x** (Tensor) - A 4-D tensor with shape (N, C, H_{in}, W_{in}). Supported dtypes:
  - Ascend: float16, float32.
  - GPU/CPU: float16, float32, float64.
- **grid** (Tensor) - A 4-D tensor whose dtype is the same as *input_x* and whose shape is $(N, H_{out}, W_{out}, 2)$. Used to specify the sampling pixel locations normalized by the input spatial dimensions.

Outputs:

A 4-D Tensor whose dtype is the same as *input_x* and whose shape is (N, C, H_{out}, W_{out}).

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> gridsampler = ops.GridSampler2D(interpolation_mode='bilinear', padding_mode='zeros',␣
↪align_corners=True)
>>> input_x = Tensor(np.arange(16).reshape((2, 2, 2, 2)).astype(np.float32))
>>> grid = Tensor(np.arange(-9, 9, 0.5).reshape((2, 3, 3, 2)).astype(np.float32))
>>> output = gridsampler(input_x, grid)
>>> print(output)
[[[[ 0.     0.     0.   ]
   [ 0.     0.     0.   ]
   [ 0.     0.     0.5  ]]
  [[ 0.     0.     0.   ]
   [ 0.     0.     0.   ]
   [ 0.     1.5    4.5  ]]]
 [[[10.     8.25   1.375]
   [ 0.     0.     0.   ]
   [ 0.     0.     0.   ]]
  [[14.    11.25   1.875]
   [ 0.     0.     0.   ]
   [ 0.     0.     0.   ]]]]
```

mindspore.ops.GridSampler3D

class mindspore.ops.**GridSampler3D**(*interpolation_mode='bilinear'*, *padding_mode='zeros'*, *align_corners=False*)

Given an input and a grid, the output is calculated using the input values and pixel positions in the grid. Only volume (5-D) input is supported.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.grid_sample()* for more details.

Parameters

- **interpolation_mode** (*str, optional*) – An optional string specifying the interpolation method. The optional values are `"bilinear"` or `"nearest"` . Default: `"bilinear"` .
  - `"nearest"`: Nearest neighbor interpolation. Each output pixel is assigned the value of the nearest input pixel. This method is simple and fast but can result in blocky or pixelated outputs.
  - `"bilinear"`: Bilinear interpolation. Each output pixel is a weighted average of the four nearest input pixels. This method produces smoother results compared to nearest neighbor interpolation.
- **padding_mode** (*str, optional*) – An optional string specifying the pad method. The optional values are `"zeros"` , `"border"` or `"reflection"` . Default: `"zeros"` . When the sampling grid is outside input's bounds, effects of various padding modes are as follows:
  - `"zeros"`: Pads the input tensor with zeros.
  - `"border"`: Pads the input tensor with the values of the pixels on the border of the tensor.
  - `"reflection"`: Pads the input tensor by reflecting the values of the pixels at the boundary of the tensor.
- **align_corners** (*bool, optional*) – An optional bool specifying alignment method. If set to `True` , the extrema (-1 and 1) are considered as referring to the center points of the input's corner pixels. If set to `False` , they are

instead considered as referring to the corner points of the input's corner pixels, making the sampling more resolution agnostic. Default: `False` .

Inputs:

- **input_x** (Tensor) - A 5-D tensor with dtype of float16, float32 or float64 and shape of $(N, C, D_{in}, H_{in}, W_{in})$.
- **grid** (Tensor) - A 5-D tensor whose dtype is the same as *input_x* and whose shape is $(N, D_{out}, H_{out}, W_{out}, 3)$.

Outputs:

A 5-D Tensor whose dtype is the same as *input_x* and whose shape is $(N, C, D_{out}, H_{out}, W_{out})$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> gridsampler = ops.GridSampler3D(interpolation_mode='bilinear', padding_mode='zeros',␣
↪align_corners=True)
>>> input_x = Tensor(np.arange(32).reshape((2, 2, 2, 2, 2)).astype(np.float32))
>>> grid = Tensor(np.arange(-0.2, 1, 0.1).reshape((2, 2, 1, 1, 3)).astype(np.float32))
>>> output = gridsampler(input_x, grid)
>>> print(output)
[[[[[ 3.3     ]]
   [[ 4.35    ]]]
  [[[11.300001]]
   [[12.349999]]]]
 [[[[21.4     ]]
   [[22.449999]]]
  [[[29.4     ]]
   [[30.449999]]]]]
```

mindspore.ops.LayerNorm

class mindspore.ops.**LayerNorm**(*begin_norm_axis=1*, *begin_params_axis=1*, *epsilon=1e-7*)

Applies the Layer Normalization to the input tensor.

This operator will normalize the input tensor on given axis. LayerNorm is described in the paper Layer Normalization.

$$y = \frac{x - mean}{\sqrt{variance + \epsilon}} * \gamma + \beta$$

where γ is scale, β is bias, ϵ is epsilon.

Parameters

- **begin_norm_axis** (*int*) –The begin axis of the *input_x* to apply LayerNorm, the value must be in [-1, rank(input_x)). Default: `1` .
- **begin_params_axis** (*int*) –The begin axis of the parameter input (*gamma*, *beta*) to apply LayerNorm, the value must be in [-1, rank(input_x)). Default: `1` . Note: On the Ascend platform, the value of *begin_params_axis* needs to be equal to the value of *begin_norm_axis* .
- **epsilon** (*float*) –A value added to the denominator for numerical stability(ϵ). Default: `1e-7` .

Inputs:

- **input_x** (Tensor) - Tensor of shape $(N, \ldots)$. The input of LayerNorm. Supported dtypes: float16, float32, float64.
- **gamma** (Tensor) - Learnable parameter γ . Tensor of shape *input_x_shape[begin_params_axis:]*. Supported dtypes: float16, float32, float64.
- **beta** (Tensor) - Learnable parameter β . Tensor of shape *input_x_shape[begin_params_axis:]*. Supported dtypes: float16, float32, float64.

Outputs:

tuple[Tensor], tuple of 3 tensors, the normalized input and the updated parameters.

- **output_x** (Tensor) - The normalized input, has the same type and shape as the *input_x*.
- **mean** (Tensor) - The first *begin_norm_axis* dimensions of *mean* shape is the same as *input_x*, and the remaining dimensions are 1. Suppose the shape of the *input_x* is $(x_1, x_2, \ldots, x_R)$, the shape of the *mean* is $(x_1, \ldots, x_{begin\_norm\_axis}, 1, \ldots, 1)$ (when *begin_norm_axis=0*, the shape of *mean* is $(1, \ldots, 1)$).
- **rstd** (Tensor) - The reciprocal of the input standard deviation. Shape is the same as *mean* .

Raises

- **TypeError** –If *begin_norm_axis* or *begin_params_axis* is not an int.
- **TypeError** –If *epsilon* is not a float.
- **TypeError** –If *input_x*, *gamma* or *beta* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[1, 2, 3], [1, 2, 3]]), mindspore.float32)
>>> gamma = Tensor(np.ones([3]), mindspore.float32)
>>> beta = Tensor(np.ones([3]), mindspore.float32)
>>> layer_norm = ops.LayerNorm()
>>> output, _, _ = layer_norm(input_x, gamma, beta)
>>> print(output)
[[-0.2247448  1.         2.2247448]
 [-0.2247448  1.         2.2247448]]
```

mindspore.ops.LRN

class mindspore.ops.**LRN**(*depth_radius=5*, *bias=1.0*, *alpha=1.0*, *beta=0.5*, *norm_region='ACROSS_CHANNELS'*)

Local Response Normalization.

> **Warning:** LRN is deprecated on Ascend due to potential accuracy problem. It's recommended to use other normalization methods, e.g. *mindspore.ops.BatchNorm*.

$$b_c = a_c \left(k + \frac{\alpha}{n} \sum_{c'=\max(0,c-n/2)}^{\min(N-1,c+n/2)} a_{c'}^2 \right)^{-\beta}$$

where the a_c indicates the specific value of the pixel corresponding to c in feature map; where the $n/2$ indicates the *depth_radius*; where the k indicates the *bias*; where the α indicates the *alpha*; where the β indicates the *beta*.

Parameters

- **depth_radius** (*int*) –Half-width of the 1-D normalization window with the shape of 0-D. Default: `5` .
- **bias** (*float*) –An offset (usually positive to avoid dividing by 0). Default: `1.0` .
- **alpha** (*float*) –A scale factor, usually positive. Default: `1.0` .
- **beta** (*float*) –An exponent. Default: `0.5` .
- **norm_region** (*str*) –Specifies normalization region. Options: `"ACROSS_CHANNELS"` . Default: `"ACROSS_CHANNELS"` .

Inputs:

- **x** (Tensor) - A 4-D Tensor with float16 or float32 data type.

Outputs:

Tensor, with the same shape and data type as *x*.

Raises

- **TypeError** –If *depth_radius* is not an int.
- **TypeError** –If *bias*, *alpha* or *beta* is not a float.
- **TypeError** –If *norm_region* is not a str.
- **TypeError** –If *x* is not a Tensor.

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[[[0.1], [0.2]],
...                       [[0.3], [0.4]]]]), mindspore.float32)
>>> lrn = ops.LRN()
>>> output = lrn(x)
>>> print(output)
[[[[0.09534626]
   [0.1825742 ]]
  [[0.2860388 ]
   [0.3651484 ]]]]
```

mindspore.ops.LSTM

class mindspore.ops.**LSTM**(*input_size*, *hidden_size*, *num_layers*, *has_bias*, *bidirectional*, *dropout*, *proj_size=0*)

Performs the Long Short-Term Memory (LSTM) on the input.

For more information, please refer to *mindspore.nn.LSTM*.

Parameters

- **input_size** (*int*) −Number of features of input.
- **hidden_size** (*int*) −Number of features of hidden layer.
- **num_layers** (*int*) −Number of layers of stacked LSTM, , which is only support *1* on CPU.
- **has_bias** (*bool*) −Whether the cell has bias *b_ih* and *b_hh* , which is only support *False* on CPU.
- **bidirectional** (*bool*) −Specifies whether it is a bidirectional LSTM, , which is only support *False* on CPU.
- **dropout** (*float*) −If not 0, append *Dropout* layer on the outputs of each LSTM layer except the last layer. The range of dropout is [0.0, 1.0].
- **proj_size** (*int*) −If *proj_size* > 0, a projection of the corresponding size will be used, which is only supported on CPU now. Default: `0` .

Inputs:

- **input** (Tensor) - Tensor of shape $(seq\_len, batch\_size, input\_size)$ or $(batch\_size, seq\_len, input\_size)$.
- **h** (Tensor) - Tensor of shape $(num\_directions * num\_layers, batch\_size, real\_hidden\_size)$.
- **c** (Tensor) - Tensor of shape $(num\_directions * num\_layers, batch\_size, hidden\_size)$.
- **w** (Tensor) - A weight Tensor.

If $proj\_size > 0$, $real\_hidden\_size = proj\_size$, otherwise $real\_hidden\_size = hidden\_size$.

Outputs:

Tuple, a tuple contains *(output, h_n, c_n, reserve, state)*.

- **output** (Tensor) - Tensor of shape $(seq\_len, batch\_size, num\_directions * real\_hidden\_size)$.
- **h_n** (Tensor) - Tensor of shape $(num\_directions * num\_layers, batch\_size, real\_hidden\_size)$.
- **c_n** (Tensor) - Tensor of shape $(num\_directions * num\_layers, batch\_size, hidden\_size)$.
- **reserve** (Tensor) - Tensor of shape $(r, 1)$.
- **state** (Tensor) - Random number generator state and its shape is $(s, 1)$.

Raises

- **TypeError** −If *input_size*, *hidden_size* or *num_layers* is not an int.
- **TypeError** −If *has_bias* or *bidirectional* is not a bool.
- **TypeError** −If *dropout* is not a float.
- **ValueError** −If *dropout* is not in range [0.0, 1.0].
- **ValueError** −If *proj_size* is not in range [0, *hidden_size*).

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_size = 10
>>> hidden_size = 2
>>> num_layers = 1
>>> seq_len = 5
>>> batch_size = 2
>>>
>>> net = ops.LSTM(input_size, hidden_size, num_layers, True, False, 0.0)
>>> input_tensor = Tensor(np.ones([seq_len, batch_size, input_size]).astype(np.float32))
>>> h0 = Tensor(np.ones([num_layers, batch_size, hidden_size]).astype(np.float32))
>>> c0 = Tensor(np.ones([num_layers, batch_size, hidden_size]).astype(np.float32))
>>> w = Tensor(np.ones([112, 1, 1]).astype(np.float32))
>>> output, hn, cn, _, _ = net(input_tensor, h0, c0, w)
>>> print(output)
[[[0.9640267  0.9640267 ]
  [0.9640267  0.9640267 ]]
 [[0.9950539  0.9950539 ]
  [0.9950539  0.9950539 ]]
 [[0.99932843 0.99932843]
  [0.99932843 0.99932843]]
 [[0.9999084  0.9999084 ]
  [0.9999084  0.9999084 ]]
 [[0.9999869  0.9999869 ]
  [0.9999869  0.9999869 ]]]
```

mindspore.ops.MaxPool

class mindspore.ops.**MaxPool**(*kernel_size=1*, *strides=1*, *pad_mode='valid'*, *data_format='NCHW'*)

Max pooling operation.

Applies a 2D max pooling over an input Tensor which can be regarded as a composition of 2D planes.

Typically the input is of shape $(N_{in}, C_{in}, H_{in}, W_{in})$, MaxPool outputs regional maximum in the (H_{in}, W_{in})-dimension. Given kernel size $ks = (h_{ker}, w_{ker})$ and stride $s = (s_0, s_1)$, the operation is as follows:

$$\text{output}(N_i, C_j, h, w) = \max_{m=0,\ldots,h_{ker}-1} \max_{n=0,\ldots,w_{ker}-1} \text{input}(N_i, C_j, s_0 \times h + m, s_1 \times w + n)$$

Parameters

- **kernel_size** (*Union[int, tuple[int]]*) – The size of kernel used to take the maximum value, is an int number that represents height and width of the kernel, or a tuple of two int numbers that represent height and width respectively. Default: `1` .
- **strides** (*Union[int, tuple[int]]*) – The distance of kernel moving, an int number that represents not only the height of movement but also the width of movement, or a tuple of two int numbers that represent height and width of movement respectively. Default: `1` .
- **pad_mode** (*str, optional*) – Specifies the padding mode with a padding value of 0. It can be set to: `'same'` or `'valid'` . Default: `'valid'` .
  - `'same'`: Pad the input around its edges so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally, If the amount is even, it is uniformly distributed around the input, if it is odd, the excess amount goes to the right/bottom side.
  - `'valid'`: No padding is applied to the input, and the output returns the maximum possible height and width. Extra pixels that could not complete a full stride will be discarded.

- **data_format** (*str*) –The optional value for data format, is `'NHWC'` or `'NCHW'` . Default: `'NCHW'` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C_{in}, H_{in}, W_{in})$. Supported dtypes:
  - CPU: float16, float32, float64.
  - GPU/Ascend: float16, float32.

Outputs:

Tensor, with shape $(N, C_{out}, H_{out}, W_{out})$.

Raises

- **TypeError** –If *kernel_size* or *strides* is neither int nor tuple.
- **ValueError** –If *pad_mode* is neither `'valid'` nor `'same'` with not case sensitive.
- **ValueError** –If *data_format* is neither `'NCHW'` nor `'NHWC'`.
- **ValueError** –If *kernel_size* or *strides* is less than 1.
- **ValueError** –If length of shape of *input* is not equal to 4.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.arange(1 * 3 * 3 * 4).reshape((1, 3, 3, 4)), mindspore.float32)
>>> maxpool_op = ops.MaxPool(pad_mode="VALID", kernel_size=2, strides=1)
>>> output = maxpool_op(x)
>>> print(output)
[[[[ 5.  6.  7.]
   [ 9. 10. 11.]]
  [[17. 18. 19.]
   [21. 22. 23.]]
  [[29. 30. 31.]
   [33. 34. 35.]]]]
```

mindspore.ops.MaxPool3D

class mindspore.ops.**MaxPool3D**(*kernel_size=1*, *strides=1*, *pad_mode='VALID'*, *pad_list=0*, *ceil_mode=None*, *data_format='NCDHW'*)

Applies a 3D max pooling over an input Tensor which can be regarded as a composition of 3D planes.

Typically the input is of shape $(N_{in}, C_{in}, D_{in}, H_{in}, W_{in})$, MaxPool outputs regional maximum in the (D_{in}, H_{in}, W_{in})-dimension. Given kernel size $ks = (d_{ker}, h_{ker}, w_{ker})$ and stride $s = (s_0, s_1, s_2)$, the operation is as follows:

$$\text{output}(N_i, C_j, d, h, w) = \max_{l=0,\ldots,d_{ker}-1} \max_{m=0,\ldots,h_{ker}-1} \max_{n=0,\ldots,w_{ker}-1} \text{input}(N_i, C_j, s_0 \times d + l, s_1 \times h + m, s_2 \times w + n)$$

Note: For Atlas training series products, this primitive is not supported.

Parameters

- **kernel_size** (*Union[int, tuple[int]]*) –The size of kernel used to take the maximum value, is an int number that represents depth, height and width of the kernel, or a tuple of three int numbers that represent depth, height and width respectively. Default: `1` .
- **strides** (*Union[int, tuple[int]]*) –The distance of kernel moving, an int number that represents not only the depth, height of movement but also the width of movement,, or a tuple of three int numbers that represent depth, height and width of movement respectively. Default: `1` .
- **pad_mode** (*str, optional*) –Specifies the padding mode with a padding value of 0. It can be set to: `"SAME"` , `"VALID"` or `"PAD"` . Default: `"VALID"` .
  - `"SAME"`: Pad the input around its depth/height/width dimension so that the shape of input and output are the same when *stride* is set to `1`. The amount of padding to is calculated by the operator internally. If the amount is even, it isuniformly distributed around the input, if it is odd, the excess amount goes to the front/right/bottom side. If this mode is set, *pad_list* must be 0.
  - `"VALID"`: No padding is applied to the input, and the output returns the maximum possible depth, height and width. Extra pixels that could not complete a full stride will be discarded. If this mode is set, *pad_list* must be 0.
  - `"PAD"`: Pad the input with a specified amount. In this mode, the amount of padding in the depth, height and width dimension is determined by the *pad_list* parameter. If this mode is set, *pad_list* must be greater than or equal to 0.
- **pad_list** (*Union(int, tuple[int])*) –The pad value to be filled. Default: `0` . If *pad* is an integer, the paddings of head, tail, top, bottom, left and right are the same, equal to pad. If *pad* is a tuple of six integers, the padding of head, tail, top, bottom, left and right equals to pad[0], pad[1], pad[2], pad[3], pad[4] and pad[5] correspondingly.
- **ceil_mode** (*Union[bool, None]*) –Whether to use ceil instead of floor to calculate output shape. Only effective in "pad" mode. When *pad_mode* is `"pad"` and "ceil_mode" is `None` , *ceil_mode* will be set as `False`. Default: `None` .
- **data_format** (*str*) –The optional value for data format. Currently only support `"NCDHW"` . Default: `"NCDHW"` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N, C, D_{in}, H_{in}, W_{in})$. Data type must be float16, float32 or float64.

Outputs:

Tensor, with shape $(N, C, D_{out}, H_{out}, W_{out})$. Has the data type of *x*.

Raises

- **TypeError** –If *kernel_size* or *strides* is neither an int nor a tuple.
- **TypeError** –If *pad_mode* or *data_format* is not a string.
- **ValueError** –If numbers in *kernel_size* or *strides* are not positive.
- **ValueError** –If *pad_mode* is not one of `"SAME"`, `"VALID"` or `"PAD"`.
- **ValueError** –If *pad_mode* is `"SAME"` or `"VALID"`, *ceil_mode* is not `None`.
- **ValueError** –If *kernel_size* or *strides* is a tuple whose length is not equal to 3.
- **ValueError** –If *data_format* is not `"NCDHW"`.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.arange(1 * 2 * 2 * 2 * 3).reshape((1, 2, 2, 2, 3)), mindspore.float32)
>>> max_pool3d = ops.MaxPool3D(kernel_size=2, strides=1, pad_mode="VALID")
>>> output = max_pool3d(x)
>>> print(output)
[[[[[10. 11.]]]
  [[[22. 23.]]]]]
```

mindspore.ops.MaxPool3DWithArgmax

class mindspore.ops.**MaxPool3DWithArgmax**(*ksize*, *strides*, *pads*, *dilation=(1, 1, 1)*, *ceil_mode=False*, *data_format='NCDHW'*, *argmax_type=mstype.int64*)

Performs a 3D max pooling on the input Tensor and returns both max values and indices.

Typically the input is a Tensor with shape $(N_{in}, C_{in}, D_{in}, H_{in}, W_{in})$, outputs regional maximum in the (D_{in}, H_{in}, W_{in})-dimension. Given *ksize* $ks = (d_{ker}, h_{ker}, w_{ker})$ and *strides* $s = (s_0, s_1, s_2)$, the operation is as follows.

$$\text{output}(N_i, C_j, d, h, w) = \max_{l=0,\ldots,d_{ker}-1} \max_{m=0,\ldots,h_{ker}-1} \max_{n=0,\ldots,w_{ker}-1} \text{input}(N_i, C_j, s_0 \times d + l, s_1 \times h + m, s_2 \times w + n)$$

The output is a Tensor with shape $(N_{out}, C_{out}, D_{out}, H_{out}, W_{out})$ and its depth, height and width are:

$$\begin{aligned} D_{out} &= \frac{D_{in}+2\times\text{pads}[0]-\text{dilation}[0]\times(\text{ksize}[0]-1)-1}{\text{stride}[0]} + 1 \\ H_{out} &= \frac{H_{in}+2\times\text{pads}[1]-\text{dilation}[1]\times(\text{ksize}[1]-1)-1}{\text{stride}[1]} + 1 \\ W_{out} &= \frac{W_{in}+2\times\text{pads}[2]-\text{dilation}[2]\times(\text{ksize}[2]-1)-1}{\text{stride}[2]} + 1 \end{aligned}$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **ksize** (*Union[int, tuple[int]]*) – The size of kernel used to take the maximum value and arg value, is an int number that represents depth, height and width of the kernel, or a tuple of three int numbers that represent depth, height and width respectively.
- **strides** (*Union[int, tuple[int]]*) – The distance of kernel moving, an int number that represents the depth, height and width of movement are both strides, or a tuple of three int numbers that represent depth, height and width of movement respectively.
- **pads** (*Union[int, tuple[int]]*) – An int number that represents the depth, height and width of movement are both strides, or a tuple of three int numbers that represent depth, height and width of movement respectively.
- **dilation** (*Union[int, tuple[int]]*) – Default: `(1, 1, 1)` .
- **ceil_mode** (*bool*) – Whether to use ceil instead of floor to calculate output shape. Default: `False` .
- **data_format** (*str*) – The optional value for data format. Currently only support `'NCDHW'` . Default: `'NCDHW'` .
- **argmax_type** (`mindspore.dtype`) – The dtype for argmax. Default: `mstype.int64` .

Inputs:

- **x** (Tensor) - Tensor of shape $(N_{in}, C_{in}, D_{in}, H_{in}, W_{in})$ with data type of int8, int16, int32, int64, uint8, uint16, uint32, uint64, float16, float32 or float64.

Outputs:

Tuple of 2 Tensors, representing the maxpool result and where the max values are generated.

- **output** (Tensor) - Maxpooling result, with shape $(N_{out}, C_{out}, D_{out}, H_{out}, W_{out})$. It has the same data type as *x*.
- **argmax** (Tensor) - Index corresponding to the maximum value. Data type is int32 or int64.

Raises

- **TypeError** – If *x* is not a Tensor.
- **ValueError** – If length of shape of *x* is not equal to 5.
- **TypeError** – If *ksize* , *strides* , *pads* or *dilation* is not int or tuple.
- **ValueError** – If *ksize* or *strides* is less than 1.
- **ValueError** – If *pads* is less than 0.
- **ValueError** – If *data_format* is not `'NCDHW'`.
- **ValueError** – If *argmax_type* is not mindspore.int64 or mindspore.int32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.arange(2 * 1 * 2 * 2 * 2).reshape((2, 1, 2, 2, 2)), mindspore.float32)
>>> max_pool3d_with_arg_op = ops.MaxPool3DWithArgmax(ksize=2, strides=1, pads=1)
>>> output_tensor, argmax = max_pool3d_with_arg_op(x)
>>> print(output_tensor.shape)
(2, 1, 3, 3, 3)
>>> print(argmax.shape)
(2, 1, 3, 3, 3)
```

mindspore.ops.MaxUnpool2D

class mindspore.ops.**MaxUnpool2D**(*ksize*, *strides=0*, *pads=0*, *output_shape=()*, *data_format='NCHW'*)

Calculates the partial inverse of MaxPool2D operation.

Since MaxPool2D loses non-maximal values, it is not fully invertible. Therefore, MaxUnpool2D takes the output of MaxPool2D, including the indices of the maximal values, and computes a partial inverse where all non-maximal values are set to zero. Typically the input is of shape (N, C, H_{in}, W_{in}) , the output is of shape (N, C, H_{out}, W_{out}) , the operation is as follows:

$$H_{out} = (Hin - 1) \times strides[0] - 2 \times pads[0] + ksize[0]$$
$$W_{out} = (Win - 1) \times strides[1] - 2 \times pads[1] + ksize[1]$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **ksize** (*Union[int, tuple[int]]*) –The size of kernel used to take the maximum value, is an int number that represents height and width of the kernel, or a tuple of two int numbers that represent height and width respectively.
- **strides** (*Union[int, tuple[int]], optional*) –The strides of kernel moving. If *strides* is 0 or (0, 0), then *strides* equal to *ksize* . Default: `0` .
  - An int number that represents the height and width of movement are both *strides* .
  - A tuple of two int numbers that represent height and width of movement respectively.
- **pads** (*Union[int, tuple[int]], optional*) –The pad value to be filled. Default: `0` .
  - If *pads* is an integer, the paddings of height and width are the same, equal to pads.
  - If *pads* is a tuple of two integers, the padding of height and width equal to pads[0] and pads[1] correspondingly.
- **output_shape** (*tuple[int], optional*) –The target output size is an optional input. Default: `()` .
  - If $output\_shape == ()$, then the shape of output computed by *kszie*, *strides* and *pads* .
  - If $output\_shape! = ()$, then *output_shape* must be (N, C, H, W) or (N, H, W, C) and *output_shape* must belong to $[(N, C, H_{out} - strides[0], W_{out} - strides[1]), (N, C, H_{out} + strides[0], W_{out} + strides[1])]$.
- **data_format** (*str, optional*) –The optional value for data format. Currently support `"NCHW"` and `"NHWC"` . Default: `"NCHW"` .

Inputs:

- **x** (Tensor) - The input Tensor to invert. Tensor of shape (N, C, H_{in}, W_{in}) or (N, H_{in}, W_{in}, C).
- **argmax** (Tensor) - Max values' index represented by the *argmax*. Tensor of shape must be same with input *x*. Values of *argmax* must belong to $[0, H_{in} \times W_{in} - 1]$. Data type must be in int32 or int64.

Outputs:

Tensor, with shape (N, C, H_{out}, W_{out}) or (N, H_{out}, W_{out}, C). Has the same data type with *x*.

Raises

- **TypeError** –If data type of *x* or *argmax* is not supported.
- **TypeError** –If *ksize*, *strides* or *pads* is neither int nor tuple.
- **ValueError** –If numbers in *strides* (also support 0 and (0, 0)) or *ksize* is not positive.
- **ValueError** –If numbers in *pads* is negative.
- **ValueError** –If *ksize*, *strides* or *pads* is a tuple whose length is not equal to 2.
- **ValueError** –If *data_format* is not a str or is neither *NCHW* nor *NHWC*.
- **ValueError** –If *output_shape* whose length is neither 0 or 4.
- **ValueError** –If *output_shape* is not close to output size computed by attr *ksize*, *strides* and *pads*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[[[0, 1], [8, 9]]]]).astype(np.float32))
>>> argmax = Tensor(np.array([[[[0, 1], [2, 3]]]]).astype(np.int64))
>>> maxunpool2d = ops.MaxUnpool2D(ksize=1, strides=1, pads=0)
>>> output = maxunpool2d(x, argmax)
>>> print(output.asnumpy())
[[[[0. 1.]
    [8. 9.]]]]
```

mindspore.ops.MaxUnpool3D

class mindspore.ops.**MaxUnpool3D**(*ksize*, *strides=0*, *pads=0*, *output_shape=()*, *data_format='NCDHW'*)

Computes the inverse of *mindspore.ops.MaxPool3D*.

MaxUnpool3D keeps the maximal value and set all position of non-maximal values to zero. Typically the input is of shape $(N, C, D_{in}, H_{in}, W_{in})$, the output is of shape $(N, C, D_{out}, H_{out}, W_{out})$, the operation is as follows.

$$
\begin{aligned}
D_{out} &= (Din - 1) \times strides[0] - 2 \times pads[0] + ksize[0] \\
H_{out} &= (Hin - 1) \times strides[1] - 2 \times pads[1] + ksize[1] \\
W_{out} &= (Win - 1) \times strides[2] - 2 \times pads[2] + ksize[2]
\end{aligned}
$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **ksize** (*Union[int, tuple[int]]*) –The size of kernel used to take the maximum value, is an int number that represents depth, height and width of the kernel, or a tuple of three int numbers that represent depth, height and width respectively.
- **strides** (*Union[int, tuple[int]], optional*) –The distance of kernel moving. Default: `0` .
  - If it is an int number, the depth, height and width of movement are all equal to *strides*.
  - If it is a tuple of three int numbers, they represent depth, height and width of movement respectively.
  - If strides is 0 or (0, 0, 0), then *strides* equal to *ksize*.
- **pads** (*Union[int, tuple[int]], optional*) –The pad value to be filled. Default: `0` .
  - If *pads* is an integer, the paddings of depth, height and width are the same, equal to pads.
  - If *pads* is a tuple of three integers, the padding of depth, height and width equal to pads[0], pads[1] and pads[2] correspondingly.
- **output_shape** (*tuple[int], optional*) –The target output size. Default: `()` . If $output\_shape == ()$, then the shape of output computed by kszie, strides and pads shown above. If $output\_shape != ()$, then output_shape format must be (N, C, D, H, W) or (N, D, H, W, C) and output_shape must be in range $[(N, C, D_{out} - strides[0], H_{out} - strides[1], W_{out} - strides[2]), (N, C, D_{out} + strides[0], H_{out} + strides[1], W_{out} + strides[2])]$.
- **data_format** (*str, optional*) –The optional value for data format. Currently support `'NCDHW'` and `'NDHWC'` . Default: `'NCDHW'` .

Inputs:

- **x** (Tensor) - The input Tensor to invert. Tensor of shape $(N, C, D_{in}, H_{in}, W_{in})$ or $(N, D_{in}, H_{in}, W_{in}, C)$.
- **argmax** (Tensor) - Max values' index. Tensor that has the same shape as *x*. Values of *argmax* must be in range $[0, D_{in} \times H_{in} \times W_{in} - 1]$. Data type must be int32 or int64.

Outputs:

Tensor, with shape $(N, C, D_{out}, H_{out}, W_{out})$ or $(N, D_{out}, H_{out}, W_{out}, C)$. Has the same data type with *x*.

Raises

- **TypeError** –If data type of *x* or *argmax* is Number.
- **TypeError** –If *ksize*, *strides* or *pads* is neither int nor tuple.
- **ValueError** –If numbers in *strides* or *ksize* is negative.
- **ValueError** –If numbers in *pads* is negative.
- **ValueError** –If *ksize*, *strides* or *pads* is a tuple whose length is not equal to 3.
- **ValueError** –If *data_format* is not a str or is neither `'NCDHW'` nor `'NDHWC'`.
- **ValueError** –If *output_shape* whose length is neither 0 or 5.
- **ValueError** –If *output_shape* is not close to output size range computed by attr *ksize, strides, pads*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[[[[0, 1], [8, 9]]]]]).astype(np.float32))
>>> argmax = Tensor(np.array([[[[[0, 1], [2, 3]]]]]).astype(np.int64))
>>> maxunpool3d = ops.MaxUnpool3D(ksize=1, strides=1, pads=0)
>>> output = maxunpool3d(x, argmax)
>>> print(output.asnumpy())
[[[[[0. 1.]
    [8. 9.]]]]]
```

mindspore.ops.MirrorPad

class mindspore.ops.**MirrorPad**(*mode='REFLECT'*)

Pads the input tensor according to the paddings and mode.

Parameters

mode (*str, optional*) –An optional string specifying the pad method. The optional values are `'REFLECT'` and `'SYMMETRIC'`. Default: `'REFLECT'`.

- `'REFLECT'`: Reflect the value on the edge while omitting the last one. For example, pad [1, 2, 3, 4] with 2 elements on both sides will result in [3, 2, 1, 2, 3, 4, 3, 2].
- `'SYMMETRIC'`: Reflect the value on the edge while repeating the last one. For example, pad [1, 2, 3, 4] with 2 elements on both sides will result in [2, 1, 1, 2, 3, 4, 4, 3].

Inputs:

- **input_x** (Tensor) - Tensor of shape $(N, *)$, where $*$ means, any number of additional dimensions.
- **paddings** (Tensor) - Paddings requires constant tensor. The value of *paddings* is a matrix(list), and its shape is $(N, 2)$. N is the rank of input data. All elements of paddings are int type. For the input in the *D* th dimension, paddings[D, 0] indicates how many sizes to be extended ahead of the input tensor in the *D* th dimension, and paddings[D, 1] indicates how many sizes to be extended behind the input tensor in the *D* th dimension. Both paddings[D, 0] and paddings[D, 1] must be no greater than input_x.dim_size(D) (or input_x.dim_size(D) - 1) if mode is SYMMETRIC (if REFLECT, respectively).

Outputs:

Tensor, the tensor after padding.

- If *mode* is `'REFLECT'`, it uses a way of symmetrical copying through the axis of symmetry to fill in. If the *input_x* is [[1,2,3], [4,5,6], [7,8,9]] and *paddings* is [[1,1], [2,2]], then the *Outputs* is [[6,5,4,5,6,5,4], [3,2,1,2,3,2,1], [6,5,4,5,6,5,4], [9,8,7,8,9,8,7], [6,5,4,5,6,5,4]]. For a more intuitive understanding, please see the example below.
- If *mode* is `'SYMMETRIC'`, the filling method is similar to the `'REFLECT'`. It is also copied according to the symmetry axis, except that it includes the symmetry axis. If the *input_x* is [[1,2,3], [4,5,6], [7,8,9]] and *paddings* is [[1,1], [2,2]], then the *Outputs* is [[2,1,1,2,3,3,2], [2,1,1,2,3,3,2], [5,4,4,5,6,6,5], [8,7,7,8,9,9,8], [8,7,7,8,9,9,8]]. For a more intuitive understanding, please see the example below.

Raises

- **TypeError** –If *input_x* or *paddings* is not a Tensor.
- **TypeError** –If *mode* is not a str.
- **ValueError** –If paddings.size is not equal to 2 * rank of input_x.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor, nn, ops
>>> # case1: mode="REFLECT"
>>> class Net(nn.Cell):
...     def __init__(self, mode):
...         super(Net, self).__init__()
...         self.pad = ops.MirrorPad(mode=mode)
...         self.paddings = Tensor([[1, 1], [2, 2]])
...     def construct(self, input_x):
...         return self.pad(input_x, self.paddings)
...
>>> input_x = Tensor([[1,2,3], [4,5,6], [7,8,9]])
>>> pad = Net("REFLECT")
>>> output = pad(input_x)
>>> print(output)
[[6 5 4 5 6 5 4]
 [3 2 1 2 3 2 1]
 [6 5 4 5 6 5 4]
 [9 8 7 8 9 8 7]
 [6 5 4 5 6 5 4]]
>>> # case2: mode="SYMMETRIC"
>>> pad = Net("SYMMETRIC")
>>> output = pad(input_x)
```

(continues on next page)

(continued from previous page)

```
>>> print(output)
[[2 1 1 2 3 3 2]
 [2 1 1 2 3 3 2]
 [5 4 4 5 6 6 5]
 [8 7 7 8 9 9 8]
 [8 7 7 8 9 9 8]]
```

mindspore.ops.Pad

class mindspore.ops.**Pad**(*paddings*)

Pads the input tensor according to the paddings.

Refer to *mindspore.ops.pad()* for more details. Use *mindspore.ops.pad()* instead if *paddings* has negative values.

Parameters

paddings (*tuple*) – The shape of parameter *paddings* is (N, 2). N is the rank of input data. All elements of paddings are int type. For the input in *D* th dimension, paddings[D, 0] indicates how many sizes to be extended ahead of the input tensor in the *D* th dimension, and paddings[D, 1] indicates how many sizes to be extended behind the input tensor in the *D* th dimension.

Inputs:

- **input_x** (Tensor) - Tensor to be padded. It has shape $(N, *)$, where $*$ means any number of additional dimensions.

Outputs:

Tensor, the tensor after padding.

Raises

- **TypeError** – If *paddings* is not a tuple.
- **TypeError** – If *input_x* is not a Tensor.
- **ValueError** – If shape of *paddings* is not $(N, 2)$.
- **ValueError** – If paddings.size is not equal to 2 * len(input_x).

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]), mindspore.float32)
>>> pad_op = ops.Pad(((1, 2), (2, 1)))
>>> output = pad_op(input_x)
>>> print(output)
[[ 0.   0.   0.   0.   0.   0. ]
 [ 0.   0.  -0.1  0.3  3.6  0. ]
 [ 0.   0.   0.4  0.5 -3.2  0. ]
 [ 0.   0.   0.   0.   0.   0. ]
 [ 0.   0.   0.   0.   0.   0. ]]
```

mindspore.ops.EmbeddingLookup

class mindspore.ops.**EmbeddingLookup**

Returns a slice of input tensor based on the specified indices.

This Primitive has the similar functionality as GatherV2 operating on *axis = 0*, but has one more inputs: *offset*.

Inputs:

- **input_params** (Tensor) - a Tensor slice, the shape is $(x_1, x_2, ..., x_R)$. Currently, the dimension is restricted to be 2.
- **input_indices** (Tensor) - Specifies the indices of elements of the original Tensor. The shape is $(y_1, y_2, ..., y_S)$. Values can be out of range of *input_params*, and the exceeding part will be filled with 0 in the output. Values do not support negative and the result is undefined if values are negative. The data type should be int32 or int64.
- **offset** (int) - Specifies the offset value of this *input_params* slice. Thus the real indices are equal to *input_indices* minus *offset*.

Outputs:

Tensor, the shape of tensor is $(z_1, z_2, ..., z_N)$. The data type is the same with *input_params*.

Raises

- **TypeError** –If dtype of *input_indices* is not int.
- **ValueError** –If length of shape of *input_params* is greater than 2.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_params = Tensor(np.array([[8, 9], [10, 11], [12, 13], [14, 15]]), mindspore.
↪float32)
>>> input_indices = Tensor(np.array([[5, 2], [8, 5]]), mindspore.int32)
>>> offset = 4
>>> output = ops.EmbeddingLookup()(input_params, input_indices, offset)
>>> print(output)
[[[10. 11.]
  [ 0.  0.]]
 [[ 0.  0.]
  [10. 11.]]]
```

mindspore.ops.Padding

class mindspore.ops.**Padding**(*pad_dim_size=8*)

Extends the last dimension of the input tensor from 1 to pad_dim_size, by filling with 0.

Refer to *mindspore.ops.padding()* for more details.

Parameters

pad_dim_size (*int, optional*) – The value of the last dimension of *x* to be extended, which must be positive. Default: 8.

Inputs:

- **x** (Tensor) - Input Tensor of 2D or higher-dimensional. The last dimension of *x* must be 1. The data type is Number.

Outputs:

Tensor, the padded Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[8], [10]]), mindspore.float32)
>>> pad_dim_size = 4
>>> output = ops.Padding(pad_dim_size)(x)
>>> print(output)
[[ 8.  0.  0.  0.]
 [10.  0.  0.  0.]]
```

mindspore.ops.ResizeBicubic

class mindspore.ops.**ResizeBicubic**(*align_corners=False*, *half_pixel_centers=False*)

Resize images to size using bicubic interpolation.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **align_corners** (*bool, optional*) – If True, the centers of the 4 corner pixels of the input and output tensors are aligned, preserving the values at the corner pixels. Default: False.
- **half_pixel_centers** (*bool, optional*) – Whether to use half-pixel center alignment. If set to True, *align_corners* should be False. Default: False.

Inputs:

- **images** (Tensor) - The input image must be a 4-D tensor of shape $(batch, channels, height, width)$. The format must be NCHW. Types allowed: float16, float32, float64.

- **size** (Union[tuple[int], Tensor[int]]) - A 1-D tensor or tuple with 2 elements: new_height, new_width. Besides, tuple[int] is recommended.

Outputs:

A 4-D tensor with shape $(batch, channels, new\_height, new\_width)$ whose dtype is the same as *images* .

Raises

- **TypeError** –If the type of *images* is not allowed.
- **TypeError** –If the type of *align_corners* is not bool.
- **TypeError** –If the type of *half_pixel_centers* is not bool.
- **ValueError** –If the dim of *images* is not 4.
- **ValueError** –If the dim of *size* is not 1 when *size* is a tensor.
- **ValueError** –If the number of elements in *size* is not 2.
- **ValueError** –If any value of *size* is not positive.
- **ValueError** –If the values of *align_corners* and *half_pixel_centers* are both `True` .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, nn
>>> class NetResizeBicubic(nn.Cell):
...     def __init__(self):
...         super(NetResizeBicubic, self).__init__()
...         align_corners = False
...         half_pixel_centers = False
...         self.resize = ops.ResizeBicubic(align_corners, half_pixel_centers)
...
...     def construct(self, images, size):
...         return self.resize(images, size)
...
>>> images = Tensor(np.array([1, 2, 3, 4]).reshape(1, 1, 2, 2).astype(np.float32))
>>> size = Tensor([1, 4], mindspore.int32)
>>> resizebicubic = NetResizeBicubic()
>>> output = resizebicubic(images, size)
>>> print(output)
    [[[[1. 1.5 2. 2.09375]]]]
```

mindspore.ops.ResizeNearestNeighbor

class mindspore.ops.**ResizeNearestNeighbor**(*size*, *align_corners=False*, *half_pixel_centers=False*)

Resizes the input tensor to a given size by using the nearest neighbor algorithm. The nearest neighbor algorithm selects the value of the nearest point and does not consider the values of neighboring points at all, yielding a piecewise-constant interpolant.

Parameters

- **size** (*Union[tuple, list]*) –The target size. The dimension of size must be 2.
- **align_corners** (*bool, optional*) –Whether the centers of the 4 corner pixels of the input and output tensors are aligned. Default: `False` .
- **half_pixel_centers** (*bool, optional*) –Whether half pixel center. If set to `True` , *align_corners* should be False. Default: `False` .

Inputs:

- **input_x** (Tensor) - The input tensor. The shape of the tensor is (N, C, H, W).

Outputs:

Tensor, the shape of the output tensor is (N, C, NEW_H, NEW_W). The data type is the same as the *input_x*.

Raises

- **TypeError** –If *size* is neither tuple nor list.
- **TypeError** –If *align_corners* is not a bool.
- **ValueError** –If length of *size* is not equal to 2.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> input_tensor = Tensor(np.array([[[[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]]]), mindspore.
 ↪float32)
>>> size = (2, 2)
>>> output = ops.ResizeNearestNeighbor(size=size)(input_tensor)
>>> print(output)
[[[[-0.1  0.3]
   [ 0.4  0.5]]]]
```

18.2.2 Loss Function

API Name	Description	Supported Platforms
mindspore.ops.BCEWithLogitsLoss	Adds sigmoid activation function to *input* as logits, and uses the given logits to compute binary cross entropy between the logits and the target.	Ascend GPU CPU
mindspore.ops.BinaryCrossEntropy	Computes the binary cross entropy between the logits and the labels.	Ascend GPU CPU
mindspore.ops.CTCLoss	Calculates the CTC (Connectionist Temporal Classification) loss and the gradient.	Ascend GPU CPU
mindspore.ops.CTCLossV2	Calculates the CTC (Connectionist Temporal Classification) loss and the gradient.	Ascend GPU CPU
mindspore.ops.KLDivLoss	Computes the Kullback-Leibler divergence between the logits and the labels.	Ascend GPU CPU
mindspore.ops.L2Loss	Calculates half of the L2 norm, but do not square the result.	Ascend GPU CPU
mindspore.ops.MultilabelMarginLoss	Creates a loss criterion that minimizes the hinge loss for multi-class classification tasks.	Ascend GPU
mindspore.ops.MultiMarginLoss	Creates a loss function that minimizes the hinge loss for multi-class classification tasks.	Ascend GPU CPU
mindspore.ops.NLLLoss	Gets the negative log likelihood loss between logits and labels.	Ascend GPU CPU
mindspore.ops.RNNTLoss	Computes the RNNTLoss and its gradient with respect to the softmax outputs.	Ascend
mindspore.ops.SigmoidCrossEntropyWithLogits	Uses the given logits to compute sigmoid cross entropy between the logits and the label.	Ascend GPU CPU
mindspore.ops.SmoothL1Loss	Calculate the smooth L1 loss, and the L1 loss function has robustness.	Ascend GPU CPU
mindspore.ops.SoftMarginLoss	Refer to *mindspore.ops.soft_margin_loss()* for more details.	Ascend GPU
mindspore.ops.SoftmaxCrossEntropyWithLogits	Gets the softmax cross-entropy value between logits and labels with one-hot encoding.	Ascend GPU CPU
mindspore.ops.SparseSoftmaxCrossEntropyWithLogits	Computes the softmax cross-entropy value between logits and sparse encoding labels.	GPU CPU
mindspore.ops.TripletMarginLoss	TripletMarginLoss operation.	GPU

mindspore.ops.BCEWithLogitsLoss

class mindspore.ops.**BCEWithLogitsLoss**(*reduction='mean'*)

Adds sigmoid activation function to *input* as logits, and uses the given logits to compute binary cross entropy between the logits and the target.

Sets input *input* as X, input *target* as Y, input weight as W, output as L. Then,

$$p_{ij} = sigmoid(X_{ij}) = \frac{1}{1+e^{-X_{ij}}}$$
$$L_{ij} = -[Y_{ij}log(p_{ij}) + (1 - Y_{ij})log(1 - p_{ij})]$$

i indicates the i^{th} sample, j indicates the category. Then,

$$\ell(x, y) = \begin{cases} L, & \text{if reduction = 'none';} \\ \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

ℓ indicates the method of calculating the loss. There are three methods: the first method is to provide the loss value directly, the second method is to calculate the average value of all losses, and the third method is to calculate the sum of all losses.

This operator will multiply the output by the corresponding weight. The tensor *weight* assigns different weights to each piece of data in the batch, and the tensor *pos_weight* adds corresponding weights to the positive examples of each category.

In addition, it can trade off recall and precision by adding weights to positive examples. In the case of multi-label classification the loss can be described as:

$$p_{ij,c} = sigmoid(X_{ij,c}) = \frac{1}{1+e^{-X_{ij,c}}}$$
$$L_{ij,c} = -[P_c Y_{ij,c} * log(p_{ij,c}) + (1 - Y_{ij,c}) log(1 - p_{ij,c})]$$

where c is the class number (c>1 for multi-label binary classification, c=1 for single-label binary classification), n is the number of the sample in the batch and P_c is the weight of the positive answer for the class c. $P_c > 1$ increases the recall, $P_c < 1$ increases the precision.

Parameters

reduction (*str, optional*) – Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .

- `'none'`: no reduction will be applied.
- `'mean'`: compute and return the weighted mean of elements in the output.
- `'sum'`: the output elements will be summed.

Inputs:

- **input** (Tensor) - Input *input*. Tensor of shape $(N, *)$ where $*$ means, any number of additional dimensions. Data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported).
- **target** (Tensor) - Ground truth label, has the same shape as *input*. Data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported).
- **weight** (Tensor) - A rescaling weight applied to the loss of each batch element. It can be broadcast to a tensor with shape of *input*. Data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported).
- **pos_weight** (Tensor) - A weight of positive examples. Must be a vector with length equal to the number of classes. It can be broadcast to a tensor with shape of *input*. Data type must be float16, float32 or bfloat16(only Atlas A2 series products are supported).

Outputs:

Tensor or Scalar, if *reduction* is `'none'`, it's a tensor with the same shape and type as input *input*. Otherwise, the output is a scalar.

Raises

- **TypeError** – If any input is not Tensor.
- **TypeError** – If data type of any input is not float16, float32 or bfloat16.
- **TypeError** – If data type of *reduction* is not string.
- **ValueError** – If *weight* or *pos_weight* can not be broadcast to a tensor with shape of *input*.
- **ValueError** – If *reduction* is not one of `'none'`, `'mean'` or `'sum'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.array([[-0.8, 1.2, 0.7], [-0.1, -0.4, 0.7]]), mindspore.float32)
>>> target = Tensor(np.array([[0.3, 0.8, 1.2], [-0.6, 0.1, 2.2]]), mindspore.float32)
>>> weight = Tensor(np.array([1.0, 1.0, 1.0]), mindspore.float32)
>>> pos_weight = Tensor(np.array([1.0, 1.0, 1.0]), mindspore.float32)
>>> loss = ops.BCEWithLogitsLoss()
>>> output = loss(input, target, weight, pos_weight)
>>> print(output)
0.3463612
```

mindspore.ops.BinaryCrossEntropy

class mindspore.ops.**BinaryCrossEntropy**(*reduction='mean'*)

Computes the binary cross entropy between the logits and the labels.

Sets logits as x, labels as y, output as $\ell(x, y)$. Let,

$$L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -w_n \left[y_n \cdot \log x_n + (1 - y_n) \cdot \log(1 - x_n) \right]$$

In which, L indicates the loss of all batch_sizes, l indicates the loss of one batch_size, and n indicates one batch_size in the 1-N range, w_n indicates the weight of n-th batch of binary cross entropy. Then,

$$\ell(x, y) = \begin{cases} L, & \text{if reduction = 'none';} \\ \text{mean}(L), & \text{if reduction = 'mean';} \\ \text{sum}(L), & \text{if reduction = 'sum'.} \end{cases}$$

Warning:

- The value of x must range from 0 to 1.

Parameters

reduction (*str, optional*) – Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .

- `'none'`: no reduction will be applied.
- `'mean'`: compute and return the weighted mean of elements in the output.
- `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - The predictive value whose data type must be float16 or float32, The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **labels** (Tensor) - The target value which has the same shape and data type as *logits*. And the data type is float16 or float32.
- **weight** (Tensor, optional) - A rescaling weight applied to the loss of each batch element. And it must have the same shape and data type as *logits*. Default: `None` .

Outputs:

Tensor or Scalar. Returns Tensor that has the same dtype and shape as *logits* if *reduction* is 'none'. Otherwise, returns a scalar Tensor.

Raises

- **TypeError** –If dtype of *logits*, *labels* or *weight* (if given) is neither float16 nor float32.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'` or `'sum'`.
- **ValueError** –If shape of *labels* is not the same as *logits* or *weight* (if given).
- **TypeError** –If *logits*, *labels* or *weight* is not a Tensor.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.binary_cross_entropy = ops.BinaryCrossEntropy()
...     def construct(self, logits, labels, weight):
...         result = self.binary_cross_entropy(logits, labels, weight)
...         return result
...
>>> net = Net()
>>> logits = Tensor(np.array([0.2, 0.7, 0.1]), mindspore.float32)
>>> labels = Tensor(np.array([0., 1., 0.]), mindspore.float32)
>>> weight = Tensor(np.array([1, 2, 2]), mindspore.float32)
>>> output = net(logits, labels, weight)
>>> print(output)
0.38240486
```

mindspore.ops.CTCLoss

class mindspore.ops.**CTCLoss**(*preprocess_collapse_repeated=False*, *ctc_merge_repeated=True*, *ignore_longer_outputs_than_inputs=False*)

Calculates the CTC (Connectionist Temporal Classification) loss and the gradient.

The bottom layer of this interface calls the implementation of the third-party baidu-research::warp-ctc. The CTC algorithm is proposed in Connectionist Temporal Classification: Labeling Unsegmented Sequence Data with Recurrent Neural Networks.

CTCLoss calculates loss between a continuous time series and a target sequence. CTCLoss sums over the probability of input to target, producing a loss value which is differentiable with respect to each input node. The alignment of input to target is assumed to be "many-to-one", such that the length of target series must be less than or equal to the length of input.

Parameters

- **preprocess_collapse_repeated** (*bool, optional*) –If `True`, repeated labels will be collapsed prior to the CTC calculation. Default: `False`.

- **ctc_merge_repeated** (*bool, optional*) –If `False` , during CTC calculation, repeated non-blank labels will not be merged and these labels will be interpreted as individual ones. This is a simplified version of CTC. Default: `True` .
- **ignore_longer_outputs_than_inputs** (*bool, optional*) –If `True` , sequences with longer outputs than inputs will be ignored. Default: `False` .

Inputs:

- **x** (Tensor) - The input Tensor must be a *3-D* tensor whose shape is $(max\_time, batch\_size, num\_classes)$. *num_classes* must be *num_labels + 1* classes, *num_labels* indicates the number of actual labels. Blank labels are reserved. Default blank label is *num_classes - 1*. Data type must be float16, float32 or float64.
- **labels_indices** (Tensor) - The indices of labels. *labels_indices[i, :] = [b, t]* means *labels_values[i]* stores the id for *(batch b, time t)*. The type must be int64 and rank must be 2.
- **labels_values** (Tensor) - A *1-D* input tensor. The values are associated with the given batch and time. The type must be int32. *labels_values[i]* must be in the range of *[0, num_classes)*.
- **sequence_length** (Tensor) - A tensor containing sequence lengths with the shape of $(batch\_size,)$. The type must be int32. Each value in the tensor must not be greater than *max_time*.

Outputs:

- **loss** (Tensor) - A tensor containing log-probabilities, the shape is $(batch\_size,)$. The tensor has the same data type as *x*.
- **gradient** (Tensor) - The gradient of *loss*, has the same shape and data type as *x*.

Raises

- **TypeError** –If *preprocess_collapse_repeated*, *ctc_merge_repeated* or *ignore_longer_outputs_than_inputs* is not a bool.
- **TypeError** –If *x*, *labels_indices*, *labels_values* or *sequence_length* is not a Tensor.
- **ValueError** –If rank of *labels_indices* is not equal to 2.
- **TypeError** –If dtype of *x* is not one of the following: float16, float32 nor float64.
- **TypeError** –If dtype of *labels_indices* is not int64.
- **TypeError** –If dtype of *labels_values* or *sequence_length* is not int32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[[0.3, 0.6, 0.6],
...                       [0.4, 0.3, 0.9]],
...
...                      [[0.9, 0.4, 0.2],
...                       [0.9, 0.9, 0.1]]]).astype(np.float32))
>>> labels_indices = Tensor(np.array([[0, 0], [1, 0]]), mindspore.int64)
>>> labels_values = Tensor(np.array([2, 2]), mindspore.int32)
>>> sequence_length = Tensor(np.array([2, 2]), mindspore.int32)
```

(continues on next page)

(continued from previous page)

```
>>> ctc_loss = ops.CTCLoss()
>>> loss, gradient = ctc_loss(x, labels_indices, labels_values, sequence_length)
>>> print(loss)
[ 0.79628  0.5995158 ]
>>> print(gradient)
[[[ 0.27029088  0.36485454  -0.6351454  ]
  [ 0.28140804  0.25462854  -0.5360366 ]]
 [[ 0.47548494  0.2883962    0.04510255 ]
  [ 0.4082751   0.4082751    0.02843709 ]]]
```

mindspore.ops.CTCLossV2

class mindspore.ops.**CTCLossV2**(*blank=0*, *reduction='none'*, *zero_infinity=False*)

Calculates the CTC (Connectionist Temporal Classification) loss and the gradient.

The CTC algorithm is proposed in Connectionist Temporal Classification: Labeling Unsegmented Sequence Data with Recurrent Neural Networks.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **blank** (*int, optional*) – The blank label. Default: `0` .
- **reduction** (*str, optional*) – Apply specific reduction method to the output. Currently only support `'none'`. Default: `'none'` .
- **zero_infinity** (*bool, optional*) – If loss is infinite, this parameter determines whether to set that loss and its correlated gradient to zero. Default: `False` .

Inputs:

- **log_probs** (Tensor) - A 3D tensor of shape (T, N, C), where T is input length, N is batch size and C is number of classes (including blank). Supported dtypes: float32, float64.
- **targets** (Tensor) - A 2D tensor of shape (N, S), where S is max target length, means the target sequences. Supported dtypes: int32, int64.
- **input_lengths** (Union(Tuple, Tensor)) - A tuple or Tensor of shape (N). It means the lengths of the input. Supported dtypes: int32, int64.
- **target_lengths** (Union(Tuple, Tensor)) - A tuple or Tensor of shape (N). It means the lengths of the target. Supported dtypes: int32, int64.

Outputs:

- **neg_log_likelihood** (Tensor) - A loss value which is differentiable with respect to each input node.
- **log_alpha** (Tensor) - The probability of possible trace of input to target.

Raises

- **TypeError** – If *zero_infinity* is not a bool.
- **TypeError** – If *reduction* is not string.
- **TypeError** – If the dtype of *log_probs* is not float or double.

- **TypeError** –If the dtype of *targets*, *input_lengths* or *target_lengths* is not int32 or int64.
- **ValueError** –If the rank of *log_probs* is not 3.
- **ValueError** –If the rank of *targets* is not 2.
- **ValueError** –If the shape of *input_lengths* does not match batch_size *N*.
- **ValueError** –If the shape of *target_lengths* does not match batch_size *N*.
- **TypeError** –If the types of *targets*, *input_lengths* or *target_lengths* are different.
- **ValueError** –If the value of *blank* is not in range [0, C).
- **RuntimeError** –If any value of *input_lengths* is larger than (num_labels|C).
- **RuntimeError** –If any *target_lengths[i]* is not in range [0, *input_length[i]*].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> log_probs = Tensor(np.array([[[0.3, 0.6, 0.6]],
...                              [[0.9, 0.4, 0.2]]]).astype(np.float32))
>>> targets = Tensor(np.array([[0, 1]]), mstype.int32)
>>> input_lengths = Tensor(np.array([2]), mstype.int32)
>>> target_lengths = Tensor(np.array([1]), mstype.int32)
>>> CTCLossV2 = ops.CTCLossV2(blank=0, reduction='none', zero_infinity=False)
>>> neg_log_hood, log_alpha = CTCLossV2(
...     log_probs, targets, input_lengths, target_lengths)
>>> print(neg_log_hood)
[-2.2986124]
>>> print(log_alpha)
[[[0.3       0.3           -inf      -inf      -inf]
  [1.2       1.8931472 1.2           -inf      -inf]]]
```

mindspore.ops.KLDivLoss

class mindspore.ops.**KLDivLoss**(*reduction='mean'*)

Computes the Kullback-Leibler divergence between the logits and the labels.

For tensors of the same shape x and $target$, the updating formulas of KLDivLoss algorithm are as follows,

$$L(x, target) = target \cdot (\log target - x)$$

Then,

$$\ell(x, target) = \begin{cases} L(x, target), & \text{if reduction = 'none';} \\ \text{mean}(L(x, target)), & \text{if reduction = 'mean';} \\ \text{sum}(L(x, target))/x.\text{shape}[0], & \text{if reduction = 'batchmean';} \\ \text{sum}(L(x, target)), & \text{if reduction = 'sum'.} \end{cases}$$

where x represents *logits*, $target$ represents *labels*, and $\ell(x, target)$ represents *output*.

Note:

- On Ascend, float64 dtype is not currently supported.
- The output aligns with the mathematical definition of Kullback-Leibler divergence only when *reduction* is set to `'batchmean'`.
- On Ascend, the value of *reduction* must be one of `'batchmean'`, `'none'` or `'sum'`.
- On GPU, the value of *reduction* must be one of `'mean'`, `'none'` or `'sum'`.
- On CPU, the value of *reduction* must be one of `'mean'`, `'batchmean'`, `'none'` or `'sum'`.

Parameters

reduction (*str, optional*) – Specifies the reduction to be applied to the output. Default: `'mean'` .

- `'none'`: no reduction will be applied.
- `'mean'`: compute and return the mean of elements in the output.
- `'sum'`: the output elements will be summed.
- `'batchmean'`: average loss is taken over the batch, similar to the mean mode.

Inputs:

- **logits** (Tensor) - The input Tensor. The data type must be float16, float32 or float64.
- **labels** (Tensor) - The label Tensor which has the same shape and data type as *logits*.

Outputs:

Tensor or Scalar, if *reduction* is `'none'`, then output is a tensor and has the same shape as *logits*. Otherwise it is a scalar.

Raises

- **TypeError** – If *reduction* is not a str.
- **TypeError** – If neither *logits* nor *labels* is a Tensor.
- **TypeError** – If dtype of *logits* or *labels* is not currently supported.
- **ValueError** – If shape of *logits* is not the same as *labels*.
- **RuntimeError** – If *logits* or *labels* is a scalar when *reduction* is `'batchmean'`.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.kldiv_loss = ops.KLDivLoss(reduction='sum')
...     def construct(self, logits, labels):
```

(continues on next page)

(continued from previous page)

```
...         result = self.kldiv_loss(logits, labels)
...         return result
...
>>> net = Net()
>>> logits = Tensor(np.array([0.2, 0.7, 0.1]), mindspore.float32)
>>> labels = Tensor(np.array([0., 1., 0.]), mindspore.float32)
>>> output = net(logits, labels)
>>> print(output)
-0.7
```

mindspore.ops.L2Loss

class mindspore.ops.**L2Loss**

Calculates half of the L2 norm, but do not square the result.

Set input as x and output as loss.

$$loss = \frac{\sum x^2}{2}$$

Inputs:

- **input_x** (Tensor) - Tensor for computing the L2 norm. Data type must be float16, float32 or float64.

Outputs:

Tensor, has a Scalar Tensor with the same data type as *input_x*.

Raises

- **TypeError** – If *input_x* is not a Tensor.
- **TypeError** – If dtype of *input_x* is not float16, float32 or float64.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([1, 2, 3]), mindspore.float16)
>>> l2_loss = ops.L2Loss()
>>> output = l2_loss(input_x)
>>> print(output)
7.0
```

mindspore.ops.MultilabelMarginLoss

class mindspore.ops.**MultilabelMarginLoss**(*reduction='mean'*)

Creates a loss criterion that minimizes the hinge loss for multi-class classification tasks. It takes a 2D mini-batch Tensor *x* as input and a 2D Tensor *y* containing target class indices as output.

Refer to *mindspore.ops.multilabel_margin_loss()* for more details.

Parameters

reduction (*str, optional*) – Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'mean'`.

- `'none'`: no reduction will be applied.
- `'mean'`: compute and return the mean of elements in the output.
- `'sum'`: the output elements will be summed.

Inputs:

- **x** (Tensor) - Predict data. Tensor of shape (C) or (N, C), where N is the batch size and C is the number of classes. Data type must be float16 or float32.
- **target** (Tensor) - Ground truth data, with the same shape as *input*, data type must be int32 and label targets padded by -1.

Outputs:

- **y** (Union[Tensor, Scalar]) - The loss of MultilabelMarginLoss. If *reduction* is `"none"`, its shape is (N). Otherwise, a scalar value will be returned.
- **is_target** (Tensor) - Output tensor for backward input, with the same shape as *target*, data type must be int32.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> loss = ops.MultilabelMarginLoss()
>>> x = Tensor(np.array([[0.1, 0.2, 0.4, 0.8], [0.2, 0.3, 0.5, 0.7]]), mindspore.float32)
>>> target = Tensor(np.array([[1, 2, 0, 3], [2, 3, -1, 1]]), mindspore.int32)
>>> output = loss(x, target)
>>> print(output)
(Tensor(shape=[], dtype=Float32, value= 0.325), Tensor(shape=[2, 4], dtype=Int32, value=
[[1, 1, 1, 1], [0, 0, 1, 1]]))
```

mindspore.ops.MultiMarginLoss

class mindspore.ops.**MultiMarginLoss**(*p=1*, *margin=1.0*, *reduction='mean'*)

Creates a loss function that minimizes the hinge loss for multi-class classification tasks. The loss is calculated by comparing the input and output of the function.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.multi_margin_loss()* for more details.

Parameters

- **p** (*int, optional*) – The norm degree for pairwise distance. Should be 1 or 2. Default: `1` .
- **margin** (*int, optional*) – A parameter to change pairwise distance. Default: `1.0` .
- **reduction** (*str, optional*) – Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **inputs** (Tensor) - Input , with shape (N, C). Data type only support float32, float16 or float64.
- **target** (Tensor) - Ground truth labels, with shape $(N,)$. Data type only support int64. The value of target should be non-negative, less than C.
- **weight** (Tensor, optional) - The rescaling weight to each class with shape $(C,)$. Data type only support float16, float32 or float64.

Outputs:

Tensor, When *reduction* is `'none'`, the shape is $(N,)$. Otherwise, it is a scalar. Has the same data type with *inputs*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.ones(shape=[3, 3]), mindspore.float32)
>>> target = Tensor(np.array([1, 2, 1]), mindspore.int64)
>>> weight = Tensor(np.array([1, 1, 1]), mindspore.float32)
>>> loss = ops.MultiMarginLoss()
>>> output = loss(x, target, weight)
>>> print(output)
0.6666667
```

mindspore.ops.NLLLoss

class mindspore.ops.**NLLLoss**(*reduction='mean'*, *ignore_index=- 100*)

Gets the negative log likelihood loss between logits and labels.

The nll loss with $reduction = none$ can be described as:

$$\ell(x, t) = L = \{l_1, \ldots, l_N\}^\top, \quad l_n = -w_{t_n} x_{n,t_n}, \quad w_c = \text{weight}\,[c] \cdot 1$$

where x is the logits, t is the labels, w is the weight, N is the batch size, c belonging to [0, C-1] is class index, where C is the number of classes.

If $reduction \neq none$ (default `'mean'`), then

$$\ell(x, t) = \begin{cases} \sum_{n=1}^{N} \frac{1}{\sum_{n=1}^{N} w_{tn}} l_n, & \text{if reduction = 'mean';} \\ \sum_{n=1}^{N} l_n, & \text{if reduction = 'sum'} \end{cases}$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **reduction** (*str, optional*) – Apply specific reduction method to the output: `'none'` , `'mean'` , `'sum'` . Default: `'mean'` .
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the weighted mean of elements in the output.
  - `'sum'`: the output elements will be summed.
- **ignore_index** (*int, optional*) – Specifies a target value that is ignored and does not contribute to the input gradient. Default: `-100` .

Inputs:

- **logits** (Tensor) - Input logits, with shape (N, C). Data type only supports float32 or float16 or bfloat16(only supported by Atlas A2 training series products).
- **labels** (Tensor) - Ground truth labels, with shape $(N,)$, where each value belong to $[0, C-1]$. Data type only supports uint8 or int32 or int64.
- **weight** (Tensor) - The rescaling weight to each class, with shape $(C,)$ and data type only supports float32 or float16 or bfloat16(only supported by Atlas A2 training series products). It should have the same data type as *logits* .

Returns

Tuple of 2 tensors composed with *loss* and *total_weight*.

- **loss** (Tensor) - When *reduction* is `'none'` and *logits* is a 2D tensor, the *loss* shape is $(N,)$. Otherwise, the *loss* is a scalar. The data type is the same with that of *logits*.
- **total_weight** (Tensor) - The *total_weight* is a scalar. The data type is the same with that of *weight*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> logits = Tensor(np.array([[0.5488135, 0.71518934],
...                           [0.60276335, 0.5448832],
...                           [0.4236548, 0.6458941]]).astype(np.float32))
>>> labels = Tensor(np.array([0, 0, 0]).astype(np.int32))
>>> weight = Tensor(np.array([0.3834415, 0.79172504]).astype(np.float32))
>>> nll_loss = ops.NLLLoss(reduction="mean")
>>> loss, weight = nll_loss(logits, labels, weight)
>>> print(loss)
-0.52507716
>>> print(weight)

```

mindspore.ops.RNNTLoss

class mindspore.ops.**RNNTLoss**(*blank_label=0*)

Computes the RNNTLoss and its gradient with respect to the softmax outputs.

Parameters

blank_label (*int*) – blank label. Default: `0` .

Inputs:

- **acts** (Tensor) - Tensor of shape (B, T, U, V), where B is batch, T is sequence length, U is label length and V is output dim. Data type must be float16 or float32.
- **labels** (Tensor) - Tensor of shape $(B, U-1)$. Data type is int32.
- **input_lengths** (Tensor) - Tensor of shape $(B,)$. Data type is int32.
- **label_lengths** (Tensor) - Tensor of shape $(B,)$. Data type is int32.

Outputs:

- **costs** (Tensor) - Tensor of shape $(B,)$. Data type is int32.
- **grads** (Tensor) - Has the same shape and dtype as *acts*.

Raises

- **TypeError** – If *acts*, *labels*, *input_lengths* or *label_lengths* is not a Tensor.
- **TypeError** – If dtype of *acts* is neither float16 nor float32.
- **TypeError** – If dtype of *labels*, *input_lengths* or *label_lengths* is not int32.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import ops, Tensor
>>> B, T, U, V = 1, 2, 3, 5
>>> blank = 0
>>> acts = np.random.random((B, T, U, V)).astype(np.float32)
>>> labels = np.array([[1, 2]]).astype(np.int32)
>>> input_length = np.array([T] * B).astype(np.int32)
>>> label_length = np.array([len(l) for l in labels]).astype(np.int32)
>>> rnnt_loss = ops.RNNTLoss(blank_label=0)
>>> costs, grads = rnnt_loss(Tensor(acts), Tensor(labels), Tensor(input_length),␣
↪Tensor(label_length))
>>> print(costs.shape)
(1,)
>>> print(grads.shape)
(1, 2, 3, 5)
```

mindspore.ops.SigmoidCrossEntropyWithLogits

class mindspore.ops.**SigmoidCrossEntropyWithLogits**

Uses the given logits to compute sigmoid cross entropy between the logits and the label.

Measures the distribution error in discrete classification tasks where each class is independent and not mutually exclusive using cross entropy loss.

Sets input logits as X, input label as Y, output as $loss$. Then,

$$
\begin{aligned}
p_{ij} &= sigmoid(X_{ij}) = \frac{1}{1+e^{-X_{ij}}} \\
loss_{ij} &= -[Y_{ij} * ln(p_{ij}) + (1 - Y_{ij})ln(1 - p_{ij})]
\end{aligned}
$$

Inputs:

- **logits** (Tensor) - Input logits. Tensor of shape $(N, *)$ where $*$ means any number of additional dimensions.
- **label** (Tensor) - Ground truth label. With the same shape and type as *logits*.

Outputs:

Tensor, with the same shape and type as input *logits*.

Raises

TypeError – If *logits* or *label* is not a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> logits = Tensor(np.array([[-0.8, 1.2, 0.7], [-0.1, -0.4, 0.7]]).astype(np.float32))
>>> labels = Tensor(np.array([[0.3, 0.8, 1.2], [-0.6, 0.1, 2.2]]).astype(np.float32))
>>> sigmoid = ops.SigmoidCrossEntropyWithLogits()
>>> output = sigmoid(logits, labels)
>>> print(output)
[[ 0.6111007   0.5032824   0.26318604]
 [ 0.58439666  0.5530153  -0.4368139 ]]
```

mindspore.ops.SmoothL1Loss

class mindspore.ops.**SmoothL1Loss**(*beta=1.0*, *reduction='none'*)

Calculate the smooth L1 loss, and the L1 loss function has robustness.

Refer to *mindspore.ops.smooth_l1_loss()* for more details.

> **Warning:** This API has poor performance on CPU and it is recommended to run it on the Ascend/GPU.

Parameters

- **beta** (*number, optional*) – A parameter used to control the point where the function will change between L1 to L2 loss. Default: `1.0`.
  - Ascend: The value should be equal to or greater than zero.
  - CPU/GPU: The value should be greater than zero.
- **reduction** (*str, optional*) – Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'none'`.
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **logits** (Tensor) - Input Tensor of any dimension. Supported dtypes:
  - Ascend: float16, float32, bfloat16.
  - CPU/GPU: float16, float32, float64.
- **labels** (Tensor) - Ground truth data.
  - CPU/Ascend: has the same shape as the *logits*, *logits* and *labels* comply with the implicit type conversion rules to make the data types consistent.
  - GPU: has the same shape and dtype as the *logits*.

Outputs:

Tensor, if *reduction* is `'none'`, then output is a tensor with the same shape as *logits*. Otherwise the shape of output tensor is ().

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> loss = ops.SmoothL1Loss()
>>> logits = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> labels = Tensor(np.array([1, 2, 2]), mindspore.float32)
>>> output = loss(logits, labels)
>>> print(output)
[0.  0.  0.5]
```

mindspore.ops.SoftMarginLoss

class mindspore.ops.**SoftMarginLoss**(*reduction='mean'*)

```
prim = ops.SoftMarginLoss(reduction)
out = prim(input, target)
```

is equivalent to

```
ops.soft_margin_loss(input, target, reduction)
```

Refer to *mindspore.ops.soft_margin_loss()* for more details.

mindspore.ops.SoftmaxCrossEntropyWithLogits

class mindspore.ops.**SoftmaxCrossEntropyWithLogits**

Gets the softmax cross-entropy value between logits and labels with one-hot encoding.

The updating formulas of SoftmaxCrossEntropyWithLogits algorithm are as follows,

$$p_{ij} = softmax(X_{ij}) = \frac{\exp(x_i)}{\sum_{j=0}^{N-1}\exp(x_j)}$$
$$loss_{ij} = -\sum_j Y_{ij} * ln(p_{ij})$$

where X represents *logits*. Y represents *label*. $loss$ represents *output*.

Inputs:

- **logits** (Tensor) - Input logits, with shape (N, C). Data type must be float16 or float32.
- **labels** (Tensor) - Ground truth labels, with shape (N, C), has the same data type with *logits*.

Outputs:

Tuple of 2 tensors(*loss* , *dlogits*), the *loss* shape is $(N,)$, and the *dlogits* with the same shape as *logits*.

Raises

- **TypeError** –If dtype of *logits* or *labels* is neither float16 nor float32.
- **TypeError** –If *logits* or *labels* is not a Tensor.
- **ValueError** –If shape of *logits* is not the same as *labels*.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> logits = Tensor([[2, 4, 1, 4, 5], [2, 1, 2, 4, 3]], mindspore.float32)
>>> labels = Tensor([[0, 0, 0, 0, 1], [0, 0, 0, 1, 0]], mindspore.float32)
>>> softmax_cross = ops.SoftmaxCrossEntropyWithLogits()
>>> loss, dlogits = softmax_cross(logits, labels)
>>> print(loss)
[0.5899297  0.52374405]
>>> print(dlogits)
[[ 0.02760027  0.20393994  0.01015357  0.20393994 -0.44563377]
 [ 0.08015892  0.02948882  0.08015892 -0.4077012   0.21789455]]
```

mindspore.ops.SparseSoftmaxCrossEntropyWithLogits

class mindspore.ops.**SparseSoftmaxCrossEntropyWithLogits**(*is_grad=False*)

Computes the softmax cross-entropy value between logits and sparse encoding labels.

Sets input logits as X, input label as Y, output as *loss*. The formula is as follows:

$$
\begin{aligned}
p_{ij} &= softmax(X_{ij}) = \frac{\exp(x_i)}{\sum_{j=0}^{N-1}\exp(x_j)} \\
loss_{ij} &= \begin{cases} -ln(p_{ij}), & j = y_i \\ 0, & j \neq y_i \end{cases} \\
loss &= \sum_{ij} loss_{ij}
\end{aligned}
$$

Parameters

is_grad (*bool, optional*) – If `True` , this operation returns the computed gradient. Default: `False` .

Inputs:

- **logits** (Tensor) - Input logits, with shape (N, C). Data type must be float16 or float32.
- **labels** (Tensor) - Ground truth labels, with shape (N). Data type must be int32 or int64.

Outputs:

Tensor, if *is_grad* is `False`, the output tensor is the value of loss; if *is_grad* is `True` , the output tensor is the gradient of input with the same shape as *logits*.

Raises

- **TypeError** – If *is_grad* is not a bool.
- **TypeError** – If dtype of *logits* is neither float16 nor float32.
- **TypeError** – If dtype of *labels* is neither int32 nor int64.
- **ValueError** – If $logits.shape[0] != labels.shape[0]$.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> logits = Tensor([[2, 3, 1, 4, 5], [2, 1, 2, 4, 3]], mindspore.float32)
>>> labels = Tensor([0, 1], mindspore.int32)
>>> sparse_softmax_cross = ops.SparseSoftmaxCrossEntropyWithLogits()
>>> loss = sparse_softmax_cross(logits, labels)
>>> print(loss)
3.4878292
>>> sparse_softmax_cross_grad = ops.SparseSoftmaxCrossEntropyWithLogits(is_grad=True)
>>> loss_grad = sparse_softmax_cross_grad(logits, labels)
>>> print(loss_grad)
[[-0.48415753  0.04306427  0.00582811  0.11706084  0.3182043 ]
 [ 0.04007946 -0.4852556   0.04007946  0.2961494   0.10894729]]
```

mindspore.ops.TripletMarginLoss

class mindspore.ops.**TripletMarginLoss**(*p=2*, *swap=False*, *eps=1e-6*, *reduction='mean'*)

TripletMarginLoss operation.

Creates a criterion that measures the triplet loss given an input tensors $x1$, $x2$, $x3$ and a margin with a value greater than 0. This is used for measuring a relative similarity between samples. A triplet is composed by a, p and n (i.e., *anchor*, *positive examples* and *negative examples* respectively). The shapes of all input tensors should be (N, D).

The distance swap is described in detail in the paper Learning local feature descriptors with triplets and shallow convolutional neural networks by V. Balntas, E. Riba et al.

The loss function for each sample in the mini-batch is:

$$L(a, p, n) = \max\{d(a_i, p_i) - d(a_i, n_i) + \text{margin}, 0\}$$

where

$$d(x_i, y_i) = \|\mathbf{x}_i - \mathbf{y}_i\|_p$$

Parameters

- **p** (*int, optional*) – The norm degree for pairwise distance. Default: `2`.
- **eps** (*float, optional*) – Default: `1e-6`.
- **swap** (*bool, optional*) – The distance swap. Default: `False`.
- **reduction** (*str, optional*) – Apply specific reduction method to the output: `'none'`, `'mean'`, `'sum'`. Default: `'mean'`.
  - `'none'`: no reduction will be applied.
  - `'mean'`: compute and return the mean of elements in the output.
  - `'sum'`: the output elements will be summed.

Inputs:

- **x** (Tensor) - A sample randomly selected from the training set. Data type must be BasicType.
- **positive** (Tensor) - A sample belonging to the same category as x, with the same type and shape as *x*.
- **negative** (Tensor) - A sample belonging to the different class from x, with the same type and shape as *x*.

- **margin** (Tensor) - Make a margin between the positive pair and the negative pair.

Outputs:

Union[Tensor, Scalar], if *reduction* is `"none"`, a Ten sor will be returned with a shape of (N). Otherwise, a scalar value will be returned.

Raises

- **TypeError** –If *x*, *positive*, *negative*, or *margin* is not a Tensor.
- **TypeError** –If dtype of *x*, *positive*, or *negative* is not BasicType.
- **TypeError** –If dtypes of *x*, *positive* and *negative* are not the same.
- **TypeError** –If *margin* is not float32.
- **TypeError** –If *p* is not an int.
- **TypeError** –If *eps* is not a float.
- **TypeError** –If *swap* is not a bool.
- **ValueError** –If dimensions of input *x*, *positive* and *negative* are less than or equal to 1 at the same time.
- **ValueError** –If the dimension of input *x* or *positive* or *negative* is bigger than or equal to 8.
- **ValueError** –If length of shape of *margin* is not 0.
- **ValueError** –If shapes of *x*, *positive* and *negative* cannot broadcast.
- **ValueError** –If *reduction* is not one of `'none'`, `'mean'`, `'sum'`.

Supported Platforms:

`GPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> loss = ops.TripletMarginLoss()
>>> x = Tensor(np.array([[0.3, 0.7], [0.5, 0.5]]), mindspore.float32)
>>> positive = Tensor(np.array([[0.4, 0.6], [0.4, 0.6]]), mindspore.float32)
>>> negative = Tensor(np.array([[0.2, 0.9], [0.3, 0.7]]), mindspore.float32)
>>> margin = Tensor(1.0, mindspore.float32)
>>> output = loss(x, positive, negative, margin)
>>> print(output)
0.8881968
```

mindspore.ops.CeLU

class mindspore.ops.**CeLU**(*alpha=1.0*)

```
prim = ops.CeLU(alpha)
out = prim(x)
```

is equivalent to

```
ops.celu(x, alpha)
```

Refer to *mindspore.ops.celu()* for more details.

mindspore.ops.Elu

class mindspore.ops.**Elu**(*alpha=1.0*)

```
prim = ops.Elu(alpha)
out = prim(input_x)
```

is equivalent to

```
ops.elu(input_x, alpha)
```

Refer to *mindspore.ops.elu()* for more details.

mindspore.ops.FastGeLU

class mindspore.ops.**FastGeLU**

```
prim = ops.FastGeLU()
out = prim(x)
```

is equivalent to

```
ops.fast_gelu(x)
```

Refer to *mindspore.ops.fast_gelu()* for more details.

mindspore.ops.GeLU

class mindspore.ops.**GeLU**

Gaussian Error Linear Units activation function.

GeLU is described in the paper Gaussian Error Linear Units (GELUs). Or refer to BERT: Pre-training of Deep Bidirectional Transformers for Language Understanding for more details.

GeLU is defined as follows:

$$GELU(x_i) = x_i * P(X < x_i)$$

where P is the cumulative distribution function of the standard Gaussian distribution, x_i is the input element.

Note: When calculating the input gradient of GELU with an input value of infinity, there are differences in the output of the backward between 'Ascend' and 'GPU'. when x is -inf, the computation result of 'Ascend' is 0, and the computation result of 'GPU'

is Nan. when x is inf, the computation result of 'Ascend' is dy, and the computation result of 'GPU' is Nan. In mathematical terms, Ascend's result has higher precision.

Inputs:

- **x** (Tensor) - The input of the activation function GeLU, the data type is float16, float32 or float64.

Outputs:

Tensor, with the same type and shape as *x*.

Raises

- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If dtype of *x* is not float16, float32 or float64.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([1.0, 2.0, 3.0]), mindspore.float32)
>>> result = ops.GeLU()(x)
>>> print(result)
[0.841192  1.9545976  2.9963627]
```

mindspore.ops.GLU

class mindspore.ops.**GLU**(*axis=-1*)

Computes GLU (Gated Linear Unit activation function) of the input tensor.

$$GLU(a, b) = a \otimes \sigma(b)$$

where a is the first half of the x Tensor after x is split and b is the second half.

Here σ is the sigmoid function, and $\otimes$ is the Hadamard product. See Language Modeling with Gated Convluational Networks .

Parameters

axis (*int, optional*) – Axis to split the input *x*. The value range is *[-r, r)* where *r* is the number of dimensions of *x*. Default: `-1` , the last dimension in *x*.

Inputs:

- **x** (Tensor) - Tensor to be calculated. Dtype is floating point and the shape is $(*_1, N, *_2)$ where * means, any number of additional dimensions. N is required to be an even number, where N is the size of x on the dimension selected by *axis*.

Outputs:

Tensor, the same dtype as *x*, with the shape $(*_1, M, *_2)$ where $M = N/2$.

Raises

- **TypeError** –If *x* is not a Tensor or *axis* is not an int.
- **IndexError** –If the value of *axis* is out of the range of *[-r, r)*, where *r* is the number of dimensions of *x*.
- **RuntimeError** –If dtype of *x* is not supported.
- **RuntimeError** –If the length of *x* in the dimension selected by *axis* is not even.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> from mindspore import ops, Tensor
>>> from mindspore import dtype as mstype
>>> import numpy as np
>>> axis = 0
>>> x = Tensor(np.array([0.3220, 0.9545, 0.7879, 0.0975, 0.3698,
...                      0.5135, 0.5740, 0.3435, 0.1895, 0.8764,
...                      0.4980, 0.9673, 0.9879, 0.6988, 0.9022,
...                      0.9304, 0.1558, 0.0153, 0.1559, 0.9852]).reshape([2, 2, 5]),␣
↪mstype.float32)
>>> glu = ops.GLU(axis=axis)
>>> y = glu(x)
>>> print(y)
[[[0.20028052 0.6916126  0.57412136 0.06512236 0.26307625]
  [0.3682598  0.3093122  0.17306386 0.10212085 0.63814086]]]
```

mindspore.ops.HShrink

class mindspore.ops.**HShrink**(*lambd=0.5*)

```
prim = ops.HShrink(lambd)
out = prim(input)
```

is equivalent to

```
ops.hardshrink(input, lambd)
```

Refer to *mindspore.ops.hardshrink()* for more details.

mindspore.ops.HSigmoid

class mindspore.ops.**HSigmoid**

```
prim = ops.HSigmoid()
out = prim(input)
```

is equivalent to

```
ops.hardsigmoid(input)
```

Refer to *mindspore.ops.hardsigmoid()* for more details.

mindspore.ops.HSwish

class mindspore.ops.**HSwish**

```
prim = ops.HSwish()
out = prim(input)
```

is equivalent to

```
ops.hardswish(input)
```

Refer to *mindspore.ops.hardswish()* for more details.

mindspore.ops.LogSoftmax

class mindspore.ops.**LogSoftmax**(*axis=-1*)

```
prim = ops.LogSoftmax(axis)
out = prim(logits)
```

is equivalent to

```
ops.log_softmax(logits, axis)
```

Refer to *mindspore.ops.log_softmax()* for more details.

mindspore.ops.Mish

class mindspore.ops.**Mish**

Computes MISH(A Self Regularized Non-Monotonic Neural Activation Function) of input tensors element-wise.

Refer to *mindspore.ops.mish()* for more details.

Inputs:

- **x** (Tensor) - The input Tensor. Supported dtypes:
  - GPU/CPU: float16, float32, float64.
  - Ascend: float16, float32.

Outputs:

Tensor, with the same type and shape as the *x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> mish = ops.Mish()
>>> output = mish(x)
>>> print(output.shape)
(2, 3)
>>> x = Tensor(2.1, mindspore.float32)
>>> output = mish(x)
>>> print(output)
2.050599
```

mindspore.ops.PReLU

class mindspore.ops.**PReLU**

```
prim = ops.PReLU()
out = prim(input, weight)
```

is equivalent to

```
ops.prelu(input, weight)
```

Refer to *mindspore.ops.prelu()* for more details.

mindspore.ops.ReLU

class mindspore.ops.**ReLU**

```
prim = ops.ReLU()
out = prim(input)
```

is equivalent to

```
ops.relu(input)
```

Refer to *mindspore.ops.relu()* for more details.

mindspore.ops.ReLU6

class mindspore.ops.**ReLU6**

```
prim = ops.ReLU6()
out = prim(x)
```

is equivalent to

```
ops.relu6(x)
```

Refer to *mindspore.ops.relu6()* for more details.

mindspore.ops.SeLU

class mindspore.ops.**SeLU**

Activation function SeLU (Scaled exponential Linear Unit).

The activation function is defined as:

$$E_i = scale * \begin{cases} x_i, & \text{if } x_i \geq 0; \\ \text{alpha} * (\exp(x_i) - 1), & \text{otherwise.} \end{cases}$$

where $alpha$ and $scale$ are pre-defined constants($alpha = 1.67326324$ and $scale = 1.05070098$).

See more details in Self-Normalizing Neural Networks.

Inputs:

- **input_x** (Tensor) - Tensor of any dimension. The data type is int8, int32, float16, float32, float64(only CPU, GPU).

Outputs:

Tensor, with the same type and shape as the *input_x*.

Raises

TypeError – If dtype of *input_x* is not int8, int32, float16, float32, float64.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[-1.0, 4.0, -8.0], [2.0, -5.0, 9.0]]), mindspore.float32)
>>> selu = ops.SeLU()
>>> output = selu(input_x)
>>> print(output)
[[-1.1113307 4.202804 -1.7575096]
 [ 2.101402 -1.7462534 9.456309 ]]
```

mindspore.ops.Sigmoid

class mindspore.ops.**Sigmoid**

```
prim = ops.Sigmoid()
out = prim(input)
```

is equivalent to

```
ops.sigmoid(input)
```

Refer to *mindspore.ops.sigmoid()* for more details.

mindspore.ops.Softmax

class mindspore.ops.**Softmax**(*axis=-1*)

Applies the Softmax operation to the input tensor on the specified axis.

Refer to *mindspore.ops.softmax()* for more details.

Parameters

axis (*Union[int, tuple], optional*) – The axis to perform the Softmax operation. Default: `-1` .

Inputs:

- **input** (Tensor) - Tensor of shape $(N, *)$, where $*$ means, any number of additional dimensions.

Outputs:

Tensor, with the same type and shape as the input.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> softmax = ops.Softmax()
>>> output = softmax(input)
>>> print(output)
[0.01165623 0.03168492 0.08612854 0.23412167 0.6364086 ]
```

mindspore.ops.Softplus

class mindspore.ops.**Softplus**

Softplus activation function.

Softplus is a smooth approximation to the ReLU function. It can be used to constrain the output of a machine to always be positive. The function is shown as follows:

$$\text{output} = \log(1 + \exp(x))$$

Inputs:

- **input_x** (Tensor) - Tensor of any dimension. Supported dtypes:
  - GPU/CPU: float16, float32, float64.
  - Ascend: float16, float32.

Outputs:

Tensor, with the same type and shape as the *input_x*.

Raises

- **TypeError** – If *input_x* is not a Tensor.

- **TypeError** – If the dtype of *input_x* is not float16, float32 or float64.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([1, 2, 3, 4, 5]), mindspore.float32)
>>> softplus = ops.Softplus()
>>> output = softplus(input_x)
>>> print(output)
[1.3132615 2.126928  3.0485873 4.01815   5.0067153]
```

mindspore.ops.SoftShrink

class mindspore.ops.**SoftShrink**(*lambd=0.5*)

```
prim = ops.SoftShrink(lambd)
out = prim(input)
```

is equivalent to

```
ops.softshrink(input, lambd)
```

Refer to *mindspore.ops.softshrink()* for more details.

mindspore.ops.Softsign

class mindspore.ops.**Softsign**

Softsign activation function.

Refer to *mindspore.ops.softsign()* for more details.

Inputs:

- **input_x** (Tensor) - Tensor of shape $(N, *)$, where $*$ means, any number of additional dimensions, with float16 or float32 data type.

Outputs:

Tensor, with the same type and shape as the *input_x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([0, -1, 2, 30, -30]), mindspore.float32)
>>> softsign = ops.Softsign()
>>> output = softsign(input_x)
>>> print(output)
[ 0.        -0.5         0.6666667  0.9677419 -0.9677419]
```

mindspore.ops.Tanh

class mindspore.ops.**Tanh**

```
prim = ops.Tanh()
out = prim(input)
```

is equivalent to

```
ops.tanh(input)
```

Refer to *mindspore.ops.tanh()* for more details.

18.2.4 Optimizer

API Name	Description	Supported Platforms
mindspore.ops.Adam	Updates gradients by the Adaptive Moment Estimation (Adam) algorithm.	Ascend GPU CPU
mindspore.ops.AdamWeightDecay	Updates gradients by the Adaptive Moment Estimation algorithm with weight decay (AdamWeightDecay).	Ascend GPU CPU
mindspore.ops.AdaptiveAvgPool2D	AdaptiveAvgPool2D operation.	Ascend GPU CPU
mindspore.ops.AdaptiveAvgPool3D	AdaptiveAvgPool3D operation.	Ascend GPU CPU
mindspore.ops.ApplyAdadelta	Updates relevant entries according to the adadelta scheme.	Ascend GPU CPU
mindspore.ops.ApplyAdagrad	Updates relevant entries according to the adagrad scheme.	Ascend GPU CPU
mindspore.ops.ApplyAdagradDA	Update *var* according to the proximal adagrad scheme.	Ascend GPU CPU
mindspore.ops.ApplyAdagradV2	Updates relevant entries according to the adagradv2 scheme.	Ascend GPU CPU
mindspore.ops.ApplyAdaMax	Updates relevant entries according to the adamax scheme.	Ascend GPU CPU
mindspore.ops.ApplyAdamWithAmsgradV2	Update var according to the Adam algorithm.	Ascend GPU CPU
mindspore.ops.ApplyAddSign	Updates relevant entries according to the AddSign algorithm.	Ascend GPU CPU
mindspore.ops.ApplyCenteredRMSProp	Optimizer that implements the centered RMSProp algorithm.	Ascend GPU CPU

continues on next page

Table 5 – continued from previous page

mindspore.ops.ApplyFtrl	Updates relevant entries according to the FTRL scheme.	Ascend GPU CPU
mindspore.ops.ApplyGradientDescent	Updates *var* by subtracting *alpha* * *delta* from it.	Ascend GPU CPU
mindspore.ops.ApplyMomentum	Optimizer that implements the Momentum algorithm.	Ascend GPU CPU
mindspore.ops.ApplyPowerSign	Updates relevant entries according to the AddSign algorithm.	Ascend GPU CPU
mindspore.ops.ApplyProximalAdagrad	Updates relevant entries according to the proximal adagrad algorithm.	Ascend GPU CPU
mindspore.ops.ApplyProximalGradientDescent	Updates relevant entries according to the FOBOS(Forward Backward Splitting) algorithm.	Ascend GPU CPU
mindspore.ops.ApplyRMSProp	Optimizer that implements the Root Mean Square prop(RMSProp) algorithm.	Ascend GPU CPU
mindspore.ops.LARSUpdate	Conducts LARS (layer-wise adaptive rate scaling) update on the sum of squares of gradient.	Ascend
mindspore.ops.SparseApplyAdagradV2	Updates relevant entries according to the adagrad scheme, one more epsilon attribute than SparseApplyAdagrad.	Ascend GPU CPU
mindspore.ops.SparseApplyProximalAdagrad	Updates relevant entries according to the proximal adagrad algorithm.	Ascend GPU
mindspore.ops.SGD	Computes the stochastic gradient descent.	Ascend GPU CPU
mindspore.ops.SparseApplyFtrl	Updates relevant entries according to the FTRL-proximal scheme For more details, please refer to *mindspore.nn.FTRL*.	Ascend GPU CPU
mindspore.ops.SparseApplyFtrlV2	The SparseApplyFtrlV2 interface is deprecated, please use the *mindspore.ops.SparseApplyFtrl* instead.	Deprecated

mindspore.ops.Adam

class mindspore.ops.**Adam**(*use_locking=False*, *use_nesterov=False*)

Updates gradients by the Adaptive Moment Estimation (Adam) algorithm.

The Adam algorithm is proposed in Adam: A Method for Stochastic Optimization.

For more details, please refer to *mindspore.nn.Adam*.

The updating formulas are as follows,

$$
\begin{aligned}
m &= \beta_1 * m + (1 - \beta_1) * g \\
v &= \beta_2 * v + (1 - \beta_2) * g * g \\
l &= \alpha * \frac{\sqrt{1-\beta_2^t}}{1-\beta_1^t} \\
w &= w - l * \frac{m}{\sqrt{v}+\epsilon}
\end{aligned}
$$

m represents the 1st moment vector, v represents the 2nd moment vector, g represents *gradient*, l represents scaling factor lr, β_1, β_2 represent *beta1* and *beta2*, t represents updating step while $beta_1^t(\beta_1^t)$ and $beta_2^t(\beta_2^t)$ represent *beta1_power* and *beta2_power*, α represents *learning_rate*, w represents *var*, ϵ represents *epsilon*.

Inputs of *var*, *m*, *v* and *gradient* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Parameters

- **use_locking** (*bool*) –Whether to enable a lock to protect variable tensors from being updated. If `True` , updates of the var, m, and v tensors will be protected by a lock. If `False` , the result is unpredictable. Default: `False` .
- **use_nesterov** (*bool*) –Whether to use Nesterov Accelerated Gradient (NAG) algorithm to update the gradients. If `True` , update the gradients using NAG. If `False` , update the gradients without using NAG. Default: `False` .

Inputs:

- **var** (Union[Parameter, Tensor]) - Weights to be updated. The shape is $(N, *)$ where $*$ means, any number of additional dimensions. The data type can be float16 or float32.
- **m** (Union[Parameter, Tensor]) - The 1st moment vector in the updating formula, the shape should be the same as *var*.
- **v** (Union[Parameter, Tensor]) - the 2nd moment vector in the updating formula, the shape should be the same as *var*.
- **beta1_power** (float) - $beta_1^t(\beta_1^t)$ in the updating formula.
- **beta2_power** (float) - $beta_2^t(\beta_2^t)$ in the updating formula.
- **lr** (float) - l in the updating formula. The paper suggested value is 10^{-8}.
- **beta1** (float) - The exponential decay rate for the 1st moment estimations. The paper suggested value is 0.9.
- **beta2** (float) - The exponential decay rate for the 2nd moment estimations. The paper suggested value is 0.999.
- **epsilon** (float) - Term added to the denominator to improve numerical stability.
- **gradient** (Tensor) - Gradient, has the same shape and data type as *var*.

Outputs:

Tuple of 3 Tensor, the updated parameters.

- **var** (Tensor) - The same shape and data type as Inputs *var*.
- **m** (Tensor) - The same shape and data type as Inputs *m*.
- **v** (Tensor) - The same shape and data type as Inputs *v*.

Raises

- **TypeError** –If neither *use_locking* nor *use_nesterov* is a bool.
- **TypeError** –If *var*, *m* or *v* is not a Parameter.
- **TypeError** –If *beta1_power*, *beta2_power1*, *lr*, *beta1*, *beta2*, *epsilon* or *gradient* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops
>>> from mindspore import Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_adam = ops.Adam()
...         self.var = Parameter(Tensor(np.ones([2, 2]).astype(np.float32)), name="var")
...         self.m = Parameter(Tensor(np.ones([2, 2]).astype(np.float32)), name="m")
```

(continues on next page)

(continued from previous page)

```
...         self.v = Parameter(Tensor(np.ones([2, 2]).astype(np.float32)), name="v")
...     def construct(self, beta1_power, beta2_power, lr, beta1, beta2, epsilon, grad):
...         out = self.apply_adam(self.var, self.m, self.v, beta1_power, beta2_power, lr,␣
↪beta1, beta2,
...                               epsilon, grad)
...         return out
...
>>> net = Net()
>>> gradient = Tensor(np.ones([2, 2]).astype(np.float32))
>>> output = net(0.9, 0.999, 0.001, 0.9, 0.999, 1e-8, gradient)
>>> print(net.var.asnumpy())
[[0.9996838 0.9996838]
 [0.9996838 0.9996838]]
```

mindspore.ops.AdamWeightDecay

class mindspore.ops.**AdamWeightDecay**(*use_locking=False*)

Updates gradients by the Adaptive Moment Estimation algorithm with weight decay (AdamWeightDecay).

The Adam algorithm is proposed in Adam: A Method for Stochastic Optimization. The AdamWeightDecay variant was proposed in Decoupled Weight Decay Regularization.

The updating formulas are as follows,

$$
\begin{aligned}
m &= \beta_1 * m + (1 - \beta_1) * g \\
v &= \beta_2 * v + (1 - \beta_2) * g * g \\
update &= \frac{m}{\sqrt{v} + \epsilon} \\
update &= \begin{cases} update + weight\_decay * w & \text{if } weight\_decay > 0 \\ update & \text{otherwise} \end{cases} \\
w &= w - lr * update
\end{aligned}
$$

m represents the 1st moment vector, v represents the 2nd moment vector, g represents *gradient*, β_1, β_2 represent *beta1* and *beta2*, lr represents *learning_rate*, w represents *var*, $decay$ represents *weight_decay*, ϵ represents *epsilon*.

Parameters

use_locking (*bool*) – Whether to enable a lock to protect variable tensors from being updated. If `True` , updates of the var, m, and v tensors will be protected by a lock. If `False` , the result is unpredictable. Default: `False` .

Inputs:

- **var** (Union[Parameter, Tensor]) - Weights to be updated. The shape is $(N, *)$ where $*$ means any number of additional dimensions. The data type can be float16 or float32.
- **m** (Union[Parameter, Tensor]) - The 1st moment vector in the updating formula, it should have the the shape as *var*. The data type can be float16 or float32.
- **v** (Union[Parameter, Tensor]) - The 2nd moment vector in the updating formula, it should have the same shape as m.
- **lr** (float) - lr in the updating formula. The paper suggested value is 10^{-8}, the data type should be float32.
- **beta1** (float) - The exponential decay rate for the 1st moment estimations, the data type should be float32. The paper suggested value is 0.9
- **beta2** (float) - The exponential decay rate for the 2nd moment estimations, the data type should be float32. The paper suggested value is 0.999

- **epsilon** (float) - Term added to the denominator to improve numerical stability, the data type should be float32.
- **decay** (float) - The weight decay value, must be a scalar tensor with float32 data type. Default: `0.0`.
- **gradient** (Tensor) - Gradient, has the same shape as *var*.

Outputs:

Tuple of 3 Tensor, the updated parameters.

- **var** (Tensor) - The same shape and data type as *var*.
- **m** (Tensor) - The same shape and data type as *m*.
- **v** (Tensor) - The same shape and data type as *v*.

Raises

- **TypeError** – If *use_locking* is not a bool.
- **TypeError** – If *lr*, *beta1*, *beta2*, *epsilon* or *decay* is not a float32.
- **TypeError** – If *var*, *m* or *v* is neither float16 nor float32.
- **TypeError** – If *gradient* is not a Tensor.
- **ValueError** – If *epsilon* <= 0.
- **ValueError** – If *beta1*, *beta2* is not in range (0.0,1.0).
- **ValueError** – If *decay* < 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore.nn as nn
>>> from mindspore import Tensor, Parameter, ops
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.adam_weight_decay = ops.AdamWeightDecay()
...         self.var = Parameter(Tensor(np.ones([2, 2]).astype(np.float32)), name="var")
...         self.m = Parameter(Tensor(np.ones([2, 2]).astype(np.float32)), name="m")
...         self.v = Parameter(Tensor(np.ones([2, 2]).astype(np.float32)), name="v")
...     def construct(self, lr, beta1, beta2, epsilon, decay, grad):
...         out = self.adam_weight_decay(self.var, self.m, self.v, lr, beta1, beta2,
...                                      epsilon, decay, grad)
...         return out
>>> net = Net()
>>> gradient = Tensor(np.ones([2, 2]).astype(np.float32))
>>> output = net(0.001, 0.9, 0.999, 1e-8, 0.0, gradient)
>>> print(net.var.asnumpy())
[[0.999 0.999]
[0.999 0.999]]
```

mindspore.ops.AdaptiveAvgPool2D

class mindspore.ops.**AdaptiveAvgPool2D**(*output_size*)

AdaptiveAvgPool2D operation.

Refer to *mindspore.ops.adaptive_avg_pool2d()* for more details.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

output_size (*Union[int, tuple]*) –The target output size. *output_size* can be a tuple (H, W), or an int H for (H, H). H and W can be int or None. If it is None, it means the output size is the same as the input size.

Inputs:

- **input_x** (Tensor) - The input of AdaptiveAvgPool2D, which is a 3D or 4D tensor, with float16 ,float32 or float64 data type.

Outputs:

Tensor, with the same type as the *input_x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> # case 1: output_size=(None, 2)
>>> input_x = Tensor(np.array([[[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]],
...                            [[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]],
...                            [[1.0, 2.0, 3.0], [4.0, 5.0, 6.0], [7.0, 8.0, 9.0]]]),␣
↪mindspore.float32)
>>> adaptive_avg_pool_2d = ops.AdaptiveAvgPool2D((None, 2))
>>> output = adaptive_avg_pool_2d(input_x)
>>> print(output)
[[[1.5 2.5]
  [4.5 5.5]
  [7.5 8.5]]
 [[1.5 2.5]
  [4.5 5.5]
  [7.5 8.5]]
 [[1.5 2.5]
  [4.5 5.5]
  [7.5 8.5]]]
>>> # case 2: output_size=2
>>> adaptive_avg_pool_2d = ops.AdaptiveAvgPool2D(2)
>>> output = adaptive_avg_pool_2d(input_x)
>>> print(output)
[[[3. 4.]
  [6. 7.]]
 [[3. 4.]
```

(continues on next page)

(continued from previous page)

```
  [6. 7.]]
 [[3. 4.]
  [6. 7.]]]
>>> # case 3: output_size=(1, 2)
>>> adaptive_avg_pool_2d = ops.AdaptiveAvgPool2D((1, 2))

>>> print(output)
[[[4.5 5.5]]
 [[4.5 5.5]]
 [[4.5 5.5]]]
```

mindspore.ops.AdaptiveAvgPool3D

class mindspore.ops.**AdaptiveAvgPool3D**(*output_size*)

AdaptiveAvgPool3D operation.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.adaptive_avg_pool3d()* for more details.

Parameters

output_size (*Union[int, tuple]*) – Specify the size of output tensor. It can be a single int or a tuple of three ints.

Inputs:

- **x** (Tensor) - The input of AdaptiveAvgPool3D, which is a 5D or 4D tensor.

Outputs:

Tensor, with the same type as the *x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import nn, Tensor
>>> from mindspore.ops import AdaptiveAvgPool3D
>>> class AdaptiveAvgPool3DNet(nn.Cell):
...     def __init__(self, output_size):
...         super(AdaptiveAvgPool3DNet, self).__init__()
...         self.output_size_ = output_size
...         self.adaptive_avg_pool_3d = AdaptiveAvgPool3D(self.output_size_)
...     def construct(self, x_):
...         return self.adaptive_avg_pool_3d(x_)
...
>>> output_size=(1,1,1)
>>> input_x_val = np.zeros((1,1,2,2,2))
>>> input_x_val[:,:,0,:,:]  += 1
>>> input_x = Tensor(input_x_val, mindspore.float32)
```

(continues on next page)

(continued from previous page)

```
>>> adaptive_avg_pool_3d = AdaptiveAvgPool3DNet(output_size)
>>> output = adaptive_avg_pool_3d(input_x)
>>> print(output)
[[[[[0.5]]]]]
```

mindspore.ops.ApplyAdadelta

class mindspore.ops.**ApplyAdadelta**

Updates relevant entries according to the adadelta scheme.

The Adadelta algorithm is proposed in ADADELTA: AN ADAPTIVE LEARNING RATE METHOD.

$$
\begin{aligned}
\text{accum} &= \rho * \text{accum} + (1 - \rho) * \text{grad}^2 \\
\text{update} &= \sqrt{\text{accum\_update} + \epsilon} * \frac{\text{grad}}{\sqrt{\text{accum} + \epsilon}} \\
\text{accum\_update} &= \rho * \text{accum\_update} + (1 - \rho) * \text{update}^2 \\
\text{var} &= \text{var} - \text{lr} * \text{update}
\end{aligned}
$$

where ρ represents *rho*, ϵ represents *epsilon*.

Inputs of *var*, *accum*, *accum_update* and *grad* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Inputs:

- **var** (Union[Parameter, Tensor]) - Weights to be updated. With float32 or float16 data type. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **accum** (Union[Parameter, Tensor]) - Accumulation to be updated, has the same shape and data type as *var*.
- **accum_update** (Union[Parameter, Tensor]) - Accum_update to be updated, has the same shape and data type as *var*.
- **lr** (Union[Number, Tensor]) - Learning rate, must be a scalar. With float32 or float16 data type.
- **rho** (Union[Number, Tensor]) - Decay rate, must be a scalar. With float32 or float16 data type.
- **epsilon** (Union[Number, Tensor]) - A small value added for numerical stability, must be a scalar. With float32 or float16 data type.
- **grad** (Tensor) - Gradients, has the same shape and data type as *var*.

Outputs:

Tuple of 3 Tensor, the updated parameters or tensors.

- **var** (Tensor) - The same shape and data type as *var*.
- **accum** (Tensor) - The same shape and data type as *accum*.
- **accum_update** (Tensor) - The same shape and data type as *accum_update*.

Raises

- **TypeError** – If dtype of *var*, *accum*, *accum_update*, *lr*, *rho*, *epsilon* or *grad* is neither float16 nor float32.
- **TypeError** – If *accum_update*, *lr*, *rho* or *epsilon* is neither a Number nor a Tensor.
- **TypeError** – If the data type of *var*, *accum*, *accum_update* and *grad* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import nn, Tensor, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_adadelta = ops.ApplyAdadelta()
...         self.var = Parameter(Tensor(np.array([[0.6, 0.4],
...                                               [0.1, 0.5]]).astype(np.float32)), name="var
 ↪")
...         self.accum = Parameter(Tensor(np.array([[0.6, 0.5],
...                                                 [0.2, 0.6]]).astype(np.float32)), name=
 ↪"accum")
...         self.accum_update = Parameter(Tensor(np.array([[0.9, 0.1],
...                                                        [0.7, 0.8]]).astype(np.float32)),
...                                       name="accum_update")
...     def construct(self, lr, rho, epsilon, grad):
...         out = self.apply_adadelta(self.var, self.accum, self.accum_update, lr, rho,␣
 ↪epsilon, grad)
...         return out
...
>>> net = Net()
>>> lr = Tensor(0.001, mindspore.float32)
>>> rho = Tensor(0.0, mindspore.float32)
>>> epsilon = Tensor(1e-6, mindspore.float32)
>>> grad = Tensor(np.array([[0.3, 0.7], [0.1, 0.8]]).astype(np.float32))
>>> output = net(lr, rho, epsilon, grad)
>>> print(output)
(Tensor(shape=[2, 2], dtype=Float32, value=
[[ 5.99051356e-01,  3.99683774e-01],
 [ 9.91633832e-02,  4.99105573e-01]]), Tensor(shape=[2, 2], dtype=Float32, value=
[[ 9.00000036e-02,  4.89999980e-01],
 [ 1.00000007e-02,  6.40000045e-01]]), Tensor(shape=[2, 2], dtype=Float32, value=
[[ 8.99990857e-01,  1.00000791e-01],
 [ 6.99930906e-01,  7.99999774e-01]]))
```

mindspore.ops.ApplyAdagrad

class mindspore.ops.**ApplyAdagrad**(*update_slots=True*)

Updates relevant entries according to the adagrad scheme. The Adagrad algorithm was proposed in Adaptive Subgradient Methods for Online Learning and Stochastic Optimization. This module can adaptively assign different learning rates for each parameter in view of the uneven number of samples for different parameters.

$$
\begin{aligned}
accum &+= grad * grad \\
var &-= lr * grad * \frac{1}{\sqrt{accum}}
\end{aligned}
$$

Inputs of *var*, *accum* and *grad* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Parameters

update_slots (*bool*) – If `True` , *accum* will be updated. Default: `True` .

Inputs:

- **var** (Union[Parameter, Tensor]) - Variable to be updated. With float or complex data type. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **accum** (Union[Parameter, Tensor]) - Accumulation to be updated. The shape must be the same as *var*.
- **lr** (Union[Number, Tensor]) - The learning rate value, must be a scalar. With float or complex data type.
- **grad** (Tensor) - A tensor for gradient. The shape must be the same as *var*.

Outputs:

Tuple of 2 Tensors, the updated parameters or tensors.

- **var** (Tensor) - The same shape and data type as *var*.
- **accum** (Tensor) - The same shape and data type as *accum*.

Raises

- **TypeError** –If dtype of *var*, *accum*, *lr* or *grad* is neither float nor complex.
- **TypeError** –If *lr* is neither a Number nor a Tensor.
- **TypeError** –If the data type of *var*, *accum* and *grad* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_adagrad = ops.ApplyAdagrad()
...         self.var = Parameter(Tensor(np.array([[0.6, 0.4],
...                                               [0.1, 0.5]]).astype(np.float32)), name="var
↪")
...         self.accum = Parameter(Tensor(np.array([[0.6, 0.5],
...                                                 [0.2, 0.6]]).astype(np.float32)), name=
↪"accum")
...     def construct(self, lr, grad):
...         out = self.apply_adagrad(self.var, self.accum, lr, grad)
...         return out
...
>>> net = Net()
>>> lr = Tensor(0.001, mindspore.float32)
>>> grad = Tensor(np.array([[0.3, 0.7], [0.1, 0.8]]).astype(np.float32))
>>> output = net(lr, grad)
>>> print(output)
(Tensor(shape=[2, 2], dtype=Float32, value=
[[ 5.99638879e-01,  3.99296492e-01],
 [ 9.97817814e-02,  4.99281585e-01]]), Tensor(shape=[2, 2], dtype=Float32, value=
[[ 6.90000057e-01,  9.90000010e-01],
 [ 2.10000008e-01,  1.24000001e+00]]))
```

mindspore.ops.ApplyAdagradDA

class mindspore.ops.**ApplyAdagradDA**(*use_locking=False*)

Update *var* according to the proximal adagrad scheme. The Adagrad algorithm was proposed in Adaptive Subgradient Methods for Online Learning and Stochastic Optimization.

$$
\begin{aligned}
&grad\_accum+ = grad\\
&grad\_squared\_accum+ = grad * grad\\
&tmp\_val = \begin{cases} sign(grad\_accum) * max\left\{|grad\_accum| - l1 * global\_step, 0\right\} & \text{if } l1 > 0\\ grad\_accum & \text{otherwise} \end{cases}\\
&x\_value = -1 * lr * tmp\_val\\
&y\_value = l2 * global\_step * lr + \sqrt{grad\_squared\_accum}\\
&var = \frac{x\_value}{y\_value}
\end{aligned}
$$

Inputs of *var*, *gradient_accumulator*, *gradient_squared_accumulator* and *grad* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Parameters

use_locking (*bool*) – If `True` , updating of the *var* and *accum* tensors will be protected by a lock. Otherwise the behavior is undefined, but may exhibit less contention. Default: `False` .

Inputs:

- **var** (Union[Parameter, Tensor]) - Variable to be updated. The data type must be float16 or float32. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **gradient_accumulator** (Union[Parameter, Tensor]) - The dict of mutable tensor $grad\_accum$. Must have the same shape as *var*.
- **gradient_squared_accumulator** (Union[Parameter, Tensor]) - The dict of mutable tensor $grad\_squared\_accum$. Must have the same shape as *var*.
- **grad** (Tensor) - A tensor for gradient. Must have the same shape as *var*.
- **lr** ([Number, Tensor]) - Scaling factor. Must be a scalar. With float32 or float16 data type.
- **l1** ([Number, Tensor]) - L1 regularization. Must be a scalar. With float32 or float16 data type.
- **l2** ([Number, Tensor]) - L2 regularization. Must be a scalar. With float32 or float16 data type.
- **global_step** ([Number, Tensor]) - Training step number. Must be a scalar. With int32 or int64 data type.

Outputs:

Tuple of 1 Tensors, the updated parameters or tensors.

- **var** (Tensor) - The same shape and data type as *var*.

Raises

- **TypeError** – If *var*, *gradient_accumulator* or *gradient_squared_accumulator* neither a Parameter nor a Tensor.
- **TypeError** – If *grad* is not a Tensor.
- **TypeError** – If *lr*, *l1*, *l2* or *global_step* is neither a Number nor a Tensor.
- **TypeError** – If use_locking is not a bool.
- **TypeError** – If dtype of *var*, *gradient_accumulator*, *gradient_squared_accumulator*, *grad*, *lr*, *l1* or *l2* is neither float16 nor float32.

- **TypeError** –If dtype of *gradient_accumulator*, *gradient_squared_accumulator* or *grad* is not same as *var*.
- **TypeError** –If dtype of *global_step* is not int32 nor int64.
- **ValueError** –If the shape size of *lr*, *l1*, *l2* and *global_step* is not 0.
- **TypeError** –If the data type of *var*, *gradient_accumulator*, *gradient_squared_accumulator* and *grad* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class ApplyAdagradDANet(nn.Cell):
...     def __init__(self, use_locking=False):

...     def construct(self, grad, lr, l1, l2, global_step):
...         out = self.apply_adagrad_d_a(self.var, self.gradient_accumulator,
...                                      self.gradient_squared_accumulator, grad, lr, l1, l2,
↪ global_step)
...         return out
...
>>> net = ApplyAdagradDANet()
>>> grad = Tensor(np.array([[0.3, 0.4], [0.1, 0.2]]).astype(np.float32))
>>> lr = Tensor(0.001, mstype.float32)
>>> l1 = Tensor(0.001, mstype.float32)
>>> l2 = Tensor(0.001, mstype.float32)
>>> global_step = Tensor(2, mstype.int32)
>>> output = net(grad, lr, l1, l2, global_step)
>>> print(output)
[[-0.00073906, -0.00136889],
 [-0.00059699, -0.00142478]]
```

mindspore.ops.ApplyAdagradV2

class mindspore.ops.**ApplyAdagradV2**(*epsilon*, *update_slots=True*)

Updates relevant entries according to the adagradv2 scheme.

$$accum += grad * grad$$
$$var -= lr * grad * \frac{1}{\sqrt{accum} + \epsilon}$$

where ϵ represents *epsilon*.

Inputs of *var*, *accum* and *grad* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Note: The difference is that *ApplyAdagradV2* has one more small constant value ϵ than *ApplyAdagrad*.

Parameters

- **epsilon** (*float*) – A small value added for numerical stability.
- **update_slots** (*bool*) – If `True` , *accum* will be updated. Default: `True` .

Inputs:

- **var** (Union[Parameter, Tensor]) - Variable to be updated. With float16 or float32 data type. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **accum** (Union[Parameter, Tensor]) - Accumulation to be updated. The shape must be the same as *var*.
- **lr** (Union[Number, Tensor]) - The learning rate value, must be a float number or a scalar tensor with float16 or float32 data type.
- **grad** (Tensor) - A tensor for gradient. The shape must be the same as *var*.

Outputs:

Tuple of 2 Tensors, the updated parameters or tensors.

- **var** (Tensor) - The same shape and data type as *var*.
- **accum** (Tensor) - The same shape and data type as *accum*.

Raises

- **TypeError** – If dtype of *var*, *accum*, *lr* or *grad* is neither float16 nor float32.
- **TypeError** – If *lr* is neither a Number nor a Tensor.
- **TypeError** – If the data type of *var*, *accum* and *grad* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_adagrad_v2 = ops.ApplyAdagradV2(epsilon=1e-6)
...         self.var = Parameter(Tensor(np.array([[0.6, 0.4],
...                                               [0.1, 0.5]]).astype(np.float32)), name="var
 ↪")
...         self.accum = Parameter(Tensor(np.array([[0.6, 0.5],
...                                                 [0.2, 0.6]]).astype(np.float32)), name=
 ↪"accum")
...     def construct(self, lr, grad):
...         out = self.apply_adagrad_v2(self.var, self.accum, lr, grad)
...         return out
...
>>> net = Net()
>>> lr = Tensor(0.001, mindspore.float32)
>>> grad = Tensor(np.array([[0.3, 0.7], [0.1, 0.8]]).astype(np.float32))
>>> output = net(lr, grad)
>>> print(output)
(Tensor(shape=[2, 2], dtype=Float32, value=
[[ 5.99638879e-01,  3.99296492e-01],
 [ 9.97817814e-02,  4.99281585e-01]]), Tensor(shape=[2, 2], dtype=Float32, value=
[[ 6.90000057e-01,  9.90000010e-01],
 [ 2.10000008e-01,  1.24000001e+00]]))
```

mindspore.ops.ApplyAdaMax

class mindspore.ops.**ApplyAdaMax**

Updates relevant entries according to the adamax scheme.

The updating formulas are as follows,

$$
\begin{aligned}
m_{t+1} &= \beta_1 * m_t + (1 - \beta_1) * g \\
v_{t+1} &= \max(\beta_2 * v_t, |g|) \\
var &= var - \frac{l}{1 - \beta_1^{t+1}} * \frac{m_{t+1}}{v_{t+1} + \epsilon}
\end{aligned}
$$

t represents updating step while m represents the 1st moment vector, m_t is the last moment of m_{t+1}, v represents the 2nd moment vector, v_t is the last moment of v_{t+1}, l represents scaling factor lr, g represents $grad$, β_1, β_2 represent $beta1$ and $beta2$, β_1^{t+1} represents $beta1\_power$, var represents the variable to be updated, ϵ represents $epsilon$.

Inputs of var, m, v and $grad$ comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Inputs:

- **var** (Union[Parameter, Tensor]) - Variable to be updated. With float32 or float16 data type. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **m** (Union[Parameter, Tensor]) - The 1st moment vector in the updating formula, has the same shape as var. With float32 or float16 data type.

- **v** (Union[Parameter, Tensor]) - The 2nd moment vector in the updating formula. Mean square gradients with the same shape as *var*. With float32 or float16 data type.
- **beta1_power** (Union[Number, Tensor]) - $beta_1^t$ in the updating formula, must be a scalar. With float32 or float16 data type.
- **lr** (Union[Number, Tensor]) - Learning rate, l in the updating formula, must be a scalar. With float32 or float16 data type.
- **beta1** (Union[Number, Tensor]) - The exponential decay rate for the 1st moment estimations, must be a scalar. With float32 or float16 data type.
- **beta2** (Union[Number, Tensor]) - The exponential decay rate for the 2nd moment estimations, must be a scalar. With float32 or float16 data type.
- **epsilon** (Union[Number, Tensor]) - A small value added for numerical stability, must be a scalar. With float32 or float16 data type.
- **grad** (Tensor) - A tensor for gradient, has the same shape as *var*. With float32 or float16 data type.

Outputs:

Tuple of 3 Tensor, the updated parameters or tensors.

- **var** (Tensor) - The same shape and data type as *var*.
- **m** (Tensor) - The same shape and data type as *m*.
- **v** (Tensor) - The same shape and data type as *v*.

Raises

- **TypeError** –If dtype of *var*, *m*, *v*, *beta_power*, *lr*, *beta1*, *beta2*, *epsilon* or *grad* is neither float16 nor float32.
- **TypeError** –If *beta_power*, *lr*, *beta1*, *beta2* or *epsilon* is neither a Number nor a Tensor.
- **TypeError** –If *grad* is not a Tensor.
- **TypeError** –If the data type of *var*, *m*, *v* and *grad* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_ada_max = ops.ApplyAdaMax()
...         self.var = Parameter(Tensor(np.array([[0.6, 0.4],
...                                               [0.1, 0.5]]).astype(np.float32)), name="var
↪")
...         self.m = Parameter(Tensor(np.array([[0.6, 0.5],
...                                             [0.2, 0.6]]).astype(np.float32)), name="m")
...         self.v = Parameter(Tensor(np.array([[0.9, 0.1],
...                                             [0.7, 0.8]]).astype(np.float32)), name="v")
...     def construct(self, beta1_power, lr, beta1, beta2, epsilon, grad):
```

(continues on next page)

(continued from previous page)

```
...         out = self.apply_ada_max(self.var, self.m, self.v, beta1_power, lr, beta1, beta2,
 ↪ epsilon, grad)
...         return out
...
>>> net = Net()
>>> beta1_power =Tensor(0.9, mindspore.float32)
>>> lr = Tensor(0.001, mindspore.float32)
>>> beta1 = Tensor(0.9, mindspore.float32)
>>> beta2 = Tensor(0.99, mindspore.float32)
>>> epsilon = Tensor(1e-10, mindspore.float32)
>>> grad = Tensor(np.array([[0.3, 0.7], [0.1, 0.8]]).astype(np.float32))
>>> output = net(beta1_power, lr, beta1, beta2, epsilon, grad)
>>> print(output)
(Tensor(shape=[2, 2], dtype=Float32, value=
[[ 5.93602717e-01,  3.92571449e-01],

```

mindspore.ops.ApplyAdamWithAmsgradV2

class mindspore.ops.**ApplyAdamWithAmsgradV2**(*use_locking=False*)

Update var according to the Adam algorithm.

$$
\begin{aligned}
lr_t &:= learning\_rate * \sqrt{1 - \beta_2^t} / (1 - \beta_1^t) \\
m_t &:= \beta_1 * m_{t-1} + (1 - \beta_1) * g \\
v_t &:= \beta_2 * v_{t-1} + (1 - \beta_2) * g * g \\
\hat{v}_t &:= \max(\hat{v}_{t-1}, v_t) \\
var &:= var - lr_t * m_t / (\sqrt{\hat{v}_t} + \epsilon)
\end{aligned}
$$

t represents updating step while m represents the 1st moment vector, v represents the 2nd moment vector, $\hat{v}_t$ represents *vhat*, lr represents learning rate, g represents *grad*, β_1, β_2 represent *beta1* and *beta2*, β_1^t represents *beta1_power*, β_2^t represents *beta2_power*, var represents the variable to be updated, ϵ represents *epsilon*.

All of the inputs are consistent with implicit type conversion rules, which ensure that the data types are the same. If they have different data types, the lower precision data type will be converted to the data type with relatively higher precision.

Parameters

use_locking (*bool*) – If `True` , updating of the *var*, *m*, and *v* tensors will be protected by a lock; Otherwise some contention may occur. Default: `False` .

Inputs:

- **var** (Union[Parameter, Tensor]) - Variable to be updated. The data type can be float16, float32 or float64.
- **m** (Union[Parameter, Tensor]) - The 1st moment vector in the updating formula, the shape should be the same as *var*.
- **v** (Union[Parameter, Tensor]) - The 2nd moment vector in the updating formula, the shape should be the same as *var*.
- **vhat** (Union[Parameter, Tensor]) - $\hat{v}_t$ in the updating formula, the shape and data type value should be the same as *var*.
- **beta1_power** (Union[float, Tensor]) - $beta_1^t(\beta_1^t)$ in the updating formula, with float16, float32 or float64 data type.
- **beta2_power** (Union[float, Tensor]) - $beta_2^t(\beta_2^t)$ in the updating formula, with float16, float32 or float64 data type.

- **lr** (Union[float, Tensor]) - Learning rate, with float16, float32 or float64 data type.
- **beta1** (Union[float, Tensor]) - Exponential decay rate of the first moment. The data type can be float16, float32 or float64.
- **beta2** (Union[float, Tensor]) - Exponential decay rate of the second moment. The data type can be float16, float32 or float64.
- **epsilon** (Union[float, Tensor]) - A value added to the denominator to ensure numerical stability. The data type can be float16, float32 or float64.
- **grad** (Tensor) - The gradient, has the same shape as *var*.

Outputs:

Tuple of 4 Tensors, the updated parameters or tensors.

- **var** (Tensor) - The same shape and data type as *var*.
- **m** (Tensor) - The same shape and data type as *m*.
- **v** (Tensor) - The same shape and data type as *v*.
- **vhat** (Tensor) - The same shape and data type as *vhat*.

Raises

- **TypeError** –If *var*, *m*, *v*, *vhat* neither a Parameter nor a Tensor.
- **TypeError** –If dtype of *var*, *m*, *v*, *vhat*, *beta1_power*, *beta2_power*, *lr*, *beta1* , *beta2* , *epsilon* or *grad* is not float64, float32 or float16.
- **RuntimeError** –If the data type of *var*, *m*, *v* , *vhat* and *grad* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import ops
>>> import mindspore.nn as nn
>>> from mindspore import Tensor, Parameter
>>> import numpy as np
>>> class ApplyAdamWithAmsgradNet(nn.Cell):
...     def __init__(self, use_locking=False):
...         super(ApplyAdamWithAmsgradNet, self).__init__()
...         self.apply_adam_with_amsgrad = ops.ApplyAdamWithAmsgradV2(use_locking)

[0.19853032 0.19849943]]
```

mindspore.ops.ApplyAddSign

class mindspore.ops.**ApplyAddSign**

Updates relevant entries according to the AddSign algorithm.

$$
\begin{aligned}
m_{t+1} &= \beta * m_t + (1 - \beta) * g \\
\text{update} &= (\alpha + \text{sign\_decay} * sign(g) * sign(m)) * g \\
var &= var - lr_{t+1} * \text{update}
\end{aligned}
$$

t represents updating step while m represents the 1st moment vector, m_t is the last moment of m_{t+1}, lr represents scaling factor lr, g represents *grad*, α represents *alpha*, β represents *beta*.

The data type of all inputs must be float16 or float32 on Ascend and float16, float32 or float64 on CPU and GPU.

Inputs of *var*, *accum* and *grad* , *sign_decay* and *beta* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Inputs:

- **var** (Union[Parameter, Tensor]) - Variable tensor to be updated. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **m** (Union[Parameter, Tensor]) - Variable tensor to be updated, has the same data type as *var*.
- **lr** (Union[Number, Tensor]) - The learning rate value, must be a scalar.
- **alpha** (Union[Number, Tensor]) - Must be a scalar.
- **sign_decay** (Union[Number, Tensor]) - Must be a scalar.
- **beta** (Union[Number, Tensor]) - The exponential decay rate, must be a scalar.
- **grad** (Tensor) - A tensor of the same shape as *var*, for the gradient.

Outputs:

Tuple of 2 Tensors, the updated parameters or tensors.

- **var** (Tensor) - The same shape and data type as *var*.
- **m** (Tensor) - The same shape and data type as *m*.

Raises

- **TypeError** –If dtype of *var*, *lr* and *alpha* is not float16, float32 or float64.

- **TypeError** – If dtype of *sign_decay* and *beta* are both not float16, float32 or float64.
- **TypeError** – If *lr*, *alpha* or *sign_decay* is neither a Number nor a Tensor.
- **TypeError** – If *grad* is not a Tensor.
- **TypeError** – If the data type of *var*, *accum* and *grad* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_add_sign = ops.ApplyAddSign()
...         self.var = Parameter(Tensor(np.array([[0.6, 0.4],
...                                               [0.1, 0.5]]).astype(np.float32)), name="var
↪")
...         self.m = Parameter(Tensor(np.array([[0.6, 0.5],
...                                             [0.2, 0.6]]).astype(np.float32)), name="m")
...         self.lr = 0.001
...         self.alpha = 1.0
...         self.sign_decay = 0.99
...         self.beta = 0.9
...     def construct(self, grad):
...         out = self.apply_add_sign(self.var, self.m, self.lr, self.alpha, self.sign_decay,
↪ self.beta, grad)
...         return out
...
>>> net = Net()
>>> grad = Tensor(np.array([[0.3, 0.7], [0.1, 0.8]]).astype(np.float32))
>>> output = net(grad)
>>> print(output)
(Tensor(shape=[2, 2], dtype=Float32, value=
[[ 5.99403024e-01,  3.98607016e-01],
 [ 9.98010039e-02,  4.98407990e-01]]), Tensor(shape=[2, 2], dtype=Float32, value=
[[ 5.70000052e-01,  5.19999981e-01],
 [ 1.89999998e-01,  6.20000064e-01]]))
```

mindspore.ops.ApplyCenteredRMSProp

class mindspore.ops.**ApplyCenteredRMSProp**(*use_locking=False*)

Optimizer that implements the centered RMSProp algorithm. Please refer to the usage in source code of *mindspore.nn.RMSProp*.

The updating formulas of ApplyCenteredRMSProp algorithm are as follows,

$$
\begin{aligned}
g_{t+1} &= \rho g_t + (1-\rho)\nabla Q_i(w) \\
s_{t+1} &= \rho s_t + (1-\rho)(\nabla Q_i(w))^2 \\
m_{t+1} &= \beta m_t + \frac{\eta}{\sqrt{s_{t+1} - g_{t+1}^2 + \epsilon}}\nabla Q_i(w) \\
w &= w - m_{t+1}
\end{aligned}
$$

where w represents *var*, which will be updated. g_{t+1} represents *mean_gradient*, g_t is the last moment of g_{t+1}. s_{t+1} represents *mean_square*, s_t is the last moment of s_{t+1}, m_{t+1} represents *moment*, m_t is the last moment of m_{t+1}. ρ represents *decay*. β is the momentum term, represents *momentum*. ϵ is a smoothing term to avoid division by zero, represents *epsilon*. η represents *learning_rate*. $\nabla Q_i(w)$ represents *grad*.

Note: The difference between *ApplyCenteredRMSProp* and *ApplyRMSProp* is that the former uses the centered RMSProp algorithm, and the centered RRMSProp algorithm uses an estimate of the centered second moment(i.e., the variance) for normalization, as opposed to regular RMSProp, which uses the (uncertained) second moment. This often helps with training, but is slightly more expensive in terms of computation and memory.

Warning: In dense implementation of this algorithm, *mean_gradient*, *mean_square*, and *moment* will update even if the *grad* is zero. But in this sparse implementation, *mean_gradient*, *mean_square*, and *moment* will not update in iterations during which the *grad* is zero.

Parameters

use_locking (*bool*) – Whether to enable a lock to protect the variable and accumulation tensors from being updated. Default: `False`.

Inputs:

- **var** (Parameter) - Weights to be updated.
- **mean_gradient** (Tensor) - Mean gradients, must be the same type as *var*.
- **mean_square** (Tensor) - Mean square gradients, must be the same type as *var*.
- **moment** (Tensor) - Delta of *var*, must be the same type as *var*.
- **grad** (Tensor) - Gradient, must be the same type as *var*.
- **learning_rate** (Union[Number, Tensor]) - Learning rate. Must be a float number or a scalar tensor with float16 or float32 data type.
- **decay** (float) - Decay rate.
- **momentum** (float) - Momentum.
- **epsilon** (float) - Ridge term.

Outputs:

Tensor, parameters to be updated.

Raises

- **TypeError** – If *use_locking* is not a bool.
- **TypeError** – If *var*, *mean_gradient*, *mean_square*, *moment* or *grad* is not a Tensor.
- **TypeError** – If *learing_rate* is neither a Number nor a Tensor.
- **TypeError** – If dtype of *learing_rate* is neither float16 nor float32.
- **TypeError** – If *decay*, *momentum* or *epsilon* is not a float.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_centerd_rms_prop = ops.ApplyCenteredRMSProp()
...         self.var = Parameter(Tensor(np.ones([2, 2]).astype(np.float32)), name="var")
...
...     def construct(self, mean_grad, mean_square, moment, grad, decay, momentum, epsilon,␣
↪lr):
...         out = self.apply_centerd_rms_prop(self.var, mean_grad, mean_square, moment, grad,
...                                           lr, decay, momentum, epsilon)
...         return out
...
>>> net = Net()
>>> mean_grad = Tensor(np.ones([2, 2]).astype(np.float32))
>>> mean_square = Tensor(np.ones([2, 2]).astype(np.float32))
>>> moment = Tensor(np.ones([2, 2]).astype(np.float32))
>>> grad = Tensor(np.ones([2, 2]).astype(np.float32))
>>> output = net(mean_grad, mean_square, moment, grad, 0.0, 1e-10, 0.001, 0.01)
>>> print(net.var.asnumpy())
[[0.68377227  0.68377227]
 [0.68377227  0.68377227]]
```

mindspore.ops.ApplyFtrl

class mindspore.ops.**ApplyFtrl**(*use_locking=False*)

Updates relevant entries according to the FTRL scheme.

For more details, please refer to *mindspore.nn.FTRL*.

Note:

- Currently, only positive numbers are supported on the Ascend platform, and the calculation results for other scenarios are not defined.
- Inputs of *var*, *accum*, *linear* and *grad* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Parameters

use_locking (*bool*) – Use locks for updating operation if `True` . Default: `False` .

Inputs:

- **var** (Union[Parameter, Tensor]) - The variable to be updated. The data type must be float16 or float32. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **accum** (Union[Parameter, Tensor]) - The accumulation to be updated, must be same shape as *var*.
- **linear** (Union[Parameter, Tensor]) - The linear coefficient to be updated, must be same shape as *var*.
- **grad** (Tensor) - Gradient. The data type must be float16 or float32.

- **lr** (Union[Number, Tensor]) - The learning rate value, must be positive. Default: `0.001` . It must be a float number or a scalar tensor with float16 or float32 data type.
- **l1** (Union[Number, Tensor]) - l1 regularization strength, must be greater than or equal to zero. Default: `0.0` . It must be a float number or a scalar tensor with float16 or float32 data type.
- **l2** (Union[Number, Tensor]) - l2 regularization strength, must be greater than or equal to zero. Default: `0.0` . It must be a float number or a scalar tensor with float16 or float32 data type.
- **lr_power** (Union[Number, Tensor]) - Learning rate power controls how the learning rate decreases during training, must be less than or equal to zero. Use fixed learning rate if lr_power is zero. Default: `-0.5` . It must be a float number or a scalar tensor with float16 or float32 data type.

Outputs:

- **var** (Tensor) - Represents the updated *var*. As the input parameters or tensors has been updated in-place, this value is always zero when the platform is GPU.

Raises

- **TypeError** –If *use_locking* is not a bool.
- **TypeError** –If dtype of *var*, *grad*, *lr*, *l1*, *l2* or *lr_power* is neither float16 nor float32.
- **TypeError** –If *lr*, *l1*, *l2* or *lr_power* is neither a Number nor a Tensor.
- **TypeError** –If *grad* is not a Tensor.
- **TypeError** –If the parameter or tensor types of *var*, *accum* and *linear* are inconsistent.
- **TypeError** –If the parameter or tensor types of *grad*, *lr*, *l1*, *l2*, *lr_power* are inconsistent with *var* and the precision is greater than *var*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class ApplyFtrlNet(nn.Cell):
...     def __init__(self):
...         super(ApplyFtrlNet, self).__init__()
...         self.apply_ftrl = ops.ApplyFtrl()
...         self.lr = 0.001
...         self.l1 = 0.0
...         self.l2 = 0.0
...         self.lr_power = -0.5
...         self.var = Parameter(Tensor(np.array([[0.6, 0.4],
...                                               [0.1, 0.5]]).astype(np.float32)), name="var
↪")
...         self.accum = Parameter(Tensor(np.array([[0.6, 0.5],
...                                                 [0.2, 0.6]]).astype(np.float32)), name=
↪"accum")
...         self.linear = Parameter(Tensor(np.array([[0.9, 0.1],
...                                                  [0.7, 0.8]]).astype(np.float32)), name=
↪"linear")
...
...     def construct(self, grad):

 [ 0.00066425 0.15075898]]
```

mindspore.ops.ApplyGradientDescent

class mindspore.ops.**ApplyGradientDescent**

Updates *var* by subtracting *alpha* * *delta* from it.

$$var = var - \alpha * \delta$$

where α represents *alpha*, δ represents *delta*.

Inputs of *var* and *delta* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Inputs:

- **var** (Union[Parameter, Tensor]) - Variable tensor to be updated. With float32 or float16 data type. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **alpha** (Union[Number, Tensor]) - Scaling factor, must be a scalar. With float32 or float16 data type.
- **delta** (Tensor) - A tensor for the change, has the same shape as *var*.

Outputs:

Tensor, represents the updated *var*.

Raises

- **TypeError** – If dtype of *var* or *alpha* is neither float16 nor float32.
- **TypeError** – If *delta* is not a Tensor.
- **TypeError** – If *alpha* is neither a Number nor a Tensor.
- **TypeError** – If the data type of *var* and *delta* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_gradient_descent = ops.ApplyGradientDescent()
...         self.var = Parameter(Tensor(np.ones([2, 2]).astype(np.float32)), name="var")
...         self.alpha = 0.001
...     def construct(self, delta):
...         out = self.apply_gradient_descent(self.var, self.alpha, delta)
...         return out
...
>>> net = Net()
>>> delta = Tensor(np.array([[0.1, 0.1], [0.1, 0.1]]).astype(np.float32))
>>> output = net(delta)
>>> print(output)
[[0.9999 0.9999]
 [0.9999 0.9999]]
```

mindspore.ops.ApplyMomentum

class mindspore.ops.**ApplyMomentum**(*use_nesterov=False*, *use_locking=False*, *gradient_scale=1.0*)

Optimizer that implements the Momentum algorithm.

Refer to the paper On the importance of initialization and momentum in deep learning for more details.

Inputs of *variable*, *accumulation* and *gradient* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Refer to *mindspore.nn.Momentum* for more details about the formula and usage.

Parameters

- **use_locking** (*bool, optional*) – Whether to enable a lock to protect the variable and accumulation tensors from being updated. Default: `False`.
- **use_nesterov** (*bool, optional*) – Enable Nesterov momentum. Default: `False`.
- **gradient_scale** (*float, optional*) – The scale of the gradient. Default: `1.0`.

Inputs:

- **variable** (Union[Parameter, Tensor]) - Weights to be updated. Data type must be float64, int64, float, float16, int16, int32, int8, uint16, uint32, uint64, uint8, complex64, complex128.
- **accumulation** (Union[Parameter, Tensor]) - Accumulated gradient value by moment weight, has the same data type with *variable*.
- **learning_rate** (Union[Number, Tensor]) - The learning rate value, must be a float64, int64, float, float16, int16, int32, int8, uint16, uint32, uint64, uint8, complex64, complex128 number or a scalar tensor with float64, int64, float, float16, int16, int32, int8, uint16, uint32, uint64, uint8, complex64, complex128 data type.
- **gradient** (Tensor) - Gradient, has the same data type as *variable*.
- **momentum** (Union[Number, Tensor]) - Momentum, must be a float64, int64, float, float16, int16, int32, int8, uint16, uint32, uint64, uint8, complex64, complex128 number or a scalar tensor with float64, int64, float, float16, int16, int32, int8, uint16, uint32, uint64, uint8, complex64, complex128 data type.

Outputs:

Tensor, parameters to be updated.

Raises

- **TypeError** – If the *use_locking* or *use_nesterov* is not a bool or *gradient_scale* is not a float.
- **TypeError** – If the data type of *var*, *accum* and *grad* conversion is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_momentum = ops.ApplyMomentum()
...         self.variable = Parameter(Tensor(np.array([[0.6, 0.4],
...                                                    [0.1, 0.5]]).astype(np.float32)), name=
 ↪"variable")
...         self.accumulate = Parameter(Tensor(np.array([[0.6, 0.5],
...                                                    [0.2, 0.6]]).astype(np.float32)), name=
 ↪"accumulate")
...     def construct(self, lr, grad, moment):
...         out = self.apply_momentum(self.variable, self.accumulate, lr, grad, moment)
...         return out
>>> net = Net()
>>> lr = Tensor(0.1, mindspore.float32)
>>> moment = Tensor(0.9, mindspore.float32)
>>> grad = Tensor(np.array([[0.3, 0.7], [0.1, 0.8]]).astype(np.float32))
>>> output = net(lr, grad, moment)
>>> print(output)
[[0.51600003 0.285     ]
[0.072      0.366     ]]
```

mindspore.ops.ApplyPowerSign

class mindspore.ops.**ApplyPowerSign**

Updates relevant entries according to the AddSign algorithm.

The AddSign algorithm was proposed in Neural Optimizer Search with Reinforcement Learning.

$$
\begin{aligned}
m_{t+1} &= \beta * m_t + (1 - \beta) * g \\
\text{update} &= \exp(\text{logbase} * \text{sign\_decay} * sign(g) * sign(m)) * g \\
var &= var - lr_{t+1} * \text{update}
\end{aligned}
$$

t represents updating step while m represents the 1st moment vector, m_t is the last moment of m_{t+1}, lr represents scaling factor lr, g represents *grad*, β represents *beta*.

All of inputs comply with the implicit type conversion rules to make the data types consistent. If *lr*, *logbase*, *sign_decay* or *beta* is a number, the number is automatically converted to Tensor, and the data type is consistent with the Tensor data type involved

in the operation. If inputs are tensors and have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Note: On Ascend, input data type of float64 is currently not supported.

Inputs:

- **var** (Union[Parameter, Tensor]) - Variable tensor to be updated. With float64, float32 or float16 data type. If data type of *var* is float16, all inputs must have the same data type as *var*. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **m** (Union[Parameter, Tensor]) - Variable tensor to be updated, has the same shape as *var*.
- **lr** (Union[Number, Tensor]) - The learning rate value, should be a scalar or Tensor with float64, float32 or float16 data type.
- **logbase** (Union[Number, Tensor]) - Should be a scalar or Tensor with float64, float32 or float16 data type.
- **sign_decay** (Union[Number, Tensor]) - Should be a scalar or Tensor with float64, float32 or float16 data type.
- **beta** (Union[Number, Tensor]) - The exponential decay rate, should be a scalar or Tensor with float64, float32 or float16 data type.
- **grad** (Tensor) - A tensor of the same shape as *var*, for the gradient.

Outputs:

Tuple of 2 Tensors, the updated parameters or tensors.

- **var** (Tensor) - The same shape and data type as *var*.
- **m** (Tensor) - The same shape and data type as *m*.

Raises

- **TypeError** –If dtype of *var*, *lr*, *logbase*, *sign_decay*, *beta* or *grad* is not one of float16,
- **float32 or float64.** –
- **TypeError** –If *lr*, *logbase*, *sign_decay* or *beta* is neither a Number nor a Tensor.
- **TypeError** –If *grad* is not a Tensor.
- **TypeError** –If the data type of *lr*, *logbase*, *sign_decay* and *grad* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_power_sign = ops.ApplyPowerSign()
...         self.var = Parameter(Tensor(np.array([[0.6, 0.4],
...                                               [0.1, 0.5]]).astype(np.float32)), name="var
↪")
```

```

mindspore.ops.ApplyProximalAdagrad

class mindspore.ops.**ApplyProximalAdagrad**(*use_locking=False*)

Updates relevant entries according to the proximal adagrad algorithm. The proximal adagrad algorithm was proposed in Efficient Learning using Forward-Backward Splitting.

$$
\begin{aligned}
&accum += grad * grad \\
&\text{prox\_v} = var - lr * grad * \frac{1}{\sqrt{accum}} \\
&var = \frac{sign(\text{prox\_v})}{1 + lr * l2} * \max(|\text{prox\_v}| - lr * l1, 0)
\end{aligned}
$$

Inputs of *var*, *accum* and *grad* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Parameters

use_locking (*bool, optional*) – If `True` , the var and accumulation tensors will be protected from being updated. Default: `False` .

Inputs:

- **var** (Union[Parameter, Tensor]) - Variable to be updated. The data type must be float16 or float32. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **accum** (Union[Parameter, Tensor]) - Accumulation to be updated, must have the same shape and dtype as *var*.
- **lr** (Union[Number, Tensor]) - The learning rate value, must be a scalar. The data type must be float16 or float32.
- **l1** (Union[Number, Tensor]) - l1 regularization strength, must be a scalar. The data type must be float16 or float32.
- **l2** (Union[Number, Tensor]) - l2 regularization strength, must be a scalar. The data type must be float16 or float32.
- **grad** (Tensor) - Gradient with the same shape and dtype as *var*.

Outputs:

Tuple of 2 Tensors, the updated parameters or tensors.

- **var** (Tensor) - The same shape and data type as *var*.
- **accum** (Tensor) - The same shape and data type as *accum*.

Raises

- **TypeError** – If *use_blocking* is not a bool.
- **TypeError** – If dtype of *var*, *lr*, *l1* or *l2* is neither float16 nor float32.
- **TypeError** – If *lr*, *l1* or *l2* is neither a Number nor a Tensor.
- **TypeError** – If *grad* is not a Tensor.
- **TypeError** – If the data type of *var*, *accum* and *grad* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_proximal_adagrad = ops.ApplyProximalAdagrad()
...         self.var = Parameter(Tensor(np.array([[0.6, 0.4],
...                                               [0.1, 0.5]]).astype(np.float32)), name="var
 ↪")
...         self.accum = Parameter(Tensor(np.array([[0.6, 0.5],
...                                                 [0.2, 0.6]]).astype(np.float32)), name=
 ↪"accum")
...         self.lr = 0.01
...         self.l1 = 0.0
...         self.l2 = 0.0
...     def construct(self, grad):
...         out = self.apply_proximal_adagrad(self.var, self.accum, self.lr, self.l1, self.
 ↪l2, grad)
...         return out
...
>>> net = Net()
>>> grad = Tensor(np.array([[0.3, 0.7], [0.1, 0.8]]).astype(np.float32))
>>> output = net(grad)
>>> print(output)
(Tensor(shape=[2, 2], dtype=Float32, value=
[[ 5.96388459e-01,  3.92964751e-01],
 [ 9.78178233e-02,  4.92815793e-01]]), Tensor(shape=[2, 2], dtype=Float32, value=
[[ 6.90000057e-01,  9.90000010e-01],
 [ 2.10000008e-01,  1.24000001e+00]]))
```

mindspore.ops.ApplyProximalGradientDescent

class mindspore.ops.**ApplyProximalGradientDescent**

Updates relevant entries according to the FOBOS(Forward Backward Splitting) algorithm. Refer to the paper Efficient Learning using Forward-Backward Splitting for more details.

$$\begin{aligned}\text{prox\_v} &= var - \alpha * \delta \\ var &= \frac{sign(\text{prox\_v})}{1+\alpha * l2} * \max(|\text{prox\_v}| - \alpha * l1, 0)\end{aligned}$$

where α represents *alpha*, δ represents *delta*.

Inputs of *var* and *delta* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Inputs:

- **var** (Union[Parameter, Tensor]) - Variable tensor to be updated. With float32 or float16 data type. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **alpha** (Union[Number, Tensor]) - Scaling factor, must be a scalar. With float32 or float16 data type.
- **l1** (Union[Number, Tensor]) - l1 regularization strength, must be a scalar. With float32 or float16 data type.
- **l2** (Union[Number, Tensor]) - l2 regularization strength, must be a scalar. With float32 or float16 data type.
- **delta** (Tensor) - A tensor for the change.

Outputs:

Tensor, represents the updated *var*.

Raises

- **TypeError** – If dtype of *var*, *alpha*, *l1* or *l2* is neither float16 nor float32.
- **TypeError** – If *alpha*, *l1* or *l2* is neither a Number nor a Tensor.
- **TypeError** – If *delta* is not a Tensor.
- **TypeError** – If the data type of *var*, and *delta* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_proximal_gradient_descent = ops.ApplyProximalGradientDescent()
...         self.var = Parameter(Tensor(np.ones([2, 2]).astype(np.float32)), name="var")
...         self.alpha = 0.001
...         self.l1 = 0.1
...         self.l2 = 0.1
...     def construct(self, delta):
...         out = self.apply_proximal_gradient_descent(self.var, self.alpha, self.l1, self.
↪l2, delta)
```

(continues on next page)

(continued from previous page)

```
...         return out
...
>>> net = Net()
>>> delta = Tensor(np.array([[0.1, 0.1], [0.1, 0.1]]).astype(np.float32))
>>> output = net(delta)
>>> print(output)
[[0.99969995 0.99969995]
 [0.99969995 0.99969995]]
```

mindspore.ops.ApplyRMSProp

class mindspore.ops.**ApplyRMSProp**(*use_locking=False*)

Optimizer that implements the Root Mean Square prop(RMSProp) algorithm. Please refer to the usage in source code of *mindspore.nn.RMSProp*.

The updating formulas of ApplyRMSProp algorithm are as follows,

$$
\begin{aligned}
s_{t+1} &= \rho s_t + (1-\rho)(\nabla Q_i(w))^2 \\
m_{t+1} &= \beta m_t + \frac{\eta}{\sqrt{s_{t+1}+\epsilon}} \nabla Q_i(w) \\
w &= w - m_{t+1}
\end{aligned}
$$

where w represents *var*, which will be updated. s_{t+1} represents *mean_square*, s_t is the last moment of s_{t+1}, m_{t+1} represents *moment*, m_t is the last moment of m_{t+1}. ρ represents *decay*. β is the momentum term, represents *momentum*. ϵ is a smoothing term to avoid division by zero, represents *epsilon*. η represents *learning_rate*. $\nabla Q_i(w)$ represents *grad*.

Warning: Note that in dense implementation of this algorithm, *mean_square* and *moment* will update even if *grad* is 0, but in this sparse implementation, *mean_square* and *moment* will not update in iterations during which *grad* is 0.

Parameters

use_locking (*bool, optional*) – Whether to enable a lock to protect the variable and accumulation tensors from being updated. Default: `False` .

Inputs:

- **var** (Parameter) - Weights to be updated.
- **mean_square** (Tensor) - Mean square gradients, must be the same type as *var*.
- **moment** (Tensor) - Delta of *var*, must be the same type as *var*.
- **learning_rate** (Union[Number, Tensor]) - Learning rate. Must be a float number or a scalar tensor with float16 or float32 data type.
- **grad** (Tensor) - Gradient, must be the same type as *var*.
- **decay** (float) - Decay rate. Only constant value is allowed.
- **momentum** (float) - Momentum. Only constant value is allowed.
- **epsilon** (float) - Ridge term. Only constant value is allowed.

Outputs:

Tensor, parameters to be updated.

Raises

- **TypeError** –If *use_locking* is not a bool.
- **TypeError** –If *var*, *mean_square*, *moment* or *decay* is not a Tensor.
- **TypeError** –If *learning_rate* is neither a Number nor a Tensor.
- **TypeError** –If dtype of *decay*, *momentum* or *epsilon* is not float.
- **TypeError** –If dtype of *learning_rate* is neither float16 nor float32.
- **ValueError** –If *decay*, *momentum* or *epsilon* is not a constant value.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.apply_rms_prop = ops.ApplyRMSProp()
...         self.var = Parameter(Tensor(np.ones([2, 2]).astype(np.float32)), name="var")
...
...     def construct(self, mean_square, moment, grad, decay, momentum, epsilon, lr):
...         out = self.apply_rms_prop(self.var, mean_square, moment, lr, grad, decay,␣
↪momentum, epsilon)
...         return out
...
>>> net = Net()
>>> mean_square = Tensor(np.ones([2, 2]).astype(np.float32))
>>> moment = Tensor(np.ones([2, 2]).astype(np.float32))
>>> grad = Tensor(np.ones([2, 2]).astype(np.float32))
>>> output = net(mean_square, moment, grad, 0.0, 1e-10, 0.001, 0.01)
>>> print(net.var.asnumpy())
[[0.990005  0.990005]
 [0.990005  0.990005]]
```

mindspore.ops.LARSUpdate

class mindspore.ops.**LARSUpdate**(*epsilon=1e-05*, *hyperpara=0.001*, *use_clip=False*)

Conducts LARS (layer-wise adaptive rate scaling) update on the sum of squares of gradient.

For more details, please refer to *mindspore.nn.LARS*.

Parameters

- **epsilon** (*float, optional*) –Term added to the denominator to improve numerical stability. Default: `1e-05`.
- **hyperpara** (*float, optional*) –Trust coefficient for calculating the local learning rate. Default: `0.001`.
- **use_clip** (*bool, optional*) –Whether to use clip operation for calculating the local learning rate. Default: `False`.

Inputs:

- **weight** (Tensor) - A tensor, representing the weight. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **gradient** (Tensor) - The gradient of weight, which has the same shape and dtype with weight.
- **norm_weight** (Tensor) - A scalar tensor, representing the sum of squares of weight.
- **norm_gradient** (Tensor) - A scalar tensor, representing the sum of squares of gradient.
- **weight_decay** (Union[Number, Tensor]) - Weight decay. It must be a scalar tensor or number.
- **learning_rate** (Union[Number, Tensor]) - Learning rate. It must be a scalar tensor or number.

Outputs:

Tensor, represents the new gradient.

Raises

- **TypeError** –If neither *epsilon* nor *hyperpara* is a float.
- **TypeError** –If *use_clip* is not a bool.
- **TypeError** –If *weight*, *gradient*, *norm_weight* or *norm_gradient* is not a Tensor.
- **TypeError** –If *weight_decay* or *learning_rate* is neither a Number nor a Tensor.
- **TypeError** –If shape of *gradient* is not the same as *weight*.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.lars = ops.LARSUpdate()
...         self.reduce = ops.ReduceSum()
...         self.square = ops.Square()
...     def construct(self, weight, gradient):
...         w_square_sum = self.reduce(self.square(weight))
...         grad_square_sum = self.reduce(self.square(gradient))
...         grad_t = self.lars(weight, gradient, w_square_sum, grad_square_sum, 0.0, 1.0)
...         return grad_t
...
>>> weight = Tensor(np.array([[0.5, 0.8, 0.2], [0.6, 0.4, 0.2]]).astype(np.float32))
>>> gradient = Tensor(np.array([[0.4, 0.4, 0.5], [0.2, 0.4, 0.3]]).astype(np.float32))
>>> net = Net()
>>> output = net(Tensor(weight), Tensor(gradient))
>>> print(output)
[[0.0005265  0.0005265 0.00065813]
 [0.00026325 0.0005265 0.00039488]]
```

mindspore.ops.SparseApplyAdagradV2

class mindspore.ops.**SparseApplyAdagradV2**(*lr*, *epsilon*, *use_locking=False*, *update_slots=True*)

Updates relevant entries according to the adagrad scheme, one more epsilon attribute than SparseApplyAdagrad.

$$
\begin{aligned}
accum+ &= grad * grad \\
var- &= lr * grad * \frac{1}{\sqrt{accum+\epsilon}}
\end{aligned}
$$

where ϵ represents *epsilon*.

Inputs of *var*, *accum* and *grad* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Parameters

- **lr** (*float*) –Learning rate.
- **epsilon** (*float*) –A small value added for numerical stability.
- **use_locking** (*bool, optional*) –If `True` , the *var* and *accum* tensors will be protected from being updated. Default: `False` .
- **update_slots** (*bool, optional*) –If `True` , the computation logic will be different to *False*. Default: `True` .

Inputs:

- **var** (Union[Parameter, Tensor]) - Variable to be updated. The data type must be float16 or float32. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **accum** (Union[Parameter, Tensor]) - Accumulation to be updated. The shape must be the same as *var*.
- **grad** (Tensor) - Gradients has the same shape as *var* and $grad.shape[1:] = var.shape[1:]$ if var.shape > 1.
- **indices** (Tensor) - A vector of indices into the first dimension of *var* and *accum*. The type must be int32 and $indices.shape[0] = grad.shape[0]$. The value of indices must be unique. Otherwise, the result is unpredictable.

Outputs:

Tuple of 2 tensors, the updated parameters or tensors.

- **var** (Tensor) - The same shape and data type as *var*.
- **accum** (Tensor) - The same shape and data type as *accum*.

Raises

- **TypeError** –If neither *lr* nor *epsilon* is a float.
- **TypeError** –If neither *update_slots* nor *use_locking* is a bool.
- **TypeError** –If dtype of *var*, *accum* or *grad* is neither float16 nor float32.
- **TypeError** –If dtype of *indices* is not int32.
- **RuntimeError** –If the data type of *var*, *accum* and *grad* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.sparse_apply_adagrad_v2 = ops.SparseApplyAdagradV2(lr=1e-8, epsilon=1e-6)
...         self.var = Parameter(Tensor(np.array([[0.2]]).astype(np.float32)), name="var")
...         self.accum = Parameter(Tensor(np.array([[0.1]]).astype(np.float32)), name="accum
 ↪")
...
...     def construct(self, grad, indices):
...         out = self.sparse_apply_adagrad_v2(self.var, self.accum, grad, indices)
...         return out
...
>>> net = Net()
>>> grad = Tensor(np.array([[0.7]]).astype(np.float32))
>>> indices = Tensor(np.array([0]), mindspore.int32)
>>> output = net(grad, indices)
>>> print(output)
(Tensor(shape=[1, 1], dtype=Float32, value=
[[ 1.99999988e-01]]), Tensor(shape=[1, 1], dtype=Float32, value=
[[ 5.89999974e-01]]))
```

mindspore.ops.SparseApplyProximalAdagrad

class mindspore.ops.**SparseApplyProximalAdagrad**(*use_locking=False*)

Updates relevant entries according to the proximal adagrad algorithm. Compared with *mindspore.ops.ApplyProximalAdagrad*, an additional index tensor is input.

$$
\begin{aligned}
&accum += grad * grad \\
&\text{prox\_v} = var - lr * grad * \frac{1}{\sqrt{accum}} \\
&var = \frac{sign(\text{prox\_v})}{1 + lr * l2} * \max(|\text{prox\_v}| - lr * l1, 0)
\end{aligned}
$$

Inputs of *var*, *accum* and *grad* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Parameters

use_locking (*bool*) – If `True` , the *var* and *accum* tensors will be protected from being updated. Default: `False` .

Inputs:

- **var** (Union[Parameter, Tensor]) - Variable tensor to be updated. The data type must be float16 or float32. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **accum** (Parameterv) - Variable tensor to be updated, has the same shape as *var*.
- **lr** (Union[Number, Tensor]) - The learning rate value, must be a float number or a scalar tensor with float16 or float32 data type. It must be positive.
- **l1** (Union[Number, Tensor]) - l1 regularization strength, must be a float number or a scalar tensor with float16 or float32 data type. It must be non-negative.

- **l2** (Union[Number, Tensor]) - l2 regularization strength, must be a float number or a scalar tensor with float16 or float32 data type. It must be non-negative.
- **grad** (Tensor) - A tensor must meet with $grad.shape[1:] = var.shape[1:]$ if var.shape > 1.
- **indices** (Tensor) - A tensor of indices in the first dimension of *var* and *accum*. If there are duplicates in *indices*, the behavior is undefined. Must be one of the following types: int32, int64 and $indices.shape[0] = grad.shape[0]$.

Outputs:

Tuple of 2 tensors, the updated parameters or tensors.

- **var** (Tensor) - The same shape and data type as *var*.
- **accum** (Tensor) - The same shape and data type as *accum*.

Raises

- **TypeError** –If *use_locking* is not a bool.
- **TypeError** –If dtype of *var*, *accum*, *lr*, *l1*, *l2* or *grad* is neither float16 nor float32.
- **TypeError** –If dtype of *indices* is neither int32 nor int64.
- **ValueError** –If *lr* <= 0 or *l1* < 0 or *l2* < 0.
- **RuntimeError** –If the data type of *var*, *accum* and *grad* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.sparse_apply_proximal_adagrad = ops.SparseApplyProximalAdagrad()
...         self.var = Parameter(Tensor(np.array([[4.1, 7.2], [1.1, 3.0]], np.float32)),␣
↪name="var")
...         self.accum = Parameter(Tensor(np.array([[0, 0], [0, 0]], np.float32)), name=
↪"accum")
...         self.lr = 1.0
...         self.l1 = 1.0
...         self.l2 = 0.0
...     def construct(self, grad, indices):
...         out = self.sparse_apply_proximal_adagrad(self.var, self.accum, self.lr, self.l1,
...                                                  self.l2, grad, indices)
...         return out
...
>>> net = Net()
>>> grad = Tensor(np.array([[1, 1], [1, 1]], np.float32))
>>> indices = Tensor(np.array([0, 1], np.int32))
>>> output = net(grad, indices)
>>> print(output)
(Tensor(shape=[2, 2], dtype=Float32, value=
[[ 2.09999990e+00,  5.19999981e+00],
 [ 0.00000000e+00,  1.00000000e+00]]), Tensor(shape=[2, 2], dtype=Float32, value=
```

(continues on next page)

(continued from previous page)

```
[[ 1.00000000e+00,  1.00000000e+00],

```

mindspore.ops.SGD

class mindspore.ops.**SGD**(*dampening=0.0*, *weight_decay=0.0*, *nesterov=False*)

Computes the stochastic gradient descent. Momentum is optional.

Nesterov momentum is based on the formula from paper On the importance of initialization and momentum in deep learning.

Note: If parameters are not grouped, the *weight_decay* in optimizer will be applied on the network parameters without 'beta' or 'gamma' in their names. Users can group parameters to change the strategy of decaying weight. When parameters are grouped, each group can set *weight_decay*. If not, the *weight_decay* in optimizer will be applied. For more details, please refer to *mindspore.nn.SGD*.

Parameters

- **dampening** (*float*) – The dampening for momentum. Default: 0.0 .
- **weight_decay** (*float*) – Weight decay (L2 penalty). Default: 0.0 .
- **nesterov** (*bool*) – Enable Nesterov momentum. Default: False .

Inputs:

- **parameters** (Tensor) - Parameters to be updated. With float16 or float32 data type.
- **gradient** (Tensor) - Gradient, with float16 or float32 data type.
- **learning_rate** (Tensor) - Learning rate, a scalar tensor with float16 or float32 data type. e.g. Tensor(0.1, mindspore.float32)
- **accum** (Tensor) - Accum(velocity) to be updated. With float16 or float32 data type.
- **momentum** (Tensor) - Momentum, a scalar tensor with float16 or float32 data type. e.g. Tensor(0.1, mindspore.float32).
- **stat** (Tensor) - States to be updated with the same shape as gradient, with float16 or float32 data type.

Outputs:

Tensor, parameters to be updated.

Raises

- **TypeError** – If *dampening* or *weight_decay* is not a float.
- **TypeError** – If *nesterov* is not a bool.
- **TypeError** – If *parameters*, *gradient*, *learning_rate*, *accum*, *momentum* or *stat* is not a Tensor.
- **TypeError** – If dtype of *parameters*, *gradient*, *learning_rate*, *accum*, *momentum* or *stat* is neither float16 nor float32.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> sgd = ops.SGD()
>>> parameters = Tensor(np.array([2, -0.5, 1.7, 4]), mindspore.float32)
>>> gradient = Tensor(np.array([1, -1, 0.5, 2]), mindspore.float32)
>>> learning_rate = Tensor(0.01, mindspore.float32)
>>> accum = Tensor(np.array([0.1, 0.3, -0.2, -0.1]), mindspore.float32)
>>> momentum = Tensor(0.1, mindspore.float32)
>>> stat = Tensor(np.array([1.5, -0.3, 0.2, -0.7]), mindspore.float32)
>>> output = sgd(parameters, gradient, learning_rate, accum, momentum, stat)
>>> print(output.asnumpy())
[1.99 -0.4903 1.695 3.9801]
```

mindspore.ops.SparseApplyFtrl

class mindspore.ops.**SparseApplyFtrl**(*lr*, *l1*, *l2*, *lr_power*, *use_locking=False*)

Updates relevant entries according to the FTRL-proximal scheme For more details, please refer to *mindspore.nn.FTRL*.

All of inputs except *indices* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Parameters

- **lr** (*float*) –The learning rate value, must be positive.
- **l1** (*float*) –l1 regularization strength, must be greater than or equal to zero.
- **l2** (*float*) –l2 regularization strength, must be greater than or equal to zero.
- **lr_power** (*float*) –Learning rate power controls how the learning rate decreases during training, must be less than or equal to zero. Use fixed learning rate if *lr_power* is zero.
- **use_locking** (*bool, optional*) –Use locks for updating operation if `True` . Default: `False` .

Inputs:

- **var** (Union[Parameter, Tensor]) - The variable to be updated. The data type must be float16 or float32. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **accum** (Union[Parameter, Tensor]) - The accumulation to be updated, must be same shape as *var*.
- **linear** (Union[Parameter, Tensor]) - The linear coefficient to be updated, must be the same shape as *var*.
- **grad** (Tensor) - A tensor must meet with $grad.shape[1:] = var.shape[1:]$ if var.shape > 1.
- **indices** (Tensor) - A tensor of indices in the first dimension of *var* and *accum*. If there are duplicates in *indices*, the behavior is undefined. The type must be int32 or int64 and $indices.shape[0] = grad.shape[0]$.

Outputs:

- **var** (Tensor) - Tensor, has the same shape and data type as *var*.
- **accum** (Tensor) - Tensor, has the same shape and data type as *accum*.
- **linear** (Tensor) - Tensor, has the same shape and data type as *linear*.

Raises

- **TypeError** –If *lr*, *l1*, *l2* or *lr_power* is not a float.

- **TypeError** – If *use_locking* is not a bool.
- **TypeError** – If dtype of *var*, *accum*, *linear* or *grad* is neither float16 nor float32.
- **TypeError** – If dtype of *indices* is neither int32 nor int64.
- **RuntimeError** – If the data type of all of inputs except *indices* conversion of Parameter is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, nn, Parameter, ops
>>> class SparseApplyFtrlNet(nn.Cell):
...     def __init__(self):
...         super(SparseApplyFtrlNet, self).__init__()
...         self.sparse_apply_ftrl = ops.SparseApplyFtrl(lr=0.01, l1=0.0, l2=0.0, lr_power=-
↪0.5)
...         self.var = Parameter(Tensor(np.array([[0.2]]).astype(np.float32)), name="var")
...         self.accum = Parameter(Tensor(np.array([[0.1]]).astype(np.float32)), name="accum
↪")
...         self.linear = Parameter(Tensor(np.array([[0.6]]).astype(np.float32)), name=
↪"linear")
...
...     def construct(self, grad, indices):
...         out = self.sparse_apply_ftrl(self.var, self.accum, self.linear, grad, indices)
...         return out
...
>>> net = SparseApplyFtrlNet()
>>> grad = Tensor(np.array([[0.7]]).astype(np.float32))
>>> indices = Tensor(np.ones([1]), mindspore.int32)
>>> output = net(grad, indices)
>>> print(output)
(Tensor(shape=[1, 1], dtype=Float32, value=
[[2.00000003e-01]]), Tensor(shape=[1, 1], dtype=Float32, value=
[[1.00000001e-01]]), Tensor(shape=[1, 1], dtype=Float32, value=
[[6.00000024e-01]]))
```

mindspore.ops.SparseApplyFtrlV2

class mindspore.ops.**SparseApplyFtrlV2**(*lr*, *l1*, *l2*, *l2_shrinkage*, *lr_power*, *use_locking=False*)

The SparseApplyFtrlV2 interface is deprecated, please use the *mindspore.ops.SparseApplyFtrl* instead.

Supported Platforms:

Deprecated

18.2.5 Distance Function

API Name	Description	Supported Platforms
mindspore.ops.Cdist	Refer to *mindspore.ops.cdist()* for more details.	Ascend GPU CPU
mindspore.ops.EditDistance	Computes the Levenshtein Edit Distance.	Ascend CPU
mindspore.ops.LpNorm	Return the p-norm of a matrix or vector.	Ascend GPU CPU
mindspore.ops.Pdist	Computes the p-norm distance between each pair of row vectors in the input.	GPU CPU

mindspore.ops.Cdist

class mindspore.ops.**Cdist**(*p=2.0*)

```
prim = ops.Cdist(p)
out = prim(x1, x2)
```

is equivalent to

```
ops.cdist(x1, x2, p)
```

Refer to *mindspore.ops.cdist()* for more details.

mindspore.ops.EditDistance

class mindspore.ops.**EditDistance**(*normalize=True*)

Computes the Levenshtein Edit Distance. It is used to measure the similarity of two sequences. The inputs are variable-length sequences provided by SparseTensors (hypothesis_indices, hypothesis_values, hypothesis_shape) and (truth_indices, truth_values, truth_shape).

$$\mathrm{lev}_{a,b}(i,j) = \begin{cases} \max(i,j) & \text{if } \min(i,j) = 0 \\ \min \begin{cases} \mathrm{lev}_{a,b}(i-1,j)+1 \\ \mathrm{lev}_{a,b}(i,j-1)+1 \\ \mathrm{lev}_{a,b}(i-1,j-1)+1_{(a_i \neq b_j)} \end{cases} & \text{otherwise.} \end{cases}$$

Where the a indicates the hypothesis and the b indicates the truth. For ease of understanding, i and j here in may be considered as lengths of a and b.

> **Warning:** Unorded *truth_indices* or *hypothesis_indices* might lead to expected result, so it is suggested to make sure *truth_indices* and *hypothesis_indices* are both in ascending order before calling this API.

Parameters

normalize (*bool*) – If `True` , edit distances are normalized by length of truth. Default: `True` .

Inputs:

- **hypothesis_indices** (Tensor) - The indices of the hypothesis list SparseTensor. With int64 data type. The shape of tensor is (N, R).
- **hypothesis_values** (Tensor) - The values of the hypothesis list SparseTensor. Must be 1-D vector with length of N.

- **hypothesis_shape** (Tensor) - The shape of the hypothesis list SparseTensor. Must be R-length vector with int64 data type. Only constant value is allowed.
- **truth_indices** (Tensor) - The indices of the truth list SparseTensor. With int64 data type. The shape of tensor is (M, R).
- **truth_values** (Tensor) - The values of the truth list SparseTensor. Must be 1-D vector with length of M.
- **truth_shape** (Tensor) - The shape of the truth list SparseTensor. Must be R-length vector with int64 data type. Only constant value is allowed.

Outputs:

Tensor, a dense tensor with rank *R-1* and float32 data type.

Raises

TypeError – If *normalize* is not a bool.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> class EditDistance(nn.Cell):
...     def __init__(self, hypothesis_shape, truth_shape, normalize=True):
...         super(EditDistance, self).__init__()
...         self.edit_distance = ops.EditDistance(normalize)
...         self.hypothesis_shape = hypothesis_shape
...         self.truth_shape = truth_shape
...
...     def construct(self, hypothesis_indices, hypothesis_values, truth_indices, truth_
↪values):
...         return self.edit_distance(hypothesis_indices, hypothesis_values, self.hypothesis_
↪shape,
...                                   truth_indices, truth_values, self.truth_shape)
...
>>> hypothesis_indices = Tensor(np.array([[0, 0, 0], [1, 0, 1], [1, 1, 1]]).astype(np.int64))
>>> hypothesis_values = Tensor(np.array([1, 2, 3]).astype(np.float32))
>>> hypothesis_shape = Tensor(np.array([1, 1, 2]).astype(np.int64))
>>> truth_indices = Tensor(np.array([[0, 1, 0], [0, 0, 1], [1, 1, 0], [1, 0, 1]]).astype(np.
↪int64))
>>> truth_values = Tensor(np.array([1, 3, 2, 1]).astype(np.float32))
>>> truth_shape = Tensor(np.array([2, 2, 2]).astype(np.int64))
>>> edit_distance = EditDistance(hypothesis_shape, truth_shape)
>>> output = edit_distance(hypothesis_indices, hypothesis_values, truth_indices, truth_
↪values)
>>> print(output)
[[1. 1.]
 [1. 1.]]
```

mindspore.ops.LpNorm

class mindspore.ops.**LpNorm**(*axis*, *p=2*, *keep_dims=False*, *epsilon=1e-12*)

Return the p-norm of a matrix or vector.

$$output = \|input\|_p = \left(\sum_{i=1}^{n} |input|^p\right)^{1/p}$$

Parameters

- **axis** (*int*, *list*, *tuple*) – Specifies which dimension or dimensions of input to calculate the norm across.
- **p** (*int*, *optional*) – The order of norm. Default: `2` .
- **keep_dims** (*bool*, *optional*) – Whether the output tensors have dim retained or not. Default: `False` .
- **epsilon** (*float*, *optional*) – The lower bound value, when the calculated norm is less than this value, replace this result with *epsilon*. Default: `1e-12` .

Inputs:

- **input** (Tensor) - Input tensor of type float16, float32.

Outputs:

Tensor, has the same dtype as *input*, its shape depends on *axis*. For example, if the shape of input is $(2, 3, 4)$, *axis* is $[0, 1]$, output shape will be $(4,)$.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If dtype of *input* is not one of: float16, float32.
- **TypeError** – If *p* is not an int.
- **TypeError** – If *axis* is not an int, a tuple or a list.
- **TypeError** – If *axis* is a tuple or a list, but the element of *axis* is not an int.
- **TypeError** – If *keep_dims* is not a bool.
- **ValueError** – If the element of *axis* is out of the range $[-r, r)$, where r is the rank of *input*.
- **ValueError** – If the length of shape of *axis* is bigger than the length of shape of *input*.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[[1.0, 2.0], [3.0, 4.0]], [[5.0, 6.0], [7.0, 8.0]]]).
↪astype(np.float32))
>>> op = ops.LpNorm(axis=[0, 1], p=2, keep_dims=False)
>>> output = op(input_x)
>>> print(output)
[ 9.165152 10.954452]
```

mindspore.ops.Pdist

class mindspore.ops.**Pdist**(*p=2.0*)

Computes the p-norm distance between each pair of row vectors in the input.

Refer to *mindspore.ops.pdist()* for more details.

Note: The pdist operator involves exponentiation, the inf/nan calculation result may be generated when the float16 input is used. The float32 input is recommended.

Parameters

p (*float, optional*) – The order of norm distance, $p \in [0,)$. Default: `2.0`.

Inputs:

- **x** (Tensor) - Input tensor. Supported dtypes: float16, float32 or float64.

Outputs:

Tensor, has the same dtype as *x*.

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> from mindspore import Tensor, ops
>>> import numpy as np
>>> x = Tensor(np.array([[1.0, 1.0], [2.0, 2.0], [3.0, 3.0]]).astype(np.float32))
>>> op = ops.Pdist(p=2.0)
>>> y = op(x)
>>> print(y)
[1.4142135 2.828427  1.4142135]
```

18.2.6 Sampling Operator

API Name	Description	Supported Platforms
mindspore.ops.ComputeAccidentalHits	Compute accidental hits of sampled classes which match target classes.	`Ascend`
mindspore.ops.LogUniformCandidateSampler	Generates random labels with a log-uniform distribution for sampled_candidates.	`Ascend` `CPU`
mindspore.ops.UniformCandidateSampler	Uniform candidate sampler.	`Ascend` `GPU` `CPU`

mindspore.ops.ComputeAccidentalHits

class mindspore.ops.**ComputeAccidentalHits**(*num_true=1*)

Compute accidental hits of sampled classes which match target classes.

When a target class matches the sample class, we call it "accidental hit". The result of calculating accidental hits contain three parts (index, id, weight), where index represents the row number in true_classes, and id represents the position in sampled_candidates, the weight is FLOAT_MAX. FLOAT_MAX indicates the max value in the type of Float

Parameters

num_true (*int, optional*) – The number of target classes per training example. Default: `1` .

Inputs:

- **true_classes** (Tensor) - The target classes. With data type of int64 and shape $(batch\_size, num\_true)$.
- **sampled_candidates** (Tensor) - The Candidate sampling results of operators, types of training samples, with data type of int64 and shape $(num\_sampled,)$.

Outputs:

Tuple of 3 Tensors.

- **indices** (Tensor) - A Tensor with shape $(num\_accidental\_hits,)$, with data type of int32.
- **ids** (Tensor) - A Tensor with shape $(num\_accidental\_hits,)$, with data type of int64.
- **weights** (Tensor) - A Tensor with shape $(num\_accidental\_hits,)$, with the type float32.

Raises

- **TypeError** – If dtype of *num_true* is not int.
- **TypeError** – If *true_classes* or *sampled_candidates* is not a Tensor.
- **TypeError** – If dtype of *true_classes* or *sampled_candidates* is neither int32 nor int64.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> true_classes = np.array([[1, 2], [0, 4], [3, 3]])
>>> sampled_candidates = np.array([0, 1, 2, 3, 4])
>>> sampler = ops.ComputeAccidentalHits(2)
>>> indices, ids, weights = sampler(Tensor(true_classes), Tensor(sampled_candidates))
>>> print(indices, ids, weights)
[0 0 1 1 2 2]
[1 2 0 4 3 3]
[-3.4028235e+38 -3.4028235e+38 -3.4028235e+38 -3.4028235e+38 -3.4028235e+38 -3.4028235e+38]
```

mindspore.ops.LogUniformCandidateSampler

class mindspore.ops.**LogUniformCandidateSampler**(*num_true=1*, *num_sampled=5*, *unique=True*, *range_max=5*, *seed=0*)

Generates random labels with a log-uniform distribution for sampled_candidates.

Randomly samples a tensor of sampled classes from the range of integers [0, range_max).

Refer to *mindspore.ops.log _uniform_candidate_sampler()* for more details.

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

- **num_true** (*int, optional*) –The number of target classes per training example. Default: `1` .
- **num_sampled** (*int, optional*) –The number of classes to randomly sample. Default: `5` .
- **unique** (*bool, optional*) –Determines whether sample with rejection. If *unique* is `True` , all sampled classes in a batch are unique. Default: `True` .
- **range_max** (*int, optional*) –The number of possible classes. When *unique* is `True` , *range_max* must be greater than or equal to *num_sampled*. Default: `5` .
- **seed** (*int, optional*) –Random seed, must be non-negative. Default: `0` .

Inputs:

- **true_classes** (Tensor) - The target classes. With data type of int64 and shape $(batch\_size, num\_true)$.

Outputs:

Tuple of 3 Tensors.

- **sampled_candidates** (Tensor) - A Tensor with shape $(num\_sampled,)$ and the same type as *true_classes*.
- **true_expected_count** (Tensor) - A Tensor with the same shape as *true_classes and* type float32.
- **sampled_expected_count** (Tensor) - A Tensor with the same shape as *sampled_candidates* and type float32.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> sampler = ops.LogUniformCandidateSampler(2, 5, True, 5)
>>> output1, output2, output3 = sampler(Tensor(np.array([[1, 7], [0, 4], [3, 3]])))
>>> print(output1, output2, output3)
[3 2 0 4 1]
[[0.92312991 0.49336370]
 [0.99248987 0.65806371]
 [0.73553443 0.73553443]]
[0.73553443 0.82625800 0.99248987 0.65806371 0.92312991]
```

mindspore.ops.UniformCandidateSampler

class mindspore.ops.**UniformCandidateSampler**(*num_true*, *num_sampled*, *unique*, *range_max*, *seed=0*, *remove_accidental_hits=False*)

Uniform candidate sampler.

This function samples a set of classes(sampled_candidates) from [0, range_max-1] based on uniform distribution.

Refer to *mindspore.ops.uniform _candidate_sampler()* for more details.

Warning:

- The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.
- The Ascend backend does not support dynamic shape scenarios currently.

Parameters

- **num_true** (*int*) −The number of target classes in each training example.
- **num_sampled** (*int*) −The number of classes to randomly sample. The sampled_candidates will have a shape of num_sampled. If unique=True, num_sampled must be less than or equal to range_max.
- **unique** (*bool*) −Whether all sampled classes in a batch are unique.
- **range_max** (*int*) −The number of possible classes, must be non-negative.
- **seed** (*int, optional*) −Used for random number generation, must be non-negative. If seed has a value of 0, the seed will be replaced with a randomly generated value. Default: `0` .
- **remove_accidental_hits** (*bool, optional*) −Whether accidental hit is removed. Accidental hit is when one of the true classes matches one of the sample classes. Set `True` to remove which accidentally sampling the true class as sample class. Default: `False` .

Inputs:

- **true_classes** (Tensor) - A Tensor. The target classes with a Tensor shape of $(batch\_size, num\_true)$. The value range of the elements must be $[0, range\_max)$.

Outputs:

- **sampled_candidates** (Tensor) - The sampled_candidates is independent of the true classes. Shape: $(num\_sampled,)$.
- **true_expected_count** (Tensor) - The expected counts under the sampling distribution of each of true_classes. Shape: $(batch\_size, num\_true)$.
- **sampled_expected_count** (Tensor) - The expected counts under the sampling distribution of each of sampled_candidates. Shape: $(num\_sampled,)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> sampler = ops.UniformCandidateSampler(1, 3, False, 4, 1)
>>> output1, output2, output3 = sampler(Tensor(np.array([[1], [3], [4], [6], [3]], dtype=np.
↪int64)))
>>> print(output1.shape)
(3,)
>>> print(output2.shape)
(5, 1)
>>> print(output3.shape)
(3,)
```

18.2.7 Image Processing

API Name	Description	Supported Platforms
mindspore.ops.BoundingBoxDecode	Decodes bounding boxes locations.	Ascend GPU CPU
mindspore.ops.BoundingBoxEncode	Encodes bounding boxes locations.	Ascend GPU CPU
mindspore.ops.CheckValid	Checks bounding box.	Ascend GPU CPU
mindspore.ops.CropAndResize	Extracts crops from the input image tensor and resizes them.	Ascend GPU CPU
mindspore.ops.ExtractVolumePatches	*ops.ExtractVolumePatches* is deprecated from version 2.3 and will be removed in a future version.	Deprecated
mindspore.ops.IOU	Calculates intersection over union for boxes.	Ascend GPU CPU
mindspore.ops.L2Normalize	L2 Normalization Operator.	Ascend GPU CPU
mindspore.ops.NMSWithMask	Non-maximum Suppression.	Ascend GPU CPU
mindspore.ops.ResizeBilinearV2	Resizes an image to a certain size using the bilinear interpolation.	Ascend GPU CPU
mindspore.ops.ROIAlign	Computes the Region of Interest (RoI) Align operator.	Ascend GPU CPU
mindspore.ops.UpsampleNearest3D	Performs nearest neighbor upsampling operation.	Ascend GPU CPU
mindspore.ops.UpsampleTrilinear3D	Performs upsampling with trilinear interpolation across 3dims for 5dim input Tensor.	Ascend GPU CPU

mindspore.ops.BoundingBoxDecode

class mindspore.ops.**BoundingBoxDecode**(*max_shape*, *means=(0.0, 0.0, 0.0, 0.0)*, *stds=(1.0, 1.0, 1.0, 1.0)*, *wh_ratio_clip=0.016*)

Decodes bounding boxes locations.

The function of the operator is to calculate the offset, and this operator converts the offset into a Bbox, which is used to mark the target in the subsequent images, etc.

Parameters

- **max_shape** (*tuple*) –The max size limit for decoding box calculation.
- **means** (*tuple, optional*) –The means of deltas calculation. Default: `(0.0, 0.0, 0.0, 0.0)`.
- **stds** (*tuple, optional*) –The standard deviations of deltas calculation. Default: `(1.0, 1.0, 1.0, 1.0)`.

- **wh_ratio_clip** (*float, optional*) –The limit of width and height ratio for decoding box calculation. Default: `0.016`.

Inputs:

- **anchor_box** (Tensor) - Anchor boxes. The shape of *anchor_box* must be $(n, 4)$.
- **deltas** (Tensor) - Delta of boxes. Which has the same shape with *anchor_box*.

Outputs:

Tensor, decoded boxes. It has the same data type and shape as *anchor_box*.

Raises

- **TypeError** –If *means*, *stds* or *max_shape* is not a tuple.
- **TypeError** –If *wh_ratio_clip* is not a float.
- **TypeError** –If *anchor_box* or *deltas* is not a Tensor.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> anchor_box = Tensor([[4, 1, 2, 1], [2, 2, 2, 3]], mindspore.float32)
>>> deltas = Tensor([[3, 1, 2, 2], [1, 2, 1, 4]], mindspore.float32)
>>> boundingbox_decode = ops.BoundingBoxDecode(means=(0.0, 0.0, 0.0, 0.0), stds=(1.0, 1.0, 1.
↪0, 1.0),
...                                            max_shape=(768, 1280), wh_ratio_clip=0.016)
>>> output = boundingbox_decode(anchor_box, deltas)
>>> print(output)
[[ 4.194528  0.         0.         5.194528]
 [ 2.1408591   0.         3.8591409  60.598152  ]]
```

mindspore.ops.BoundingBoxEncode

class mindspore.ops.**BoundingBoxEncode**(*means=(0.0, 0.0, 0.0, 0.0)*, *stds=(1.0, 1.0, 1.0, 1.0)*)

Encodes bounding boxes locations.

This operator will calculate the offset between the predicted bounding boxes and the real bounding boxes, and this offset will be used as a variable for the loss.

Parameters

- **means** (*tuple*) –Means for encoding bounding boxes calculation. Default: `(0.0, 0.0, 0.0, 0.0)`.
- **stds** (*tuple*) –The standard deviations of deltas calculation. Default: `(1.0, 1.0, 1.0, 1.0)`.

Inputs:

- **anchor_box** (Tensor) - Anchor boxes. The shape of anchor_box must be $(n, 4)$.
- **groundtruth_box** (Tensor) - Ground truth boxes. Which has the same shape with anchor_box.

Outputs:

Tensor, encoded bounding boxes. It has the same data type and shape as input *anchor_box*.

Raises

- **TypeError** – If *means* or *stds* is not a tuple.
- **TypeError** – If *anchor_box* or *groundtruth_box* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> anchor_box = Tensor([[2, 2, 2, 3], [2, 2, 2, 3]], mindspore.float32)
>>> groundtruth_box = Tensor([[1, 2, 1, 4], [1, 2, 1, 4]], mindspore.float32)
>>> boundingbox_encode = ops.BoundingBoxEncode(means=(0.0, 0.0, 0.0, 0.0), stds=(1.0, 1.0, 1.
↪0, 1.0))
>>> output = boundingbox_encode(anchor_box, groundtruth_box)
>>> print(output)
[[ -1.   0.25  0.   0.40551758]
 [ -1.   0.25  0.   0.40551758]]
```

mindspore.ops.CheckValid

class mindspore.ops.**CheckValid**

Checks bounding box.

Checks whether the bounding boxes specified by *bboxes* is valid. Returns True if the box is within borders specified by *img_metas*, False if not.

Inputs:

- **bboxes** (Tensor) - Bounding boxes tensor with shape $(N, 4)$. N indicates the number of bounding boxes, the value "4" indicates "x0", "y0", "x1", and "y1". Data type must be float16 or float32.
- **img_metas** (Tensor) - Raw image size information with the format of $(height, width, ratio)$, specifying the valid boundary $(height * ratio, width * ratio)$. Data type must be float16 or float32.

Outputs:

Tensor, with shape of $(N,)$ and dtype of bool, specifying whether the bounding boxes is in the image. "True" indicates valid, while "False" indicates invalid.

Raises

- **TypeError** – If *bboxes* or *img_metas* is not a Tensor.
- **TypeError** – If dtype of *bboxes* or *img_metas* is neither float16 nor float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.check_valid = ops.CheckValid()
...     def construct(self, x, y):
...         valid_result = self.check_valid(x, y)
...         return valid_result
...
>>> bboxes = Tensor(np.linspace(0, 6, 12).reshape(3, 4), mindspore.float32)
>>> img_metas = Tensor(np.array([2, 1, 3]), mindspore.float32)
>>> net = Net()
>>> output = net(bboxes, img_metas)
>>> print(output)
[ True False False]
```

mindspore.ops.CropAndResize

class mindspore.ops.**CropAndResize**(*method='bilinear'*, *extrapolation_value=0.0*)

Extracts crops from the input image tensor and resizes them.

Note: In case that the output shape depends on crop_size, the crop_size must be constant. For now, the backward of the operator only support bilinear method, for other methods, will return 0.

Parameters

- **method** (*str, optional*) – An optional string that specifies the sampling method for resizing. It can be "bilinear", "nearest" or "bilinear_v2". Default: "bilinear".
  - "nearest": Nearest neighbor interpolation. Each output pixel is assigned the value of the nearest input pixel. This method is simple and fast but can result in blocky or pixelated outputs.
  - "bilinear": Bilinear interpolation. Each output pixel is a weighted average of the four nearest input pixels, computed using bilinear interpolation. This method produces smoother results compared to nearest neighbor interpolation.
  - "bilinear_v2": The optimized variant of "bilinear", it may achieve better result(higher precision and speed) in some cases.
- **extrapolation_value** (*float, optional*) – An optional float value used extrapolation, if applicable. Default: 0.0.

Inputs:

- **x** (Tensor) - The input image must be a 4-D tensor of shape $(batch, image\_height, image\_width, depth)$. Types allowed: int8, int16, int32, int64, float16, float32, float64, uint8, uint16.
- **boxes** (Tensor) - A 2-D tensor of shape $(num\_boxes, 4)$. The i-th row of the tensor specifies the coordinates of a box in the box_ind[i] image and is specified in normalized coordinates [y1, x1, y2, x2]. A normalized coordinate value of y is mapped to the image coordinate at y * (image_height - 1), so as the [0, 1] interval of normalized image height is mapped to [0, image_height - 1] in image height coordinates. We do allow y1 > y2, in which case the sampled crop is

an up-down flipped version of the original image. The width dimension is treated similarly. Normalized coordinates outside the [0, 1] range are allowed, in which case we use *extrapolation_value* to extrapolate the input image values. Types allowed: float32.

- **box_index** (Tensor) - A 1-D tensor of shape (num_boxes) with int32 values in [0, batch). The value of *box_index[i]* specifies the image that the i-th box refers to. Types allowed: int32.
- **crop_size** (Tuple[int]) - A tuple of two int32 elements: (crop_height, crop_width). Only constant value is allowed. All cropped image patches are resized to this size. The aspect ratio of the image content is not preserved. Both crop_height and crop_width need to be positive.

Outputs:

A 4-D tensor of shape ($num\_boxes, crop\_height, crop\_width, depth$) with type: float32.

Raises

- **TypeError** – If *x* or *boxes* or *box_index* is not a Tensor.
- **TypeError** – If *crop_size* is not a Tuple with two int32 elements.
- **TypeError** – If dtype of *boxes* is not float or that of *box_index* is not int.
- **TypeError** – If *method* is not a str.
- **TypeError** – If *extrapolation_value* is not a float.
- **ValueError** – If the shape rank of *x* is not 4.
- **ValueError** – If the shape rank of *boxes* is not 2.
- **ValueError** – If the second dim of *boxes* is not 4.
- **ValueError** – If the shape rank of *box_index* is not 1.
- **ValueError** – If the first dim of *box_index* is not equal to that of *boxes*.
- **ValueError** – If existing element in *box_index* is out of range *[0, batch)*.
- **ValueError** – If the data of *crop_size* is not positive.
- **ValueError** – If *method* is not one of 'bilinear', 'nearest', 'bilinear_v2'.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import nn, ops, Tensor
>>> class CropAndResizeNet(nn.Cell):
...     def __init__(self, crop_size):
...         super(CropAndResizeNet, self).__init__()
...         self.crop_and_resize = ops.CropAndResize()
...         self.crop_size = crop_size
...
...     def construct(self, x, boxes, box_index):
...         return self.crop_and_resize(x, boxes, box_index, self.crop_size)
...
>>> BATCH_SIZE = 1
>>> NUM_BOXES = 5
```

>>> CHANNELS = 3
>>> image = np.random.normal(size=[BATCH_SIZE, IMAGE_HEIGHT, IMAGE_WIDTH, CHANNELS]).
↪astype(np.float32)
>>> boxes = np.random.uniform(size=[NUM_BOXES, 4]).astype(np.float32)
>>> box_index = np.random.uniform(size=[NUM_BOXES], low=0, high=BATCH_SIZE).astype(np.int32)
>>> crop_size = (24, 24)
>>> crop_and_resize = CropAndResizeNet(crop_size=crop_size)
>>> output = crop_and_resize(Tensor(image), Tensor(boxes), Tensor(box_index))
>>> print(output.shape)
(5, 24, 24, 3)
```

mindspore.ops.ExtractVolumePatches

class mindspore.ops.**ExtractVolumePatches**(*kernel_size*, *strides*, *padding*)

ops.ExtractVolumePatches is deprecated from version 2.3 and will be removed in a future version.

Supported Platforms:

Deprecated

mindspore.ops.IOU

class mindspore.ops.**IOU**(*mode='iou'*)

Calculates intersection over union for boxes.

Computes the intersection over union (IOU) or the intersection over foreground (IOF) based on the truth and predicted regions.

Refer to *mindspore.ops.iou()* for more details.

Parameters

mode (*str*) – The mode is used to specify the calculation method, now supporting `'iou'` (intersection over union) or `'iof'` (intersection over foreground) mode. Default: `'iou'` .

Inputs:

- **anchor_boxes** (Tensor) - Anchor boxes, tensor of shape $(N, 4)$. "N" indicates the number of anchor boxes, and the value "4" refers to "x0", "y0", "x1", and "y1". Data type must be float16 or float32.
- **gt_boxes** (Tensor) - The truth boxes, tensor of shape $(M, 4)$. "M" indicates the number of truth boxes, and the value "4" refers to "x0", "y0", "x1", and "y1". Data type must be float16 or float32.

Outputs:

Tensor, the 'iou' values, tensor of shape (M, N), with the same data type as *anchor_boxes*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> iou = ops.IOU(mode='iou')
>>> anchor_boxes = Tensor(np.random.randint(1.0, 5.0, [3, 4]), mindspore.float16)
>>> gt_boxes = Tensor(np.random.randint(1.0, 5.0, [3, 4]), mindspore.float16)
>>> output = iou(anchor_boxes, gt_boxes)
>>> print(output.shape)
(3, 3)
```

mindspore.ops.L2Normalize

class mindspore.ops.**L2Normalize**(*axis=0*, *epsilon=1e-4*)

L2 Normalization Operator.

This operator will normalize the input using the given axis. The function is shown as follows:

$$\text{output} = \frac{x}{\sqrt{\max(\sum_i |x_i|^2, \epsilon)}}$$

where ϵ is epsilon and $\sum_i |x_i|^2$ calculate the sum of squares of the input x along the dimension *axis*.

Note: On Ascend, input data type of float64 is currently not supported.

Parameters

- **axis** (*Union[list(int), tuple(int), int], optional*) – Specify the axis for calculating the L2 norm. Default: `0` .
- **epsilon** (*float, optional*) – A small value added for numerical stability. Default: `1e-4` .

Inputs:

- **x** (Tensor) - Input to compute the normalization. Tensor of shape $(N, *)$, where $*$ means any number of additional dimensions. Data type must be float16, float32 or float64.

Outputs:

Tensor, with the same type and shape as the *x*.

Raises

- **TypeError** – If *axis* is not one of the following: list, tuple or int.
- **TypeError** – If *epsilon* is not a float.
- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If dtype of *x* is not in [float16, float32, float64].
- **ValueError** – If dimension of *x* is not greater than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> l2_normalize = ops.L2Normalize()
>>> x = Tensor(np.random.randint(-256, 256, (2, 3, 4)), mindspore.float32)
>>> output = l2_normalize(x)
>>> print(output.shape)
(2, 3, 4)
```

mindspore.ops.NMSWithMask

class mindspore.ops.**NMSWithMask**(*iou_threshold=0.5*)

Non-maximum Suppression. When object detection problem is performed in the computer vision field, object detection algorithm generates a plurality of bounding boxes. Use the box with the highest score, calculate the overlap between other boxes and the current box, and delete the box based on a certain threshold(IOU). On Ascend platform, the input box score is ignored, which only selects boexs based on the IOU between boxes, which means if you want to remove boxes that has lower scores, you need to sort the input boxes by score in descending order in advance. The IOU is as follows:

$$\text{IOU} = \frac{\text{Area of Overlap}}{\text{Area of Union}}$$

> **Warning:** Only supports up to 2864 input boxes at one time.

Parameters

iou_threshold (*float*) –Specifies the threshold of overlap boxes with respect to IOU. Default: `0.5` .

Inputs:

- **bboxes** (Tensor) - The shape of tensor is $(N, 5)$. Input bounding boxes. N is the number of input bounding boxes. Every bounding box contains 5 values, the first 4 values are the coordinates(x0, y0, x1, y1) of bounding box which represents the point of top-left and bottom-right, and the last value is the score of this bounding box. The data type must be float16 or float32.

Outputs:

tuple[Tensor], tuple of three tensors, they are output_boxes, output_idx and selected_mask.

- **output_boxes** (Tensor) - The shape of tensor is $(N, 5)$. On GPU and CPU platform, it is a sorted list of bounding boxes by sorting the input *bboxes* in descending order of score. On Ascend platform, it is same as input *bboxes*.
- **output_idx** (Tensor) - The shape of tensor is $(N,)$. The indexes list of *output_boxes*.
- **selected_mask** (Tensor) - The shape of tensor is $(N,)$. A mask list of valid output bounding boxes. Apply this mask on *output_boxes* to get the list of bounding boxes after non-max suppression calculation, or apply this mask on *output_idx* to get the indexes list of bounding boxes after non-max suppression calculation.

Raises

- **ValueError** –If the *iou_threshold* is not a float number.
- **ValueError** –if the first dimension of input Tensor is less than or equal to 0.
- **TypeError** –if the dtype of the *bboxes* is not float16 or float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bbox = np.array([[100.0, 100.0, 50.0, 68.0, 0.63], [150.0, 75.0, 165.0, 115.0, 0.55],
...                  [12.0, 190.0, 288.0, 200.0, 0.9], [28.0, 130.0, 106.0, 172.0, 0.3]])
>>> bbox[:, 2] += bbox[:, 0]
>>> bbox[:, 3] += bbox[:, 1]
>>> inputs = Tensor(bbox, mindspore.float32)
>>> nms = ops.NMSWithMask(0.1)
>>> output_boxes, indices, mask = nms(inputs)
>>> indices_np = indices.asnumpy()
>>> print(indices_np[mask.asnumpy()])
[0 1 2]
```

mindspore.ops.ResizeBilinearV2

class mindspore.ops.**ResizeBilinearV2**(*align_corners=False*, *half_pixel_centers=False*)

Resizes an image to a certain size using the bilinear interpolation.

The resizing only affects the lower two dimensions which represent the height and width of the image.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **align_corners** (*bool, optional*) –If `True` , rescale input by $(new\_height-1)/(height-1)$, which exactly aligns the 4 corners of images and resized images. If `False` , rescale by $new\_height/height$. Default: `False` .
- **half_pixel_centers** (*bool, optional*) –Whether half pixel center. If set to `True` , *align_corners* should be `False` . Default: `False` .

Inputs:

- **x** (Tensor) - Image to be resized. Input images must be a 4-D tensor with shape $(batch, channels, height, width)$, with data type of float32 or float16.
- **size** (Union[tuple[int], list[int], Tensor]) - The new size of the images. A tuple or list or Tensor of 2 int elements (new_height, new_width).

Outputs:

Tensor, resized image. 4-D with shape $(batch, channels, new\_height, new\_width)$, with the same data type as input *x*.

Raises

- **TypeError** –If *align_corners* is not a bool.
- **TypeError** –If *half_pixel_centers* is not a bool.
- **TypeError** –If *align_corners* and *half_pixel_centers* are `True` .
- **ValueError** –If *half_pixel_centers* is `True` and device_target is CPU.
- **ValueError** –If dim of *x* is not 4.
- **ValueError** –If *size* is Tensor and its dim is not 1.
- **ValueError** –If *size* contains other than 2 elements.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> x = Tensor([[[[1, 2, 3, 4, 5], [1, 2, 3, 4, 5]]]], mindspore.float32)
>>> output = ops.ResizeBilinearV2()(x, (5, 5))
>>> print(output)
[[[[1. 2. 3. 4. 5.]
   [1. 2. 3. 4. 5.]
   [1. 2. 3. 4. 5.]
   [1. 2. 3. 4. 5.]
   [1. 2. 3. 4. 5.]]]]
```

mindspore.ops.ROIAlign

class mindspore.ops.**ROIAlign**(*pooled_height*, *pooled_width*, *spatial_scale*, *sample_num=2*, *roi_end_mode=1*)

Computes the Region of Interest (RoI) Align operator.

The operator computes the value of each sampling point by bilinear interpolation from the nearby grid points on the feature map. No quantization is performed on any coordinates involved in the RoI, its bins, or the sampling points. The details of (RoI) Align operator are described in Mask R-CNN.

Parameters

- **pooled_height** (*int*) –The output features height.
- **pooled_width** (*int*) –The output features width.
- **spatial_scale** (*float*) –A scaling factor that maps the raw image coordinates to the input feature map coordinates. Suppose the height of a RoI is *ori_h* in the raw image and *fea_h* in the input feature map, the *spatial_scale* must be *fea_h / ori_h*.
- **sample_num** (*int*) –Number of sampling points. Default: `2` .
- **roi_end_mode** (*int*) –Number must be 0 or 1. If roi_end_mode=0, use the legacy implementation. If roi_end_mode=1, end pixel of the roi_box will be shifted by +1*spatial_scale. Default: `1` .

Inputs:

- **features** (Tensor) - The input features, whose shape must be (N, C, H, W), with data type of float16 or float32.

- **rois** (Tensor) - The shape is $(rois\_n, 5)$, with data type of float16 or float32. *rois_n* represents the number of RoI. The size of the second dimension must be *5* and the *5* colunms are $(image\_index, top\_left\_x, top\_left\_y, bottom\_right\_x, bottom\_right\_y)$. *image_index* represents the index of image. *top_left_x* and *top_left_y* represent the *x, y* coordinates of the top left corner of corresponding RoI, respectively. *bottom_right_x* and *bottom_right_y* represent the *x, y* coordinates of the bottom right corner of corresponding RoI, respectively.

Outputs:

Tensor, the shape is $(rois\_n, C, pooled\_height, pooled\_width)$.

Raises

- **TypeError** –If *pooled_height*, *pooled_width*, *sample_num* or *roi_end_mode* is not an int.
- **TypeError** –If *spatial_scale* is not a float.
- **TypeError** –If *features* or *rois* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> features = Tensor(np.array([[[[1., 2.], [3., 4.]]]]), mindspore.float32)
>>> rois = Tensor(np.array([[0, 0.2, 0.3, 0.2, 0.3]]), mindspore.float32)
>>> roi_align = ops.ROIAlign(2, 2, 0.5, 2)
>>> output = roi_align(features, rois)
>>> print(output)
[[[[1.775 2.025]
   [2.275 2.525]]]]
```

mindspore.ops.UpsampleNearest3D

class mindspore.ops.**UpsampleNearest3D**

Performs nearest neighbor upsampling operation.

This operator scale up the volumetric input with specified *output_size* or *scales* factors, using nearest neighbor algorithm.

One of *output_size* or *scales* must be given, and can not specified both at the same time.

Inputs:

- **x** (Tensor) - 5D tensor of shape $(N, C, D_{in}, H_{in}, W_{in})$. Supporting types: [float16, float32, float64].
- **output_size** (Union[tuple[int], list[int]]): A tuple or list of int specifying the output volumetric size. Default: `None`.
- **scales** (Union[tuple[float], list[float]]): A tuple or list of float specifying the upsampling factors. Default: `None`.

Outputs:

- **y** (Tensor) - Upsampled output with the same type as *x* , whose shape is $(N, C, D_{out}, H_{out}, W_{out})$.

Raises

- **TypeError** –When *output_size* is not `None` and *output_size* is not list[int] or tuple[int].

- **TypeError** – When *scales* is not `None` and *scales* is not list[float] or tuple[float].
- **TypeError** – If dtype of *x* is not int [float16, float32, float64].
- **ValueError** – If any value of *output_size* is negative or zero when *output_size* is not `None`.
- **ValueError** – If any value of *scales* is negative or zero when *scales* is not `None`.
- **ValueError** – If shape of *x* is not 5D.
- **ValueError** – If none of *scales* and *output_size* is specified or both specified.
- **ValueError** – If size of *scales* is not equal 3 when *scales* is specified.
- **ValueError** – If size of *output_size* is not equal 3 when *output_size* is specified.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor(np.array([1, 2, 3, 4, 5, 6, 7, 8, 9, 10, 11, 12, 13, 14, 15, 16])
...        .reshape([1, 1, 2, 2, 4]), mstype.float32)
>>> output_size = [3, 4, 5]
>>> net = ops.UpsampleNearest3D()
>>> output = net(x, output_size, None)
>>> print(output)
[[[[[ 1.  1.  2.  3.  4.]
    [ 1.  1.  2.  3.  4.]
    [ 5.  5.  6.  7.  8.]
    [ 5.  5.  6.  7.  8.]]
   [[ 1.  1.  2.  3.  4.]
    [ 1.  1.  2.  3.  4.]
    [ 5.  5.  6.  7.  8.]
    [ 5.  5.  6.  7.  8.]]
   [[ 9.  9. 10. 11. 12.]
    [ 9.  9. 10. 11. 12.]
    [13. 13. 14. 15. 16.]
    [13. 13. 14. 15. 16.]]]]]
```

mindspore.ops.UpsampleTrilinear3D

class mindspore.ops.**UpsampleTrilinear3D**(*align_corners=False*)

Performs upsampling with trilinear interpolation across 3dims for 5dim input Tensor.

This operator scale up the volumetric input with specified *output_size* or *scales* factors, using trilinear upscaling algorithm.

Note: One of *scales* and *output_size* must be specified. And it is an error if both are specified.

Parameters

align_corners (*bool, optional*) –An optional bool. Default: `False`. If `True`, the input and output tensors are aligned by the center points of their corner pixels, preserving the values at the corner pixels. If `False` , the input and output tensors are aligned by the corner points of their corner pixels, and the interpolation use edge value padding for out of boundary values.

Inputs:

- **x** (Tensor) - 5D tensor of shape $(N, C, D_{in}, H_{in}, W_{in})$. Supporting types: [float16, float32, float64].
- **output_size** (Union[tuple[int], list[int]]): A tuple or list of 3 int elements $(output\_depth, output\_height, output\_width)$. Default: `None`.
- **scales** (Union[tuple[float], list[float]]): A tuple or list of 3 float elements $(scale\_depth, scale\_height, scale\_width)$. Default: `None`.

Outputs:

- **y** (Tensor) - Upsampled output with the same data type as *x*, whose shape is $(N, C, D_{out}, H_{out}, W_{out})$.

Raises

- **TypeError** –When *output_size* is not `None` and *output_size* is not list[int] or tuple[int].
- **TypeError** –When *scales* is not `None` and *scales* is not list[float] or tuple[float].
- **TypeError** –If dtype of *x* is not in [float16, float32, float64].
- **TypeError** –If type of *align_corners* is not bool.
- **ValueError** –If any value of *output_size* is negative or zero when *output_size* is not `None`.
- **ValueError** –If any value of *scales* is negative or zero when *scales* is not `None`.
- **ValueError** –If shape of *x* is not 5D.
- **ValueError** –If none of *scales* and *output_size* is specified or both specified.
- **ValueError** –If size of *scales* is not equal 3 when *scales* is specified.
- **ValueError** –If size of *output_size* is not equal 3 when *output_size* is specified.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> net = ops.UpsampleTrilinear3D()
>>> in_x = Tensor(input_data=np.random.randn(2, 3, 4, 512, 256))
>>> output_size=[4, 64, 48]
>>> out = net(in_x, output_size, None)
>>> print(out.shape)
(2, 3, 4, 64, 48)
>>>
>>> net = ops.UpsampleTrilinear3D()
>>> in_x = Tensor(np.arange(1, 5, dtype=np.float32).reshape((1, 1, 1, 2, 2)))
>>> output_size=[2, 4, 4]
>>> out = net(in_x, output_size, None)
>>> print(out)
```

18.2.8 Text Processing

API Name	Description	Supported Platforms
mindspore.ops.NoRepeatNGram	Updates the probability of occurrence of words with its corresponding n-grams.	Ascend GPU CPU

mindspore.ops.NoRepeatNGram

class mindspore.ops.**NoRepeatNGram**(*ngram_size=1*)

Updates the probability of occurrence of words with its corresponding n-grams.

During beam search, if consecutive *ngram_size* words exist in the generated word sequence, the consecutive *ngram_size* words will be avoided during subsequent prediction. For example, when *ngram_size* is 3, the generated word sequence is [1, 2, 3, 2, 3], the next predicted word will not be 2 and the value of *log_probs* will be replaced with -FLOAT_MAX. Because 3 consecutive words [2, 3, 2] do not appear twice in the word sequence.

Parameters

ngram_size (*int, optional*) – Size of n-grams, must be greater than 0. Default: `1` .

Inputs:

- **state_seq** (Tensor) - n-gram word series, a 3-D tensor with shape: $(batch\_size, beam\_width, m)$.
- **log_probs** (Tensor) - Probability of occurrence of n-gram word series, a 3-D tensor with shape: $(batch\_size, beam\_width, vocab\_size)$. The value of log_probs will be replaced with -FLOAT_MAX when n-grams repeated.

Outputs:

- **log_probs** (Tensor) - The output Tensor with same shape and type as original *log_probs*.

Raises

- **TypeError** – If *ngram_size* is not an int.
- **TypeError** – If neither *state_seq* nor *log_probs* is a Tensor.
- **TypeError** – If the dtype of *state_seq* is not int.
- **TypeError** – If the dtype of *log_probs* is not float.
- **ValueError** – If *ngram_size* is less than zero.
- **ValueError** – If *ngram_size* is greater than m.
- **ValueError** – If neither *state_seq* nor *log_probs* is not a 3-D Tensor.

- **ValueError** – If the batch_size of *state_seq* and *log_probs* are not equal.
- **ValueError** – If the beam_width of *state_seq* and *log_probs* are not equal.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> no_repeat_ngram = ops.NoRepeatNGram(ngram_size=3)
>>> state_seq = Tensor([[[1, 2, 1, 2, 5, 1, 2],
...                      [9, 3, 9, 5, 4, 1, 5]],
...                     [[4, 8, 6, 4, 5, 6, 4],
...                      [4, 8, 8, 4, 3, 4, 8]]], dtype=mindspore.int32)
>>> log_probs = Tensor([[[0.7, 0.8, 0.6, 0.9, 0.2, 0.8, 0.4, 0.6, 0.2, 0.7],
...                      [0.4, 0.5, 0.6, 0.7, 0.8, 0.1, 0.9, 0.8, 0.7, 0.1]],
...                     [[0.9, 0.7, 0.6, 0.3, 0.5, 0.3, 0.5, 0.4, 0.8, 0.6],
...                      [0.5, 0.8, 0.8, 0.7, 0.7, 0.8, 0.2, 0.7, 0.9, 0.7]]],␣
↪dtype=mindspore.float32)
>>> output = no_repeat_ngram(state_seq, log_probs)
>>> print(output)

mindspore.ops.Gcd	Refer to *mindspore.ops.gcd()* for more details.	Ascend GPU CPU

18.3.1 mindspore.ops.Bincount

class mindspore.ops.**Bincount**

Counts the number of occurrences of each value in an integer array.

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **array** (Tensor) - A Tensor of type int32, whose value can not be less than zero.
- **size** (Tensor) - A non-negative Tensor of type int32.
- **weights** (Tensor) - A Tensor with the same shape as array, or a length-0 Tensor, in which case it acts as all weights equal to 1. Must be one of the following types: int32, int64, float32, float64.

Outputs:

A Tensor. Has the same type as weights.

Raises

- **TypeError** – If dtype of *array* is not int32.
- **TypeError** – If dtype of *size* is not int32.
- **ValueError** – If *size* is negative.
- **ValueError** – If *weights* are empty.
- **ValueError** – If size of *weights* is not zero and the shape of *weights* is different with the shape of *array*.
- **TypeError** – If dtype of *weights* is not in int32,int64,float32,float64

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> array = Tensor(np.array([1, 2, 2, 3, 3, 3, 4, 4, 4, 4]), mindspore.int32)
>>> size = Tensor(5, mindspore.int32)
>>> weights = Tensor(np.array([1, 1, 1, 1, 1, 1, 1, 1, 1, 1]), mindspore.float32)
>>> bincount = ops.Bincount()
>>> bins = bincount(array, size, weights)
>>> print(bins)
[0. 1. 2. 3. 4.]
```

18.3.2 mindspore.ops.Cholesky

class mindspore.ops.**Cholesky**(*upper=False*)

Performs the Cholesky decomposition on a single or a batch of symmetric positive-definite matrices.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.cholesky()* for more details.

Parameters

upper (*bool, optional*) – Flag that indicates whether to return a upper or lower triangular matrix. Default: `False` .

Inputs:

- **input_x** (Tensor) - Tensor of shape $(*, N, N)$, where $*$ is zero or more batch dimensions consisting of symmetric positive-definite matrices, with float32 or float64 data type.

Outputs:

Tensor, has the same shape and data type as *input_x*.

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[1.0, 1.0], [1.0, 2.0]]), mindspore.float32)
>>> output = ops.Cholesky()(input_x)
>>> print(output)
[[1. 0.]
 [1. 1.]]
```

18.3.3 mindspore.ops.Complex

class mindspore.ops.**Complex**

Returns a complex Tensor from the real part and the imag part.

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **real** (Tensor) - The real input tensor. types: float32, float64.
- **imag** (Tensor) - The imag input tensor. types: float32, float64.

Outputs:

Tensor, has the complex type.

Raises

- **TypeError** –If the dtype of input is not one of: float32, float64.
- **TypeError** –If the dtypes of two inputs are not same.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> real = Tensor(np.array([1]), mindspore.float32)
>>> imag = Tensor(np.array([2]), mindspore.float32)
>>> complex = ops.Complex()
>>> output = complex(real, imag)
>>> print(output)
[1.+2.j]
```

18.3.4 mindspore.ops.ComplexAbs

class mindspore.ops.**ComplexAbs**

Returns a Tensor that contains the magnitudes of the input.

The complex numbers in input must be of the form $a + bj$, where a is the real part and b is the imaginary part.

$$y = \sqrt{a^2 + b^2}$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - A Tensor, types: complex64, complex128.

Outputs:

Tensor, has the same shape as x. If the type of x is complex64, the type of output is float32. If the type of x is complex128, the type of output is float64.

Raises

- **TypeError** –If the input is not a Tensor.
- **TypeError** –If the input type is not complex64 or complex128.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.asarray(np.complex(3+4j)), mindspore.complex64)
>>> complex_abs = ops.ComplexAbs()
>>> output = complex_abs(x)
>>> print(output)
5.0
```

18.3.5 mindspore.ops.Cross

class mindspore.ops.**Cross**(*dim=- 65530*)

Returns the cross product of vectors in dimension *dim* of input and other.

Warning: This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.cross()* for more details.

Parameters

dim (*int, optional*) – Specified dim along which to compute cross product with. Default: `-65530`.

Inputs:

- **input** (Tensor) - Input Tensor.
- **other** (Tensor) - Another input Tensor, must have the same shape and the same type as *input*, and the size of their *dim* dimension should be 3.

Outputs:

Tensor, has the same shape and type as inputs.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import dtype as mstype
>>> from mindspore import ops
>>> cross = ops.Cross(dim = 0)
>>> x1 = Tensor([1, 2, 3], mstype.int8)
>>> x2 = Tensor([1, 2, 3], mstype.int8)
>>> output = cross(x1, x2)
>>> print(output)
[0 0 0]
```

18.3.6 mindspore.ops.FFTWithSize

class mindspore.ops.**FFTWithSize**(*signal_ndim*, *inverse*, *real*, *norm='backward'*, *onesided=True*, *signal_sizes=()*)

Fourier transform, can be adjusted by parameters to achieve FFT/IFFT/RFFT/IRFFT.

For fft, it computes the following expression:

$$X[\omega_1, \ldots, \omega_d] = \sum_{n_1=0}^{N_1-1} \cdots \sum_{n_d=0}^{N_d-1} x[n_1, \ldots, n_d] e^{-j\ 2\pi \sum_{i=0}^{d} \frac{\omega_i n_i}{N_i}},$$

where d = *signal_ndim* is number of dimensions for the signal, and N_i is the size of signal dimension i.

For ifft, it computes the following expression:

$$X[\omega_1, \ldots, \omega_d] = \frac{1}{\prod_{i=1}^{d} N_i} \sum_{n_1=0}^{N_1-1} \cdots \sum_{n_d=0}^{N_d-1} x[n_1, \ldots, n_d] e^{\ j\ 2\pi \sum_{i=0}^{d} \frac{\omega_i n_i}{N_i}},$$

where d = *signal_ndim* is number of dimensions for the signal, and N_i is the size of signal dimension i.

Note:

- FFT/IFFT requires complex64 or complex128 inputs, return complex64 or complex128 outputs.
- RFFT requires bool, uint8, int8, int16, int32, int64, float32 and float64 inputs, return complex64 or complex128 outputs.
- IRFFT requires complex64 or complex128 inputs, return float32 or float64 outputs.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **signal_ndim** (*int*) −The number of dimensions in each signal, this controls how many dimensions of the fourier transform are realized, can only be 1, 2 or 3.
- **inverse** (*bool*) −Whether it is the inverse transformation, used to select from FFT and RFFT or IFFT and IRFFT.
  - when set to `True`: IFFT and IRFFT.
  - when set to `False`: FFT and RFFT.
- **real** (*bool*) −Whether it is the real transformation, combines with *inverse* to select a specific transformation mode:
  - *inverse* is `False` , *real* is `False` : corresponds to FFT.
  - *inverse* is `True` , *real* is `False` : corresponds to IFFT.
  - *inverse* is `False` , *real* is `True` : corresponds to RFFT.
  - *inverse* is `True` , *real* is `True` : corresponds to IRFFT.
- **norm** (*str, optional*) −The normalization, optional values: [`"backward"` , `"forward"` , `"ortho"`]. Default value: `"backward"` .
  - `"backward"` has the direct transforms unscaled and the inverse transforms scaled by $1/n$, where n is the input x's element numbers.
  - `"ortho"` has both direct and inverse transforms are scaled by $1/\sqrt{n}$.
  - `"forward"` has the direct transforms scaled by $1/n$ and the inverse transforms unscaled.

- **onesided** (*bool, optional*) –Controls whether the input is halved to avoid redundancy. Default: `True` .
- **signal_sizes** (*tuple, optional*) –Size of the original signal (the signal before rfft, no batch dimension), only in IRFFT mode and set *onesided* to `True` requires the parameter, the following conditions must be satisfied. Default: `()` .
  - The length of *signal_sizes* is equal to the signal_ndim of the IRFFT: $len(signal\_sizes) = signal\_ndim$.
  - The last dimension of *signal_sizes* divided by 2 is equal to the last dimension of the IRFFT input: $signal\_size[-1]/2 + 1 = x.shape[-1]$.
  - *signal_sizes* has exactly the same dimensions as the input shape except for the last dimension: $signal\_sizes[:-1] = x.shape[:-1]$.

Inputs:

- **x** (Tensor) - The dimension of the input tensor must be greater than or equal to signal_ndim.

Outputs:

A tensor containing the complex-to-complex, real-to-complex or complex-to-real Fourier transform result.

Raises

- **TypeError** –If the input type of FFT/IFFT/IRFFT is not one of: complex64, complex128.
- **TypeError** –If the input type is not Tensor.
- **ValueError** –If *x* dimension is less than signal_ndim.
- **ValueError** –If signal_ndim is greater than 3 or less than 1.
- **ValueError** –If norm is none of "backward", "forward" or "ortho".

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> # case FFT: signal_ndim: 1, inverse: False, real: False.
>>> fft_in = Tensor(np.array([2, 1, 2]), mindspore.complex64)
>>> fft_net = ops.FFTWithSize(signal_ndim=1, inverse=False, real=False)
>>> fft_output = fft_net(fft_in)
>>> print(fft_output)
[5.        +0.j         0.5       +0.86602545j 0.50000006-0.8660255j ]
>>> # case IFFT: signal_ndim: 1, inverse: True, real: False.
>>> ifft_in = fft_output
>>> ifft_net = ops.FFTWithSize(signal_ndim=1, inverse=True, real=False)
>>> ifft_output = ifft_net(ifft_in)
>>> print(ifft_output)
[2.        -1.9868216e-08j 0.99999994+0.0000000e+00j
 1.9999999 +7.9472862e-08j]
>>> # case RFFT2D: signal_ndim: 2, inverse: False, real: True.
>>> rfft_in = Tensor(np.array([[2, 1, 2], [3, 1, 6]]), mindspore.float32)
>>> rfft_net = ops.FFTWithSize(signal_ndim=2, inverse=False, real=True)
>>> rfft_output = rfft_net(rfft_in)
```

(continues on next page)

(continued from previous page)

mindspore.ops.Sqrt	Refer to mindspore.ops.sqrt() for more details.	Ascend GPU CPU
mindspore.ops.Square	Refer to mindspore.ops.square() for more details.	Ascend GPU CPU
mindspore.ops.SquaredDifference	Subtracts the second input tensor from the first input tensor element-wise and returns square of it.	Ascend GPU CPU
mindspore.ops.SquareSumAll	Returns the square sum of a tensor element-wise.	Ascend GPU CPU
mindspore.ops.Sub	Subtracts the second input tensor from the first input tensor element-wise.	Ascend GPU CPU
mindspore.ops.Tan	Computes tangent of *input* element-wise.	Ascend GPU CPU
mindspore.ops.Trunc	Refer to mindspore.ops.trunc() for more details.	Ascend GPU CPU
mindspore.ops.TruncateDiv	Divides the first input tensor by the second input tensor element-wise and rounds the results of division towards zero.	Ascend GPU CPU
mindspore.ops.TruncateMod	Returns the remainder of division element-wise.	Ascend GPU CPU
mindspore.ops.Xdivy	Divides the first input tensor by the second input tensor element-wise.	Ascend GPU CPU
mindspore.ops.Xlogy	Computes the first input tensor multiplied by the logarithm of second input tensor element-wise.	Ascend GPU CPU
mindspore.ops.Zeta	Compute the Hurwitz zeta function ζ(x,q) of input Tensor.	Ascend GPU CPU

mindspore.ops.Abs

class mindspore.ops.**Abs**

```
prim = ops.Abs()
out = prim(input)
```

is equivalent to

```
ops.abs(input)
```

Refer to *mindspore.ops.abs()* for more details.

mindspore.ops.AccumulateNV2

class mindspore.ops.**AccumulateNV2**

Computes accumulation of all input tensors element-wise.

Refer to *mindspore.ops.accumulate_n()* for more details.

Inputs:

- **x** (Union(tuple[Tensor], list[Tensor])) - The input tuple or list is made up of multiple tensors whose dtype is number to be added together. Each element of tuple or list should have the same shape.

Outputs:

Tensor, has the same shape and dtype as each entry of the *x*.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, nn
>>> class NetAccumulateNV2(nn.Cell):
...     def __init__(self):
...         super(NetAccumulateNV2, self).__init__()
...         self.accumulateNV2 = ops.AccumulateNV2()
...
...     def construct(self, *z):
...         return self.accumulateNV2(z)
...
>>> net = NetAccumulateNV2()
>>> x = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> y = Tensor(np.array([4, 5, 6]), mindspore.float32)
>>> output = net(x, y, x, y)
>>> print(output)
[10. 14. 18.]
```

mindspore.ops.ACos

class mindspore.ops.**ACos**

```
prim = ops.ACos()
out = prim(input)
```

is equivalent to

```
ops.acos(input)
```

Refer to *mindspore.ops.acos()* for more details.

mindspore.ops.Acosh

class mindspore.ops.**Acosh**

```
prim = ops.Acosh()
out = prim(input)
```

is equivalent to

```
ops.acosh(input)
```

Refer to *mindspore.ops.acosh()* for more details.

mindspore.ops.Add

class mindspore.ops.**Add**

```
prim = ops.Add()
out = prim(input, other)
```

is equivalent to

```
ops.add(input, other)
```

Refer to *mindspore.ops.add()* for more details.

mindspore.ops.Addcdiv

class mindspore.ops.**Addcdiv**

Adds the element-wise division of *x1* by *x2*, multiplied by *value* to *input_data*. It computes the following operation:

$$y[i] = input\_data[i] + value[i] * (x1[i]/x2[i])$$

Inputs:

- **input_data** (Tensor) - The tensor to be added.
- **x1** (Tensor) - The numerator tensor.
- **x2** (Tensor) - The denominator tensor.
- **value** (Tensor) - The multiplier for tensor x1/x2.

Outputs:

Tensor, has the same shape and dtype as x1/x2.

Raises

- **TypeError** –If dtype of *x1*, *x2*, *value*, *input_data* is not tensor.
- **TypeError** –If dtype of *x1*, *x2*, *value*, *input_data* are not the same.
- **ValueError** –If *x1* could not be broadcast to *x2*.
- **ValueError** –If *value* could not be broadcast to *x1/x2*.
- **ValueError** –If *input_data* could not be broadcast to *value*(x1/x2)*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_data = Tensor(np.array([1, 1, 1, 1]), mindspore.float32)
>>> x1 = Tensor(np.array([1, 2, 3, 4]), mindspore.float32)
>>> x2 = Tensor(np.array([4, 3, 2, 1]), mindspore.float32)
>>> value = Tensor([1], mindspore.float32)
>>> addcdiv = ops.Addcdiv()
>>> y = addcdiv(input_data, x1, x2, value)
>>> print(y)
[1.25      1.6666667 2.5       5.       ]
```

mindspore.ops.Addcmul

class mindspore.ops.**Addcmul**

Adds the element-wise product of *x1* by *x2*, multiplied by *value* to *input_data*. It computes the following operation:

$$output[i] = input\_data[i] + value[i] * (x1[i] * x2[i])$$

Inputs:

- **input_data** (Tensor) - The tensor to be added.
- **x1** (Tensor) - The tensor to be multiplied.
- **x2** (Tensor) - The tensor to be multiplied.
- **value** (Tensor) - The multiplier for tensor x1*x2.

Outputs:

Tensor, has the same shape and dtype as x1*x2.

Raises

- **TypeError** – If dtype of *x1*, *x2*, *value*, *input_data* is not tensor.
- **TypeError** – If dtype of *x1*, *x2*, *value*, *input_data* are not the same.
- **ValueError** – If *x1* could not be broadcast to *x2*.
- **ValueError** – If *value* could not be broadcast to *x1 * x2*.
- **ValueError** – If *input_data* could not be broadcast to *value*(x1*x2)*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_data = Tensor(np.array([1, 1, 1]), mindspore.float32)
>>> x1 = Tensor(np.array([[1], [2], [3]]), mindspore.float32)
>>> x2 = Tensor(np.array([[1, 2, 3]]), mindspore.float32)
>>> value = Tensor([1], mindspore.float32)
>>> addcmul = ops.Addcmul()
>>> y = addcmul(input_data, x1, x2, value)
>>> print(y)
[[ 2.  3.  4.]
 [ 3.  5.  7.]
 [ 4.  7. 10.]]
```

mindspore.ops.AddN

class mindspore.ops.**AddN**

Computes addition of all input tensors element-wise.

Refer to *mindspore.ops.addn()* for more details.

Inputs:

- **x** (Union(tuple[Tensor], list[Tensor])) - A tuple or list composed of Tensor, the data type is boolean or numeric.

Outputs:

Tensor, has the same shape and dtype as each Tensor of *x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops
>>> class NetAddN(nn.Cell):
...     def __init__(self):
...         super(NetAddN, self).__init__()
...         self.addN = ops.AddN()
...
...     def construct(self, *z):
...         return self.addN(z)
...
>>> net = NetAddN()
>>> x = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> y = Tensor(np.array([4, 5, 6]), mindspore.float32)
>>> output = net(x, y, x, y)
>>> print(output)
[10. 14. 18.]
```

mindspore.ops.Angle

class mindspore.ops.**Angle**

```
prim = ops.Angle()
out = prim(input)
```

is equivalent to

```
ops.angle(input)
```

Refer to *mindspore.ops.angle()* for more details.

mindspore.ops.Asin

class mindspore.ops.**Asin**

```
prim = ops.Asin()
out = prim(input)
```

is equivalent to

```
ops.asin(input)
```

Refer to *mindspore.ops.asin()* for more details.

mindspore.ops.Asinh

class mindspore.ops.**Asinh**

```
prim = ops.Asinh()
out = prim(input)
```

is equivalent to

```
ops.asinh(input)
```

Refer to *mindspore.ops.asinh()* for more details.

mindspore.ops.Atan

class mindspore.ops.**Atan**

```
prim = ops.Atan()
out = prim(input)
```

is equivalent to

```
ops.atan(input)
```

Refer to *mindspore.ops.atan()* for more details.

mindspore.ops.Atan2

class mindspore.ops.**Atan2**

```
prim = ops.Atan2()
out = prim(input, other)
```

is equivalent to

```
ops.atan2(input, other)
```

Refer to *mindspore.ops.atan2()* for more details.

mindspore.ops.Atanh

class mindspore.ops.**Atanh**

```
prim = ops.Atanh()
out = prim(input)
```

is equivalent to

```
ops.atanh(input)
```

Refer to *mindspore.ops.atanh()* for more details.

mindspore.ops.BesselI0

class mindspore.ops.**BesselI0**

Computes modified Bessel function of the first kind, order 0 element-wise.

The formula is defined as:

$$I_0(x) = J_0(\mathrm{i}x) = \sum_{m=0}^{\infty} \frac{x^{2m}}{2^{2m}(m!)^2}$$

where J_0 is Bessel function of the first kind, order 0.

Warning: This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.bessel_i0()* for more details.

Inputs:

- **x** (Tensor) - The input tensor. Data type must be float16, float32 or float64.

Outputs:

Tensor, has the same shape as x.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bessel_i0 = ops.BesselI0()
>>> x = Tensor(np.array([0.24, 0.83, 0.31, 0.09]), mindspore.float32)
>>> output = bessel_i0(x)
>>> print(output)
[1.0144521 1.1797839 1.0241698 1.0020262]
```

mindspore.ops.BesselI0e

class mindspore.ops.**BesselI0e**

Computes exponential scaled modified Bessel function of the first kind, order 0 element-wise.

The formula is defined as:

$$\mathrm{I}_0e(x) = e^{(-|x|)} * I_0(x) = e^{(-|x|)} * \sum_{m=0}^{\infty} \frac{x^{2m}}{2^{2m}(m!)^2}$$

where I_0 is modified Bessel function of the first kind, order 0.

Inputs:

- **x** (Tensor) - The input tensor. Data type must be float16, float32 or float64.

Outputs:

Tensor, has the same shape as x.

Raises

- **TypeError** – If x is not a Tensor.
- **TypeError** – If dtype of x is not float16, float32 or float64.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bessel_i0e = ops.BesselI0e()
>>> x = Tensor(np.array([0.24, 0.83, 0.31, 0.09]), mindspore.float32)
>>> output = bessel_i0e(x)
>>> print(output)
[0.7979961  0.5144438  0.75117415  0.9157829 ]
```

mindspore.ops.BesselI1

class mindspore.ops.**BesselI1**

Computes modified Bessel function of the first kind, order 1 element-wise.

The formula is defined as:

$$I_1(x) = \mathrm{i}^{-1} J_1(\mathrm{i}x) = \sum_{m=0}^{\infty} \frac{x^{2m+1}}{2^{2m+1} m!(m+1)!}$$

where J_1 is Bessel function of the first kind, order 1.

Warning: This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.bessel_i1()* for more details.

Inputs:

- **x** (Tensor) - The input tensor. Data type must be float16, float32 or float64.

Outputs:

Tensor, has the same shape as x.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bessel_i1 = ops.BesselI1()
>>> x = Tensor(np.array([0.24, 0.83, 0.31, 0.09]), mindspore.float32)
>>> output = bessel_i1(x)
>>> print(output)
[0.1208661  0.45177728 0.1568694  0.04504559]
```

mindspore.ops.BesselI1e

class mindspore.ops.**BesselI1e**

Computes exponential scaled modified Bessel function of the first kind, order 1 element-wise.

The formula is defined as:

$$\mathrm{I}_1 e(x) = e^{(-|x|)} * I_1(x) = e^{(-|x|)} * \sum_{m=0}^{\infty} \frac{x^{2m+1}}{2^{2m+1} m!(m+1)!}$$

where I_1 is modified Bessel function of the first kind, order 1.

Inputs:

- **x** (Tensor) - The input tensor. Data type must be float16 or float32, float64.

Outputs:

Tensor, has the same shape as x.

Raises

- **TypeError** – If x is not a Tensor.
- **TypeError** – If dtype of x is not float16, float32 or float64.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bessel_i1e = ops.BesselI1e()
>>> x = Tensor(np.array([0.24, 0.83, 0.31, 0.09]), mindspore.float32)
>>> output = bessel_i1e(x)
>>> print(output)
[0.09507662 0.19699717 0.11505538 0.04116856]
```

mindspore.ops.BesselJ0

class mindspore.ops.**BesselJ0**

Computes Bessel function of the first kind, order 0 element-wise.

The formula is defined as:

$$J_0(x) = \frac{1}{\pi}\int_0^{\pi}\cos(x\sin\theta)d\theta = \sum_{m=0}^{\infty}\frac{(-1)^m x^{2m}}{2^{2m}(m!)^2}$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - The input tensor. Data type must be float16, float32 or float64.

Outputs:

Tensor, has the same shape as x.

Raises

TypeError – If x is not a Tensor of float16, float32 or float64.

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bessel_j0 = ops.BesselJ0()
>>> x = Tensor(np.array([0.5, 1., 2., 4.]), mindspore.float32)
>>> output = bessel_j0(x)
>>> print(output)
[0.93846981  0.76519769  0.22389078  -0.39714981]
```

mindspore.ops.BesselJ1

class mindspore.ops.**BesselJ1**

Computes Bessel function of the first kind, order 1 element-wise.

The formula is defined as:

$$J_1(x) = \frac{1}{\pi}\int_0^{\pi}\cos(x\sin\theta-\theta)d\theta = \sum_{m=0}^{\infty}\frac{(-1)^m x^{2m+1}}{2^{2m+1}m!(m+1)!}$$

Warning: This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - The input tensor. Data type must be float16, float32 or float64.

Outputs:

Tensor, has the same shape as *x*.

Raises

TypeError – If *x* is not a Tensor of float16, float32 or float64.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bessel_j1 = ops.BesselJ1()
>>> x = Tensor(np.array([0.5, 1., 2., 4.]), mindspore.float32)
>>> output = bessel_j1(x)
>>> print(output)
[0.24226846  0.44005059  0.57672481  -0.06604333]
```

mindspore.ops.BesselK0

class mindspore.ops.**BesselK0**

Computes modified Bessel function of the second kind, order 0 element-wise.

The formula is defined as:

$$K_0(x) = \lim_{\nu \to 0} \left(\frac{\pi}{2}\right) \frac{I_{-\nu}(x) - I_{\nu}(x)}{\sin(\nu\pi)} = \int_0^{\infty} e^{-x\cosh t} dt$$

where I_0 is modified Bessel function of the first kind, order 0.

Warning: This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - The input tensor. Data type must be float16, float32, float64.

Outputs:

Tensor, has the same shape as x.

Raises

TypeError – If x is not a Tensor of float16, float32, float64.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bessel_k0 = ops.BesselK0()
>>> x = Tensor(np.array([0.24, 0.83, 0.31, 0.09]), mindspore.float32)
>>> output = bessel_k0(x)
>>> print(output)
[1.579826  0.5402144 1.3424659 2.5310173]
```

mindspore.ops.BesselK0e

class mindspore.ops.**BesselK0e**

Computes exponential scaled modified Bessel function of the second kind, order 0 element-wise.

The formula is defined as:

$$K_0e(x) = e^{(-|x|)} * K_0(x) = e^{(-|x|)} * \int_0^{\infty} e^{-x\cosh t} dt$$

where K_0 is modified Bessel function of the second kind, order 0.

Warning: This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - The input tensor. Data type must be float16, float32, float64.

Outputs:

Tensor, has the same shape as *x*.

Raises

TypeError – If *x* is not a Tensor of float16, float32, float64.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bessel_k0e = ops.BesselK0e()
>>> x = Tensor(np.array([0.24, 0.83, 0.31, 0.09]), mindspore.float32)
>>> output = bessel_k0e(x)
>>> print(output)
[2.0083523 1.2388839 1.8303517 2.769374 ]
```

mindspore.ops.BesselK1

class mindspore.ops.**BesselK1**

Computes modified Bessel function of the second kind, order 1 element-wise.

The formula is defined as:

$$K_1(x) = \lim_{\nu \to 1} \left(\frac{\pi}{2}\right) \frac{I_{-\nu}(x) - I_{\nu}(x)}{\sin(\nu\pi)} = \int_0^{\infty} e^{-x\cosh t} \cosh(t) dt$$

where I_1 is modified Bessel function of the first kind, order 1.

Warning: This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - The input tensor. Data type must be float16, float32, float64.

Outputs:

Tensor, has the same shape as *x*.

Raises

TypeError – If *x* is not a Tensor of float16, float32, float64.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bessel_k1 = ops.BesselK1()
>>> x = Tensor(np.array([0.24, 0.83, 0.31, 0.09]), mindspore.float32)
>>> output = bessel_k1(x)
>>> print(output)
[3.9190812  0.8143549  2.9440577 10.974864]
```

mindspore.ops.BesselK1e

class mindspore.ops.**BesselK1e**

Computes exponential scaled modified Bessel function of the second kind, order 1 element-wise.

The formula is defined as:

$$K_1e(x) = e^{(-|x|)} * K_1(x) = e^{(-|x|)} * \int_0^\infty e^{-x\cosh t}\cosh(t)dt$$

where K_1 is modified Bessel function of the second kind, order 1.

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - The input tensor. Data type must be float16, float32, float64.

Outputs:

Tensor, has the same shape as *x*.

Raises

TypeError – If *x* is not a Tensor of float16, float32, float64.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bessel_k1e = ops.BesselK1e()
>>> x = Tensor(np.array([0.24, 0.83, 0.31, 0.09]), mindspore.float32)
>>> output = bessel_k1e(x)
>>> print(output)
[ 4.9821286  1.8675754  4.0140023 12.008413 ]
```

mindspore.ops.BesselY0

class mindspore.ops.**BesselY0**

Computes Bessel function of the second kind, order 0 element-wise.

The formula is defined as:

$$Y_0(x) = \lim_{n \to 0} \frac{J_n(x)\cos n\pi - J_{-n}(x)}{\sin n\pi}$$

where J_0 is Bessel function of the first kind, order 0.

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - The input tensor. Data type must be float16, float32 or float64.

Outputs:

Tensor, has the same shape as *x*.

Raises

TypeError – If *x* is not a Tensor of float16, float32, float64.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bessel_y0 = ops.BesselY0()
>>> x = Tensor(np.array([0.5, 1., 2., 4.]), mindspore.float32)
>>> output = bessel_y0(x)
>>> print(output)
[-0.44451873  0.08825696  0.51037567  -0.01694074]
```

mindspore.ops.BesselY1

class mindspore.ops.**BesselY1**

Computes Bessel function of the second kind, order 1 element-wise.

The formula is defined as:

$$Y_1(x) = \lim_{n \to 1} \frac{J_n(x)\cos n\pi - J_{-n}(x)}{\sin n\pi}$$

where J_1 is Bessel function of the first kind, order 1.

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - The input tensor. Data type must be float16, float32 or float64.

Outputs:

Tensor, has the same shape as *x*.

Raises

TypeError – If *x* is not a Tensor of float16, float32, float64.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> bessel_y1 = ops.BesselY1()
>>> x = Tensor(np.array([0.5, 1., 2., 4.]), mindspore.float32)
>>> output = bessel_y1(x)
>>> print(output)
[-1.47147239  -0.78121282  -0.10703243  0.39792571]
```

mindspore.ops.BitwiseAnd

class mindspore.ops.**BitwiseAnd**

Returns bitwise *and* of two tensors element-wise.

Refer to *mindspore.ops.bitwise_and()* for more details.

Inputs:

- **x** (Tensor) - The first input tensor with shape $(N, *)$ where $*$ means, any number of additional dimensions.
- **y** (Tensor) - The second input tensor with same type as the *x*.

Outputs:

Tensor, has the same type as the *x*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([0, 0, 1, -1, 1, 1, 1]), mindspore.int16)
>>> y = Tensor(np.array([0, 1, 1, -1, -1, 2, 3]), mindspore.int16)
>>> bitwise_and = ops.BitwiseAnd()
>>> output = bitwise_and(x, y)
```

(continues on next page)

(continued from previous page)

```
>>> print(output)
[ 0  0  1 -1  1  0  1]
```

mindspore.ops.BitwiseOr

class mindspore.ops.**BitwiseOr**

Returns bitwise *or* of two tensors element-wise.

Refer to *mindspore.ops.bitwise_or()* for more details.

Inputs:

- **x** (Tensor) - The first input tensor with shape $(N, *)$ where $*$ means, any number of additional dimensions.
- **y** (Tensor) - The second input tensor with same type as the *x*.

Outputs:

Tensor, has the same type as the *x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([0, 0, 1, -1, 1, 1, 1]), mindspore.int16)
>>> y = Tensor(np.array([0, 1, 1, -1, -1, 2, 3]), mindspore.int16)
>>> bitwise_or = ops.BitwiseOr()
>>> output = bitwise_or(x, y)
>>> print(output)
[ 0  1  1 -1 -1  3  3]
```

mindspore.ops.BitwiseXor

class mindspore.ops.**BitwiseXor**

Returns bitwise *xor* of two tensors element-wise.

> **Warning:** This API has poor performance on CPU and it is recommended to run it on the Ascend/GPU.

Refer to *mindspore.ops.bitwise_xor()* for more details.

Inputs:

- **x** (Tensor) - The first input tensor with shape $(N, *)$ where $*$ means, any number of additional dimensions.
- **y** (Tensor) - The second input tensor with same type as the *x*.

Outputs:

Tensor, has the same type as the *x*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([0, 0, 1, -1, 1, 1, 1]), mindspore.int16)
>>> y = Tensor(np.array([0, 1, 1, -1, -1, 2, 3]), mindspore.int16)
>>> bitwise_xor = ops.BitwiseXor()
>>> output = bitwise_xor(x, y)
>>> print(output)
[ 0  1  0  0 -2  3  2]
```

mindspore.ops.Ceil

class mindspore.ops.**Ceil**

```
prim = ops.Ceil()
out = prim(input)
```

is equivalent to

```
ops.ceil(input)
```

Refer to *mindspore.ops.ceil()* for more details.

mindspore.ops.Conj

class mindspore.ops.**Conj**

```
prim = ops.Conj()
out = prim(input)
```

is equivalent to

```
ops.conj(input)
```

Refer to *mindspore.ops.conj()* for more details.

mindspore.ops.Cos

class mindspore.ops.**Cos**

```
prim = ops.Cos()
out = prim(input)
```

is equivalent to

```
ops.cos(input)
```

Refer to *mindspore.ops.cos()* for more details.

mindspore.ops.Cosh

class mindspore.ops.**Cosh**

```
prim = ops.Cosh()
out = prim(input)
```

is equivalent to

```
ops.cosh(input)
```

Refer to *mindspore.ops.cosh()* for more details.

mindspore.ops.Digamma

class mindspore.ops.**Digamma**

Computes the grad of the lgamma function on input.

$$P(x) = grad(ln(gamma(x)))$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - The input tensor. With type of float16 or float32 or float64.

Outputs:

Tensor, has the same dtype as *x*.

Raises

- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If dtype of input *x* is not float16 or float32 or float64.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([1.5, 0.5, 9]).astype(np.float16))
>>> digamma = ops.Digamma()
>>> output = digamma(x)
>>> print(output)
[ 0.0365 -1.964   2.14  ]
```

mindspore.ops.Div

class mindspore.ops.**Div**

Computes the quotient of dividing the first input tensor by the second input tensor element-wise.

Refer to *mindspore.ops.div()* for more details.

Note:

- One of the two inputs must be a Tensor, when the two inputs have different shapes, they must be able to broadcast to a common shape.
- The two inputs can not be bool type at the same time, [True, Tensor(True, bool_), Tensor(np.array([True]), bool_)] are all considered bool type.
- The two inputs comply with the implicit type conversion rules to make the data types consistent.

Inputs:

- **x** (Union[Tensor, number.Number, bool]) - The first input is a number.Number or a bool or a tensor whose data type is number or bool_.
- **y** (Union[Tensor, number.Number, bool]) - The second input is a number.Number or a bool or a tensor whose data type is number or bool_.

Outputs:

Tensor, the shape is the same as the one of the input x , y after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> # case 1 :has same data type and shape of the two inputs
>>> x = Tensor(np.array([-4.0, 5.0, 6.0]), mindspore.float32)
>>> y = Tensor(np.array([3.0, 2.0, 3.0]), mindspore.float32)
>>> div = ops.Div()
>>> output = div(x, y)
>>> print(output)
[-1.3333334  2.5        2.        ]
>>> # case 2 : different data type and shape of the two inputs
>>> x = Tensor(np.array([-4.0, 5.0, 6.0]), mindspore.float32)
>>> y = Tensor(2, mindspore.int32)
>>> output = div(x, y)
>>> print(output)
[-2.  2.5  3.]
>>> print(output.dtype)
Float32
```

mindspore.ops.DivNoNan

class mindspore.ops.**DivNoNan**

Operates a safe division between *x1* and *x2* element-wise. Returns 0 if element of *x2* is zero.

Inputs of *x1* and *x2* comply with the implicit type conversion rules to make the data types consistent. The inputs must be two tensors or one tensor and one scalar. When the inputs are two tensors, dtypes of them cannot be bool at the same time, and the shapes of them could be broadcast. When the inputs are one tensor and one scalar, the scalar could only be a constant.

$$output_i = \begin{cases} 0, & \text{if } x2_i = 0 \\ x1_i / x2_i, & \text{if } x2_i \neq 0 \end{cases}$$

Inputs:

- **x1** (Union[Tensor, number.Number, bool]) - The first input is a number.Number or a bool or a tensor whose data type is number or bool_.
- **x2** (Union[Tensor, number.Number, bool]) - The second input is a number.Number or a bool when the first input is a bool or a tensor whose data type is number or bool_. When the first input is Scalar, the second input must be a Tensor whose data type is number or bool_.

Outputs:

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Raises

TypeError – If *x1* and *x2* is not a number.Number or a bool or a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x1 = Tensor(np.array([-1.0, 0., 1.0, 5.0, 6.0]), mindspore.float32)
>>> x2 = Tensor(np.array([0., 0., 0., 2.0, 3.0]), mindspore.float32)
>>> div_no_nan = ops.DivNoNan()
>>> output = div_no_nan(x1, x2)
>>> print(output)
[0.  0.  0.  2.5 2. ]
```

mindspore.ops.Einsum

class mindspore.ops.**Einsum**(*equation*)

Sums the product of the elements of the input Tensor along dimensions specified notation based on the Einstein summation convention(Einsum). You can use this operator to perform diagonal/reducesum/transpose/matmul/mul/inner product operations, etc.

Parameters

equation (*str*) – An attribute, represent the operation you want to do. the value can contain only letters([a-z][A-Z]), commas(,), ellipsis(···), and arrow(->). the letters represent inputs's tensor dimension, commas(,)represent separate tensors, ellipsis(···) indicates the tensor dimension that you do not care about, the left of the arrow(->) indicates the input tensors, and the right of it indicates the desired output dimension.

Inputs:

- **x** () - Input tensor used for calculation. The inputs must be a tuple/list of Tensors. When the inputs are only one tensor, you can input (tensor,). Dtypes of them should be float16/float32/float64 and dtype of the tensor(s) must be the same.

Outputs:

Tensor, the shape of it can be obtained from the equation, and the data type is the same as input tensors.

Raises

- **TypeError** – If equation itself is invalid, or the equation does not match the input tensor.
- **TypeError** – If dtype of the input Tensors are not the same or dtype is not float16, float32 or float64.

Supported Platforms:

GPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([1.0, 2.0, 4.0]), mindspore.float32)
>>> equation = "i->"
>>> einsum = ops.Einsum(equation)
>>> output = einsum([x])
>>> print(output)
[7.]
>>>
>>> x = Tensor(np.array([1.0, 2.0, 4.0]), mindspore.float32)
>>> y = Tensor(np.array([2.0, 4.0, 3.0]), mindspore.float32)
>>> equation = "i,i->i"
>>> einsum = ops.Einsum(equation)
>>> output = einsum((x, y))
>>> print(output)
[ 2. 8. 12.]
>>>
>>> x = Tensor(np.array([[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]]), mindspore.float32)
>>> y = Tensor(np.array([[2.0, 3.0], [1.0, 2.0], [4.0, 5.0]]), mindspore.float32)
>>> equation = "ij,jk->ik"
>>> einsum = ops.Einsum(equation)
>>> output = einsum((x, y))
>>> print(output)
[[16. 22.]
[37. 52.]]
>>>
>>> x = Tensor(np.array([[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]]), mindspore.float32)
>>> equation = "ij->ji"
>>> einsum = ops.Einsum(equation)
>>> output = einsum((x,))
>>> print(output)
```

(continues on next page)

(continued from previous page)

```

mindspore.ops.Erf

class mindspore.ops.**Erf**

```
prim = ops.Erf()
out = prim(input)
```

is equivalent to

```
ops.erf(input)
```

Refer to *mindspore.ops.erf()* for more details.

mindspore.ops.Erfc

class mindspore.ops.**Erfc**

```
prim = ops.Erfc()
out = prim(input)
```

is equivalent to

```
ops.erfc(input)
```

Refer to *mindspore.ops.erfc()* for more details.

mindspore.ops.Erfinv

class mindspore.ops.**Erfinv**

```
prim = ops.Erfinv()
out = prim(input)
```

is equivalent to

```
ops.erfinv(input)
```

Refer to *mindspore.ops.erfinv()* for more details.

mindspore.ops.Exp

class mindspore.ops.**Exp**

```
prim = ops.Exp()
out = prim(input)
```

is equivalent to

```
ops.exp(input)
```

Refer to *mindspore.ops.exp()* for more details.

mindspore.ops.Expm1

class mindspore.ops.**Expm1**

```
prim = ops.Expm1()
out = prim(input)
```

is equivalent to

```
ops.expm1(input)
```

Refer to *mindspore.ops.expm1()* for more details.

mindspore.ops.Floor

class mindspore.ops.**Floor**

```
prim = ops.Floor()
out = prim(input)
```

is equivalent to

```
ops.floor(input)
```

Refer to *mindspore.ops.floor()* for more details.

mindspore.ops.FloorDiv

class mindspore.ops.**FloorDiv**

```
prim = ops.FloorDiv()
out = prim(input, other)
```

is equivalent to

```
ops.floor_divide(input, other)
```

Refer to *mindspore.ops.floor_divide()* for more details.

mindspore.ops.FloorMod

class mindspore.ops.**FloorMod**

```
prim = ops.FloorMod()
out = prim(x, y)
```

is equivalent to

```
ops.floor_mod(x, y)
```

Refer to *mindspore.ops.floor_mod()* for more details.

mindspore.ops.Geqrf

class mindspore.ops.**Geqrf**

```
prim = ops.Geqrf()
out = prim(input)
```

is equivalent to

```
ops.geqrf(input)
```

Refer to *mindspore.ops.geqrf()* for more details.

mindspore.ops.Imag

class mindspore.ops.**Imag**

Returns a new tensor containing imaginary value of the input. If input is real, it is returned zeros.

Inputs:

- **input** (Tensor) - The input tensor.

Outputs:

Tensor, the shape is the same as the input.

Raises

TypeError – If the input is not a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import ops
>>> x = mindspore.tensor(1.3+0.4j, mindspore.complex64)
>>> imag = ops.Imag()
>>> output = imag(x)
>>> print(output)
0.4
```

mindspore.ops.Inv

class mindspore.ops.**Inv**

Computes Reciprocal of input tensor element-wise.

Refer to *mindspore.ops.inv()* for more details.

Inputs:

- **x** (Tensor) - Input tensor, it must be one of the following types: float16, float32 or int32.

Outputs:

Tensor, has the same shape and data type as *x*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> inv = ops.Inv()
>>> x = Tensor(np.array([0.25, 0.4, 0.31, 0.52]), mindspore.float32)
>>> output = inv(x)
>>> print(output)
[4.        2.5       3.2258065 1.923077 ]
```

mindspore.ops.Invert

class mindspore.ops.**Invert**

Flips all bits of input tensor element-wise.

Refer to *mindspore.ops.invert()* for more details.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> invert = ops.Invert()
>>> x = Tensor(np.array([25, 4, 13, 9]), mindspore.int16)
>>> output = invert(x)
>>> print(output)
[-26 -5 -14 -10]
```

mindspore.ops.Lerp

class mindspore.ops.**Lerp**

```
prim = ops.Lerp()
out = prim(input, end, weight)
```

is equivalent to

```
ops.lerp(input, end, weight)
```

Refer to *mindspore.ops.lerp()* for more details.

mindspore.ops.Log

class mindspore.ops.**Log**

```
prim = ops.Log()
out = prim(input)
```

is equivalent to

```
ops.log(input)
```

Refer to *mindspore.ops.log()* for more details.

mindspore.ops.Log1p

class mindspore.ops.**Log1p**

```
prim = ops.Log1p()
out = prim(input)
```

is equivalent to

```
ops.log1p(input)
```

Refer to *mindspore.ops.log1p()* for more details.

mindspore.ops.LogicalAnd

class mindspore.ops.**LogicalAnd**

Computes the "logical AND" of two tensors element-wise.

Refer to *mindspore.ops.logical_and()* for more details.

Inputs:

- **x** (Union[Tensor, bool]) - The first input is a bool or a tensor whose data type can be implicitly converted to bool.
- **y** (Union[Tensor, bool]) - The second input is a bool when the first input is a tensor or a tensor whose data type can be implicitly converted to bool.

Outputs:

Tensor, the shape is the same as the *x* and *y* after broadcasting, and the data type is bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([True, False, True]), mindspore.bool_)
>>> y = Tensor(np.array([True, True, False]), mindspore.bool_)
>>> logical_and = ops.LogicalAnd()
>>> output = logical_and(x, y)
>>> print(output)
[ True False False]
>>> x = Tensor(1, mindspore.bool_)
>>> y = Tensor(0, mindspore.bool_)
>>> output = ops.LogicalAnd()(x, y)
>>> print(output)
False
>>> x = True
>>> y = Tensor(0, mindspore.bool_)
>>> output = ops.LogicalAnd()(x, y)
>>> print(output)
False
>>> x = True
>>> y = Tensor(np.array([True, False]), mindspore.bool_)
>>> output = ops.LogicalAnd()(x, y)
>>> print(output)
[True False]
```

mindspore.ops.LogicalNot

class mindspore.ops.**LogicalNot**

Computes the "logical NOT" of a tensor element-wise.

Refer to *mindspore.ops.logical_not()* for more details.

Inputs:

- **x** (Tensor) - The input tensor.

Outputs:

Tensor, the shape is the same as the *x*, and the dtype is bool.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([True, False, True]), mindspore.bool_)
>>> logical_not = ops.LogicalNot()
>>> output = logical_not(x)
>>> print(output)
[False  True False]
```

mindspore.ops.LogicalOr

class mindspore.ops.**LogicalOr**

Computes the "logical OR" of two tensors element-wise.

Refer to *mindspore.ops.logical_or()* for more details.

Inputs:

- **x** (Union[Tensor, bool]) - The first input is a bool or a tensor whose data type can be implicitly converted to bool.
- **y** (Union[Tensor, bool]) - The second input is a bool when the first input is a tensor or a tensor whose data type can be implicitly converted to bool.

Outputs:

Tensor, the shape is the same as the *x* and *y* after broadcasting, and the data type is bool.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([True, False, True]), mindspore.bool_)
>>> y = Tensor(np.array([True, True, False]), mindspore.bool_)
>>> logical_or = ops.LogicalOr()
>>> output = logical_or(x, y)
>>> print(output)
[ True  True  True]
>>> x = Tensor(1, mindspore.bool_)
>>> y = Tensor(0, mindspore.bool_)
>>> output = ops.LogicalOr()(x, y)
>>> print(output)
True
>>> x = True
>>> y = Tensor(0, mindspore.bool_)
>>> output = ops.LogicalOr()(x, y)
>>> print(output)
True
>>> x = True
>>> y = Tensor(np.array([True, False]), mindspore.bool_)
>>> output = ops.LogicalOr()(x, y)
>>> print(output)
[True True]
```

mindspore.ops.LogicalXor

class mindspore.ops.**LogicalXor**

Computes the "logical XOR" of two tensors element-wise.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.logical_xor()* for more details.

Inputs:

- **x** (Union[Tensor, bool]) - The first input is a bool or a tensor whose data type can be implicitly converted to bool.
- **y** (Union[Tensor, bool]) - The second input is a bool when the first input is a tensor or a tensor whose data type can be implicitly converted to bool.

Outputs:

Tensor, the shape is the same as the *x* and *y* after broadcasting, and the data type is bool.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([True, False, True]), mindspore.bool_)
>>> y = Tensor(np.array([True, True, False]), mindspore.bool_)
>>> logical_xor = ops.LogicalXor()
>>> output = logical_xor(x, y)
>>> print(output)
[ False True True]
>>> x = Tensor(1, mindspore.bool_)
>>> y = Tensor(0, mindspore.bool_)
>>> output = ops.LogicalXor()(x, y)
>>> print(output)
True
>>> x = True
>>> y = Tensor(0, mindspore.bool_)
>>> output = ops.LogicalXor()(x, y)
>>> print(output)
True
>>> x = True
>>> y = Tensor(np.array([True, False]), mindspore.bool_)
>>> output = ops.LogicalXor()(x, y)
>>> print(output)
[False True]
```

mindspore.ops.Logit

class mindspore.ops.**Logit**(*eps=- 1.0*)

Calculate the logit of a tensor element-wise. Element in *x* is clamped to [eps, 1-eps].

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.logit()* for more details.

Parameters

eps (*float, optional*) – The epsilon. The input clamp bound is defined as [eps, 1-eps]. Default: `-1.0`.

Inputs:

- **x** (Tensor) - The input tensor of type float16, float32 or float64.

Outputs:

Tensor, with the same shape and dtype as the *x*.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([0.1, 0.2, 0.3]).astype(np.float32))
>>> op = ops.Logit(eps=1e-5)
>>> output = op(x)
>>> print(output)
[-2.1972246 -1.3862944 -0.8472978]
```

mindspore.ops.Mod

class mindspore.ops.**Mod**

Computes the remainder of dividing the first input tensor by the second input tensor element-wise.

Inputs of *x* and *y* comply with the implicit type conversion rules to make the data types consistent. The inputs must be two tensors or one tensor and one scalar. When the inputs are two tensors, both dtypes cannot be bool, and the shapes of them could be broadcast. When the inputs are one tensor and one scalar, the scalar could only be a constant.

When the elements of input exceed 2048, the accuracy of operator cannot guarantee the requirement of double thousandths in the mini form. Due to different architectures, the calculation results of this operator on NPU and CPU may be inconsistent. If shape is expressed as $(D1, D2, ..., Dn)$, then $D1 * D2... * DN <= 1000000, n <= 8$.

Inputs:

- **x** (Union[Tensor, numbers.Number, bool]) - The first input is a number, a bool or a tensor whose data type is number.
- **y** (Union[Tensor, numbers.Number, bool]) - When the first input is a tensor, The second input could be a number, a bool or a tensor whose data type is number. When the first input is a number or a bool the second input must be a tensor whose data type is number.

Outputs:

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Raises

- **TypeError** – If neither *x* nor *y* is one of the following: Tensor, number, bool.
- **TypeError** – If neither *x* nor *y* is a Tensor.
- **ValueError** – If the shape *x* and *y* cannot be broadcasted to each other.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([-4.0, 5.0, 6.0]), mindspore.float32)
>>> y = Tensor(np.array([3.0, 2.0, 3.0]), mindspore.float32)
>>> mod = ops.Mod()
>>> output = mod(x, y)
>>> print(output)
[-1.  1.  0.]
```

mindspore.ops.Mul

class mindspore.ops.**Mul**

```
prim = ops.Mul()
out = prim(input, other)
```

is equivalent to

```
ops.mul(input, other)
```

Refer to *mindspore.ops.mul()* for more details.

mindspore.ops.MulNoNan

class mindspore.ops.**MulNoNan**

Computes *x* * *y* element-wise. If *y* is zero, no matter what *x* is, it will return 0.

Inputs of *x* and *y* comply with the implicit type conversion rules to make the data types consistent. The inputs must be two tensors or one tensor and one scalar. When the inputs are two tensors, the shapes of them could be broadcasted. When the inputs are one tensor and one scalar, the scalar could only be a constant.

$$output_{ij} = \begin{cases} 0, & y_{ij} = 0; \\ x_{ij} * y_{ij}, & otherwise. \end{cases}$$

Note: The shapes of *x* and *y* should be the same or can be broadcasted. This is noncommutative: if *y* is NaN or infinite and *x* is 0, the result will be NaN.

Inputs:

- **x** (Union[Tensor]) - The first input is a tensor whose data type is one of int32, int64, float16, float32, float64, complex64, complex128 currently or scalar.
- **y** (Union[Tensor]) - The second input is a tensor whose data type is one of int32, int64, float16, float32, float64, complex64, complex128 currently or scalar.

Outputs:

Tensor, the shape is the same as the shape of input Tensor after broadcasting, and the data type is the one with higher precision among the two inputs.

Raises

TypeError – If neither *x* nor *y* is a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> # case 1 : same data type and shape of two inputs, there are some 0 in y.
>>> x = Tensor(np.array([[-1.0, 6.0, np.inf], [np.nan, -7.0, 4.0]]), mindspore.float32)
>>> y = Tensor(np.array([[-1.0, 4.0, 0], [0, -3.0, 1.0]]), mindspore.float32)
>>> mul_no_nan = ops.MulNoNan()
>>> output = mul_no_nan(x, y)
>>> print(output)
[[ 1. 24. 0.]
[ 0. 21. 4.]]
>>> # case 2 : the shape of two inputs is same, there are some 0 in x, y.
>>> x = Tensor(np.array([[-1.0, 6.0, 0], [0, np.nan, 4.0]]), mindspore.float32)
>>> y = Tensor(np.array([[-1.0, 4.0, np.inf], [np.nan, 0, 1.0]]), mindspore.float32)
>>> output = mul_no_nan(x, y)
>>> print(output)
[[ 1. 24. nan]
 [nan  0. 4.]]
>>> print(output.dtype)
Float32
>>> # case 3 : the y is a scalar.
>>> x = Tensor(np.array([[-1.0, 6.0, 0], [0, np.nan, 4.0]]), mindspore.float32)
>>> y = Tensor(0, mindspore.float32)
>>> output = mul_no_nan(x, y)
>>> print(output)
[[0. 0. 0.]
 [0. 0. 0.]]
```

mindspore.ops.Neg

class mindspore.ops.**Neg**

```
prim = ops.Neg()
out = prim(input)
```

is equivalent to

```
ops.neg(input)
```

Refer to *mindspore.ops.neg()* for more details.

mindspore.ops.NextAfter

class mindspore.ops.**NextAfter**

```
prim = ops.NextAfter()
out = prim(input, other)
```

is equivalent to

```
ops.nextafter(input, other)
```

Refer to *mindspore.ops.nextafter()* for more details.

mindspore.ops.Pow

class mindspore.ops.**Pow**

```
prim = ops.Pow()
out = prim(input, exponent)
```

is equivalent to

```
ops.pow(input, exponent)
```

Refer to *mindspore.ops.pow()* for more details.

mindspore.ops.Polar

class mindspore.ops.**Polar**

Converts polar coordinates to Cartesian coordinates.

Returns a complex tensor, its elements are Cartesian coordinates constructed with the polar coordinates which is specified by radial distance *abs* and polar angle *angle*.

Refer to *mindspore.ops.polar()* for more details.

$$y_i = abs_i * \cos(angle_i) + abs_i * \sin(angle_i) * j$$

Warning: This is an experimental API that is subject to change.

Inputs:

- **abs** (Tensor, float) - Radial distance. Tensor of any dimension, with dtype required to be float32.
- **angle** (Tensor, float) - Polar angle. It has the same shape and dtype as *abs*.

Outputs:

Tensor, with the same shape as *abs* and the dtype is complex64.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> x1 = Tensor(np.array([1, 2]), mindspore.float32)
>>> x2 = Tensor(np.array([3, 4]), mindspore.float32)
>>> op_polar = ops.Polar()
>>> output = op_polar(x1, x2)
>>> print(output)
[-0.9899925 +0.14112002j -1.3072872-1.5136049j]
>>> x1 = Tensor(2.1, mindspore.float32)
>>> x2 = Tensor(2.1, mindspore.float32)
>>> output = op_polar(x1, x2)
>>> print(output)
(-1.0601765+1.8127397j)
```

mindspore.ops.Polygamma

class mindspore.ops.**Polygamma**

Computes the a.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.polygamma()* for more details.

Inputs:

- **a** (Tensor) - The order of the polygamma function, it has shape (), supported types: int32, int64.
- **x** (Tensor) - The tensor to compute the a-th derivative of the polygamma function with, supported types: float16, float32, float64.

Outputs:

Tensor, has the same dtype as x.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([1.0, -0.5]), mindspore.float32)
>>> a = Tensor(np.array(1), mindspore.int64)
>>> polygamma = ops.Polygamma()
>>> output = polygamma(a, x)
>>> print(output)
[1.644934 8.934802]
>>> a = Tensor(np.array(2), mindspore.int64)
>>> output = polygamma(a, x)
```

(continues on next page)

(continued from previous page)

```
>>> print(output)
[-2.404114  -0.8287967]
>>> a = Tensor(np.array(3), mindspore.int64)
>>> output = polygamma(a, x)
>>> print(output)
[  6.4939404 193.40909  ]
>>> a = Tensor(np.array(4), mindspore.int64)
>>> output = polygamma(a, x)
>>> print(output)
[-24.886265   -3.4742498]
```

mindspore.ops.Real

class mindspore.ops.**Real**

```
prim = ops.Real()
out = prim(input)
```

is equivalent to

```
ops.real(input)
```

Refer to *mindspore.ops.real()* for more details.

mindspore.ops.RealDiv

class mindspore.ops.**RealDiv**

Divides the first input tensor by the second input tensor in floating-point type element-wise.

Refer to *mindspore.ops.div()* for more details.

Inputs:

- **x** (Union[Tensor, Number, bool]) - The first input is a number or a bool or a tensor whose data type is number or bool.
- **y** (Union[Tensor, Number, bool]) - The second input is a number or a bool when the first input is a tensor or a tensor whose data type is number or bool.

Outputs:

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([1.0, 2.0, 3.0]), mindspore.float32)
>>> y = Tensor(np.array([4.0, 5.0, 6.0]), mindspore.float32)
>>> realdiv = ops.RealDiv()
>>> output = realdiv(x, y)
>>> print(output)
[0.25 0.4  0.5 ]
```

mindspore.ops.Reciprocal

class mindspore.ops.**Reciprocal**

Returns reciprocal of a tensor element-wise.

$$out_i = \frac{1}{x_i}$$

Inputs:

- **x** (Tensor) - The input tensor.

Outputs:

Tensor, has the same shape as the x.

Raises

TypeError – If x is not a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([1.0, 2.0, 4.0]), mindspore.float32)
>>> reciprocal = ops.Reciprocal()
>>> output = reciprocal(x)
>>> print(output)
[1.   0.5  0.25]
```

mindspore.ops.Rint

class mindspore.ops.**Rint**

Returns an integer that is closest to *input_x* element-wise.

Inputs:

- **input_x** (Tensor) - Input tensor of any dimension, which must be one of the following types: float16, float32, float64.

Outputs:

Tensor, has the same shape and type as *input_x*.

Raises

TypeError – If dtype of *input_x* is not in [float16, float32, float64].

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([-1.6, -0.1, 1.5, 2.0]), mindspore.float32)
>>> op = ops.Rint()
>>> output = op(input_x)
>>> print(output)
[-2.  0.  2.  2.]
>>> input_x = Tensor(np.array([[-2.0, -1.9, -1.8, -1.7, -1.6],
...                            [-2.0, -1.9, -1.8, -1.7, -1.6]]), mindspore.float32)
>>> output = op(input_x)
>>> print(output)
[[-2. -2. -2. -2. -2.]
 [-2. -2. -2. -2. -2.]]
```

mindspore.ops.Round

class mindspore.ops.**Round**

Returns half to even of a tensor element-wise.

$$out_i \approx input_i$$

Note: The input data types supported by the Ascend platform include bfloat16 (Atlas training series products are not supported), float16, float32, float64, int32, and int64.

Inputs:

- **input** (Tensor) - The input tensor.
- **decimals** (int, optional) - Number of decimal places to round to (default: 0). If decimals is negative, it specifies the number of positions to the left of the decimal point. It supports converting the single-element tensor to an int. When *input* type is int32 or int64, the *decimals* should be 0.

Outputs:

Tensor, has the same shape and type as the *input*.

Raises

- **TypeError** –If *input* is not a Tensor.
- **RuntimeError** –If *input* type is int32 or int64, the *decimals* is not 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.array([0.8, 1.5, 2.3, 2.5, -4.5]), mindspore.float32)
>>> round = ops.Round()
>>> output = round(input)
>>> print(output)
[ 1.  2.  2.  2. -4.]
```

mindspore.ops.Rsqrt

class mindspore.ops.**Rsqrt**

```
prim = ops.Rsqrt()
out = prim(input)
```

is equivalent to

```
ops.rsqrt(input)
```

Refer to *mindspore.ops.rsqrt()* for more details.

mindspore.ops.Sign

class mindspore.ops.**Sign**

```
prim = ops.Sign()
out = prim(input)
```

is equivalent to

```
ops.sign(input)
```

Refer to *mindspore.ops.sign()* for more details.

mindspore.ops.Sin

class mindspore.ops.**Sin**

```
prim = ops.Sin()
out = prim(input)
```

is equivalent to

```
ops.sin(input)
```

Refer to *mindspore.ops.sin()* for more details.

mindspore.ops.Sinc

class mindspore.ops.**Sinc**

```
prim = ops.Sinc()
out = prim(input)
```

is equivalent to

```
ops.sinc(input)
```

Refer to *mindspore.ops.sinc()* for more details.

mindspore.ops.Sinh

class mindspore.ops.**Sinh**

```
prim = ops.Sinh()
out = prim(input)
```

is equivalent to

```
ops.sinh(input)
```

Refer to *mindspore.ops.sinh()* for more details.

mindspore.ops.Sqrt

class mindspore.ops.**Sqrt**

```
prim = ops.Sqrt()
out = prim(x)
```

is equivalent to

```
ops.sqrt(x)
```

Refer to *mindspore.ops.sqrt()* for more details.

mindspore.ops.Square

class mindspore.ops.**Square**

```
prim = ops.Square()
out = prim(input)
```

is equivalent to

```
ops.square(input)
```

Refer to *mindspore.ops.square()* for more details.

mindspore.ops.SquaredDifference

class mindspore.ops.**SquaredDifference**

Subtracts the second input tensor from the first input tensor element-wise and returns square of it.

Inputs of *x* and *y* comply with the implicit type conversion rules to make the data types consistent. The inputs must be two tensors or one tensor and one scalar. When the inputs are two tensors, dtypes of them cannot be bool at the same time, and the shapes of them could be broadcast. When the inputs are one tensor and one scalar, the scalar could only be a constant.

$$out_i = (x_i - y_i) * (x_i - y_i) = (x_i - y_i)^2$$

Inputs:

- **x** (Union[Tensor, Number, bool]) - The first input is a number, or a bool, or a tensor.
- **y** (Union[Tensor, Number, bool]) - The second input is a number, or a bool when the first input is a tensor, or a tensor.

Outputs:

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Raises

TypeError – if *x* and *y* is not a Number or a bool or a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([1.0, 2.0, 3.0]), mindspore.float32)
>>> y = Tensor(np.array([2.0, 4.0, 6.0]), mindspore.float32)
>>> squared_difference = ops.SquaredDifference()
>>> output = squared_difference(x, y)
>>> print(output)
[1. 4. 9.]
```

mindspore.ops.SquareSumAll

class mindspore.ops.**SquareSumAll**

Returns the square sum of a tensor element-wise.

$$\begin{cases} out_x = \sum_0^N (x_i)^2 \\ out_y = \sum_0^N (y_i)^2 \end{cases}$$

Note: SquareSumAll only supports float16 and float32 data type.

Inputs:

- **x** (Tensor) - The input tensor. The data type must be float16 or float32. $(N, *)$ where $*$ means, any number of additional dimensions.
- **y** (Tensor) - The input tensor has the same type and shape as the *x*.

Outputs:

- **output_x** (Tensor) - The same type as the *x*.
- **output_y** (Tensor) - The same type as the *x*.

Raises

- **TypeError** –If neither *x* nor *y* is a Tensor.
- **ValueError** –If *x* and *y* are not the same shape.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import ops
>>> from mindspore import Tensor
>>> x = Tensor(np.array([0, 0, 2, 0]), mindspore.float32)
>>> y = Tensor(np.array([0, 0, 2, 4]), mindspore.float32)
>>> square_sum_all = ops.SquareSumAll()
>>> output = square_sum_all(x, y)
>>> print(output)
(Tensor(shape=[], dtype=Float32, value= 4),
 Tensor(shape=[], dtype=Float32, value= 20))
```

mindspore.ops.Sub

class mindspore.ops.**Sub**

Subtracts the second input tensor from the first input tensor element-wise.

Refer to *mindspore.ops.sub()* for more details.

Note:

- When the two inputs have different shapes, they must be able to broadcast to a common shape.
- The two inputs can not be bool type at the same time, [True, Tensor(True, bool_), Tensor(np.array([True]), bool_)] are all considered bool type.
- The two inputs comply with the implicit type conversion rules to make the data types consistent.

Inputs:

- **x** (Union[Tensor, number.Number, bool]) - The first input is a number.Number or a bool or a tensor whose data type is number or bool_.
- **y** (Union[Tensor, number.Number, bool]) - The second input, when the first input is a Tensor, the second input should be a number.Number or bool value, or a Tensor whose data type is number or bool.

Outputs:

Tensor, the shape is the same as the two inputs after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([1, 2, 3]), mindspore.int32)
>>> y = Tensor(np.array([4, 5, 6]), mindspore.int32)
>>> sub = ops.Sub()
>>> output = sub(x, y)
>>> print(output)
[-3 -3 -3]
```

mindspore.ops.Tan

class mindspore.ops.**Tan**

Computes tangent of *input* element-wise.

Refer to *mindspore.ops.tan()* for more details.

Inputs:

- **input** (Tensor) - Input tensor of any dimension.

Outputs:

Tensor, has the same shape as *input*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> tan = ops.Tan()
>>> x = Tensor(np.array([-1.0, 0.0, 1.0]), mindspore.float32)
>>> output = tan(x)
>>> print(output)
[-1.5574081 0. 1.5574081]
```

mindspore.ops.Trunc

class mindspore.ops.**Trunc**

```
prim = ops.Trunc()
out = prim(input)
```

is equivalent to

```
ops.trunc(input)
```

Refer to *mindspore.ops.trunc()* for more details.

mindspore.ops.TruncateDiv

class mindspore.ops.**TruncateDiv**

Divides the first input tensor by the second input tensor element-wise and rounds the results of division towards zero. Equivalent to C-style integer division.

Inputs of *x* and *y* comply with the implicit type conversion rules to make the data types consistent. When the inputs are two tensors, dtypes of them cannot be bool at the same time, and the shapes of them could be broadcast. When the inputs are one tensor and one scalar, the scalar could only be a constant.

Note: Broadcasting is supported.

Inputs:

- **x** (Union[Tensor, Number, bool]) - The first input is a number, or a bool, or a tensor whose data type is number or bool.
- **y** (Union[Tensor, Number, bool]) - The second input is a number, or a bool when the first input is a tensor, or a tensor whose data type is number or bool.

Outputs:

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Raises

TypeError – If *x* and *y* is not one of the following: Tensor, Number, bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([2, 4, -1]), mindspore.int32)
>>> y = Tensor(np.array([3, 3, 3]), mindspore.int32)
>>> truncate_div = ops.TruncateDiv()
>>> output = truncate_div(x, y)
>>> print(output)
[0 1 0]
```

mindspore.ops.TruncateMod

class mindspore.ops.**TruncateMod**

Returns the remainder of division element-wise.

Inputs of *x* and *y* comply with the implicit type conversion rules to make the data types consistent. When the inputs are two tensors, dtypes of them cannot be bool at the same time, and the shapes of them could be broadcast. When the inputs are one tensor and one scalar, the scalar could only be a constant.

Warning:

- The input data does not support 0.
- When the elements of input exceed 2048, the accuracy of operator cannot guarantee the requirement of double thousandths in the mini form.
- Due to different architectures, the calculation results of this operator on NPU and CPU may be inconsistent.
- If shape is expressed as (D1,D2⋯,Dn), then D1*D2⋯*DN<=1000000,n<=8.

Inputs:

- **x** (Union[Tensor, numbers.Number, bool]) - The first input is a number, or a bool, or a tensor whose data type is number or bool.
- **y** (Union[Tensor, numbers.Number, bool]) - The second input is a number, or a bool when the first input is a tensor, or a tensor whose data type is number or bool.

Outputs:

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision among the two inputs.

Raises

- **TypeError** – If neither *x* nor *y* is one of the following: Tensor, number, bool.

- **TypeError** –If neither *x* nor *y* is a Tensor.
- **ValueError** –If the shape *x* and *y* cannot be broadcasted to each other.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([2, 4, -1]), mindspore.int32)
>>> y = Tensor(np.array([3, 3, 3]), mindspore.int32)
>>> truncate_mod = ops.TruncateMod()
>>> output = truncate_mod(x, y)
>>> print(output)
[ 2  1 -1]
```

mindspore.ops.Xdivy

class mindspore.ops.**Xdivy**

Divides the first input tensor by the second input tensor element-wise. Returns zero when *x* is zero.

Inputs of *x* and *y* comply with the implicit type conversion rules to make the data types consistent. When the inputs are two tensors, dtypes of them cannot be bool at the same time, and the shapes of them could be broadcast. If one of the inputs is scalar, the scalar could only be a constant.

Inputs:

- **x** (Union[Tensor, Number, bool]) - The first input is a number, or a bool, or a tensor whose data type is float16, float32, float64, complex64, complex128 or bool.
- **y** (Union[Tensor, Number, bool]) - The second input is a number, or a bool when the first input is a tensor, or a tensor whose data type is float16, float32, float64, complex64, complex128 or bool.

Outputs:

Tensor, the shape is the same as the one after broadcasting, and the data type is the one with higher precision or higher digits among the two inputs.

Raises

- **TypeError** –If *x* and *y* is not one of the following: Tensor, Number, bool.
- **TypeError** –If dtype of *x* and 'y' is not in [float16, float32, float64, complex64, complex128, bool].
- **ValueError** –If *x* could not be broadcast to a tensor with shape of *y*.
- **RuntimeError** –If the data type of *x*, *y* conversion of Parameter is given but data type conversion of Parameter is not supported.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([2, 4, -1]), mindspore.float32)
>>> y = Tensor(np.array([2, 2, 2]), mindspore.float32)
>>> xdivy = ops.Xdivy()
>>> output = xdivy(x, y)
>>> print(output)
[ 1.   2.  -0.5]
```

mindspore.ops.Xlogy

class mindspore.ops.**Xlogy**

Computes the first input tensor multiplied by the logarithm of second input tensor element-wise. Returns zero when *input* is zero.

$$out_i = input_i \ln other_i$$

Inputs of *input* and *other* comply with the implicit type conversion rules to make the data types consistent.

Inputs:

- **input** (Tensor) - The first input is a tensor whose data type is number or bool_.
- **other** (Tensor) - The second input is a tensor whose data type is number or bool_.

Outputs:

- **y** (Tensor) - the shape is the broadcast of *input* and *other*, and the data type is the one with higher precision or higher digits among the two inputs.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If *other* is not a Tensor.
- **ValueError** – If *input* and *other* can not broadcast.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.array([-5, 0, 4]), mindspore.float32)
>>> other = Tensor(np.array([2, 2, 2]), mindspore.float32)
>>> op = ops.Xlogy()
>>> output = op(input, other)
>>> print(output)
[-3.465736   0.        2.7725887]
```

mindspore.ops.Zeta

class mindspore.ops.**Zeta**

Compute the Hurwitz zeta function ζ(x,q) of input Tensor.

$$\zeta(x,q) = \sum_{n=0}^{\infty} (q+n)^{-x}$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - A Tensor, types: float32, float64.
- **q** (Tensor) - A Tensor, must have the same shape and type as *x*.

Outputs:

Tensor, has the same dtype and shape as the x.

Raises

- **TypeError** – If either of *x* and *q* is not tensor.
- **TypeError** – If dtype of *x* is neither float32 nor float64.
- **TypeError** – If dtype of *q* is neither float32 nor float64.
- **ValueError** – If shape of *x* is not same as the *q*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([10.]), mindspore.float32)
>>> q = Tensor(np.array([1.]), mindspore.float32)
>>> zeta = ops.Zeta()
>>> z = zeta(x, q)
>>> print(z)
[1.0009946]
```

18.3.9 Reduction Operator

API Name	Description	Supported Platforms
mindspore.ops.Argmax	Returns the indices of the maximum value along a specified *axis* of a Tensor.	`Ascend` `GPU` `CPU`
mindspore.ops.ArgMaxWithValue	Calculates the maximum value along with the given axis for the input tensor, and returns the maximum values and indices.	`Ascend` `GPU` `CPU`

continues on next page

Table 12 – continued from previous page

mindspore.ops.Argmin	Returns the indices of the minimum value along a specified *axis* of a Tensor.	Ascend GPU CPU
mindspore.ops.ArgMinWithValue	Calculates the minimum value along with the given axis for the input tensor, and returns the minimum values and indices.	Ascend GPU CPU
mindspore.ops.Median	Computes the median and its corresponding indices of input tensor in the *axis* dimension.	GPU CPU
mindspore.ops.ReduceAll	Refer to *mindspore.ops.all()* for more details.	Ascend GPU CPU
mindspore.ops.ReduceAny	Reduces a dimension of a tensor by the "logical OR" of all elements in the dimension, by default.	Ascend GPU CPU
mindspore.ops.ReduceMax	Reduces a dimension of a tensor by the maximum value in this dimension, by default.	Ascend GPU CPU
mindspore.ops.ReduceMean	Reduces a dimension of a tensor by averaging all elements in the dimension, by default.	Ascend GPU CPU
mindspore.ops.ReduceMin	Reduces a dimension of a tensor by the minimum value in the dimension, by default.	Ascend GPU CPU
mindspore.ops.ReduceProd	Reduces a dimension of a tensor by multiplying all elements in the dimension, by default.	Ascend GPU CPU
mindspore.ops.ReduceSum	Reduces a dimension of a tensor by summing all elements in the dimension, by default.	Ascend GPU CPU

mindspore.ops.Argmax

class mindspore.ops.**Argmax**(*axis=- 1*, *output_type=mstype.int32*)

Returns the indices of the maximum value along a specified *axis* of a Tensor.

Refer to *mindspore.ops.argmax()* for more details.

Parameters

- **axis** (*int*) – Axis where the Argmax operation applies to. Default: `-1` .
- **output_type** (*mindspore.dtype*) – Output data type. Supported types: `mstype.int32` , `mstype.int64` . Default: `mstype.int32` .

Inputs:

- **input_x** (Tensor) - The input tensor. $(N, *)$ where $*$ means, any number of additional dimensions.

Outputs:

Tensor, indices of the max value of input tensor across the axis.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[1, 20, 5], [67, 8, 9], [130, 24, 15]]).astype(np.float32))
>>> output = ops.Argmax(output_type=mindspore.int32)(input_x)
>>> print(output)
[1 0 0]
```

mindspore.ops.ArgMaxWithValue

class mindspore.ops.**ArgMaxWithValue**(*axis=0*, *keep_dims=False*)

Calculates the maximum value along with the given axis for the input tensor, and returns the maximum values and indices.

Note: In auto_parallel and semi_auto_parallel mode, the first output index can not be used.

Warning:

- If there are multiple maximum values, the index of the first maximum value is used.
- The value range of *axis* is [-dims, dims - 1]. "dims" is the dimension length of *input*.

Also see *mindspore.ops.max()*.

Parameters

- **axis** (*int*) – The dimension to reduce. Default: `0` .
- **keep_dims** (*bool*) – Whether to reduce dimension, if `True` , the output will keep same dimension with the input, the output will reduce dimension if `False` . Default: `False` .

Inputs:

- **input** (Tensor) - The input tensor, can be any dimension. Set the shape of input tensor as $(input_1, input_2, ..., input_N)$.

Outputs:

tuple (Tensor), tuple of 2 tensors, containing the corresponding index and the maximum value of the input tensor.

- **index** (Tensor) - The index for the maximum value of the input tensor, with dtype int64. If *keep_dims* is `True` , the shape of output tensors is $(input_1, input_2, ..., input_{axis-1}, 1, input_{axis+1}, ..., input_N)$. Otherwise, the shape is $(input_1, input_2, ..., input_{axis-1}, input_{axis+1}, ..., input_N)$.
- **values** (Tensor) - The maximum value of input tensor, with the same shape as *index*, and same dtype as *input*.

Raises

- **TypeError** – If *keep_dims* is not a bool.
- **TypeError** – If *axis* is not an int.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([0.0, 0.4, 0.6, 0.7, 0.1]), mindspore.float32)
>>> index, output = ops.ArgMaxWithValue()(input_x)
>>> print(index, output)
3 0.7
>>> index, output = ops.ArgMaxWithValue(keep_dims=True)(input_x)
>>> print(index, output)
[3] [0.7]
```

mindspore.ops.Argmin

class mindspore.ops.**Argmin**(*axis=- 1*, *output_type=mstype.int32*)

Returns the indices of the minimum value along a specified *axis* of a Tensor.

If the shape of input tensor is $(x_1, ..., x_N)$, the shape of the output tensor is $(x_1, ..., x_{axis-1}, x_{axis+1}, ..., x_N)$.

Parameters

- **axis** (*int, optional*) – Axis where the Argmin operation applies to. Default: `-1` .
- **output_type** (*mindspore.dtype*, optional) – Output data type. Supported types: `mstype.int32` , `mstype.int64` . Default: `mstype.int32` .

Inputs:

- **input_x** (Tensor) - Input tensor. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.

Outputs:

Tensor, which is the minimum index in the specified axis of input Tensor.

Raises

- **TypeError** – If *axis* is not an int.
- **TypeError** – If *output_type* is neither int32 nor int64.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([2.0, 3.1, 1.2]), mindspore.float32)
>>> index = ops.Argmin()(input_x)
>>> print(index)
2
```

mindspore.ops.ArgMinWithValue

class mindspore.ops.**ArgMinWithValue**(*axis=0*, *keep_dims=False*)

Calculates the minimum value along with the given axis for the input tensor, and returns the minimum values and indices.

Note: In auto_parallel and semi_auto_parallel mode, the first output index can not be used.

Warning:

- If there are multiple minimum values, the index of the first minimum value is used.
- The value range of *axis* is [-dims, dims - 1]. "dims" is the dimension length of *input*.

Also see *mindspore.ops.min()*.

Parameters

- **axis** (*int*) −The dimension to reduce. Default: `0` .
- **keep_dims** (*bool*) −Whether to reduce dimension, if `True` the output will keep the same dimension as the input, the output will reduce dimension if `False` . Default: `False` .

Inputs:

- **input** (Tensor) - The input tensor, can be any dimension. Set the shape of input tensor as $(input_1, input_2, ..., input_N)$ .Complex tensor is not supported.

Outputs:

tuple (Tensor), tuple of 2 tensors, containing the corresponding index and the minimum value of the input tensor.

- **index** (Tensor) - The index for the minimum value of the input tensor, with dtype int64. If *keep_dims* is `True` , the shape of output tensors is $(input_1, input_2, ..., input_{axis-1}, 1, input_{axis+1}, ..., input_N)$. Otherwise, the shape is $(input_1, input_2, ..., input_{axis-1}, input_{axis+1}, ..., input_N)$.
- **values** (Tensor) - The minimum value of input tensor, with the same shape as *index*, and same dtype as *input*.

Raises

- **TypeError** −If *input* is not Tensor.
- **TypeError** −If *keep_dims* is not a bool.
- **TypeError** −If *axis* is not an int.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([0.0, 0.4, 0.6, 0.7, 0.1]), mindspore.float32)
>>> index, output = ops.ArgMinWithValue()(x)
>>> print(index, output)
0 0.0
>>> index, output = ops.ArgMinWithValue(keep_dims=True)(x)
>>> print(index, output)
[0] [0.0]
```

mindspore.ops.Median

class mindspore.ops.**Median**(*global_median=False*, *axis=0*, *keep_dims=False*, *ignore_nan=False*)

Computes the median and its corresponding indices of input tensor in the *axis* dimension. If *global_median* is True, computes the median of all elements of tensor.

Warning:

- *indices* does not necessarily contain the first occurrence of each median value found in the *input*, unless it is unique. The specific implementation of this API is device-specific. The results may be different on CPU and GPU.
- When attr *global_median* is `True` , the value of the second output tensor *indices* is meaningless.

Parameters

- **global_median** (*bool, optional*) – Whether the output tensor is the median of all input tensor elements or not. Default: `False` .
- **axis** (*int, optional*) – The specified dimension to compute median. Default: `0` .
- **keep_dims** (*bool, optional*) – Whether the output tensor need to retain *axis* dimension or not. Default: `False` .
- **ignore_nan** (*bool, optional*) – Whether to ignore the `NaN` values in input Tensor. When `False`, if the input range (determined by *global_median*) contains a `NaN` value, the corresponding element of *values* is `NaN`. When `True`, calculates the median of the remaining elements after excluding `NaN`. Default: `False` .

Inputs:

- **x** (Tensor) - A Tensor to calculate median with.

Outputs:

- **y** (Tensor) - Median, has the same dtype as the *x*.
  - If *global_median* is `True` , the *y* has only one element.
  - If *keep_dims* is `True` , the *y* has the same shape as the *x* except the size of *y* in dimension *axis* is 1.
  - Otherwise, the *y* lacks *axis* dimension than input.
- **indices** (Tensor) - Indices, Has the same shape as the *y*, with dtype int64.

Raises

- **TypeError** – If input *x* is not a Tensor.

- **TypeError** – If *global_median* , *keep_dims* or *ignore_nan* is assigned a nonboolean value.
- **TypeError** – If *axis* is not int.
- **ValueError** – If *axis* is not in range of [-x.dim, x.dim-1].

Supported Platforms:

GPU CPU

Examples

```
>>> # case 1 : common median compute
>>> from mindspore import Tensor, ops
>>> import numpy as np
>>> x = Tensor(np.array([[5, 1, 2],[3, 5, 7], [1, 6, 4]]).astype(np.int64))
>>> median = ops.Median(global_median=False, axis=0, keep_dims=False)
>>> y = median(x)
>>> print(y)
(Tensor(shape=[3], dtype=Int64, value= [3, 5, 4]), Tensor(shape=[3], dtype=Int64, value= [1,␣
↪1, 2]))
>>> # case 2 : global median compute
>>> from mindspore import Tensor, ops
>>> import numpy as np
>>> x = Tensor(np.array([[1, 7, 6],[5, 1, 3],[9, 17, 1]]).astype(np.int32))
>>> median = ops.Median(global_median=True)
>>> y = median(x)
>>> print(y)
(Tensor(shape=[], dtype=Int32, value= 5), Tensor(shape=[], dtype=Int64, value= 0))
```

mindspore.ops.ReduceAll

class mindspore.ops.**ReduceAll**(*keep_dims=False*)

```
prim = ops.ReduceAll(keep_dims)
out = prim(input, axis)
```

is equivalent to

```
ops.all(input, axis, keep_dims)
```

Refer to *mindspore.ops.all()* for more details.

mindspore.ops.ReduceAny

class mindspore.ops.**ReduceAny**(*keep_dims=False*)

Reduces a dimension of a tensor by the "logical OR" of all elements in the dimension, by default. And also can reduce a dimension of *x* along the *axis*. Determine whether the dimensions of the output and input are the same by controlling *keep_dims*.

Note: The *axis* with tensor type is only used for compatibility with older versions and is not recommended.

Parameters

keep_dims (*bool, optional*) –If `True` , keep these reduced dimensions and the length is 1. If `False` , don't keep these dimensions. Default: `False` .

Inputs:

- **x** (Tensor[bool]) - The input tensor. The dtype of the tensor to be reduced is bool.
- **axis** (Union[int, tuple(int), list(int), Tensor], optional) - The dimensions to reduce. Default: `()` , reduce all dimensions. Only constant value is allowed. Must be in the range [-rank(x), rank(x)).

Outputs:

Tensor, the dtype is bool.

- If *axis* is `()` , and *keep_dims* is `False` , the output is a 0-D tensor representing the "logical or" of all elements in the input tensor.
- If *axis* is int, set as 2, and *keep_dims* is `False` , the shape of output is $(x_1, x_3, ..., x_R)$.
- If *axis* is tuple(int), set as (2, 3), and *keep_dims* is `False` , the shape of output is $(x_1, x_4, ..., x_R)$.
- If *axis* is 1-D Tensor, set as [2, 3], and *keep_dims* is `False` , the shape of output is $(x_1, x_4, ..., x_R)$.

Raises

- **TypeError** –If *keep_dims* is not a bool.
- **TypeError** –If *x* is not a Tensor.
- **TypeError** –If *axis* is not one of the following: int, tuple, list or Tensor.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[True, False], [True, True]]))
>>> op = ops.ReduceAny(keep_dims=True)
>>> # case 1: Reduces a dimension by the "logical OR" of all elements in the dimension.
>>> output = op(x)
>>> print(output)
[[ True]]
>>> print(output.shape)
(1, 1)
>>> # case 2: Reduces a dimension along axis 0.
>>> output = op(x, 0)
>>> print(output)
[[ True True]]
>>> # case 3: Reduces a dimension along axis 1.
>>> output = op(x, 1)
>>> print(output)
[[True]
[ True]]
>>> # case 4: input is a scalar.
>>> x = Tensor(True)
>>> op = ops.ReduceAny()
>>> output = op(x)
```

(continues on next page)

(continued from previous page)

```
>>> print(output)
True
```

mindspore.ops.ReduceMax

class mindspore.ops.**ReduceMax**(*keep_dims=False*)

Reduces a dimension of a tensor by the maximum value in this dimension, by default. And also can reduce a dimension of *x* along the *axis*. Determine whether the dimensions of the output and input are the same by controlling *keep_dims*.

Note: The *axis* with tensor type is only used for compatibility with older versions and is not recommended.

Parameters

keep_dims (*bool*) – If `True` , keep these reduced dimensions and the length is 1. If `False` , don't keep these dimensions. Default: `False` .

Inputs:

- **x** (Tensor[Number]) - The input tensor.
- **axis** (Union[int, tuple(int), list(int), tensor]) - The dimensions to reduce. Default: `()` , reduce all dimensions. Must be in the range [-r, r).

Outputs:

output(Tensor): has the same dtype as the *x*.

- If *axis* is `()` , and *keep_dims* is `False` , the output is a 0-D tensor representing the maximum of all elements in the input tensor.
- If *axis* is int, set as 1, and *keep_dims* is `False` , the shape of output is $(x_0, x_2, ..., x_R)$.
- If *axis* is tuple(int) or list(int), set as (1, 2), and *keep_dims* is `False` , the shape of output is $(x_0, x_3, ..., x_R)$.
- If *axis* is 1-D Tensor, set as [1, 2], and *keep_dims* is `False` , the shape of output is $(x_0, x_3, ..., x_R)$.

Raises

- **TypeError** – If *keep_dims* is not a bool.
- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If *axis* is not one of the following: int, tuple, list or Tensor.
- **ValueError** – If *axis* is out of range.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.random.randn(3, 4, 5, 6).astype(np.float32))
>>> output = ops.ReduceMax(keep_dims=True)(x, 1)
>>> result = output.shape
>>> print(result)
(3, 1, 5, 6)
>>> # case 1: Reduces a dimension by the maximum value of all elements in the dimension.
>>> x = Tensor(np.array([[[1, 1, 1, 1, 1, 1], [2, 2, 2, 2, 2, 2], [3, 3, 3, 3, 3, 3]],
...                      [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
...                      [[7, 7, 7, 7, 7, 7], [8, 8, 8, 8, 8, 8], [9, 9, 9, 9, 9, 9]]]),␣
↪mindspore.float32)

```

mindspore.ops.ReduceMean

class mindspore.ops.**ReduceMean**(*keep_dims=False*)

Reduces a dimension of a tensor by averaging all elements in the dimension, by default. And also can reduce a dimension of *x* along the *axis*. Determine whether the dimensions of the output and input are the same by controlling *keep_dims*.

Note: The *axis* with tensor type is only used for compatibility with older versions and is not recommended.

Parameters

keep_dims (*bool*) –If `True` , keep these reduced dimensions and the length is 1. If `False` , don't keep these dimensions. Default: `False` .

Inputs:

- **x** (Tensor[Number]) - The input tensor.
- **axis** (Union[int, tuple(int), list(int), Tensor]) - The dimensions to reduce. Default: `()` , reduce all dimensions. Only constant value is allowed. Must be in the range [-r, r).

Outputs:

Tensor, has the same dtype as the *x*.

- If *axis* is `()` , and *keep_dims* is `False` , the output is a 0-D tensor representing the mean of all elements in the input tensor.
- If *axis* is int, set as 1, and *keep_dims* is `False` , the shape of output is $(x_0, x_2, ..., x_R)$.
- If *axis* is tuple(int) or list(int), set as (1, 2), and *keep_dims* is `False` , the shape of output is $(x_0, x_3, ..., x_R)$.
- If *axis* is 1-D Tensor, set as [1, 2], and *keep_dims* is `False` , the shape of output is $(x_0, x_3, ..., x_R)$.

Raises

- **TypeError** –If *keep_dims* is not a bool.
- **TypeError** –If *x* is not a Tensor.
- **TypeError** –If *axis* is not one of the following: int, tuple, list or Tensor.
- **ValueError** –If *axis* is out of range.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.random.randn(3, 4, 5, 6).astype(np.float32))

mindspore.ops.ReduceMin

class mindspore.ops.**ReduceMin**(*keep_dims=False*)

Reduces a dimension of a tensor by the minimum value in the dimension, by default. And also can reduce a dimension of *x* along the *axis*. Determine whether the dimensions of the output and input are the same by controlling *keep_dims*.

Note: The *axis* with tensor type is only used for compatibility with older versions and is not recommended.

Parameters

keep_dims (*bool*) – If `True` , keep these reduced dimensions and the length is 1. If `False` , don't keep these dimensions. Default: `False` .

Inputs:

- **x** (Tensor[Number]) - The input tensor.
- **axis** (Union[int, tuple(int), list(int), Tensor]) - The dimensions to reduce. Default: `()` , reduce all dimensions. Only constant value is allowed. Must be in the range [-r, r).

Outputs:

Tensor, has the same dtype as the *x*.

- If *axis* is `()` , and *keep_dims* is `False` , the output is a 0-D tensor representing the minimum of all elements in the input tensor.
- If *axis* is int, set as 1, and *keep_dims* is `False` , the shape of output is $(x_0, x_2, ..., x_R)$.
- If *axis* is tuple(int), set as (1, 2), and *keep_dims* is `False` , the shape of output is $(x_0, x_3, ..., x_R)$.
- If *axis* is 1-D Tensor, set as [1, 2], and *keep_dims* is `False` , the shape of output is $(x_0, x_3, ..., x_R)$.

Raises

- **TypeError** –If *keep_dims* is not a bool.
- **TypeError** –If *x* is not a Tensor.
- **TypeError** –If *axis* is not one of the following: int, tuple, list or Tensor.
- **ValueError** –If *axis* is out of range.

Supported Platforms:

mindspore.ops.ReduceProd

class mindspore.ops.**ReduceProd**(*keep_dims=False*)

Reduces a dimension of a tensor by multiplying all elements in the dimension, by default. And also can reduce a dimension of x along the *axis*. Determine whether the dimensions of the output and input are the same by controlling *keep_dims*.

Note: The *axis* with tensor type is only used for compatibility with older versions and is not recommended.

Parameters

keep_dims (*bool*) – If `True` , keep these reduced dimensions and the length is 1. If `False` , don't keep these dimensions. Default: `False` .

Inputs:

- **x** (Tensor[Number]) - The input tensor.
- **axis** (Union[int, tuple(int), list(int), Tensor]) - The dimensions to reduce. Default: `()` , reduce all dimensions. Only constant value is allowed. Must be in the range [-r, r).

Outputs:

Tensor, has the same dtype as the x.

- If *axis* is `()` , and *keep_dims* is `False` , the output is a 0-D tensor representing the product of all elements in the input tensor.
- If *axis* is int, set as 1, and *keep_dims* is `False` , the shape of output is $(x_0, x_2, ..., x_R)$.
- If *axis* is tuple(int), set as (1, 2), and *keep_dims* is `False` , the shape of output is $(x_0, x_3, ..., x_R)$.
- If *axis* is 1-D Tensor, set as [1, 2], and *keep_dims* is `False` , the shape of output is $(x_0, x_3, ..., x_R)$.

Raises

- **TypeError** – If *keep_dims* is not a bool.
- **TypeError** – If x is not a Tensor.
- **TypeError** – If *axis* is not one of the following: int, tuple, list or Tensor.
- **ValueError** – If *axis* is out of range.

Supported Platforms:

`Ascend` `GPU` `CPU`

mindspore.ops.ReduceSum

class mindspore.ops.**ReduceSum**(*keep_dims=False*, *skip_mode=False*)

Reduces a dimension of a tensor by summing all elements in the dimension, by default. And also can reduce a dimension of *x* along the *axis*. Determine whether the dimensions of the output and input are the same by controlling *keep_dims*.

Note: The *axis* with tensor type is only used for compatibility with older versions and is not recommended.

Parameters

- **keep_dims** (*bool, optional*) –If `True` , keep these reduced dimensions and the length is 1. If `False` , don't keep these dimensions. Default: `False` .
- **skip_mode** (*bool, optional*) –If `True` and *axis* is empty tuple or empty list, the ReduceSum operation isn't performed, skip it. If `True` and *axis* is other values, the ReduceSum calculation is performed normally. If `False` , do reduce. Default: `False` .

Inputs:

- **x** (Tensor[Number]) - The input tensor.
- **axis** (Union[int, tuple(int), list(int), Tensor]) - The dimensions to reduce. Default: `()` , reduce all dimensions when *skip_mode* is `False` . Only constant value is allowed. Must be in the range [-rank(x), rank(x)).

Outputs:

Tensor, has the same dtype as the x.

- If *axis* is `()` , *keep_dims* is `False` , and *skip_mode* is `False` , the output is a 0-D tensor representing the sum of all elements in the input tensor.
- If *axis* is `()` , and *skip_mode* is `True` , the ReduceSum operation is not performed, output tensor is equal to the input tensor.
- If *axis* is int, set as 2, and *keep_dims* is `False` , the shape of output is $(x_1, x_3, ..., x_R)$.
- If *axis* is tuple(int) or list(int), set as (2, 3), and *keep_dims* is `False` , the shape of output is $(x_1, x_4, ..., x_R)$.
- If *axis* is 1-D Tensor, set as [2, 3], and *keep_dims* is `False` , the shape of output is $(x_1, x_4, ..., x_R)$.

Raises

- **TypeError** –If *keep_dims* is not a bool.
- **TypeError** –If *skip_mode* is not a bool.
- **TypeError** –If *x* is not a Tensor.
- **ValueError** –If *axis* is None.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.random.randn(3, 4, 5, 6).astype(np.float32))
>>> op = ops.ReduceSum(keep_dims=True)
>>> output = op(x, 1)
>>> output.shape
(3, 1, 5, 6)
>>> # case 1: Reduces a dimension by summing all elements in the dimension.
>>> x = Tensor(np.array([[[1, 1, 1, 1, 1, 1], [2, 2, 2, 2, 2, 2], [3, 3, 3, 3, 3, 3]],
...                      [[4, 4, 4, 4, 4, 4], [5, 5, 5, 5, 5, 5], [6, 6, 6, 6, 6, 6]],
...                      [[7, 7, 7, 7, 7, 7], [8, 8, 8, 8, 8, 8], [9, 9, 9, 9, 9, 9]]]),␣

mindspore.ops.ApproximateEqual

class mindspore.ops.**ApproximateEqual**(*tolerance=1e-05*)

Returns `True` if abs(x-y) is smaller than tolerance element-wise, otherwise False.

$$out_i = \begin{cases} \text{if } |x_i - y_i| < \text{tolerance}, & True \\ \text{if } |x_i - y_i| \geq \text{tolerance}, & False \end{cases}$$

where *tolerance* indicates Acceptable maximum tolerance.

Inputs of *x* and *y* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower precision data type will be converted to the relatively highest precision data type.

Parameters

tolerance (*float, optional*) – The maximum deviation that two elements can be considered equal. Default: `1e-05`.

Inputs:

- **x** (Tensor) - A tensor. Must be one of the following types: float32, float16. $(N, *)$ where $*$ means, any number of additional dimensions, its rank should be less than 8.
- **y** (Tensor) - A tensor of the same type and shape as *x*.

Outputs:

Tensor, the shape is the same as the shape of *x*, and the data type is bool.

Raises

- **TypeError** – If *tolerance* is not a float.
- **TypeError** – If the data type of *x*, *y* conversion of Parameter is given but data type conversion of Parameter is not supported.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([1, 2, 3]), mindspore.float32)
>>> y = Tensor(np.array([2, 3, 6]), mindspore.float32)
>>> approximate_equal = ops.ApproximateEqual(2.)
>>> output = approximate_equal(x, y)
>>> print(output)
[ True  True  False]
```

mindspore.ops.Equal

class mindspore.ops.**Equal**

```
prim = ops.Equal()
out = prim(input, other)
```

is equivalent to

```
ops.equal(input, other)
```

Refer to *mindspore.ops.equal()* for more details.

mindspore.ops.EqualCount

class mindspore.ops.**EqualCount**

Computes the number of the same elements of two tensors.

The two input tensors must have the same data type and shape.

Inputs:

- **x** (Tensor) - The first input tensor. If the data type and shape of y are determined, then x must be the same as y, and vice versa. $(N, *)$ where $*$ means, any number of additional dimensions.
- **y** (Tensor) - The second input tensor. If the data type and shape of x are determined, then y must be the same as x, and vice versa.

Outputs:

Tensor, with the type same as input tensor and shape as $(1,)$.

Raises

- **TypeError** – If x or y is not a Tensor.
- **ValueError** – If shape of x is not equal to shape of y.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([1, 2, 3]), mindspore.int32)
>>> y = Tensor(np.array([1, 2, 4]), mindspore.int32)
>>> equal_count = ops.EqualCount()
>>> output = equal_count(x, y)
>>> print(output)
[2]
```

mindspore.ops.Greater

class mindspore.ops.**Greater**

```
prim = ops.Greater()
out = prim(input, other)
```

is equivalent to

```
ops.greater(input, other)
```

Refer to *mindspore.ops.greater()* for more details.

mindspore.ops.GreaterEqual

class mindspore.ops.**GreaterEqual**

```
prim = ops.GreaterEqual()
out = prim(input, other)
```

is equivalent to

```
ops.greater_equal(input, other)
```

Refer to *mindspore.ops.greater_equal()* for more details.

mindspore.ops.InTopK

class mindspore.ops.**InTopK**(*k*)

Determines whether the targets are in the top *k* predictions.

Refer to *mindspore.ops.intopk()* for more details.

Parameters

k (*int*) −Specifies the number of top elements to be used for computing precision along the last dimension.

Inputs:

- **x1** (Tensor) - A 2D Tensor defines the predictions of a batch of samples with float16 or float32 data type.
- **x2** (Tensor) - A 1D Tensor defines the labels of a batch of samples with int32 data type. The size of *x2* must be equal to the first dimension of *x1*. The values of *x2* can not be negative and must be equal to or less than index of x1's second dimension.

Outputs:

Tensor has 1 dimension of type bool and the same shape with *x2*. For labeling sample *i* in *x2*, if the label in the first *k* predictions for sample *i* is in *x1*, then the value is `True` , otherwise `False` .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x1 = Tensor(np.array([[1, 8, 5, 2, 7], [4, 9, 1, 3, 5]]), mindspore.float32)
>>> x2 = Tensor(np.array([1, 3]), mindspore.int32)
>>> in_top_k = ops.InTopK(3)
>>> output = in_top_k(x1, x2)
>>> print(output)
[ True  False]
```

mindspore.ops.IsFinite

class mindspore.ops.**IsFinite**

```
prim = ops.IsFinite()
out = prim(input)
```

is equivalent to

```
ops.isfinite(input)
```

Refer to *mindspore.ops.isfinite()* for more details.

mindspore.ops.IsInf

class mindspore.ops.**IsInf**

```
prim = ops.IsInf()
out = prim(input)
```

is equivalent to

```
ops.isinf(input)
```

Refer to *mindspore.ops.isinf()* for more details.

mindspore.ops.IsNan

class mindspore.ops.**IsNan**

Determines which elements are NaN for each position.

Refer to *mindspore.ops.isnan()* for more details.

Inputs:

- **x** (Tensor) - The input tensor.

Outputs:

Tensor, has the same shape of input, and the dtype is bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> is_nan = ops.IsNan()
>>> x = Tensor(np.array([np.log(-1), 1, np.log(0)]), mindspore.float32)
>>> output = is_nan(x)
>>> print(output)
[ True False False]
>>> x = Tensor(2.1, mindspore.float64)
>>> output = is_nan(x)
>>> print(output)
False
```

mindspore.ops.Less

class mindspore.ops.**Less**

```
prim = ops.Less()
out = prim(input, other)
```

is equivalent to

```
ops.less(input, other)
```

Refer to *mindspore.ops.less()* for more details.

mindspore.ops.LessEqual

class mindspore.ops.**LessEqual**

```
prim = ops.LessEqual()
out = prim(input, other)
```

is equivalent to

```
ops.less_equal(input, other)
```

Refer to *mindspore.ops.less_equal()* for more details.

mindspore.ops.Maximum

class mindspore.ops.**Maximum**

```
prim = ops.Maximum()
out = prim(input, other)
```

is equivalent to

```
ops.maximum(input, other)
```

Refer to *mindspore.ops.maximum()* for more details.

mindspore.ops.Minimum

class mindspore.ops.**Minimum**

```
prim = ops.Minimum()
out = prim(input, other)
```

is equivalent to

```
ops.minimum(input, other)
```

Refer to *mindspore.ops.minimum()* for more details.

mindspore.ops.NotEqual

class mindspore.ops.**NotEqual**

```
prim = ops.NotEqual()
out = prim(input, other)
```

is equivalent to

```
ops.not_equal(input, other)
```

Refer to *mindspore.ops.not_equal()* for more details.

mindspore.ops.TopK

class mindspore.ops.**TopK**(*sorted=True*)

Finds values and indices of the *k* largest entries along the last dimension.

> **Warning:**
>
> - If sorted is set to False, it will use the aicpu operator, the performance may be reduced. In addition, due to different memory layout and traversal methods on different platforms, the display order of calculation results may be inconsistent when *sorted* is False.

If the *input_x* is a one-dimensional Tensor, finds the *k* largest entries in the Tensor, and outputs its value and index as a Tensor. values[*k*] is the *k* largest item in *input_x*, and its index is indices [*k*].

For a multi-dimensional matrix, calculates the first *k* entries in each row (corresponding vector along the last dimension), therefore:

$$values.shape = indices.shape = input.shape[:-1] + [k]$$

If the two compared elements are the same, the one with the smaller index value is returned first.

Parameters

sorted (*bool, optional*) – If `True` , the obtained elements will be sorted by the values in descending order. If `False` , the obtained elements will not be sorted. Default: `True` .

Inputs:

- **input_x** (Tensor) - Input to be computed, 0-D input is supported on GPU, but not on Ascend or CPU. supported dtypes:
  - Ascend: int8, uint8, int32, int64, float16, float32.
  - GPU: float16, float32.
  - CPU: all numeric types.
- **k** (Union(Tensor, int)) - The number of top elements to be computed along the last dimension. The supported dtype is int32 and it should be 0-D or 1-D Tensor with shape $(1,)$.

Outputs:

A tuple consisting of *values* and *indexes*.

- **values** (Tensor) - The *k* largest elements in each slice of the last dimension.
- **indices** (Tensor) - The indices of values within the last dimension of input.

Raises

- **TypeError** – If *sorted* is not a bool.
- **TypeError** – If *input_x* is not a Tensor.
- **TypeError** – If *k* is not an int.
- **TypeError** – If dtype of *input_x* is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> import mindspore
>>> input_x = Tensor([1, 2, 3, 4, 5], mindspore.float16)
>>> k = 3
>>> values, indices = ops.TopK(sorted=True)(input_x, k)
>>> print((values, indices))
(Tensor(shape=[3], dtype=Float16, value= [ 5.0000e+00,  4.0000e+00,  3.0000e+00]),␣
↪Tensor(shape=[3],
  dtype=Int32, value= [4, 3, 2]))
```

18.3.11 Linear Algebraic Operator

API Name	Description	Supported Platforms
mindspore.ops.BatchMatMul	Computes matrix multiplication between two tensors by batch.	Ascend GPU CPU
mindspore.ops.BiasAdd	Returns the sum of the input Tensor and the bias Tensor.	Ascend GPU CPU
mindspore.ops.Ger	Ger product of *x1* and *x2*.	Ascend GPU CPU
mindspore.ops.MatMul	Multiplies matrix *a* and matrix *b*.	Ascend GPU CPU
mindspore.ops.MatrixInverse	Returns the inverse of the input matrix.	Ascend GPU CPU
mindspore.ops.Ormqr	Computes the matrix-matrix multiplication of a product of Householder matrices with a general matrix.	GPU
mindspore.ops.Orgqr	Calculates the explicit representation of the orthogonal matrix Q returned by *mindspore.ops.Geqrf*.	Ascend GPU CPU
mindspore.ops.Svd	Computes the singular value decompositions of one or more matrices.	Ascend GPU CPU

mindspore.ops.BatchMatMul

class mindspore.ops.**BatchMatMul**(*transpose_a=False*, *transpose_b=False*)

Computes matrix multiplication between two tensors by batch.

text{output}[···, :, :] = text{matrix}(x[···, :, :]) * text{matrix}(y[···, :, :])

The rank of the two input tensors must be at least *2*, and the two input tensors must have the same rank if the environment is GPU or CPU.

Parameters

- **transpose_a** (*bool, optional*) – If `True` , the last two dimensions of *x* is transposed before multiplication. Default: `False` .
- **transpose_b** (*bool, optional*) – If `True` , the last two dimensions of *y* is transposed before multiplication. Default: `False` .

Inputs:

- **x** (Tensor) - The first tensor to be multiplied. The shape of the tensor is $(*B, N, C)$, where $*B$ represents the batch size which can be multidimensional, N and C are the size of the last two dimensions. If *transpose_a* is `True` , its

shape must be $(*B, C, N)$.

- **y** (Tensor) - The second tensor to be multiplied. The shape of the tensor is $(*B, C, M)$. If *transpose_b* is `True` , its shape must be $(*B, M, C)$.

Outputs:

Tensor, the shape of the output tensor is $(*B, N, M)$.

Raises

- **TypeError** –If *transpose_a* or *transpose_b* is not a bool.
- **ValueError** –If length of shape of *x* is not equal to length of shape of *y* or length of shape of inputs is less than 2.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.ones(shape=[2, 4, 1, 3]), mindspore.float32)
>>> y = Tensor(np.ones(shape=[2, 4, 3, 4]), mindspore.float32)
>>> batmatmul = ops.BatchMatMul()
>>> output = batmatmul(x, y)
>>> print(output.shape)
(2, 4, 1, 4)
>>> x = Tensor(np.ones(shape=[2, 4, 3, 1]), mindspore.float32)
>>> y = Tensor(np.ones(shape=[2, 4, 3, 4]), mindspore.float32)
>>> batmatmul = ops.BatchMatMul(transpose_a=True)
>>> output = batmatmul(x, y)
>>> print(output.shape)
(2, 4, 1, 4)
```

mindspore.ops.BiasAdd

class mindspore.ops.**BiasAdd**(*data_format='NCHW'*)

Returns the sum of the input Tensor and the bias Tensor. Before adding, the bias Tensor will be broadcasted to be consistent with the shape of the input Tensor.

Parameters

data_format (*str, optional*) –The format of input and output data. It should be `"NHWC"` , `"NCHW"` or `"NCDHW"` . Default is `"NCHW"` .

Inputs:

- **input_x** (Tensor) - The input tensor. The shape can be 2-5 dimensions. Supported dtypes:
  - Ascend/CPU: all Number type.
  - GPU: float16, float32, int8.
- **bias** (Tensor) - The bias tensor, with shape (C). C must be the same as channel dimension C of *input_x*. It has the same type as *input_x*.

Outputs:

Tensor, with the same shape and data type as *input_x*.

Raises

- **TypeError** –If *data_format* is not a str.
- **ValueError** –If value of *data_format* is not in the range of ['NHWC','NCHW','NCDHW'].
- **TypeError** –If *input_x* or *bias* is not a Tensor.
- **TypeError** –If dtype of *input_x* or *bias* is inconsistent.
- **TypeError** –If dimension of *input_x* is not in the range [2, 5].

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.arange(6).reshape((2, 3)), mindspore.float32)
>>> bias = Tensor(np.random.random(3).reshape((3,)), mindspore.float32)
>>> bias_add = ops.BiasAdd()
>>> output = bias_add(input_x, bias)
>>> print(output.shape)
(2, 3)
```

mindspore.ops.Ger

class mindspore.ops.**Ger**

Ger product of *x1* and *x2*. Calculate the outer product of two arrays. If *x1* is a 1D Tensor of shape $(m,)$ and *x2* is a 1D Tensor of shape $(n,)$, then *output* must be a 2D Tensor of shape (m, n).

Refer to *mindspore.ops.ger()* for more details.

Inputs:

- **x1** - (Tensor) - 1-D input Tensor.
- **x2** - (Tensor) - 1-D input Tensor, has the same dtype as *x1*.

Outputs:

Tensor, output matrix with the same dtype as inputs.With *x1* shape $(m,)$ and *x2* shape of $(n,)$,the *output* has shape (m, n).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> x1 = Tensor([1., 2., 3., 4.], mindspore.float32)
>>> x2 = Tensor([1., 2., 3.], mindspore.float32)
>>> ger = ops.Ger()
>>> output = ger(x1, x2)
>>> print(output)
[[ 1.  2.  3.]
 [ 2.  4.  6.]
 [ 3.  6.  9.]
 [ 4.  8. 12.]]
```

mindspore.ops.MatMul

class mindspore.ops.**MatMul**(*transpose_a=False*, *transpose_b=False*)

Multiplies matrix *a* and matrix *b*.

$$(Output)_{ij} = \sum_{k=1}^{p} a_{ik} b_{kj} = a_{i1} b_{1j} + a_{i2} b_{2j} + \cdots + a_{ip} b_{pj}, p \in N$$

where the i, j indicates the output of the i-th row and j-th column element.

Note:

- If $N * M$ cannot be divided by 16, the performance will be poor in ascend environment.
- The dtype of inputs must be same.
- On Ascend, float64 doesn't be supported.

Parameters

- **transpose_a** (*bool, optional*) – If `True` , *a* is transposed before multiplication. Default: `False` .
- **transpose_b** (*bool, optional*) – If `True` , *b* is transposed before multiplication. Default: `False` .

Inputs:

- **a** (Tensor) - The first tensor to be multiplied. The shape of the tensor is (N, C). If *transpose_a* is `True` , its shape must be (C, N) after transpose.
- **b** (Tensor) - The second tensor to be multiplied. The shape of the tensor is (C, M). If *transpose_b* is `True` , its shape must be (M, C) after transpose.

Outputs:

Tensor, the shape of the output tensor is (N, M).

Raises

- **TypeError** – If *transpose_a* or *transpose_b* is not a bool.
- **TypeError** – If the dtype of *a* and the dtype of *b* are not the same.
- **ValueError** – If the column of matrix dimensions of *a* is not equal to the row of matrix dimensions of *b*.

- **ValueError** –If length of shape of *a* or *b* is not equal to 2.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> a = Tensor(np.ones(shape=[1, 3]), mindspore.float32)
>>> b = Tensor(np.ones(shape=[3, 4]), mindspore.float32)
>>> matmul = ops.MatMul()
>>> output = matmul(a, b)
>>> print(output)
[[3. 3. 3. 3.]]
```

mindspore.ops.MatrixInverse

class mindspore.ops.**MatrixInverse**(*adjoint=False*)

Returns the inverse of the input matrix. If the matrix is irreversible, an error may be reported or an unknown result may be returned.

Note: The parameter 'adjoint' is only supporting `False` right now, because complex number is not supported at present.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

adjoint (*bool*) –An optional bool. Default: `False` .

Inputs:

- **x** (Tensor) - A matrix to be calculated. The matrix must be at least two dimensions, and the last two dimensions must be the same size.

Outputs:

Tensor, has the same type and shape as input *x*.

Raises

- **TypeError** –If *adjoint* is not a bool.
- **TypeError** –If *x* is not a Tensor.
- **ValueError** –If the last two dimensions of *x* is not same size.
- **ValueError** –If the dimension of *x* is less than 2.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[[-0.710504  , -1.1207525],
...                       [-1.7651395 , -1.7576632]],
...                      [[ 0.52412605,  1.9070215],
...                       [ 1.3384849 ,  1.4274558]]]), mindspore.float32)
>>> matrix_inverse = ops.MatrixInverse(adjoint=False)
>>> output = matrix_inverse(x)
>>> print(output)
[[[ 2.4095478  -1.5364188 ]
  [-2.419797    0.9740167 ]]
 [[-0.79111797  1.0569006 ]
  [ 0.74180895 -0.2904787 ]]]
```

mindspore.ops.Ormqr

class mindspore.ops.**Ormqr**(*left=True*, *transpose=False*)

Computes the matrix-matrix multiplication of a product of Householder matrices with a general matrix. Multiplies a(m, n) matrix C (given by other) with a matrix Q, where Q is represented using Householder reflectors (x, tau), which is the output of *mindspore.ops.geqrf()*.

Refer to *mindspore.ops.ormqr()* for more details.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **left** (*bool, optional*) – controls the order of multiplication. If `True` , compute op(Q)*C. If `False` , compute C*op(Q). Default: `True` .
- **transpose** (*bool, optional*) – controls whether the matrix Q is conjugate transposed or not.Default: `False` .

Inputs:

- **x** (Tensor) - Tensor of shape $(*, mn, k)$ where the value of mn depending on *left*, When *left* is `True`, the value of mn is equal to m; otherwise, the value of mn is equal to n. and * is zero or more batch dimensions.
- **tau** (Tensor) - Tensor of shape $(*, min(mn, k))$ where * is zero or more batch dimensions, and its type is the same as *x*.
- **other** (Tensor) - Tensor of shape $(*, m, n)$ where * is zero or more batch dimensions, and its type is the same as *x*.

Outputs:

- **y** (Tensor) - the output Tensor, has the same shape and data type as *other*.

Raises

- **TypeError** – If *x* or *tau* or *other* is not Tensor.
- **TypeError** – If dtype of *x* or *tau* or *other* is not one of: float64, float32, complex64, complex128.
- **ValueError** – If *x* or *other* is less than 2D.

- **ValueError** –If rank(x) - rank(tau) != 1.
- **ValueError** –If tau.shape[:-1] != x.shape[:-2]
- **ValueError** –If other.shape[:-2] != x.shape[:-2]
- **ValueError** –If left == True, other.shape[-2] < tau.shape[-1].
- **ValueError** –If left == True, other.shape[-2] != x.shape[-2].
- **ValueError** –If left == False, other.shape[-1] < tau.shape[-1].
- **ValueError** –If left == False, other.shape[-1] != x.shape[-2].

Supported Platforms:

GPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[-114.6, 10.9, 1.1], [-0.304, 38.07, 69.38], [-0.45, -0.17, 62]]),␣
↪mindspore.float32)
>>> tau = Tensor(np.array([1.55, 1.94, 3.0]), mindspore.float32)
>>> other = Tensor(np.array([[-114.6, 10.9, 1.1],
...                          [-0.304, 38.07, 69.38],
...                          [-0.45, -0.17, 62]]), mindspore.float32)
>>> net = ops.Ormqr()
>>> y = net(x, tau, other)
>>> print(y)
[[  63.82713   -13.823125 -116.28614 ]
 [ -53.659264  -28.157839  -70.42702 ]
 [ -79.54292    24.00183   -41.34253 ]]
```

mindspore.ops.Orgqr

class mindspore.ops.**Orgqr**

Calculates the explicit representation of the orthogonal matrix Q returned by *mindspore.ops.Geqrf*.

Warning: This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.orgqr()* for more details.

Inputs:

- **x** (Tensor) - Tensor of shape $(*, M, N)$, indicating 2D or 3D matrices, with float32, float64, complex64 and complex128 data type.
- **tau** (Tensor) - Indicates the reflecting coefficient in Householder transformation, it has shape $(*, K)$, where K is less than or equal to N, and it has the same type as x.

Outputs:

Tensor, has the same shape and data type as x.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[-114.6, 10.9, 1.1], [-0.304, 38.07, 69.38], [-0.45, -0.17, 62.]]),␣
↪mindspore.float32)
>>> tau = Tensor(np.array([1.55, 1.94, 0.0]), mindspore.float32)
>>> net = ops.Orgqr()
>>> y = net(x, tau)
>>> print(y)
[[-0.54999995 -0.2128925   0.8137956 ]
 [ 0.47119996 -0.8752807   0.08240613]
 [ 0.69749993  0.42560163  0.57772595]]
```

mindspore.ops.Svd

class mindspore.ops.**Svd**(*full_matrices=False*, *compute_uv=True*)

Computes the singular value decompositions of one or more matrices.

Refer to *mindspore.ops.svd()* for more details.

Parameters

- **full_matrices** (*bool, optional*) – If `True` , compute full-sized U and V. If `False`, compute only the leading P singular vectors, with P is the minimum of M and N. Default: `False` .
- **compute_uv** (*bool, optional*) – If `True` , compute the left and right singular vectors. If `False` , compute only the singular values. Default: `True` .

Inputs:

- **input** (Tensor) - Tensor of the matrices to be decomposed. The shape should be $(*, M, N)$, the supported dtype are float32 and float64.

Outputs:

- **s** (Tensor) - Singular values. The shape is $(*, P)$.
- **u** (Tensor) - Left singular vectors. If *compute_uv* is `False` , u will be zero value. The shape is $(*, M, P)$. If *full_matrices* is `True` , the shape will be $(*, M, M)$.
- **v** (Tensor) - Right singular vectors. If *compute_uv* is `False` , v will be zero value. The shape is $(*, N, P)$. If *full_matrices* is `True` , the shape will be $(*, N, N)$.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> ms.set_device(device_target="CPU")
>>> svd = ops.Svd(full_matrices=True, compute_uv=True)
>>> a = Tensor(np.array([[1, 2], [-4, -5], [2, 1]]).astype(np.float32))
>>> s, u, v = svd(a)
>>> print(s)
[7.0652843 1.040081 ]
>>> print(u)
[[ 0.30821905 -0.48819482 0.81649697]
 [-0.90613353  0.11070572 0.40824813]
 [ 0.2896955   0.8656849  0.4082479 ]]
>>> print(v)
[[ 0.63863593 0.769509  ]
 [ 0.769509  -0.63863593]]
```

18.4 Tensor Operation Operator

18.4.1 Tensor Construction

API Name	Description	Supported Platforms
mindspore.ops.Eps	Create a Tensor with the same data type and shape as input, and the element value is the minimum value that the corresponding data type can express.	Ascend GPU CPU
mindspore.ops.Eye	Returns a tensor with ones on the diagonal and zeros in the rest.	Ascend GPU CPU
mindspore.ops.Fill	The Fill interface is deprecated, please use the *mindspore.ops.FillV2* instead.	Deprecated
mindspore.ops.LinSpace	Generate a one-dimensional tensor with *steps* elements, evenly distributed in the interval [start, end].	Ascend GPU CPU
mindspore.ops.OneHot	Computes a one-hot tensor.	Ascend GPU CPU
mindspore.ops.Ones	Creates a tensor filled with value ones.	Ascend GPU CPU
mindspore.ops.OnesLike	Returns a Tensor with a value of 1 and its shape and data type is the same as the input.	Ascend GPU CPU
mindspore.ops.Zeros	Zeros will be deprecated in the future.	Ascend GPU CPU
mindspore.ops.ZerosLike	Returns a Tensor with a value of 0 and its shape and data type is the same as the input.	Ascend GPU CPU

mindspore.ops.Eps

class mindspore.ops.**Eps**

Create a Tensor with the same data type and shape as input, and the element value is the minimum value that the corresponding data type can express.

Refer to *mindspore.ops.eps()* for more detail.

Inputs:

- **x** (Tensor) - Tensor of any dimension used to obtain the minimum value that its data type can express. The data type must be float16, float32 or float64.

Outputs:

Tensor, has the same type and shape as *x*, but filled with *x* dtype minimum val.

Raises

- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If data type of *x* is neither float16, float32, nor float64.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> x = Tensor([4, 1, 2, 3], mindspore.float32)
>>> output = ops.Eps()(x)
>>> print(output)
[1.1920929e-07 1.1920929e-07 1.1920929e-07 1.1920929e-07]
```

mindspore.ops.Eye

class mindspore.ops.**Eye**

Returns a tensor with ones on the diagonal and zeros in the rest.

Inputs:

- **n** (int) - The number of rows returned.
- **m** (int) - The number of columns returned.
- **t** (mindspore.dtype) - The data type returned.

Outputs:

Tensor

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> eye = mindspore.ops.Eye()
>>> output = eye(3, 3, mindspore.int32)
>>> print(output)
[[1 0 0]
 [0 1 0]
 [0 0 1]]
>>>
>>> output = eye(3, 4, mindspore.float32)
>>> print(output)
[[1. 0. 0. 0.]
 [0. 1. 0. 0.]
 [0. 0. 1. 0.]]
```

mindspore.ops.Fill

class mindspore.ops.**Fill**

The Fill interface is deprecated, please use the *mindspore.ops.FillV2* instead.

Supported Platforms:

Deprecated

mindspore.ops.LinSpace

class mindspore.ops.**LinSpace**

Generate a one-dimensional tensor with *steps* elements, evenly distributed in the interval [start, end].

$$step = (end - start)/(steps - 1)$$
$$output = [start, start + step, start + 2 * step, ..., end]$$

Inputs:

- **start** (Tensor) - Start value of interval.
- **stop** (Tensor) - Last value of interval.
- **num** (Union[int, Tensor]) - Number of elements.

Outputs:

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> start = mindspore.tensor(3, mindspore.float32)
>>> stop = mindspore.tensor(10, mindspore.float32)
>>> num = 5
>>> output = mindspore.ops.LinSpace()(start, stop, num)
>>> print(output)
[ 3.    4.75  6.5   8.25 10.  ]
>>>
>>> start = mindspore.tensor(-10, mindspore.float32)
>>> stop = mindspore.tensor(10, mindspore.float32)
>>> num = 5
>>> output = mindspore.ops.LinSpace()(start, stop, num)
>>> print(output)
[-10.  -5.   0.   5.  10.]
>>>
>>> start = mindspore.tensor(-10, mindspore.float32)
>>> stop = mindspore.tensor(10, mindspore.float32)
>>> num = 1
>>> output = mindspore.ops.LinSpace()(start, stop, num)
>>> print(output)
[-10.]
```

mindspore.ops.OneHot

class mindspore.ops.**OneHot**(*axis=-1*)

Computes a one-hot tensor.

The locations represented by indices in *indices* take value *on_value*, while all other locations take value *off_value*.

Note: If the input indices is rank *N*, the output will have rank *N+1*. The new axis is created at dimension *axis*. On Ascend, if *on_value* is Int64 dtype, *indices* must be Int64 dtype, and the value for *on_value* and *off_value* can only be 1 and 0.

Parameters

axis (*int*) – Position to insert the value. e.g. If shape of *indices* is (N, C), and *axis* is -1, the output shape will be (N, C, D), If *axis* is 0, the output shape will be (D, N, C). Default: `-1` .

Inputs:

- **indices** (Tensor) - A tensor of indices. Tensor of shape $(X_0, \ldots, X_n)$. Data type must be int32 or int64.
- **depth** (Union[int, Tensor]) - A scalar defining the depth of the one-hot dimension.
- **on_value** (Tensor) - A value to fill in output when *indices[j] = i*.
- **off_value** (Tensor) - A value to fill in output when *indices[j] != i*. It has the same data type as *on_value*.

Outputs:

Tensor, one-hot tensor. Tensor of shape $(X_0, \ldots, X_{axis}, \text{depth}, X_{axis+1}, \ldots, X_n)$.

Raises

- **TypeError** – If *axis* or *depth* is not an int.
- **TypeError** – If dtype of *on_value* is not int32, int64, float16 or float32.

- **TypeError** – If dtype of *indices* is not int32 or int64.
- **TypeError** – If *indices*, *on_value* or *off_value* is not a Tensor.
- **ValueError** – If *axis* is not in range [-1, len(indices_shape)].
- **ValueError** – If *depth* is less than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> indices = Tensor(np.array([0, 1, 2]), mindspore.int32)
>>> depth, on_value, off_value = 3, Tensor(1.0, mindspore.float32), Tensor(0.0, mindspore.
↪float32)
>>> onehot = ops.OneHot()
>>> output = onehot(indices, depth, on_value, off_value)
>>> print(output)
[[1. 0. 0.]
 [0. 1. 0.]
 [0. 0. 1.]]
```

mindspore.ops.Ones

class mindspore.ops.**Ones**

Creates a tensor filled with value ones.

Refer to *mindspore.ops.ones()* for more details.

> **Warning:** For argument *size*, Tensor type input will be deprecated in the future version.

Inputs:

- **shape** (Union[tuple[int], List[int], int, Tensor]) - The specified shape of output tensor.
- **type** (*mindspore.dtype*) - The specified type of output tensor.

Outputs:

Tensor, whose dtype and size are defined by input.

Raises

TypeError – If *shape* is neither an int nor a tuple/list/Tensor of int.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import ops
>>> ones = ops.Ones()
>>> output = ones((2, 2), mindspore.float32)
>>> print(output)
[[1. 1.]
 [1. 1.]]
>>> output = ones((3, 3), mindspore.float32)
>>> print(output)
[[1. 1. 1.]
 [1. 1. 1.]
 [1. 1. 1.]]
```

mindspore.ops.OnesLike

class mindspore.ops.**OnesLike**

Returns a Tensor with a value of 1 and its shape and data type is the same as the input.

Refer to *mindspore.ops.ones_like()* for more details.

Inputs:

- **input_x** (Tensor) - Tensor of any dimension.

Outputs:

Tensor, has the same shape and type as *input_x* but filled with ones.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[0, 1], [2, 1]]).astype(np.int32))
>>> output = ops.OnesLike()(input_x)
>>> print(output)
[[1 1]
[1 1]]
```

mindspore.ops.Zeros

class mindspore.ops.**Zeros**

Zeros will be deprecated in the future. Please use class *mindspore.ops.zeros()* instead.

Creates a tensor filled with value zeros.

Creates a tensor with shape described by the first argument and fills it with value zeros in type of the second argument.

Warning: For argument *size*, Tensor type input will be deprecated in the future version.

Inputs:

- **shape** (tuple[int], List[int], int, Tensor) - The specified shape of output tensor.
- **type** (mindspore.dtype) - The specified type of output tensor.

Outputs:

Tensor, whose dtype and size are defined by input.

Raises

TypeError – If *shape* is neither an int nor a tuple/list/Tensor of int.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import ops
>>> zeros = ops.Zeros()
>>> output = zeros((2, 2), mindspore.float32)
>>> print(output)
[[0. 0.]
 [0. 0.]]
```

mindspore.ops.ZerosLike

class mindspore.ops.**ZerosLike**

Returns a Tensor with a value of 0 and its shape and data type is the same as the input.

Inputs:

- **input_x** (Tensor) - Input Tensor of any dimension.

Outputs:

Tensor, has the same shape and data type as *input_x* but filled with zeros.

Raises

TypeError – If *input_x* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> zeroslike = ops.ZerosLike()
>>> input_x = Tensor(np.array([[0, 1], [2, 1]]).astype(np.float32))
>>> output = zeroslike(input_x)
>>> print(output)
[[0. 0.]
 [0. 0.]]
```

18.4.2 Random Generation Operator

API Name	Description	Supported Platforms
mindspore.ops.Bernoulli	Randomly set the elements of output to 0 or 1 with the probability of P which follows the Bernoulli distribution.	GPU CPU
mindspore.ops.Gamma	Produces random positive floating-point values x, distributed according to probability density function:	Ascend
mindspore.ops.Multinomial	Returns a tensor sampled from the multinomial probability distribution located in the corresponding row of tensor input.	Ascend GPU CPU
mindspore.ops.MultinomialWithReplacement	Returns a tensor where each row contains *numsamples* indices sampled from the multinomial distribution with replacement.	CPU
mindspore.ops.RandomCategorical	Generates random samples from a given categorical distribution tensor.	Ascend GPU CPU
mindspore.ops.RandomChoiceWithMask	Generates a random sample as index tensor with a mask tensor from a given tensor.	Ascend GPU CPU
mindspore.ops.RandomGamma	Produces random positive floating-point values x, distributed according to probability density function:	CPU
mindspore.ops.RandomPoisson	Produces random non-negative values i, distributed according to discrete probability function:	GPU CPU
mindspore.ops.Randperm	Generates n random samples from 0 to n-1 without repeating.	Ascend GPU
mindspore.ops.RandpermV2	Refer to *mindspore.ops.randperm()* for more details.	CPU
mindspore.ops.StandardLaplace	Generates random numbers according to the Laplace random number distribution (mean=0, lambda=1).	Ascend GPU CPU
mindspore.ops.StandardNormal	Generates random numbers according to the standard Normal (or Gaussian) random number distribution.	Ascend GPU CPU
mindspore.ops.UniformInt	Produces random integer values i, uniformly distributed on the closed interval [minval, maxval), that is, distributed according to the discrete probability function:	Ascend GPU CPU
mindspore.ops.UniformReal	Produces random floating-point values, uniformly distributed to the interval [0, 1).	Ascend GPU CPU

mindspore.ops.Bernoulli

class mindspore.ops.**Bernoulli**(*seed=-1*, *offset=0*)

Randomly set the elements of output to 0 or 1 with the probability of P which follows the Bernoulli distribution.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.bernoulli()* for more details.

Parameters

- **seed** (*int, optional*) – The seed value for random generating. The value of *seed* must be -1 or a positive integer, and -1 means using the current timestamp. Default: `-1` .
- **offset** (*int, optional*) – Used to change the starting position during the generation of random number sequence. Default: `0` .

Inputs:

- **x** (Tensor) - Input Tensor.
- **p** (Union[Tensor, float], optional) - Success probability, representing the probability of setting 1 for the corresponding position of the current Tensor. It has the same shape as *x*, the value of *p* must be in the range *[0, 1]*. Default: `0.5` .

Outputs:

- **y** (Tensor) - with the same shape and type as *x* .

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> input_x = Tensor([0.1, 0.2, 0.3], mindspore.float32)
>>> bernoulli = ops.Bernoulli()
>>> output = bernoulli(input_x, Tensor([1.0]))
>>> print(output)
[1. 1. 1.]
>>> input_p = Tensor([0.0, 1.0, 1.0], mindspore.float32)
>>> output = bernoulli(input_x, input_p)
>>> print(output)
[0. 1. 1.]
```

mindspore.ops.Gamma

class mindspore.ops.**Gamma**(*seed=0*, *seed2=0*)

Produces random positive floating-point values x, distributed according to probability density function:

$$\mathrm{P}(x|,) = \frac{\exp(-x/)}{\cdot\,\Gamma()} \cdot x^{-1}$$

Note:

- Random Seed: Through some complex mathematical algorithms, a set of regular random numbers can be obtained, and the random seed is the initial value of this random number. The random seed is the same, the random number obtained will not change.
- When neither the global random seed nor the operator layer random seed is set or both are 0: generate completely random numbers.
- When the global random seed is set, but the operator layer random seed is not set: splice the global random seed with 0.
- When the global random seed is not set, but the operator layer random seed is set: splice 0 with the operator layer random seed.
- When both the global random seed and the operator layer random seed are set: splice the global random seed with the operator layer random seed.

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* and *seed2* parameter have no effect.

Parameters

- **seed** (*int, optional*) – The operator-level random seed, used to generate random numbers, must be non-negative. Default: `0` .
- **seed2** (*int, optional*) – The global random seed, which combines with the operator-level random seed to determine the final generated random number, must be non-negative. Default: `0` .

Inputs:

- **shape** (tuple) - The shape of random tensor to be generated. Only constant value is allowed.
- **alpha** (Tensor) - α is the shape parameter of Gamma distribution, which mainly determines the shape of the curve. It must be greater than 0. The data type is float32.
- **beta** (Tensor) - β is the inverse scale parameter of the Gamma distribution, which mainly determines how steep the curve is. It must be greater than 0. The data type is float32.

Outputs:

Tensor. The shape must be the broadcasted shape of Input "shape" and shapes of *alpha* and *beta*. The dtype is float32.

Raises

- **TypeError** – If data type of *seed* or *seed2* is not int.
- **TypeError** – If *alpha* or *beta* is not a Tensor.
- **TypeError** – If data type of *alpha* or *beta* is not float32.
- **ValueError** – If *shape* is not a constant value.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> shape = (3, 1, 2)
>>> alpha = Tensor(np.array([[3, 4], [5, 6]]), mstype.float32)
>>> beta = Tensor(np.array([1.0]), mstype.float32)
>>> gamma = ops.Gamma(seed=3)
>>> output = gamma(shape, alpha, beta)
>>> result = output.shape
>>> print(result)
(3, 2, 2)
```

mindspore.ops.Multinomial

class mindspore.ops.**Multinomial**(*seed=0*, *seed2=0*, *dtype=mstype.int32*)

Returns a tensor sampled from the multinomial probability distribution located in the corresponding row of tensor input.

Note:

- The rows of input do not need to sum to one (in which case we use the values as weights), but must be non-negative, finite and have a non-zero sum.
- Random seed: a set of regular random numbers can be obtained through some complex mathematical algorithms, and the random seed determines the initial value of this random number. If the random seed is the same in two separate calls, the random number generated will not change.
- Using the Philox algorithm to scramble seed and seed2 to obtain random seed so that the user doesn't need to worry about which seed is more important.

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* and *seed2* parameter have no effect.

Parameters

- **seed** (*int, optional*) –The operator-level random seed, used to generate random numbers, must be non-negative. Default: `0` .
- **seed2** (*int, optional*) –The global random seed, which combines with the operator-level random seed to determine the final generated random number, must be non-negative. Default: `0` .
- **dtype** (mindspore.dtype, *optional*) –The type of output, must be `mstype.int32` or `mstype.int64`. Default: `mstype.int32`.

Inputs:

- **x** (Tensor) - the input tensor containing the cumsum of probabilities, must be 1 or 2 dimensions.
- **num_samples** (int) - number of samples to draw, must be a nonnegative number.

Outputs:

Tensor with the same rows as *x*, each row has num_samples sampled indices.

Raises

- **TypeError** –If neither *seed* nor *seed2* is an int.
- **TypeError** –If dtype of *num_samples* is not int.
- **TypeError** –If *dtype* is not mstype.int32 or mstype.int64.
- **ValueError** –If *seed* or *seed2* is less than 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor([[0., 9., 4., 0.]], mstype.float32)
>>> multinomial = ops.Multinomial(seed=10)
>>> output = multinomial(x, 2)
>>> print(output)
[[1 1]]
```

mindspore.ops.MultinomialWithReplacement

class mindspore.ops.**MultinomialWithReplacement**(*numsamples*, *replacement=False*)

Returns a tensor where each row contains *numsamples* indices sampled from the multinomial distribution with replacement. It diffs from *Multinomial* in that it allows the same outcome to be chosen multiple times.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.multinomial_with_replacement()* for more details.

Note: The rows of input do not need to sum to one (in which case we use the values as weights), but must be non-negative, finite and have a non-zero sum.

Parameters

- **numsamples** (*int*) –number of samples to draw, must be a nonnegative number.
- **replacement** (*bool, optional*) –Whether to draw with replacement or not. Default: `False` .

Inputs:

- **x** (Tensor) - the input tensor containing the cumsum of probabilities, must be 1 or 2 dimensions.
- **seed** (Tensor) - If *seed* and 'offset' are both set to 0, the random number generator is generated by a random seed. Otherwise, it is seeded by the given seed and offset. Supported dtype: int64.
- **offset** (Tensor) - Offset used to avoid seed collision. Supported dtype: int64.

Outputs:

Tensor with the same rows as *x*, each row has *numsamples* sampled indices.

Supported Platforms:

`CPU`

Examples

```
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor([[0., 9., 4., 0.]], mstype.float32)
>>> seed = Tensor(2, mstype.int64)
>>> offset = Tensor(5, mstype.int64)
>>> multinomialwithreplacement = ops.MultinomialWithReplacement(numsamples=2,
 ↪replacement=True)
>>> output = multinomialwithreplacement(x, seed, offset)
>>> print(output)
[[1 1]]
```

mindspore.ops.RandomCategorical

class mindspore.ops.**RandomCategorical**(*dtype=mstype.int64*)

Generates random samples from a given categorical distribution tensor.

> **Warning:** The Ascend backend does not support the reproducibility of random numbers, so the *seed* parameter has no effect.

Parameters

dtype (*mindspore.dtype, optional*) – The type of output. Its value must be one of mstype.int16, mstype.int32 and mstype.int64. Default: `mstype.int64`.

Inputs:

- **logits** (Tensor) - The input tensor. 2-D Tensor with shape $(batch\_size, num\_classes)$.
- **num_sample** (int) - Number of sample to be drawn. Only constant values is allowed.
- **seed** (int) - Random seed. Default: `0`. Only constant values is allowed.

Outputs:

- **output** (Tensor) - The output Tensor with shape $(batch\_size, num\_samples)$.

Raises

- **TypeError** – If *dtype* is not one of the following: mstype.int16, mstype.int32, mstype.int64.
- **TypeError** – If *logits* is not a Tensor.
- **TypeError** – If neither *num_sample* nor *seed* is an int.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import nn, ops, Tensor
>>> class Net(nn.Cell):
...   def __init__(self, num_sample):
...     super(Net, self).__init__()
...     self.random_categorical = ops.RandomCategorical(mindspore.int64)
...     self.num_sample = num_sample
...   def construct(self, logits, seed=0):
...     return self.random_categorical(logits, self.num_sample, seed)
...
>>> x = np.random.random((10, 5)).astype(np.float32)
>>> net = Net(8)
>>> output = net(Tensor(x))
>>> result = output.shape
>>> print(result)
(10, 8)
```

mindspore.ops.RandomChoiceWithMask

class mindspore.ops.**RandomChoiceWithMask**(*count=256*, *seed=0*, *seed2=0*)

Generates a random sample as index tensor with a mask tensor from a given tensor.

Refer to *mindspore.ops.choice_with_mask()* for more details.

Note:

- Random seed: a set of regular random numbers can be obtained through some complex mathematical algorithms, and the random seed determines the initial value of this random number. If the random seed is the same in two separate calls, the random number generated will not change.
- Using the Philox algorithm to scramble seed and seed2 to obtain random seed so that the user doesn't need to worry about which seed is more important.

Parameters

- **count** (*int, optional*) –Number of items expected to get and the number must be greater than 0. Default: `256`.
- **seed** (*int, optional*) –The operator-level random seed, used to generate random numbers, must be non-negative. Default: `0`.
- **seed2** (*int, optional*) –The global random seed, which combines with the operator-level random seed to determine the final generated random number, must be non-negative. Default: `0`.

Inputs:

- **input_x** (Tensor[bool]) - The input tensor. The input tensor rank must be greater than or equal to 1 and less than or equal to 5.

Outputs:

Two tensors, the first one is the index tensor and the other one is the mask tensor.

- **index** (Tensor) - The output shape is 2-D, its shape is $(count, rank of input_x)$.

- **mask** (Tensor) - The output shape is 1-D, its shape is (*count*).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> rnd_choice_mask = ops.RandomChoiceWithMask()
>>> input_x = Tensor(np.ones(shape=[240000, 4]).astype(np.bool_))
>>> output_y, output_mask = rnd_choice_mask(input_x)
>>> result = output_y.shape
>>> print(result)
(256, 2)
>>> result = output_mask.shape
>>> print(result)
(256,)
```

mindspore.ops.RandomGamma

class mindspore.ops.**RandomGamma**(*seed=0*, *seed2=0*)

Produces random positive floating-point values x, distributed according to probability density function:

Note:

- Random seed: a set of regular random numbers can be obtained through some complex mathematical algorithms, and the random seed determines the initial value of this random number. If the random seed is the same in two separate calls, the random number generated will not change.
- Using the Philox algorithm to scramble seed and seed2 to obtain random seed so that the user doesn't need to worry about which seed is more important.

Parameters

- **seed** (*int, optional*) – The operator-level random seed, used to generate random numbers, must be non-negative. Default: `0` .
- **seed2** (*int, optional*) – The global random seed, which combines with the operator-level random seed to determine the final generated random number, must be non-negative. Default: `0` .

Inputs:

- **shape** (Tensor) - The shape of random tensor to be generated. It must be constant value.
- **alpha** (Tensor) - α is the shape parameter of RandomGamma distribution, it mainly determines the shape of the graph curve. It must be greater than 0 and have date type float32.

Outputs:

Tensor. The shape should be equal to the concat shape between the input *shape* and *alpha*. The dtype is the same type as alpha.

Raises

- **TypeError** – If data type of *seed* or *seed2* is not int.

- **TypeError** –If *shape* or *alpha* is not a Tensor.
- **TypeError** –If data type of *alpha* is not float32.
- **ValueError** –If *shape* is not a constant value.

Supported Platforms:

`CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> shape = Tensor(np.array([3, 1, 2]), mstype.int32)
>>> alpha = Tensor(np.array([[3, 4], [5, 6]]), mstype.float32)
>>> gamma = ops.RandomGamma(seed=3)
>>> output = gamma(shape, alpha)
>>> result = output.shape
>>> print(result)
(3, 1, 2, 2, 2)
```

mindspore.ops.RandomPoisson

class mindspore.ops.**RandomPoisson**(*seed=0*, *seed2=0*, *dtype=mstype.int64*)

Produces random non-negative values i, distributed according to discrete probability function:

$$\mathrm{P}(i|) = \frac{\exp(-)^i}{i!}$$

Note:

- Random seed: a set of regular random numbers can be obtained through some complex mathematical algorithms, and the random seed determines the initial value of this random number. If the random seed is the same in two separate calls, the random number generated will not change.
- Using the Philox algorithm to scramble seed and seed2 to obtain random seed so that the user doesn't need to worry about which seed is more important.

Parameters

- **seed** (*int, optional*) –The operator-level random seed, used to generate random numbers, must be non-negative. Default: `0` .
- **seed2** (*int, optional*) –The global random seed, which combines with the operator-level random seed to determine the final generated random number, must be non-negative. Default: `0` .
- **dtype** (`mindspore.dtype`, *optional*) –The type of output. Default: `mstype.int64` .

Inputs:

- **shape** (Tensor) - The shape of random tensor to be generated, 1-D Tensor, whose dtype must be in [int32, int64].
- **rate** (Tensor) - μ parameter the distribution was constructed with. The parameter defines mean number of occurrences of the event. Its type must be in [float16, float32, float64, int32, int64].

Outputs:

Tensor. Its shape is $(*shape, *rate.shape)$. Its type is specified by *dtype*.

Raises

- **TypeError** – If *shape* is not a Tensor or its dtype is not int32 or int64.
- **TypeError** – If *dtype* is not int32 or int64.
- **ValueError** – If *shape* is not a 1-D tensor.
- **ValueError** – If *shape* elements are negative.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> shape = Tensor(np.array([2, 3]), mstype.int32)
>>> rate = Tensor(np.array([2, 2]), mstype.int32)
>>> seed = 0
>>> seed2 = 0
>>> random_poisson = ops.RandomPoisson(seed=seed, seed2=seed2)
>>> output = random_poisson(shape,rate)
>>> print(output.shape)
(2, 3, 2)
```

mindspore.ops.Randperm

class mindspore.ops.**Randperm**(*max_length=1*, *pad=- 1*, *dtype=mstype.int32*)

Generates n random samples from 0 to n-1 without repeating. If *max_length* > n, the last *max_length-n* elements will be filled with *pad*.

Parameters

- **max_length** (*int*) – Number of items expected to get and the number must be greater than 0. Default: `1` .
- **pad** (*int*) – The pad value to be filled. Default: `-1` .
- **dtype** (mindspore.dtype) – The type of output. Default: `mstype.int32` .

Inputs:

- **n** (Tensor) - The input tensor with shape $(1,)$ with and dtype int32 or int64. *n* must be in range [0, *max_length*].

Outputs:

- **output** (Tensor) - The output Tensor with shape: (*max_length*,) and type: *dtype*.

Raises

- **TypeError** – If neither *max_length* nor *pad* is an int.
- **TypeError** – If *n* is not a Tensor.

- **TypeError** – If *n* has non-Int elements.
- **TypeError** – If *n* has negative elements.
- **TypeError** – If *dtype* is not supported.
- **ValueError** – If *n* is out of range of *dtype*.
- **ValueError** – If *n* is larger than *max_length*.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> # The result of every execution is different because this operator will generate n␣
↪random samples.
>>> randperm = ops.Randperm(max_length=30, pad=-1)
>>> n = Tensor([20], dtype=mindspore.int32)
>>> output = randperm(n)
>>> print(output)
[15 6 11 19 14 16 9 5 13 18 4 10 8 0 17 2 1 12 3 7
 -1 -1 -1 -1 -1 -1 -1 -1 -1 -1]
```

mindspore.ops.RandpermV2

class mindspore.ops.**RandpermV2**(*seed=0*, *offset=0*, *dtype=mstype.int64*)

```
prim = ops.RandpermV2(seed, offset, dtype)
out = prim(n)
```

is equivalent to

```
ops.randperm(n, seed, offset, dtype)
```

Refer to *mindspore.ops.randperm()* for more details.

mindspore.ops.StandardLaplace

class mindspore.ops.**StandardLaplace**(*seed=0*, *seed2=0*)

Generates random numbers according to the Laplace random number distribution (mean=0, lambda=1). It is defined as:

$$\mathrm{f}(x) = \frac{1}{2}\exp(-|x|)$$

Note:

- Random seed: a set of regular random numbers can be obtained through some complex mathematical algorithms, and the random seed determines the initial value of this random number. If the random seed is the same in two separate calls, the random number generated will not change.
- Using the Philox algorithm to scramble seed and seed2 to obtain random seed so that the user doesn't need to worry about which seed is more important.

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* and *seed2* parameter have no effect.

Parameters

- **seed** (*int, optional*) –The operator-level random seed, used to generate random numbers, must be non-negative. Default: `0` .
- **seed2** (*int, optional*) –The global random seed, which combines with the operator-level random seed to determine the final generated random number, must be non-negative. Default: `0` .

Inputs:

- **shape** (Union[tuple[int], Tensor[int]]) - The shape of random tensor to be generated. Only constant value is allowed when the input type is tuple. And the operator supports dynamic shape only when the input type is Tensor.

Outputs:

Tensor. The shape that the input 'shape' denotes. The dtype is float32.

Raises

- **TypeError** –If seed or seed2 is not an int.
- **TypeError** –If shape is neither a tuple nor a Tensor.
- **ValueError** –If seed or seed2 is not a non-negative int.
- **ValueError** –If shape is a tuple containing non-positive items.
- **ValueError** –If shape is a Tensor, and the rank of the Tensor is not equal to 1.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> from mindspore import ops
>>> shape = (4, 16)
>>> stdlaplace = ops.StandardLaplace(seed=2)
>>> output = stdlaplace(shape)
>>> result = output.shape
>>> print(result)
(4, 16)
```

mindspore.ops.StandardNormal

class mindspore.ops.**StandardNormal**(*seed=0*, *seed2=0*)

Generates random numbers according to the standard Normal (or Gaussian) random number distribution.

Refer to *mindspore.ops.standard_normal()* for more details.

Note:

- Random seed: a set of regular random numbers can be obtained through some complex mathematical algorithms, and the random seed determines the initial value of this random number. If the random seed is the same in two separate calls, the random number generated will not change.
- Using the Philox algorithm to scramble seed and seed2 to obtain random seed so that the user doesn't need to worry about which seed is more important.

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* and *seed2* parameter have no effect.

Parameters

- **seed** (*int, optional*) –The operator-level random seed, used to generate random numbers, must be non-negative. Default: `0` .
- **seed2** (*int, optional*) –The global random seed, which combines with the operator-level random seed to determine the final generated random number, must be non-negative. Default: `0` .

Inputs:

- **shape** (tuple) - The shape of random tensor to be generated. Only constant value is allowed. Supported dtypes: int32, int64.

Outputs:

Tensor. The shape is the same as the input *shape*. The dtype is float32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import ops
>>> shape = (3, 4)
>>> stdnormal = ops.StandardNormal(seed=2)
>>> output = stdnormal(shape)
>>> print(output)
[[-1.3031056   0.64198005 -0.65207404 -1.767485  ]
 [-0.91792876  0.6508565  -0.9098478  -0.14092612]
 [ 0.7806437   1.1585592   1.9676613  -0.00440959]]
```

mindspore.ops.UniformInt

class mindspore.ops.**UniformInt**(*seed=0*, *seed2=0*)

Produces random integer values i, uniformly distributed on the closed interval [minval, maxval), that is, distributed according to the discrete probability function:

$$\mathrm{P}(i|a,b) = \frac{1}{b-a+1},$$

where the a indicates the min distribution parameter, the b indicates the max distribution parameter.

Note:

- The number in tensor minval must be strictly less than maxval at any position after broadcasting.
- Random seed: a set of regular random numbers can be obtained through some complex mathematical algorithms, and the random seed determines the initial value of this random number. If the random seed is the same in two separate calls, the random number generated will not change.
- Using the Philox algorithm to scramble seed and seed2 to obtain random seed so that the user doesn't need to worry about which seed is more important.

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* and *seed2* parameter have no effect.

Parameters

- **seed** (*int, optional*) – The operator-level random seed, used to generate random numbers, must be non-negative. Default: `0` .
- **seed2** (*int, optional*) – The global random seed, which combines with the operator-level random seed to determine the final generated random number, must be non-negative. Default: `0` .

Inputs:

- **shape** (Union[tuple, Tensor]) - The shape of random tensor to be generated. Only constant value is allowed.
- **minval** (Tensor) - The distribution parameter, a. It defines the minimum possibly generated value, with int32 data type. Only one number is supported.
- **maxval** (Tensor) - The distribution parameter, b. It defines the maximum possibly generated value, with int32 data type. Only one number is supported.

Outputs:

Tensor. The shape is the same as the input 'shape', and the data type is int32.

Raises

- **TypeError** – If neither *seed* nor *seed2* is an int.
- **TypeError** – If *shape* is neither a tuple nor a Tensor.
- **TypeError** – If neither *minval* nor *maxval* is a Tensor.
- **ValueError** – If *shape* is not a constant value.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> shape = (2, 4)
>>> minval = Tensor(1, mstype.int32)
>>> maxval = Tensor(5, mstype.int32)
>>> uniform_int = ops.UniformInt(seed=10)
>>> output = uniform_int(shape, minval, maxval)
>>> result = output.shape
>>> print(result)
(2, 4)
```

mindspore.ops.UniformReal

class mindspore.ops.**UniformReal**(*seed=0*, *seed2=0*)

Produces random floating-point values, uniformly distributed to the interval [0, 1).

Note:

- Random seed: a set of regular random numbers can be obtained through some complex mathematical algorithms, and the random seed determines the initial value of this random number. If the random seed is the same in two separate calls, the random number generated will not change.
- Using the Philox algorithm to scramble seed and seed2 to obtain random seed so that the user doesn't need to worry about which seed is more important.
- Currently, on the Ascend platform, *shape* as a Tensor is not supported. This is supported on CPU/GPU platforms. When the input is a Tensor, the supported data types are as follows:
  - GPU: int32, int64.
  - CPU: int16, int32, int64.

Warning: The Ascend backend does not support the reproducibility of random numbers, so the *seed* and *seed2* parameter have no effect.

Parameters

- **seed** (*int, optional*) – The operator-level random seed, used to generate random numbers, must be non-negative. Default: `0` .
- **seed2** (*int, optional*) – The global random seed, which combines with the operator-level random seed to determine the final generated random number, must be non-negative. Default: `0` .

Inputs:

- **shape** (Union[tuple, Tensor]) - The shape of tensor to be generated. Only constant value is allowed.

Outputs:

Tensor. The shape that the input 'shape' denotes. The dtype is float32.

Raises

- **TypeError** – If *seed* or *seed2* is not an int.

- **TypeError** – If *shape* is neither a tuple nor a Tensor.
- **ValueError** – If *shape* is not a constant value.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import ops
>>> shape = (2, 2)
>>> uniformreal = ops.UniformReal(seed=2)
>>> output = uniformreal(shape)
>>> result = output.shape
>>> print(result)
(2, 2)
```

18.4.3 Array Operation

API Name	Description	Supported Platforms
mindspore.ops.AffineGrid	Creates a 2D or 3D flow field (sampling grid) based on a batch of affine matrices *theta*.	`Ascend` `GPU` `CPU`
mindspore.ops.BatchToSpace	Divides batch dimension with blocks and interleaves these blocks back into spatial dimensions.	`Ascend` `GPU`
mindspore.ops.BatchToSpaceND	Please use batch_to_space_nd instead.	Deprecated
mindspore.ops.BroadcastTo	Refer to *mindspore.ops.broadcast_to()* for more details.	`Ascend` `GPU` `CPU`
mindspore.ops.Cast	Returns a tensor with the new specified data type.	`Ascend` `GPU` `CPU`
mindspore.ops.ChannelShuffle	Divide the channels in a tensor of shape $(*, C, H, W)$ into g group and rearrange them as $(*, \frac{C}{g}, g, H * W)$, while retaining the original tensor shape in the final output.	`Ascend` `CPU`
mindspore.ops.Col2Im	Rearranges a row vector to an image.	`Ascend` `GPU` `CPU`
mindspore.ops.Concat	Refer to *mindspore.ops.cat()* for more details.	`Ascend` `GPU` `CPU`
mindspore.ops.Cummax	Refer to *mindspore.ops.cummax()* for more details.	`Ascend` `GPU` `CPU`
mindspore.ops.Cummin	Returns the cumulative minimum of elements and the index.	`Ascend` `GPU` `CPU`
mindspore.ops.CumProd	Computes the cumulative product of the tensor x along axis.	`Ascend` `GPU` `CPU`
mindspore.ops.CumSum	Computes the cumulative sum of input tensor along axis.	`Ascend` `GPU` `CPU`
mindspore.ops.DataFormatDimMap	Returns the dimension index in the destination data format given in the source data format.	`Ascend` `GPU` `CPU`
mindspore.ops.DepthToSpace	Rearrange blocks of depth data into spatial dimensions.	`Ascend` `GPU` `CPU`
mindspore.ops.Diag	Refer to *mindspore.ops.diag()* for more details.	`Ascend` `GPU` `CPU`

continues on next page

Table 17 – continued from previous page

mindspore.ops.DType	Returns the data type of the input tensor as mindspore.dtype.	Ascend GPU CPU
mindspore.ops.ExpandDims	Refer to mindspore.ops.expand_dims() for more details.	Ascend GPU CPU
mindspore.ops.FillDiagonal	Fills the main diagonal of a Tensor in-place with a specified value and returns the result.	Ascend GPU CPU
mindspore.ops.FillV2	Creates a tensor with shape described by *shape* and fills it with values in *value* .	Ascend GPU CPU
mindspore.ops.FloatStatus	Determines if the elements contain Not a Number(NaN), infinite or negative infinite.	GPU
mindspore.ops.Fmax	Computes the maximum of input tensors element-wise.	CPU
mindspore.ops.Gather	Refer to mindspore.ops.gather() for more details.	Ascend GPU CPU
mindspore.ops.GatherD	Refer to mindspore.ops.gather_d() for more details.	Ascend GPU CPU
mindspore.ops.GatherNd	Refer to mindspore.ops.gather_nd() for more details.	Ascend GPU CPU
mindspore.ops.HammingWindow	Computes the hamming window function with input window length.	Ascend GPU CPU
mindspore.ops.Heaviside	Applies the Heaviside step function for input *x* element-wise.	Ascend GPU CPU
mindspore.ops.HistogramFixedWidth	Returns a rank 1 histogram counting the number of entries in values that fall into every bin.	Ascend GPU
mindspore.ops.Hypot	Computes hypotenuse of input tensors element-wise as legs of a right triangle.	Ascend GPU CPU
mindspore.ops.Identity	Refer to mindspore.ops.deepcopy() for more details.	Ascend GPU CPU
mindspore.ops.Igamma	Calculates lower regularized incomplete Gamma function.	Ascend GPU CPU
mindspore.ops.Igammac	Compute the upper regularized incomplete Gamma function Q(a, x).	Ascend GPU CPU
mindspore.ops.Im2Col	Extracts sliding local blocks from a batched input tensor.	Ascend GPU CPU
mindspore.ops.IndexAdd	Adds tensor *y* to specified axis and indices of tensor *x*.	Ascend GPU CPU
mindspore.ops.IndexFill	Fills the elements under the *dim* dimension of the input Tensor *x* with the input *value* by selecting the indices in the order given in *index*.	Ascend GPU CPU
mindspore.ops.IndexPut	According to the index number of *indexes*, replace the value corresponding to *x1* with the value in *x2*.	Ascend CPU
mindspore.ops.InplaceAdd	Adds *v* into specified rows of *x*.	Ascend GPU CPU
mindspore.ops.InplaceIndexAdd	Adds Tensor *updates* to specified axis and indices of Tensor *var* element-wise.	Ascend CPU
mindspore.ops.InplaceSub	Subtracts *v* into specified rows of *x*.	Ascend GPU CPU
mindspore.ops.InplaceUpdate	Please use mindspore.ops.InplaceUpdateV2 instead.	Deprecated
mindspore.ops.InplaceUpdateV2	Updates specified values in *x* to *v* according to *indices*.	GPU CPU
mindspore.ops.InvertPermutation	Computes the inverse of an index permutation.	Ascend GPU CPU

continues on next page

Table 17 – continued from previous page

mindspore.ops.IsClose	Returns a tensor of Boolean values indicating whether each element of *input* is "close" to the corresponding element of *other*.	Ascend GPU CPU
mindspore.ops.Lcm	Computes least common multiplier of input tensors element-wise.	Ascend GPU CPU
mindspore.ops.LeftShift	Shift the value of each position of the tensor to the left several bits.	Ascend GPU CPU
mindspore.ops.LogSpace	Generates a 1-D Tensor with a length of steps.	Ascend GPU CPU
mindspore.ops.LuUnpack	Converts *LU_data* and *LU_pivots* back into P, L and U matrices, where P is a permutation matrix, L is a lower triangular matrix, and U is an upper triangular matrix.	GPU CPU
mindspore.ops.MaskedFill	Refer to mindspore.ops.masked_fill() for more details.	Ascend GPU CPU
mindspore.ops.MaskedScatter	Updates the value in the input with value in *updates* according to the *mask*.	Ascend CPU
mindspore.ops.MaskedSelect	Refer to mindspore.ops.masked_select() for more details.	Ascend GPU CPU
mindspore.ops.MatrixBandPart	Extracts the central diagonal band of each matrix in a tensor, with all values outside the central band set to zero.	Ascend GPU CPU
mindspore.ops.MatrixDiagPartV3	Returns the diagonal part of a tensor.	Ascend GPU CPU
mindspore.ops.MatrixDiagV3	Constructs a diagonal matrix or a batch of diagonal matrices from a given input Tensor.	Ascend GPU CPU
mindspore.ops.MatrixSetDiagV3	Updates the diagonal part of a batched tensor.	Ascend GPU CPU
mindspore.ops.MatrixSolve	Solves systems of linear equations.	Ascend CPU
mindspore.ops.Meshgrid	Generates coordinate matrices from given coordinate tensors.	Ascend GPU CPU
mindspore.ops.Mvlgamma	Calculates the multivariate log-gamma function element-wise for a given dimension *p*.	Ascend GPU CPU
mindspore.ops.NanToNum	Refer to mindspore.ops.nan_to_num() for more details.	Ascend CPU
mindspore.ops.NonZero	Return a Tensor of the positions of all non-zero values.	Ascend GPU CPU
mindspore.ops.ParallelConcat	Concats input tensors along the first dimension.	Ascend GPU CPU
mindspore.ops.PopulationCount	Computes element-wise population count(a.k.a bitsum, bitcount).	Ascend GPU CPU
mindspore.ops.RandomShuffle	Randomly shuffles a Tensor along its first dimension.	Ascend GPU CPU
mindspore.ops.Range	Refer to mindspore.ops.range() for more details.	GPU CPU
mindspore.ops.Rank	Returns the rank of a tensor.	Ascend GPU CPU
mindspore.ops.Renorm	Renormalizes the sub-tensors along dimension *dim*, and each sub-tensor's p-norm should not exceed the 'maxnorm'.	Ascend GPU CPU
mindspore.ops.Reshape	Refer to mindspore.ops.reshape() for more details.	Ascend GPU CPU
mindspore.ops.ReverseSequence	Reverses variable length slices.	Ascend GPU CPU
mindspore.ops.ReverseV2	Refer to mindspore.ops.flip() for more details.	Ascend GPU CPU

continues on next page

Table 17 – continued from previous page

mindspore.ops.RightShift	Shift the value of each position of Tensor *input_x* to the right by corresponding bits in Tensor *input_y*.	Ascend GPU CPU
mindspore.ops.ScatterNd	Refer to mindspore.ops.scatter_nd() for more details.	Ascend GPU CPU
mindspore.ops.ScatterNdDiv	Applies sparse division to individual values or slices in a tensor.	GPU CPU
mindspore.ops.ScatterNdMax	Computes sparse maximum to individual values or slices in a tensor.	Ascend GPU CPU
mindspore.ops.ScatterNdMin	Applies sparse minimum to individual values or slices in a tensor.	Ascend GPU CPU
mindspore.ops.ScatterNdMul	Applies sparse multiplication to individual values or slices in a tensor.	GPU CPU
mindspore.ops.SearchSorted	Return the position indices where the elements can be inserted into the input tensor to maintain the increasing order of the input tensor.	Ascend GPU CPU
mindspore.ops.Select	Refer to mindspore.ops.select() for more details.	Ascend GPU CPU
mindspore.ops.Shape	Returns the shape of the input tensor.	Ascend GPU CPU
mindspore.ops.Size	Returns a Scalar of type int that represents the size of the input Tensor and the total number of elements in the Tensor.	Ascend GPU CPU
mindspore.ops.Slice	Slices a tensor in the specified shape.	Ascend GPU CPU
mindspore.ops.Sort	Sorts the elements of the input tensor along the given dimension in the specified order.	Ascend GPU CPU
mindspore.ops.SpaceToBatchND	Divides spatial dimensions into blocks and combines the block size with the original batch.	Ascend GPU CPU
mindspore.ops.SpaceToDepth	Rearrange blocks of spatial data into depth.	Ascend GPU CPU
mindspore.ops.SparseGatherV2	Returns a slice of input tensor based on the specified indices and axis.	Ascend GPU
mindspore.ops.Split	Splits the input tensor into output_num of tensors along the given axis and output numbers.	Ascend GPU CPU
mindspore.ops.Squeeze	Return the Tensor after deleting the dimension of size 1 in the specified *axis*.	Ascend GPU CPU
mindspore.ops.Stack	Stacks a list of tensors in specified axis.	Ascend GPU CPU
mindspore.ops.StridedSlice	Refer to mindspore.ops.strided_slice() for more details.	Ascend GPU CPU
mindspore.ops.TensorScatterAdd	Creates a new tensor by adding the values from the positions in *input_x* indicated by *indices*, with values from *updates*.	Ascend GPU CPU
mindspore.ops.TensorScatterDiv	Creates a new tensor by dividing the values from the positions in *input_x* indicated by *indices*, with values from *updates*.	GPU CPU
mindspore.ops.TensorScatterMax	By comparing the value at the position indicated by *indices* in *x* with the value in the *updates*, the value at the index will eventually be equal to the largest one to create a new tensor.	GPU CPU
mindspore.ops.TensorScatterMin	By comparing the value at the position indicated by *indices* in *input_x* with the value in the *updates*, the value at the index will eventually be equal to the smallest one to create a new tensor.	Ascend GPU CPU

continues on next page

Table 17 – continued from previous page

mindspore.ops.TensorScatterMul	Creates a new tensor by multiplying the values from the positions in *input_x* indicated by *indices*, with values from *updates*.	GPU CPU
mindspore.ops.TensorScatterSub	Creates a new tensor by subtracting the values from the positions in *input_x* indicated by *indices*, with values from *updates*.	Ascend GPU CPU
mindspore.ops.TensorScatterUpdate	Creates a new tensor by updating the positions in *input_x* indicated by *indices*, with values from *update*.	Ascend GPU CPU
mindspore.ops.TensorShape	Returns the shape of the input tensor.	Ascend GPU CPU
mindspore.ops.Tile	Replicates an input tensor with given multiple times.	Ascend GPU CPU
mindspore.ops.Trace	Refer to mindspore.ops.trace() for more details.	Ascend GPU CPU
mindspore.ops.Transpose	Refer to mindspore.ops.transpose() for more details.	Ascend GPU CPU
mindspore.ops.Tril	Returns the lower triangular portion of the 2-D matrix or the set of matrices in a batch.	Ascend GPU CPU
mindspore.ops.TrilIndices	Computes the indices of the lower triangular elements of a 2D matrix and returns them as a Tensor.	Ascend GPU CPU
mindspore.ops.Triu	Refer to mindspore.ops.triu() for more details.	Ascend GPU CPU
mindspore.ops.TriuIndices	Calculates the indices of the upper triangular elements in a *row* * *col* matrix and returns them as a 2-by-N Tensor.	Ascend GPU CPU
mindspore.ops.Unique	Returns the unique elements of input tensor and also return a tensor containing the index of each value of input tensor corresponding to the output unique tensor.	Ascend GPU CPU
mindspore.ops.UniqueConsecutive	Returns the elements that are unique in each consecutive group of equivalent elements in the input tensor.	Ascend GPU CPU
mindspore.ops.UniqueWithPad	'ops.UniqueWithPad' is deprecated from version 2.4 and will be removed in a future version.	Deprecated
mindspore.ops.UnsortedSegmentMax	Computes the maximum along segments of a tensor.	Ascend GPU CPU
mindspore.ops.UnsortedSegmentMin	Computes the minimum of a tensor along segments.	Ascend GPU CPU
mindspore.ops.UnsortedSegmentProd	Computes the product of a tensor along segments.	Ascend GPU CPU
mindspore.ops.UnsortedSegmentSum	Refer to mindspore.ops.unsorted_segment_sum() for more details.	Ascend GPU CPU
mindspore.ops.Unstack	Unstacks tensor in specified axis, this is the opposite of ops.Stack.	Ascend GPU CPU

mindspore.ops.AffineGrid

class mindspore.ops.**AffineGrid**(*align_corners=False*)

Creates a 2D or 3D flow field (sampling grid) based on a batch of affine matrices *theta*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.affine_grid()* for more details.

Parameters

align_corners (*bool, optional*) – Geometrically, each pixel of input is viewed as a squqre instead of dot. If `True`, consider extremum -1 and 1 referring to the centers of the pixels rather than pixel corners. The default value is `False` , extremum -1 and 1 refer to the corners of the pixels, so that sampling is irrelevant to resolution of the image. Default: `False` .

Inputs:

- **theta** (Tensor) - The input tensor of flow field whose dtype is float16, float32. Input batch of affine matrices with shape $(N, 2, 3)$ for 2D grid or $(N, 3, 4)$ for 3D grid.
- **output_size** (tuple[int]) - The target output image size. The value of target output with format (N, C, H, W) for 2D grid or (N, C, D, H, W) for 3D grid.

Outputs:

Tensor, a tensor whose data type is same as *theta*, and the shape is $(N, H, W, 2)$ for 2D grid or $(N, D, H, W, 3)$ for 3D grid.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> affinegrid = ops.AffineGrid(align_corners=False)
>>> theta = Tensor([[[0.8, 0.5, 0],[-0.5, 0.8, 0]]], mindspore.float32)
>>> out_size = (1, 3, 2, 3)
>>> output = affinegrid(theta, out_size)
>>> print(output)
[[[[-0.78333336 -0.06666666]
[-0.25       -0.4       ]
[ 0.28333336 -0.73333335]]
[[-0.28333336  0.73333335]
[ 0.25        0.4       ]
[ 0.78333336  0.06666666]]]]
```

mindspore.ops.BatchToSpace

class mindspore.ops.**BatchToSpace**(*block_size*, *crops*)

Divides batch dimension with blocks and interleaves these blocks back into spatial dimensions.

This operation will divide batch dimension N into blocks with block_size, the output tensor's N dimension is the corresponding number of blocks after division. The output tensor's H, W dimension is product of original H, W dimension and block_size with given amount to crop from dimension, respectively.

Parameters

- **block_size** (*int*) –The block size of division, has the value not less than 2.
- **crops** (*Union[list(int), tuple(int)]*) –The crop value for H and W dimension, containing 2 subtraction lists. Each list contains 2 integers. All values must be not less than 0. crops[i] specifies the crop values for the spatial dimension i, which corresponds to the input dimension i+2. It is required that $input\_shape[i+2] * block\_size > crops[i][0] + crops[i][1]$.

Inputs:

- **input_x** (Tensor) - The input tensor. It must be a 4-D tensor, dimension 0 must be divisible by product of *block_shape*. The data type is float16 or float32.

Outputs:

Tensor, the output tensor with the same type as input. Assume input shape is (n, c, h, w) with block_size and crops. The output shape will be (n', c', h', w'), where

$n' = n//(block\_size * block\_size)$

$c' = c$

$h' = h * block\_size - crops[0][0] - crops[0][1]$

$w' = w * block\_size - crops[1][0] - crops[1][1]$

Raises

- **TypeError** –If *block_size* or element of *crops* is not an int.
- **TypeError** –If *crops* is neither list nor tuple.
- **ValueError** –If *block_size* is less than 2.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> block_size = 2
>>> crops = [[0, 0], [0, 0]]
>>> batch_to_space = ops.BatchToSpace(block_size, crops)
>>> input_x = Tensor(np.array([[[[1]]], [[[2]]], [[[3]]], [[[4]]]]), mindspore.float32)
>>> output = batch_to_space(input_x)
>>> print(output)
[[[[1.  2.]
   [3.  4.]]]]
```

mindspore.ops.BatchToSpaceND

class mindspore.ops.**BatchToSpaceND**(*block_shape*, *crops*)

Please use batch_to_space_nd instead.

Supported Platforms:

Deprecated

mindspore.ops.BroadcastTo

class mindspore.ops.**BroadcastTo**(*shape*)

```
prim = ops.BroadcastTo(shape)
out = prim(input)
```

is equivalent to

```
ops.broadcast_to(input, shape)
```

Refer to *mindspore.ops.broadcast_to()* for more details.

mindspore.ops.Cast

class mindspore.ops.**Cast**

Returns a tensor with the new specified data type.

Note: When converting complex numbers to boolean type, the imaginary part of the complex number is not taken into account. As long as the real part is non-zero, it returns True; otherwise, it returns False.

Inputs:

- **input** (Union[Tensor, Number]) - The shape of tensor is $(x_1, x_2, ..., x_R)$. The tensor to be cast.
- **dtype** (dtype.Number) - The valid data type of the output tensor. Only constant value is allowed.

Outputs:

Tensor, the shape of tensor is the same as *input*, $(x_1, x_2, ..., x_R)$.

Raises

- **TypeError** – If *input* is neither Tensor nor Number.
- **TypeError** – If *dtype* is not a Number.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_np = np.random.randn(2, 3, 4, 5).astype(np.float32)
>>> input = Tensor(input_np)
>>> dtype = mindspore.int32
>>> cast = ops.Cast()
>>> output = cast(input, dtype)
>>> print(output.dtype)
Int32
>>> print(output.shape)
(2, 3, 4, 5)
```

mindspore.ops.ChannelShuffle

class mindspore.ops.**ChannelShuffle**(*group*)

Divide the channels in a tensor of shape $(*, C, H, W)$ into g group and rearrange them as $(*, \frac{C}{g}, g, H * W)$, while retaining the original tensor shape in the final output.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.channel_shuffle()* for more detail.

Parameters

group (*int*) –Number of group to divide channels in.

Inputs:

- **x** (Tensor) - Tensor to be divided, it has shape $(*, C, H, W)$, with float16, float32, int8, int16, int32, int64, uint8, uint16, uint32, uint64 data type.

Outputs:

A Tensor, has the same type as the x, and has the shape $(*, C, H, W)$.

Supported Platforms:

Ascend CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> group = 2
>>> x = Tensor(np.arange(1 * 4 * 2 * 2).reshape(1, 4, 2, 2).astype(np.int16))
>>> channel_shuffle_func = ops.ChannelShuffle(group)
>>> y = channel_shuffle_func(x)
>>> print(y)
[[[[ 0  1]
   [ 2  3]]
   [[ 8  9]
```

(continues on next page)

(continued from previous page)

```
[10 11]]
[[ 4  5]
[ 6  7]]
[[12 13]
[14 15]]]]
```

mindspore.ops.Col2Im

class mindspore.ops.**Col2Im**(*kernel_size*, *dilation=1*, *padding=0*, *stride=1*)

Rearranges a row vector to an image. It is usually used to reconstruct an image from a set of image patches(or sliding local blocks).

Consider an input Tensor of shape $(N, C, \prod(\text{kernel\_size}), L)$, where N is batch dimension, C is channel dimension, $\prod(\text{kernel\_size})$ is the block size, and L is the total number of blocks. This operation combines these local blocks into the large `output` tensor of shape $(N, C, \text{output\_size}[0], \text{output\_size}[1], \dots)$ by summing the overlapping values.

$$L = \prod_{d} \left\lfloor \frac{\text{output\_size}[d] + 2 \times \text{padding}[d] - \text{dilation}[d] \times (\text{kernel\_size}[d] - 1) - 1}{\text{stride}[d]} + 1 \right\rfloor$$

where d is over all spatial dimensions. The *padding*, *stride* and *dilation* arguments specify how the sliding blocks are retrieved.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **kernel_size** (*Union[int, tuple[int], list[int]]*) – The size of the kernel, should be two positive int for height and width. If type is int, it means that height equal with width. Must be specified.
- **dilation** (*Union[int, tuple[int], list[int]], optional*) – The size of the dilation, should be two positive int for height and width. If type is int, it means that height equal with width. Default: `1` .
- **padding** (*Union[int, tuple[int], list[int]], optional*) – The size of the padding, should be two int for height and width. If type is int, it means that height equal with width. Default: `0` .
- **stride** (*Union[int, tuple[int], list[int]], optional*) – The size of the stride, should be two positive int for height and width. If type is int, it means that height equal with width. Default: `1` .

Inputs:

- **x** (Tensor) - 4D input Tensor.
- **output_size** (Tensor) - 1D tensor with 2 elements of data type int32 or int64.

Outputs:

Tensor, a 4-D Tensor with same type of input *x*.

Raises

- **TypeError** – If dtype of *kernel_size* , *dilation* , *padding* or *stride* is not in Union[int, tuple[int], list[int]].
- **ValueError** – If values in *kernel_size* , *dilation* , *padding* or *stride* are not greater than zero or any one of them has more than 2 elements.
- **ValueError** – If x.shape[2] != kernel_size[0] * kernel_size[1].
- **ValueError** – If x.shape[3] does not match the calculated number of sliding blocks.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor(input_data=np.random.rand(16, 16, 4, 25), dtype=mstype.float32)
>>> output_size = Tensor(input_data=[8, 8], dtype=mstype.int32)
>>> col2im = ops.Col2Im(kernel_size=[2, 2], dilation=[2, 2], padding=[2, 2], stride=[2, 2])
>>> y = col2im(x, output_size)
>>> print(y.shape)
(16, 16, 8, 8)
```

mindspore.ops.Concat

class mindspore.ops.**Concat**(*axis=0*)

```
prim = ops.Concat(axis)
out = prim(tensors)
```

is equivalent to

```
ops.cat(tensors, axis)
```

Refer to *mindspore.ops.cat()* for more details.

mindspore.ops.Cummax

class mindspore.ops.**Cummax**(*axis*)

```
prim = ops.Cummax(axis)
out = prim(input)
```

is equivalent to

```
ops.cummax(input, axis)
```

Refer to *mindspore.ops.cummax()* for more details.

mindspore.ops.Cummin

class mindspore.ops.**Cummin**(*axis*)

Returns the cumulative minimum of elements and the index.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.cummin()* for more detail.

Parameters

axis (*int*) –The axis to accumulate the tensor's value. Must be in the range [-rank(input), rank(input)).

Inputs:

- **input** (Tensor) - The input tensor.

Outputs:

A tuple of 2 Tensors(values, indices), containing the cumulative minimum of elements and the index, the shape of each output tensor is the same as input *input*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor, ops
>>> import mindspore
>>> a = Tensor([-0.2284, -0.6628,  0.0975,  0.2680, -1.3298, -0.4220], mindspore.float32)
>>> axis = 0
>>> output = ops.Cummin(axis)(a)
>>> print(output[0])
[-0.2284 -0.6628 -0.6628 -0.6628 -1.3298 -1.3298]
>>> print(output[1])
[0 1 1 1 4 4]
```

mindspore.ops.CumProd

class mindspore.ops.**CumProd**(*exclusive=False*, *reverse=False*)

Computes the cumulative product of the tensor x along axis. For example, if input is a vector of size N, the result will also be a vector of size N, with elements.

$$y_i = x_1 * x_2 * x_3 * ... * x_i$$

Parameters

- **exclusive** (*bool, optional*) –If `True` , perform exclusive cumulative product. Default: `False` .
- **reverse** (*bool, optional*) –If `True` , reverse the result along axis. Default: `False` .

Inputs:

- **x** (Tensor[Number]) - The input Tensor with shape $(N, *)$ where $*$ means any number of additional dimensions.
- **axis** (int) - The dimensions to compute the cumulative product. Only constant value is allowed.

Outputs:

Tensor, has the same shape and dtype as the *x*.

Raises

- **TypeError** –If *exclusive* or *reverse* is not a bool.
- **TypeError** –If *axis* is not an int.
- **ValueError** –If *axis* is None.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> a, b, c, = 1, 2, 3
>>> x = Tensor(np.array([a, b, c]).astype(np.float32))
>>> op0 = ops.CumProd()
>>> output0 = op0(x, 0) # output=[a, a * b, a * b * c]
>>> op1 = ops.CumProd(exclusive=True)
>>> output1 = op1(x, 0) # output=[1, a, a * b]
>>> op2 = ops.CumProd(reverse=True)
>>> output2 = op2(x, 0) # output=[a * b * c, b * c, c]
>>> op3 = ops.CumProd(exclusive=True, reverse=True)
>>> output3 = op3(x, 0) # output=[b * c, c, 1]
>>> print(output0)
[1. 2. 6.]
>>> print(output1)
[1. 1. 2.]
>>> print(output2)
[6. 6. 3.]
>>> print(output3)
[6. 3. 1.]
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [5, 3, 5]]).astype(np.float32))
>>> output4 = op0(x, 0)
>>> output5 = op0(x, 1)
>>> print(output4)
[[ 1.  2.  3.]
 [ 4. 10. 18.]
 [20. 30. 90.]]
>>> print(output5)
[[  1.   2.   6.]
 [  4.  20. 120.]
 [  5.  15.  75.]]
```

mindspore.ops.CumSum

class mindspore.ops.**CumSum**(*exclusive=False*, *reverse=False*)

Computes the cumulative sum of input tensor along axis.

$$y_i = x_1 + x_2 + x_3 + ... + x_i$$

Parameters

- **exclusive** (*bool, optional*) – By default, this op performs an inclusive cumsum, which means that the first element of the input is identical to the first element of the output. Default: `False` .
- **reverse** (*bool, optional*) – If `True` , perform inverse cumulative sum. Default: `False` .

Inputs:

- **input** (Tensor) - The input Tensor with shape $(N, *)$ where $*$ means any number of additional dimensions.
- **axis** (int) - The axis to accumulate the tensor's value. Only constant value is allowed. Must be in the range [-rank(input), rank(input)).

Outputs:

Tensor, the shape of the output tensor is consistent with the input tensor's.

Raises

- **TypeError** –If *exclusive* or *reverse* is not a bool.
- **TypeError** –If *axis* is not an int.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[3, 4, 6, 10], [1, 6, 7, 9], [4, 3, 8, 7], [1, 3, 7, 9]]).astype(np.
↪float32))
>>> cumsum = ops.CumSum()
>>> # case 1: along the axis 0
>>> y = cumsum(x, 0)
>>> print(y)
[[ 3.  4.  6. 10.]
 [ 4. 10. 13. 19.]
 [ 8. 13. 21. 26.]
 [ 9. 16. 28. 35.]]
>>> # case 2: along the axis 1
>>> y = cumsum(x, 1)
>>> print(y)
[[ 3.  7. 13. 23.]
 [ 1.  7. 14. 23.]
 [ 4.  7. 15. 22.]
 [ 1.  4. 11. 20.]]
>>> # Next demonstrate exclusive and reverse, along axis 1
>>> # case 3: exclusive = True
>>> cumsum = ops.CumSum(exclusive=True)
>>> y = cumsum(x, 1)
>>> print(y)
[[ 0.  3.  7. 13.]
 [ 0.  1.  7. 14.]
 [ 0.  4.  7. 15.]
 [ 0.  1.  4. 11.]]
>>> # case 4: reverse = True
>>> cumsum = ops.CumSum(reverse=True)
>>> y = cumsum(x, 1)
>>> print(y)
[[23. 20. 16. 10.]
 [23. 22. 16.  9.]
 [22. 18. 15.  7.]
 [20. 19. 16.  9.]]
```

mindspore.ops.DataFormatDimMap

class mindspore.ops.**DataFormatDimMap**(*src_format='NHWC'*, *dst_format='NCHW'*)

Returns the dimension index in the destination data format given in the source data format.

Parameters

- **src_format** (*str*) – An optional value for source data format. The format can be `'NHWC'` and `'NCHW'`. Default: `'NHWC'`.
- **dst_format** (*str*) – An optional value for destination data format. The format can be `'NHWC'` and `'NCHW'`. Default: `'NCHW'`.

Inputs:

- **input_x** (Tensor) - A Tensor, each element is used as a dimension index of the source data format. The suggested values are in the range [-4, 4). Only supports int32.

Outputs:

Tensor, Return the dimension index in the given target data format, has the same data type and shape as the *input_x*.

Raises

- **TypeError** – If *src_format* or *dst_format* is not a str.
- **TypeError** – If *input_x* is not a Tensor whose dtype is not int32.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> input_x = Tensor([0, 1, 2, 3], mindspore.int32)
>>> dfdm = ops.DataFormatDimMap()
>>> output = dfdm(input_x)
>>> print(output)
[0 3 1 2]
```

mindspore.ops.DepthToSpace

class mindspore.ops.**DepthToSpace**(*block_size*)

Rearrange blocks of depth data into spatial dimensions.

This is the reverse operation of SpaceToDepth.

The depth of output tensor is $input\_depth/(block\_size * block\_size)$.

The output tensor's *height* dimension is $height * block\_size$.

The output tensor's *weight* dimension is $weight * block\_size$.

The input tensor's depth must be divisible by *block_size* * *block_size*. The data format is "NCHW".

Parameters

block_size (*int*) – The block size used to divide depth data. It must be >= 2.

Inputs:

- **x** (Tensor) - The target tensor. It must be a 4-D tensor with shape $(N, C_{in}, H_{in}, W_{in})$. The data type is Number.

Outputs:

Tensor of shape $(N, C_{in}/\text{block\_size}^2, H_{in} * \text{block\_size}, W_{in} * \text{block\_size})$.

Raises

- **TypeError** – If *block_size* is not an int.
- **ValueError** – If *block_size* is less than 2.
- **ValueError** – If length of shape of *x* is not equal to 4.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.random.rand(1, 12, 1, 1), mindspore.float32)
>>> block_size = 2
>>> depth_to_space = ops.DepthToSpace(block_size)
>>> output = depth_to_space(x)
>>> print(output.shape)
(1, 3, 2, 2)
```

mindspore.ops.Diag

class mindspore.ops.**Diag**

```
prim = ops.Diag()
out = prim(input)
```

is equivalent to

```
ops.diag(input)
```

Refer to *mindspore.ops.diag()* for more details.

mindspore.ops.DType

class mindspore.ops.**DType**

Returns the data type of the input tensor as mindspore.dtype.

Inputs:

- **input_x** (Tensor) - Input Tensor.

Outputs:

mindspore.dtype, the data type of a tensor.

Raises

TypeError – If *input_x* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_tensor = Tensor(np.array([[2, 2], [2, 2]]), mindspore.float32)
>>> output = ops.DType()(input_tensor)
>>> print(output)
Float32
```

mindspore.ops.ExpandDims

class mindspore.ops.**ExpandDims**

```
prim = ops.ExpandDims()
out = prim(input_x, axis)
```

is equivalent to

```
ops.expand_dims(input_x, axis)
```

Refer to *mindspore.ops.expand_dims()* for more details.

mindspore.ops.FillDiagonal

class mindspore.ops.**FillDiagonal**(*fill_value*, *wrap=False*)

Fills the main diagonal of a Tensor in-place with a specified value and returns the result. The input has at least 2 dimensions, and all dimensions of input must be equal in length when the dimension of input is greater than 2.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

- **fill_value** (*float*) – The value to fill the diagonal of *input_x*.
- **wrap** (*bool, optional*) – Controls whether the diagonal elements continue onto the remaining rows in case of a tall matrix(A matrix has more rows than columns). Examples blow demonstrates how it works on a tall matrix if *wrap* is set `True` . Default: `False` .

Inputs:

- **input_x** (Tensor) - The shape of tensor is $(x_1, x_2, ..., x_R)$.

Outputs:

- **y** (Tensor) - Tensor, has the same shape and data type as the input *input_x*.

Raises

- **ValueError** –If the dimension of *input_x* is not greater than 1.
- **ValueError** –If the size of each dimension is not equal, when the dimension is greater than 2.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]).astype(np.float32))
>>> fill_value = 9.9
>>> fill_diagonal = ops.FillDiagonal(fill_value)
>>> y = fill_diagonal(x)
>>> print(y)
[[9.9 2.  3. ]
 [4.  9.9 6. ]
 [7.  8.  9.9]]
>>> x = Tensor(np.array([[0, 0, 0], [1, 1, 1], [2, 2, 2], [3, 3, 3], [4, 4, 4], [5, 5, 5]]).
↪astype(np.int32))
>>> fill_value = 9.0
>>> fill_diagonal = ops.FillDiagonal(fill_value)
>>> y = fill_diagonal(x)
>>> print(y)
[[9 0 0]
 [1 9 1]
 [2 2 9]
 [3 3 3]
 [4 4 4]
 [5 5 5]]

 [3 3 3]
 [9 4 4]
 [5 9 5]
 [6 6 9]]
```

mindspore.ops.FillV2

class mindspore.ops.**FillV2**

Creates a tensor with shape described by *shape* and fills it with values in *value* .

Inputs:

- **shape** (Union[Tuple[int], Tensor[int]]) - 1-D Tensor or Tuple, specify the shape of output tensor. Its dtype must be int32 or int64.
- **value** (Tensor) - A 0-D Tensor, the value to fill the output tensor *y* .

Outputs:

- **y** (Tensor) - A tensor, its shape and value are described above.

Raises

- **TypeError** –If *shape* is not a 1-D tensor or tuple.
- **TypeError** –If the data type of *shape* is not int32 or int64.
- **ValueError** –If *value* is not a 0-D Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> fillV2 = ops.FillV2()
>>> output = fillV2(Tensor([2, 3], mindspore.int32), Tensor(1, mindspore.float32))
>>> print(output)
[[1. 1. 1.]
 [1. 1. 1.]]
>>> output = fillV2(Tensor([3, 3], mindspore.int64), Tensor(0, mindspore.int32))
>>> print(output)
[[0 0 0]
 [0 0 0]
 [0 0 0]]
```

mindspore.ops.FloatStatus

class mindspore.ops.**FloatStatus**

Determines if the elements contain Not a Number(NaN), infinite or negative infinite. 0 for normal, 1 for overflow.

Inputs:

- **x** (Tensor) - The input tensor. The data type must be float16, float32 or float64. $(N, *)$ where $*$ means, any number of additional dimensions.

Outputs:

Tensor, has the shape of $(1,)$, and the dtype is *mindspore.dtype.float32*.

Raises

TypeError – If dtype of *x* is not in [float16, float32, float64].

Supported Platforms:

GPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> float_status = ops.FloatStatus()
>>> x = Tensor(np.array([np.log(-1), 1, np.log(0)]), mindspore.float32)
>>> result = float_status(x)
>>> print(result)
[1.]
```

mindspore.ops.Fmax

class mindspore.ops.**Fmax**

Computes the maximum of input tensors element-wise.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.fmax()* for more detail.

Supported Platforms:

CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x1 = Tensor(np.array([1.0, 5.0, 3.0]), mindspore.float32)
>>> x2 = Tensor(np.array([4.0, 2.0, 6.0]), mindspore.float32)
>>> fmax = ops.Fmax()
>>> output = fmax(x1, x2)
>>> print(output)
[4. 5. 6.]
```

mindspore.ops.Gather

class mindspore.ops.**Gather**(*batch_dims=0*)

```
prim = ops.Gather(batch_dims)
out = prim(input_params, input_indices, axis)
```

is equivalent to

```
ops.gather(input_params, input_indices, axis, batch_dims)
```

Refer to *mindspore.ops.gather()* for more details.

mindspore.ops.GatherD

class mindspore.ops.**GatherD**

```
prim = ops.GatherD()
out = prim(x, dim, index)
```

is equivalent to

```
ops.gather_d(x, dim, index)
```

Refer to *mindspore.ops.gather_d()* for more details.

mindspore.ops.GatherNd

class mindspore.ops.**GatherNd**

```
prim = ops.GatherNd()
out = prim(input_x, indices)
```

is equivalent to

```
ops.gather_nd(input_x, indices)
```

Refer to *mindspore.ops.gather_nd()* for more details.

mindspore.ops.HammingWindow

class mindspore.ops.**HammingWindow**(*periodic=True*, *alpha=0.54*, *beta=0.46*, *dtype=mstype.float32*)

Computes the hamming window function with input window length.

$$w[n] = \alpha - \beta \cos\left(\frac{2\pi n}{N-1}\right),$$

where N is the full window size.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **periodic** (*bool, optional*) –a flag determines whether the returned window trims off the last duplicate value from the symmetric window. Default: `True` .
  - If True, returns a window to be used as periodic function, in above formula, N = length + 1.
  - If False, return a symmetric window, N = length.
- **alpha** (*float, optional*) –The coefficient α in the equation above. Default: `0.54` .
- **beta** (*float, optional*) –The coefficient β in the equation above. Default: `0.46` .
- **dtype** (*mindspore.dtype*, optional) –An optional data type of `mstype.float16` , `mstype.float32` and `mstype.float64` . Default: `mstype.float32`.

Inputs:

- **length** (Tensor) - a positive integer tensor controlling the returned window size, must be 1D.

Outputs:

Tensor, A 1-D tensor containing the window, whose shape is (length,).

Raises

- **TypeError** –If *length* is not a Tensor.
- **TypeError** –If dtype of *length* is not integer data type.
- **TypeError** –If *periodic* is not a bool.
- **TypeError** –If *alpha* is not a float.
- **TypeError** –If *beta* is not a float.
- **TypeError** –If *dtype* is not mindspore.float16, mindspore.float32 or mindspore.float64.
- **ValueError** –If dimension of *length* is not 1.
- **ValueError** –If data of *length* is negative.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> # case 1: periodic=True.
>>> length = Tensor(np.array([6]).astype(np.int32))
>>> hamming_window = ops.HammingWindow(periodic=True)
>>> y = hamming_window(length)
>>> print(y)
[0.08000001 0.31       0.77000004 1.         0.77000004 0.31      ]
>>> # case 2: periodic=False.
>>> length = Tensor(np.array([7]).astype(np.int32))
>>> hamming_window = ops.HammingWindow(periodic=False)
>>> y = hamming_window(length)
>>> print(y)
[0.08000001 0.31       0.77000004 1.         0.77000004 0.31       0.08000001]
```

mindspore.ops.Heaviside

class mindspore.ops.**Heaviside**

Applies the Heaviside step function for input *x* element-wise.

$$\text{heaviside}(x, \text{values}) = \begin{cases} 0, & \text{if } x < 0 \\ \text{values}, & \text{if } x == 0 \\ 1, & \text{if } x > 0 \end{cases}$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - The input tensor. With real number data type.
- **values** (Tensor) - The values to use where *x* is zero. It should be able to broadcast with *x* have the same dtype as *x*.

Outputs:

Tensor, has the same type as *x* and *values*.

Raises

- **TypeError** – If *x* or *values* is not Tensor.
- **TypeError** – If data type *x* and *values* is different.
- **ValueError** – If shape of two inputs are not broadcastable.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([-1.5, 0., 2.]))
>>> values = Tensor(np.array([0.5]))
>>> heaviside = ops.Heaviside()
>>> y = heaviside(x, values)
>>> print(y)
[0.  0.5 1. ]
```

mindspore.ops.HistogramFixedWidth

class mindspore.ops.**HistogramFixedWidth**(*nbins*, *dtype='int32'*)

Returns a rank 1 histogram counting the number of entries in values that fall into every bin. The bins are equal width and determined by the input *range* and the argument *nbins*.

Parameters

- **nbins** (*int*) – The number of histogram bins, the type is a positive integer.
- **dtype** (*str, optional*) – An optional attribute. The dtype must be str. Default: `'int32'`.

Inputs:

- **x** (Tensor) - Numeric Tensor. Must be one of the following types: int32, float32, float16.
- **range** (Tensor) - Must have the same data type as *x*, and the shape is $(2,)$. x <= range[0] will be mapped to histogram[0], x >= range[1] will be mapped to histogram[-1].

Outputs:

1-D Tensor, whose length is the type is *nbins* with dtype of int32.

Raises

- **TypeError** –If *dtype* is not a str or *nbins* is not an int.
- **ValueError** –If *nbins* is less than 1.
- **ValueError** –If *dtype* is not 'int32'.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> x = Tensor([-1.0, 0.0, 1.5, 2.0, 5.0, 15], mindspore.float16)
>>> range_op = Tensor([0.0, 5.0], mindspore.float16)
>>> hist = ops.HistogramFixedWidth(5)
>>> output = hist(x, range_op)
>>> print(output)
[2 1 1 0 2]
```

mindspore.ops.Hypot

class mindspore.ops.**Hypot**

Computes hypotenuse of input tensors element-wise as legs of a right triangle. The shape of two inputs should be broadcastable, and data type of them should be one of: float32, float64.

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x1** (Tensor) - The first input tensor.
- **x2** (Tensor) - The second input tensor.

Outputs:

Tensor, the shape is the same as the one after broadcasting, and the data type is one with higher precision in the two inputs.

Raises

- **TypeError** –If data type *x1* or *x2* is not float32 or float64.
- **ValueError** –If shape of two inputs are not broadcastable.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x1 = Tensor(np.array([3., 5., 7.]))
>>> x2 = Tensor(np.array([4., 12., 24.]))
>>> hypot_ = ops.Hypot()
>>> y = hypot_(x1, x2)
>>> print(y)
[ 5. 13. 25.]
>>> x1 = Tensor(2.1, mindspore.float32)
>>> x2 = Tensor(2.1, mindspore.float32)
>>> hypot_ = ops.Hypot()
>>> y = hypot_(x1, x2)
>>> print(y)
2.9698484
```

mindspore.ops.Identity

class mindspore.ops.**Identity**

```
prim = ops.Identity()
out = prim(input_x)
```

is equivalent to

```
ops.deepcopy(input_x)
```

Refer to *mindspore.ops.deepcopy()* for more details.

mindspore.ops.Igamma

class mindspore.ops.**Igamma**

Calculates lower regularized incomplete Gamma function.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.igamma()* for more details.

Inputs:

- **a** (Tensor) - The input tensor.
- **x** (Tensor) - The input tensor. It should have the same dtype with *a*.

Outputs:

Tensor, has the same dtype as *a* and *x*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> a = Tensor(np.array([2.0, 4.0, 6.0, 8.0]).astype(np.float32))
>>> x = Tensor(np.array([2.0, 3.0, 4.0, 5.0]).astype(np.float32))
>>> igamma = ops.Igamma()
>>> output = igamma(a, x)
>>> print (output)
[0.593994  0.35276785  0.21486944  0.13337152]
>>> a = Tensor(2.1, mindspore.float32)
>>> x = Tensor(2.1, mindspore.float32)
>>> igamma = ops.Igamma()
>>> output = igamma(a, x)
>>> print (output)
0.5917439
```

mindspore.ops.Igammac

class mindspore.ops.**Igammac**

Compute the upper regularized incomplete Gamma function Q(a, x).

Refer to *mindspore.ops.igammac()* for more details.

Inputs:

- **a** (Tensor) - The input tensor.
- **x** (Tensor) - The input tensor. It should have the same dtype with *a*.

Outputs:

Tensor, has the same dtype as *a* and *x*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> a = Tensor(np.array([2.0, 4.0, 6.0, 8.0]).astype(np.float32))
>>> x = Tensor(np.array([2.0, 3.0, 4.0, 5.0]).astype(np.float32))
>>> igammac = ops.Igammac()
>>> output = igammac(a, x)
>>> print (output)
[0.40600586 0.6472318  0.7851304  0.8666283 ]
>>> a = Tensor(2.1, mindspore.float32)
>>> x = Tensor(2.1, mindspore.float32)
>>> igammac = ops.Igammac()
>>> output = igammac(a, x)
```

(continues on next page)

(continued from previous page)

```
>>> print (output)
0.40825662
```

mindspore.ops.Im2Col

class mindspore.ops.**Im2Col**(*ksizes*, *strides=1*, *dilations=1*, *pads=0*)

Extracts sliding local blocks from a batched input tensor.

Consider a batched input tensor of shape $(N, C, *)$, where N is the batch dimension, C is the channel dimension, and $*$ represent arbitrary spatial dimensions. This operation flattens each sliding *ksizes*- sized block within the spatial dimensions of input x into a column (i.e., last dimension) of a 4-D output tensor of shape $(N, C, \prod(\text{kernel\_size}), L)$, where $C \times \prod(\text{kernel\_size})$ is the total number of elements within each block (a block has $\prod$(kernel_size) spatial locations each containing a C-channeled vector), and L is the total number of such blocks:

$$L = \prod_d \left\lfloor \frac{\text{spatial\_size}[d] + 2 \times \text{pads}[d] - \text{dilations}[d] \times (\text{kernel\_size}[d] - 1) - 1}{\text{strides}[d]} + 1 \right\rfloor,$$

where spatial_size is formed by the spatial dimensions of input x ($*$ above), and d is over all spatial dimensions.

Therefore, indexing *output* at the last dimension (column dimension) gives all values within a certain block.

The *pads*, *strides* and *dilations* arguments specify how the sliding blocks are retrieved.

Note: Currently, only 4-D input tensors (batched image-like tensors) are supported.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **ksizes** (*Union[int, tuple[int], list[int]]*) – The size of the kernel, should be two int for height and width. If type is int, it means that height equal with width. Must be specified.
- **strides** (*Union[int, tuple[int], list[int]], optional*) – The stride of the window, should be two int for height and width. If type is int, it means that height equal with width. Default: `1` .
- **dilations** (*Union[int, tuple[int], list[int]], optional*) – The dilation of the window, should be two int for height and width. If type is int, it means that height equal with width. Default: `1` .
- **pads** (*Union[int, tuple[int], list[int]], optional*) – The pad of the window, that must be a tuple of one or two *int* for height and width. Default: `0` .
  - If one int, $pad\_height = pad\_width$.
  - If two int, $pad\_height = pads[0]$, $pad\_width = pads[1]$.

Inputs:

- **x** (Tensor) - input tensor, only 4-D input tensors (batched image-like tensors) are supported.

Outputs:

Tensor, a 4-D Tensor with same type of input x.

Raises

- **TypeError** – If *ksizes* data type is not in Union[int, tuple[int], list[int]].

- **TypeError** –If *strides* data type is not in Union[int, tuple[int], list[int]].
- **TypeError** –If *dilations* data type is not in Union[int, tuple[int], list[int]].
- **TypeError** –If *pads* data type isnot in Union[int, tuple[int], list[int]].
- **ValueError** –If *ksizes* value is not greater than zero or elements number more than 2.
- **ValueError** –If *strides* value is not greater than zero or elements number more than 2.
- **ValueError** –If *dilations* value is not greater than zero or elements number more than 2.
- **ValueError** –If *pads* value is not greater than zero.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor(input_data=np.random.rand(4, 4, 32, 32), dtype=mstype.float64)
>>> im2col = ops.Im2Col(ksizes=3, strides=1, dilations=1)
>>> y = im2col(x)
>>> print(y.shape)
(4, 4, 9, 900)
```

mindspore.ops.IndexAdd

class mindspore.ops.**IndexAdd**(*axis*, *use_lock=True*, *check_index_bound=True*)

Adds tensor *y* to specified axis and indices of tensor *x*. The axis should be in [-len(x.dim), len(x.dim) - 1], and indices should be in [0, the size of *x* - 1] at the axis dimension.

Parameters

- **axis** (*int*) –The dimension along which to index.
- **use_lock** (*bool, optional*) –Whether to enable a lock to protect the updating process of variable tensors. If `True` , when updating the value of *x*, this process will be protected by a lock by using atomic operation. If `False` , the result may be unpredictable. Default: `True` .
- **check_index_bound** (*bool, optional*) –If `True` , check index boundary. If `False` , don't check index boundary. Default: `True` .

Inputs:

- **x** (Union[Parameter, Tensor]) - The input Parameter or Tensor to add to.
- **indices** (Tensor) - Add the value of *x* and *y* along the dimension of the *axis* according to the specified index value, with data type int32. The *indices* must be 1D with the same size as the size of *y* in the *axis* dimension. The values of *indices* should be in [0, b), where the b is the size of *x* in the *axis* dimension.
- **y** (Tensor) - The input tensor with the value to add. Must have same data type as *x*. The shape must be the same as *x* except the *axis* th dimension.

Outputs:

Tensor, has the same shape and dtype as *x*.

Raises

- **TypeError** –If neither *indices* nor *y* is a Tensor.
- **ValueError** –If axis is out of *x* rank's range.
- **ValueError** –If *x* rank is not the same as *y* rank.
- **ValueError** –If shape of *indices* is not 1D or size of *indices* is not equal to dimension of y[axis].
- **ValueError** –If *y*'s shape is not the same as *x* except the *axis* th dimension.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.index_add = ops.IndexAdd(axis=1)
...         self.x = Parameter(Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), mindspore.
↪float32),
...                            name="name_x")
...         self.indices = Tensor(np.array([0, 2]), mindspore.int32)
...
...     def construct(self, y):
...         return self.index_add(self.x, self.indices, y)
...
>>> y = Tensor(np.array([[0.5, 1.0], [1.0, 1.5], [2.0, 2.5]]), mindspore.float32)
>>> net = Net()
>>> output = net(y)
>>> print(output)
[[ 1.5  2.   4. ]
 [ 5.   5.   7.5]
 [ 9.   8.  11.5]]
```

mindspore.ops.IndexFill

class mindspore.ops.**IndexFill**

Fills the elements under the *dim* dimension of the input Tensor *x* with the input *value* by selecting the indices in the order given in *index*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.index_fill()* for more details.

Inputs:

- **x** (Tensor) - Input tensor.
- **dim** (Union[int, Tensor]) - Dimension along which to fill the input tensor. Only supports a 0-dimensional tensor or an int number.

- **index** (Tensor) - Indices of the input tensor to fill in.
- **value** (Union[bool, int, float, Tensor]) - Value to fill the input tensor.

Outputs:

Tensor, has the same type and shape as input tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> index_fill = ops.IndexFill()
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]).astype(np.float32))
>>> index = Tensor([0, 2], mindspore.int32)
>>> value = Tensor(-2.0, mindspore.float32)
>>> y = index_fill(x, 1, index, value)
>>> print(y)
[[-2. 2. -2.]
 [-2. 5. -2.]
 [-2. 8. -2.]]
```

mindspore.ops.IndexPut

class mindspore.ops.**IndexPut**(*accumulate=0*)

According to the index number of *indexes*, replace the value corresponding to *x1* with the value in *x2*.

Parameters

accumulate (*int*) – If accumulate is 1, the elements in x2 are added to x1, else the elements in x2 replace the corresponding element in x1, should be 0 or 1. Default: `0` .

Inputs:

- **x1** (Tensor) - The assigned target tensor, 1-D or higher dimensional.
- **x2** (Tensor) - 1-D Tensor of the same type as *x1*. If the size of *x2* is 1, it will broadcast to the same size as *x1*.
- **indices** (tuple[Tensor], list[Tensor]) - the indices of type int32 or int64, used to index into x1. The rank of tensors in indices should be 1-D, size of indices should <= x1.rank and the tensors in indices should be broadcastable.

Outputs:

Tensor, has the same dtype and shape as *x1*.

Raises

- **TypeError** – If the dtype of *x1* is not equal to the dtype of *x2*.
- **TypeError** – If *indices* is not tuple[Tensor] or list[Tensor].
- **TypeError** – If the dtype of tensors in *indices* are not int32 or int64.
- **TypeError** – If the dtype of tensors in *indices* are inconsistent.
- **TypeError** – If the dtype of *accumulate* are not int.

- **ValueError** –If rank(x2) is not 1-D.
- **ValueError** –If size(x2) is not 1 or max size of the tensors in *indices* when rank(x1) == size(indices).
- **ValueError** –If size(x2) is not 1 or x1.shape[-1] when rank(x1) > size(indices).
- **ValueError** –If the rank of tensors in *indices* is not 1-D.
- **ValueError** –If the tensors in *indices* is not be broadcastable.
- **ValueError** –If size(indices) > rank(x1).
- **ValueError** –If *accumulate* is not equal to 0 or 1.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x1 = Tensor(np.array([[1, 2, 3], [4, 5, 6]]).astype(np.int32))
>>> x2 = Tensor(np.array([3]).astype(np.int32))
>>> indices = [Tensor(np.array([0, 0]).astype(np.int32)), Tensor(np.array([0, 1]).astype(np.
↪int32))]
>>> accumulate = 1
>>> op = ops.IndexPut(accumulate = accumulate)
>>> output = op(x1, x2, indices)
>>> print(output)
[[4 5 3]
 [4 5 6]]
```

mindspore.ops.InplaceAdd

class mindspore.ops.**InplaceAdd**(*indices*)

Adds *v* into specified rows of *x*. Computes *y* = *x*; y[i,] += *v*.

Refer to *mindspore.ops.inplace_add()* for more details.

Parameters

indices (*Union[int, tuple]*) –Indices into the left-most dimension of *x*, and determines which rows of *x* to add with *v*. It is an integer or a tuple, whose value is in [0, the first dimension size of *x*).

Inputs:

- **x** (Tensor) - The tensor to be added. It has shape $(N, *)$ where $*$ means any number of additional dimensions.
- **input_v** (Tensor) - The value tensor add to *x*. It has the same dimension sizes as *x* except the first dimension, whose size must be the same as *indices*. It has the same data type with *x*.

Outputs:

Tensor, has the same shape and dtype as *x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> indices = (0, 1)
>>> x = Tensor(np.array([[1, 2], [3, 4], [5, 6]]), mindspore.float32)
>>> input_v = Tensor(np.array([[0.5, 1.0], [1.0, 1.5]]), mindspore.float32)
>>> inplaceAdd = ops.InplaceAdd(indices)
>>> output = inplaceAdd(x, input_v)
>>> print(output)
[[1.5 3. ]
 [4.  5.5]
 [5.  6. ]]
```

mindspore.ops.InplaceIndexAdd

class mindspore.ops.**InplaceIndexAdd**(*axis*)

Adds Tensor *updates* to specified axis and indices of Tensor *var* element-wise.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.inplace_index_add()* for more details.

Parameters

axis (*int*) – The dimension along which to index. It should be in range $[0, len(var.dim))$.

Inputs:

- **var** (Union[Parameter, Tensor]) - The input Parameter or Tensor to add to, with data type uint8, int8, int16, int32, float16, float32, float64.
- **indices** (Tensor) - The indies along *axis* to perform the addition. A 1D Tensor of shape $(updates.shape[axis],)$, every value of it should be in range $[0, var.shape[axis])$ with data type int32.
- **updates** (Tensor) - The input Tensor with the value to add. Must have same data type as *var*. The shape must be the same as *var* except the *axis* th dimension.

Outputs:

Tensor, updated result, has the same shape and dtype as *var*.

Supported Platforms:

Ascend CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, Parameter
>>> var = Parameter(Tensor(np.array([[1, 2], [3, 4], [5, 6]]), mindspore.float32))
>>> indices = Tensor(np.array([0, 1]), mindspore.int32)
>>> updates = Tensor(np.array([[0.5, 1.0], [1.0, 1.5]]), mindspore.float32)
>>> inplaceIndexAdd = ops.InplaceIndexAdd(axis=0)
>>> var = inplaceIndexAdd(var, indices, updates)
>>> print(var)
[[1.5 3. ]
 [4.  5.5]
 [5.  6. ]]
```

mindspore.ops.InplaceSub

class mindspore.ops.**InplaceSub**(*indices*)

Subtracts v into specified rows of x. Computes $y = x$; $y[i,] - = input\_v$.

Refer to *mindspore.ops.inplace_sub()* for more details.

Parameters

indices (*Union[int, tuple]*) −Indices into the left-most dimension of x, and determines which rows of x to subtract by v. It is an integer or a tuple, whose value is in [0, the first dimension size of x).

Inputs:

- **x** (Tensor) - The tensor to be subtracted. It has shape $(N, *)$ where $*$ means any number of additional dimensions.
- **input_v** (Tensor) - The value tensor subtract from x. It has the same dimension sizes as x except the first dimension, whose size must be the same as *indices*. It has the same data type with x.

Outputs:

Tensor, has the same shape and dtype as x.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> indices = (0, 1)
>>> x = Tensor(np.array([[1, 2], [3, 4], [5, 6]]), mindspore.float32)
>>> input_v = Tensor(np.array([[0.5, 1.0], [1.0, 1.5]]), mindspore.float32)
>>> inplaceSub = ops.InplaceSub(indices)
>>> output = inplaceSub(x, input_v)
>>> print(output)
[[0.5 1. ]
 [2.  2.5]
 [5.  6. ]]
```

mindspore.ops.InplaceUpdate

class mindspore.ops.**InplaceUpdate**(*indices*)

Please use *mindspore.ops.InplaceUpdateV2* instead.

Supported Platforms:

Deprecated

mindspore.ops.InplaceUpdateV2

class mindspore.ops.**InplaceUpdateV2**

Updates specified values in *x* to *v* according to *indices*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.inplace_update()* for more details.

Inputs:

- **x** (Tensor) - A tensor which to be inplace updated. It can be one of the following data types: float32, float16 and int32.
- **indices** (Union[int, tuple]): Indices into the left-most dimension of *x*, and determines which rows of x to update with v. It is an int or tuple, whose value is in [0, the first dimension size of x).
- **v** (Tensor) - A tensor with the same type as *x* and the same dimension size as *x* except the first dimension, which must be the same as the size of *indices*.

Outputs:

Tensor, with the same type and shape as the input *x*.

Supported Platforms:

GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> indices = (0, 1)
>>> x = Tensor(np.array([[1, 2], [3, 4], [5, 6]]), mindspore.float32)
>>> v = Tensor(np.array([[0.5, 1.0], [1.0, 1.5]]), mindspore.float32)
>>> inplace_update_v2 = ops.InplaceUpdateV2()
>>> output = inplace_update_v2(x, indices, v)
>>> print(output)
[[0.5 1. ]
 [1.  1.5]
 [5.  6. ]]
```

mindspore.ops.InvertPermutation

class mindspore.ops.**InvertPermutation**

Computes the inverse of an index permutation.

This operator is mainly used to calculate the inverse of index permutation. It requires a 1-dimensional integer tensor x, which represents the index of a zero-based array, and exchanges each value with its index position. In other words, For output tensor y and input tensor x, this operation calculates the following values:

$y[x[i]] = i, \quad i \in [0, 1, \ldots, \text{len}(x) - 1]$.

Note: These values must include 0. There must be no duplicate values and the values can not be negative.

Inputs:

- **input_x** (Union(tuple[int], list[int])) - The input is constructed by multiple integers, i.e., $(y_1, y_2, ..., y_S)$ representing the indices. The values must include 0. There can be no duplicate values or negative values. Only constant value is allowed. The maximum value must be equal to length of input_x.

Outputs:

tuple[int]. It has the same length as the input.

Raises

- **TypeError** –If *input_x* is neither tuple nor list.
- **TypeError** –If element of *input_x* is not an int.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import ops
>>> invert = ops.InvertPermutation()
>>> input_data = (3, 4, 0, 2, 1)
>>> output = invert(input_data)
>>> print(output)
(2, 4, 3, 0, 1)
```

mindspore.ops.IsClose

class mindspore.ops.**IsClose**(*rtol=1e-05*, *atol=1e-08*, *equal_nan=False*)

Returns a tensor of Boolean values indicating whether each element of *input* is "close" to the corresponding element of *other*. Closeness is defined as:

$$|input - other| <= atol + rtol * |other|$$

Refer to *mindspore.ops.isclose()* for more details.

Parameters

- **rtol** (*float, optional*) –Relative tolerance. Default: `1e-05` .

- **atol** (*float, optional*) –Absolute tolerance. Default: `1e-08` .
- **equal_nan** (*bool, optional*) –If `True` , then two NaNs will be considered equal. Default: `False` .

Inputs:

- **input** (Tensor) - First tensor to compare.
- **other** (Tensor) - Second tensor to compare.

Outputs:

Tensor, with the same shape as *input* and *other* after broadcasting, its dtype is bool.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor
>>> from mindspore.ops import IsClose
>>> input = Tensor(np.array([1.3, 2.1, 3.2, 4.1, 5.1]), mindspore.float16)
>>> other = Tensor(np.array([1.3, 3.3, 2.3, 3.1, 5.1]), mindspore.float16)
>>> isclose = IsClose()
>>> output = isclose(input, other)
>>> print(output)
[ True False False False  True]
```

mindspore.ops.Lcm

class mindspore.ops.**Lcm**

Computes least common multiplier of input tensors element-wise. The shape of two inputs should be broadcastable, and data type of them should be one of: int32, int64.

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x1** (Tensor) - The first input tensor.
- **x2** (Tensor) - The second input tensor.

Outputs:

Tensor, the shape is the same as the one after broadcasting, and the data type is one with higher digits in the two inputs.

Raises

- **TypeError** –If data type *x1* or *x2* is not int32 or int64.
- **ValueError** –If shape of two inputs are not broadcastable.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x1 = Tensor(np.array([7, 8, 9]))
>>> x2 = Tensor(np.array([14, 6, 12]))
>>> lcm_ = ops.Lcm()
>>> y = lcm_(x1, x2)
>>> print(y)
[14 24 36]
```

mindspore.ops.LeftShift

class mindspore.ops.**LeftShift**

Shift the value of each position of the tensor to the left several bits. The inputs are two tensors, dtypes of them must be consistent, and the shapes of them could be broadcast. The output does not support implicit type conversion.

$$out_i = x_i << y_i$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x1** (Tensor) - The target tensor whose dtype supports all int and uint type, will be shifted to the left by *x2* in element-wise.
- **x2** (Tensor) - The tensor must have the same dtype as *x1*. And the tensor must have the same shape as *x1* or could be broadcast with *x1*.

Outputs:

- **output** (Tensor) - The output tensor, has the same dtype as *x1*. And the shape of the output tensor is the same shape as *x1*, or the same shape as *x1* and *x2* after broadcasting.

Raises

- **TypeError** – If *x1* or *x2* has wrong type.
- **TypeError** – If *x1* or *x2* is not tensor.
- **ValueError** – If *x1* and *x2* could not be broadcast.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> left_shift = ops.LeftShift()
>>> x1 = Tensor(np.array([1, 2, 3]).astype(np.int8))
>>> x2 = Tensor(np.array([0, 1, -1]).astype(np.int8))
>>> output = left_shift(x1, x2)
>>> print(output)
[1 4 0]
```

mindspore.ops.LogSpace

class mindspore.ops.**LogSpace**(*steps=10*, *base=10*, *dtype=mstype.float32*)

Generates a 1-D Tensor with a length of steps. The tensor's values are uniformly distributed on a logarithmic scale, ranging from $base^{start}$ to $base^{end}$, including both endpoints. The logarithmic scale is based on the specified *base*.

$$step = (end - start)/(steps - 1)$$
$$output = [base^{start}, base^{start+1*step}, ..., base^{start+(steps-2)*step}, base^{end}]$$

Warning: This is an experimental API that is subject to change or deletion.

Parameters

- **steps** (*int, optional*) – The steps must be a non-negative integer. Default: `10`.
- **base** (*int, optional*) – The base must be a non-negative integer. Default: `10`.
- **dtype** (`mindspore.dtype, optional`) – The dtype of output, include `mstype.float16`, `mstype.float32` or `mstype.float64`. Default: `mstype.float32`.

Inputs:

- **start** (Tensor) - Start value of interval, with shape of 0-D, dtype is float16, float32 or float64.
- **end** (Tensor) - End value of interval, with shape of 0-D, dtype is float16, float32 or float64.

Outputs:

Tensor has the shape as $(step,)$. Its datatype is set by the attr 'dtype'.

Raises

- **TypeError** – If *input* is not a Tensor.
- **TypeError** – If *steps* is not an int.
- **TypeError** – If *base* is not an int.
- **TypeError** – If *dtype* is not mstype.float16, mstype.float32 or mstype.float64.
- **ValueError** – If *steps* is not a non-negative integer.
- **ValueError** – If *base* is not a non-negative integer.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> logspace = ops.LogSpace(steps = 10, base = 10, dtype=mstype.float32)
>>> start = Tensor(1, mstype.float32)
>>> end = Tensor(10, mstype.float32)
>>> output = logspace(start, end)
>>> print(output)
[1.e+01 1.e+02 1.e+03 1.e+04 1.e+05 1.e+06 1.e+07 1.e+08 1.e+09 1.e+10]
```

mindspore.ops.LuUnpack

class mindspore.ops.**LuUnpack**(*unpack_data=True*, *unpack_pivots=True*)

Converts *LU_data* and *LU_pivots* back into P, L and U matrices, where P is a permutation matrix, L is a lower triangular matrix, and U is an upper triangular matrix. Typically, *LU_data* and *LU_pivots* are generated from the LU decomposition of a matrix.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.lu_unpack()* for more details.

Parameters

- **unpack_data** (*bool, optional*) – A flag indicating if the LU_data should be unpacked. If `False` , then the returned L and U are None. Default: `True` .
- **unpack_pivots** (*bool, optional*) – A flag indicating if the LU_pivots should be unpacked into a permutation matrix P. If `False` , then the returned P is None. Default: `True` .

Inputs:

- **LU_data** (Tensor) - The packed LU factorization data. The shape of a tensor is $(*, M, N)$, where $*$ is batch dimensions, with data type int8, uint8, int16, int32, int64, float16, float32, float64. The dims of LU_data must be equal to or greater than 2.
- **LU_pivots** (Tensor) - The packed LU factorization pivots. The shape of a tensor is $(*, min(M, N))$, where $*$ is batch dimensions, with data type int8, uint8, int16, int32, int64.

Outputs:

- **pivots** (Tensor) - The permutation matrix of LU factorization. The shape is $(*, M, M)$, the dtype is same as *LU_data*.
- **L** (Tensor) - The L matrix of LU factorization. The dtype is the same as *LU_data*.
- **U** (Tensor) - The U matrix of LU factorization. The dtype is the same as *LU_data*.

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> LU_data = Tensor(np.array([[[-0.3806, -0.4872,  0.5536],
...                             [-0.1287,  0.6508, -0.2396],
...                             [ 0.2583,  0.5239,  0.6902]],
...                             [[ 0.6706, -1.1782,  0.4574],
...                             [-0.6401, -0.4779,  0.6701],
...                             [ 0.1015, -0.5363,  0.6165]]]), mstype.float32)
>>> LU_pivots = Tensor(np.array([[1, 3, 3],
...                              [2, 3, 3]]), mstype.int32)
>>> lu_unpack = ops.LuUnpack()
>>> pivots, L, U = lu_unpack(LU_data, LU_pivots)
>>> print(pivots)
[[[1. 0. 0.]
  [0. 0. 1.]
  [0. 1. 0.]]

 [[0. 0. 1.]
  [1. 0. 0.]
  [0. 1. 0.]]]
>>> print(L)
[[[ 1.      0.      0.    ]
  [-0.1287  1.      0.    ]
  [ 0.2583  0.5239  1.    ]]

 [[ 1.      0.      0.    ]
  [-0.6401  1.      0.    ]
  [ 0.1015 -0.5363  1.    ]]]
>>> print(U)
[[[-0.3806 -0.4872  0.5536]
  [ 0.      0.6508 -0.2396]
  [ 0.      0.      0.6902]]

 [[ 0.6706 -1.1782  0.4574]
  [ 0.     -0.4779  0.6701]
  [ 0.      0.      0.6165]]]
```

mindspore.ops.MaskedFill

class mindspore.ops.**MaskedFill**

```
prim = ops.MaskedFill()
out = prim(input_x, mask, value)
```

is equivalent to

```
ops.masked_fill(input_x, mask, value)
```

Refer to *mindspore.ops.masked_fill()* for more details.

mindspore.ops.MaskedScatter

class mindspore.ops.**MaskedScatter**

Updates the value in the input with value in *updates* according to the *mask*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor): The input Tensor to be updated.
- **mask** (Tensor[bool]): The mask Tensor indicating which elements should be modified or replaced. The shapes of *mask* and *x* must be the same or broadcastable.
- **updates** (Tensor): The values to scatter into the target tensor *x*. It has the same data type as *x*. The number of elements must be greater than or equal to the number of True's in *mask*.

Outputs:

Tensor, with the same type and shape as *x*.

Raises

- **TypeError** –If *x*, *mask* or *updates* is not a Tensor.
- **TypeError** –If data type of *x* is not be supported.
- **TypeError** –If dtype of *mask* is not bool.
- **TypeError** –If the dim of *x* less than the dim of *mask*.
- **ValueError** –If *mask* can not be broadcastable to *x*.
- **ValueError** –If the number of elements in *updates* is less than number of True's in *mask*.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([1., 2., 3., 4.]), mindspore.float32)
>>> mask = Tensor(np.array([True, True, False, True]), mindspore.bool_)
>>> updates = Tensor(np.array([5., 6., 7.]), mindspore.float32)
>>> output = ops.MaskedScatter()(input_x, mask, updates)
>>> print(output)
[5. 6. 3. 7.]
```

mindspore.ops.MaskedSelect

class mindspore.ops.**MaskedSelect**

```
prim = ops.MaskedSelect()
out = prim(input, mask)
```

is equivalent to

```
ops.masked_select(input, mask)
```

Refer to *mindspore.ops.masked_select()* for more details.

mindspore.ops.MatrixBandPart

class mindspore.ops.**MatrixBandPart**

Extracts the central diagonal band of each matrix in a tensor, with all values outside the central band set to zero.

Refer to *mindspore.ops.matrix_band_part()* for more details.

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **x** (Tensor) - Input tensor. $(*, m, n)$ where $*$ means, any number of additional dimensions.
- **lower** (Union[int, Tensor]) - Number of subdiagonals to keep. The data type must be int32 or int64. If negative, keep entire lower triangle.
- **upper** (Union[int, Tensor]) - Number of superdiagonals to keep. The data type must be int32 or int64. If negative, keep entire upper triangle.

Outputs:

Tensor, has the same type and shape as x.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> matrix_band_part = ops.MatrixBandPart()
>>> x = np.ones([2, 4, 4]).astype(np.float32)
>>> output = matrix_band_part(Tensor(x), 2, 1)
>>> print(output)
[[[1. 1. 0. 0.]
  [1. 1. 1. 0.]
  [1. 1. 1. 1.]
  [0. 1. 1. 1.]]
 [[1. 1. 0. 0.]
  [1. 1. 1. 0.]
  [1. 1. 1. 1.]
  [0. 1. 1. 1.]]]
```

mindspore.ops.MatrixDiagPartV3

class mindspore.ops.**MatrixDiagPartV3**(*align='RIGHT_LEFT'*)

Returns the diagonal part of a tensor.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.matrix_diag_part()* for more details.

Parameters

align (*str, optional*) – specifies how superdiagonals and subdiagonals should be aligned. Supported values: `"RIGHT_LEFT"` , `"LEFT_RIGHT"` , `"LEFT_LEFT"` , `"RIGHT_RIGHT"` . Default: `"RIGHT_LEFT"` .

- When set to `"RIGHT_LEFT"` , the alignment of superdiagonals will be towards the right side (padding the row on the left), while subdiagonals will be towards the left side (padding the row on the right)
- When set to `"LEFT_RIGHT"` , the alignment of superdiagonals will be towards the left side (padding the row on the right), while subdiagonals will be towards the right side (padding the row on the left)
- When set to `"LEFT_LEFT"` , the alignment of both superdiagonals and subdiagonals will be towards the left side(padding the row on the right).
- When set to `"RIGHT_RIGHT"` , the alignment of both superdiagonals and subdiagonals will be towards the right side(padding the row on the left).

Inputs:

- **x** (Tensor) - Rank r, where r >= 2.
- **k** (Tensor) - A Tensor of type int32. Diagonal offset(s). Positive value means superdiagonal, 0 refers to the main diagonal, and negative value means subdiagonals. k can be a single integer (for a single diagonal) or a pair of integers specifying the low and high ends of a matrix band. k[0] must not be larger than k[1]. The value of k has restructions, meaning value of k must be in (-x.shape[-2], x.shape[-1]).
- **padding_value** (Tensor) - A Tensor. Have the same dtype as x. The number to fill the area outside the specified diagonal band with. There must be only one value.

Outputs:

A Tensor. Has the same type as *x*. Assume *x* has r dimensions $(I, J, ..., M, N)$. Let *max_diag_len* be the maximum length among all diagonals to be extracted, $max\_diag\_len = min(M + min(k[1], 0), N + min(-k[0], 0))$ Let *num_diags* be the number of diagonals to extract, $num\_diags = k[1] - k[0] + 1$. If $num\_diags == 1$, the output tensor is of rank r - 1 with shape $(I, J, ..., L, max\_diag\_len)$ Otherwise, the output tensor has rank r with dimensions $(I, J, ..., L, num\_diags, max\_diag\_len)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[1, 2, 3, 4],
...                      [5, 6, 7, 8],
...                      [9, 8, 7, 6]]), mindspore.float32)
>>> k =Tensor(np.array([1, 3]), mindspore.int32)
>>> padding_value = Tensor(np.array(9), mindspore.float32)
>>> matrix_diag_part_v3 = ops.MatrixDiagPartV3(align='RIGHT_LEFT')
>>> output = matrix_diag_part_v3(x, k, padding_value)
>>> print(output)
[[9. 9. 4.]
 [9. 3. 8.]
 [2. 7. 6.]]
>>> print(output.shape)
(3, 3)
```

mindspore.ops.MatrixDiagV3

class mindspore.ops.**MatrixDiagV3**(*align='RIGHT_LEFT'*)

Constructs a diagonal matrix or a batch of diagonal matrices from a given input Tensor.

Warning: This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.matrix_diag()* for more details.

Parameters

align (*str, optional*) – specifies how superdiagonals and subdiagonals should be aligned. Supported values: "RIGHT_LEFT", "LEFT_RIGHT", "LEFT_LEFT", "RIGHT_RIGHT". Default: "RIGHT_LEFT".

- When set to "RIGHT_LEFT", the alignment of superdiagonals will be towards the right side (padding the row on the left), while subdiagonals will be towards the left side (padding the row on the right)
- When set to "LEFT_RIGHT", the alignment of superdiagonals will be towards the left side (padding the row on the right), while subdiagonals will be towards the right side (padding the row on the left)
- When set to "LEFT_LEFT", the alignment of both superdiagonals and subdiagonals will be towards the left side(padding the row on the right).
- When set to "RIGHT_RIGHT", the alignment of both superdiagonals and subdiagonals will be towards the right side(padding the row on the left).

Inputs:

- **x** (Tensor) - The diagonal Tensor.
- **k** (Union[int, Tensor], optional) - Diagonal offsets. A Tensor of type int32. Positive value means superdiagonal, 0 refers to the main diagonal, and negative value means subdiagonals. *k* can be a single integer (for a single diagonal) or a pair of integers specifying the low and high ends of a matrix band. k[0] must not be larger than k[1]. The value must be in the range of given or derivated *num_rows* and *num_cols*, meaning value of k must be in (-num_rows, num_cols). Default: 0.
- **num_rows** (Union[int, Tensor], optional) - The number of rows of the output Tensor. A Tensor of type int32 with only one value. If *num_rows* is -1, indicating that the innermost matrix of the output Tensor is a square matrix, and the

real number of rows will be derivated by other inputs. That is $num\_rows = x.shape[-1] - min(k[1], 0)$. Otherwise, the value must be equal or greater than $x.shape[-1] - min(k[1], 0)$. Default: -1.

- **num_cols** (Union[int, Tensor], optional) - The number of columns of the output Tensor. A Tensor of type int32 with only one value. If *num_cols* is -1, indicating that the innermost matrix of the output Tensor is a square matrix, and the real number of columns will be derivated by other inputs. That is $num\_cols = x.shape[-1] + max(k[0], 0)$. Otherwise, the value must be equal or greater than $x.shape[-1] - min(k[1], 0)$. Default: -1.
- **padding_value** (Union[int, float, Tensor], optional) - The number to fill the area outside the specified diagonal band. A Tensor with only one value. Have the same dtype as x. Default: `0` .

Outputs:

A Tensor. Has the same type as *x*. Suppose *x* has r dimensions with shape $(I, J, ..., M, N)$. The output Tensor has rank r + 1 with shape $(I, J, ..., M, num\_rows, num\_cols)$ when only one diagonal is given (k is an integer or k[0] == k[1]). Otherwise, it has rank r with shape $(I, J, ..., num\_rows, num\_cols)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[8, 9, 0],
...                      [1, 2, 3],
...                      [0, 4, 5]]), mindspore.float32)
>>> k =Tensor(np.array([-1, 1]), mindspore.int32)
>>> num_rows = Tensor(np.array(3), mindspore.int32)
>>> num_cols = Tensor(np.array(3), mindspore.int32)
>>> padding_value = Tensor(np.array(11), mindspore.float32)
>>> matrix_diag_v3 = ops.MatrixDiagV3(align='LEFT_RIGHT')
>>> output = matrix_diag_v3(x, k, num_rows, num_cols, padding_value)
>>> print(output)
[[ 1.  8. 11.]
 [ 4.  2.  9.]
 [11.  5.  3.]]
>>> print(output.shape)
(3, 3)
```

mindspore.ops.MatrixSetDiagV3

class mindspore.ops.**MatrixSetDiagV3**(*align='RIGHT_LEFT'*)

Updates the diagonal part of a batched tensor. It takes a Tensor *x* and *diagonal* as input and returns a Tensor in which the specified diagonal values in the innermost matrices will be replaced by the values in the *diagonal*.

Diagonals shorter than *max_diag_len* need to be padded, where *max_diag_len* is the longest diagonal value. The dimension of *diagonal* is $shape[-2]$ must be equal to num_diags calculated by $num\_diags = k[1] - k[0] + 1$. The dimension of *diagonal* is $shape[-1]$ must be equal to the longest diagonal value *max_diag_len* calculated by $max\_diag\_len = min(x.shape[-2] + min(k[1], 0), x.shape[-1] + min(-k[0], 0))$.

Assume x is an n-D Tensor with shape $(d_1, d_2, ..., d_{n-2}, d_{n-1}, d_n)$. If k is an integer or $k[0] == k[1]$, *diagonal* is an (n-1)-D Tensor with shape $(d_1, d_2, ..., d_{n-2}, max\_diag\_len)$ Otherwise, it has the same rank as x with shape $(d_1, d_2, ..., d_{n-2}, num\_diags, max\_diag\_len)$.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

align (*str, optional*) –specifies how superdiagonals and subdiagonals should be aligned. Supported values: "RIGHT_LEFT" , "LEFT_RIGHT", "LEFT_LEFT" , "RIGHT_RIGHT" . Default: "RIGHT_LEFT" .

- When set to "RIGHT_LEFT" , the alignment of superdiagonals will be towards the right side (padding the row on the left), while subdiagonals will be towards the left side (padding the row on the right)
- When set to "LEFT_RIGHT" , the alignment of superdiagonals will be towards the left side (padding the row on the right), while subdiagonals will be towards the right side (padding the row on the left)
- When set to "LEFT_LEFT" , the alignment of both superdiagonals and subdiagonals will be towards the left side(padding the row on the right).
- When set to "RIGHT_RIGHT" , the alignment of both superdiagonals and subdiagonals will be towards the right side(padding the row on the left).

Inputs:

- **x** (Tensor) - A n-D Tensor, where $n >= 2$.
- **diagonal** (Tensor) - A Tensor with the same dtype as *x*. Its rank depends on *k*. If *k* is an integer or $k[0] == k[1]$, its dimension is $n - 1$. Otherwise, it has dimension n.
- **k** (Tensor) - Diagonal offset(s), Tensor of type int32. *k* can either be a single integer, which represents a single diagonal, or a pair of integers that specify the low and high ends of a matrix band. In this case, *k[0]* should not be greater than *k[1]*. The value of *k* has restructions, which means that value of *k* must be in range $(-x.shape[-2], x.shape[-1])$. Input *k* must be const Tensor when taking Graph mode.
  - *k* > *0* refers to a superdiagonal.
  - *k* = *0* refers to the main diagonal.
  - *k* < *0* refers to subdiagonals.

Outputs:

Tensor. The same type and shape as *x*.

Raises

- **TypeError** –If any input is not Tensor.
- **TypeError** –If input *x* and *diagonal* are not the same dtype.
- **TypeError** –If *k* is not int32 dtype.
- **ValueError** –If *align* is not a string or not in the valid range.
- **ValueError** –If rank of *k* is not equal to 0 or 1.
- **ValueError** –If rank of *x* is not greater equal to 2.
- **ValueError** –If size of *k* is not equal to 1 or 2.
- **ValueError** –If *k[1]* is not greater equal to *k[0]* in case the size of *k* is 2.
- **ValueError** –If the *diagonal* rank size don't match with input *x* rank size.
- **ValueError** –If the *diagonal* shape value don't match with input *x* shape value.
- **ValueError** –If the diagonal $shape[-2]$ is not equal to num_diags calculated by $num\_diags = k[1] - k[0] + 1$.

- **ValueError** –If the value of k is not in $(-x.shape[-2], x.shape[-1])$.
- **ValueError** –If the diagonal $shape[-1]$ is not equal to the max_diag_len calculated by $max\_diag\_len = min(x.shape[-2] + min(k[1], 0), x.shape[-1] + min(-k[0], 0))$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[7, 7, 7, 7],
...                      [7, 7, 7, 7],
...                      [7, 7, 7, 7]]), mindspore.float32)
>>> diagonal = Tensor(np.array([[0, 9, 1],
...                             [6, 5, 8],
...                             [1, 2, 3],
...                             [4, 5, 0]]), mindspore.float32)
>>> k =Tensor(np.array([-1, 2]), mindspore.int32)
>>> matrix_set_diag_v3 = ops.MatrixSetDiagV3(align='RIGHT_LEFT')
>>> output = matrix_set_diag_v3(x, diagonal, k)
>>> print(output)
[[1. 6. 9. 7.]
 [4. 2. 5. 1.]
 [7. 5. 3. 8.]]
>>> print(output.shape)
(3, 4)
```

mindspore.ops.MatrixSolve

class mindspore.ops.**MatrixSolve**(*adjoint=False*)

Solves systems of linear equations.

Parameters

adjoint (*bool, optional*) –Indicates whether the adjoint of the matrix is used during the computation. Default: `False` , use its transpose instead.

Inputs:

- **matrix** (Tensor) - A tensor of shape $(..., M, M)$, is a matrix of coefficients for a system of linear equations.
- **rhs** (Tensor) - A tensor of shape $(..., M, K)$, is a matrix of the resulting values of a system of linear equations. *rhs* must have the same type as *matrix*.

Outputs:

Tensor, a matrix composed of solutions to a system of linear equations, which has the same type and shape as *rhs*.

Raises

- **TypeError** –If *adjoint* is not the type of bool.
- **TypeError** –If the type of *matrix* is not one of the following dtype: mstype.float16, mstype.float32, mstype.float64, mstype.complex64, mstype.complex128.

- **TypeError** –If the type of *matrix* is not the same as that of *rhs*.
- **ValueError** –If the rank of *matrix* less than 2.
- **ValueError** –If the dimension of *matrix* is not the same as *rhs* .
- **ValueError** –If the inner-most 2 dimension of *matrix* is not the same.
- **ValueError** –If the inner-most 2 dimension of *rhs* does not match *matrix* .

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> matrix = Tensor(np.array([[1.0  , 4.0],
...                           [2.0 , 7.0]]), mindspore.float32)
>>> rhs = Tensor(np.array([[1.0]  , [3.0]]), mindspore.float32)
>>> matrix_solve = ops.MatrixSolve(adjoint = False)
>>> output = matrix_solve(matrix, rhs)
>>> print(output)
[[5.0]
 [-1.0]]
```

mindspore.ops.Meshgrid

class mindspore.ops.**Meshgrid**(*indexing='xy'*)

Generates coordinate matrices from given coordinate tensors.

Refer to *mindspore.ops.meshgrid()* for more details.

Parameters

indexing (*str, optional*) –Cartesian `'xy'` or matrix ('ij') indexing of output. Valid options: xy' or `'ij'`. In the 2-D case with inputs of length M and N, for `'xy'` indexing, the shape of outputs is (N, M) for `'ij'` indexing, the shape of outputs is (M, N). In the 3-D case with inputs of length M, N and P, for `'xy'` indexing, the shape of outputs is (N, M, P) and for `'ij'` indexing, the shape of outputs is (M, N, P). Default: `'xy'` .

Inputs:

- **inputs** (Union(tuple[Tensor], list[Tensor])) - In GRAPH_MODE, a tuple of N 1-D Tensor objects and the length of input should be greater than 1. In PYNATIVE_MODE, a tuple of N 0-D or 1-D Tensor objects and the length of input should be greater than 0. The data type is Number.

Outputs:

Tensors, A Tuple of N N-D Tensor objects. The data type is the same with the Inputs.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([1, 2, 3, 4]).astype(np.int32))
>>> y = Tensor(np.array([5, 6, 7]).astype(np.int32))
>>> z = Tensor(np.array([8, 9, 0, 1, 2]).astype(np.int32))
>>> inputs = (x, y, z)
>>> meshgrid = ops.Meshgrid(indexing='xy')
>>> output = meshgrid(inputs)
>>> print(output)
(Tensor(shape=[3, 4, 5], dtype=Int32, value=
[[[1, 1, 1, 1, 1],
  [2, 2, 2, 2, 2],
  [3, 3, 3, 3, 3],
  [4, 4, 4, 4, 4]],
  [[1, 1, 1, 1, 1],
  [2, 2, 2, 2, 2],
  [3, 3, 3, 3, 3],
  [4, 4, 4, 4, 4]],
  [[1, 1, 1, 1, 1],
  [2, 2, 2, 2, 2],
  [3, 3, 3, 3, 3],
  [4, 4, 4, 4, 4]]]),
Tensor(shape=[3, 4, 5], dtype=Int32, value=
[[[5, 5, 5, 5, 5],
  [5, 5, 5, 5, 5],
  [5, 5, 5, 5, 5],
  [5, 5, 5, 5, 5]],
  [[6, 6, 6, 6, 6],
  [6, 6, 6, 6, 6],
  [6, 6, 6, 6, 6],
  [6, 6, 6, 6, 6]],
  [[7, 7, 7, 7, 7],
  [7, 7, 7, 7, 7],
  [7, 7, 7, 7, 7],
  [7, 7, 7, 7, 7]]]),
Tensor(shape=[3, 4, 5], dtype=Int32, value=
[[[8, 9, 0, 1, 2],
  [8, 9, 0, 1, 2],
  [8, 9, 0, 1, 2],
  [8, 9, 0, 1, 2]],
  [[8, 9, 0, 1, 2],
  [8, 9, 0, 1, 2],
  [8, 9, 0, 1, 2],
  [8, 9, 0, 1, 2]],
  [[8, 9, 0, 1, 2],
  [8, 9, 0, 1, 2],
  [8, 9, 0, 1, 2],
  [8, 9, 0, 1, 2]]]))
```

mindspore.ops.Mvlgamma

class mindspore.ops.**Mvlgamma**(*p*)

Calculates the multivariate log-gamma function element-wise for a given dimension *p*.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.mvlgamma()* for more details.

Parameters

p (*int*) – The number of dimensions. And the value of *p* must be greater than or equal to 1.

Inputs:

- **x** (Tensor) - The tensor to compute the multivariate log-gamma function, which must be one of the following types: float32, float64. The shape is $(N, *)$, where $*$ means any number of additional dimensions. And the value of any element in *x* must be greater than $(p - 1)/2$.

Outputs:

Tensor, has the same shape and type as *x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[3, 4, 5], [4, 2, 6]]), mindspore.float32)
>>> op = ops.Mvlgamma(p=3)
>>> y = op(x)
>>> print(y)
[[ 2.694925   5.402975   9.140645 ]
 [ 5.402975   1.5963125 13.640454 ]]
```

mindspore.ops.NanToNum

class mindspore.ops.**NanToNum**(*nan=None*, *posinf=None*, *neginf=None*)

```
prim = ops.NanToNum(nan, posinf, neginf)
out = prim(input)
```

is equivalent to

```
ops.nan_to_num(input, nan, posinf, neginf)
```

Refer to *mindspore.ops.nan_to_num()* for more details.

mindspore.ops.NonZero

class mindspore.ops.**NonZero**

Return a Tensor of the positions of all non-zero values.

Inputs:

- **input** (Tensor) - The input Tensor.
  - Ascend: its rank can be equal to 0 except O2 mode.
  - CPU/GPU: its rank should be greater than or eaqual to 1.

Outputs:

Tensor, a 2-D Tensor whose data type is int64, containing the positions of all non-zero values of the input. If the dimension of *input* is *D* and the number of non-zero in *input* is *N* , then the shape of output is (N, D) .

Raises

- **TypeError** –If *input* is not Tensor.
- **RuntimeError** –On GPU or CPU or Ascend O2 mode, if dim of *input* is equal to 0.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> input = mindspore.tensor([1, 0, 2, 0, 3], mindspore.int32)
>>> output = mindspore.ops.NonZero()(input)
>>> print(output)
[[0]
 [2]
 [4]]
```

mindspore.ops.ParallelConcat

class mindspore.ops.**ParallelConcat**

Concats input tensors along the first dimension.

The difference between Concat and ParallelConcat is that Concat requires all of the inputs be computed before the operation will begin but doesn't require that the input shapes be known during graph construction. Parallel concat will copy pieces of the input into the output as they become available, in some situations this can provide a performance benefit.

Note: The input tensors are all required to have size 1 in the first dimension.

Inputs:

- **values** (tuple, list) - A tuple or a list of input tensors. The data type and shape of these tensors must be the same and their rank should not be less than 1. The supported date type is Number on CPU, the same for Ascend except [float64, complex64, complex128].

Outputs:

Tensor, data type is the same as *values*.

Raises

- **TypeError** –If any type of the inputs is not a Tensor.
- **TypeError** –If the data type of these tensors are not the same.
- **ValueError** –If any tensor.shape[0] is not 1.
- **ValueError** –If rank of any Tensor in *values* is less than 1.
- **ValueError** –If the shape of these tensors are not the same.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> data1 = Tensor(np.array([[0, 1]]).astype(np.int32))
>>> data2 = Tensor(np.array([[2, 1]]).astype(np.int32))
>>> op = ops.ParallelConcat()
>>> output = op((data1, data2))
>>> print(output)
[[0 1]
 [2 1]]
```

mindspore.ops.PopulationCount

class mindspore.ops.**PopulationCount**

Computes element-wise population count(a.k.a bitsum, bitcount).

Refer to *mindspore.ops.population_count()* for more details.

Inputs:

- **input_x** (Tensor) - Tensor of any dimension. The data type must be int16 or uint16 (Ascend). The data type must be int8, int16, int32, int64, uint8, uint16, uint32, uint64 (CPU and GPU).

Outputs:

Tensor, with the same shape as the input, and the data type is uint8.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> input_x = Tensor([0, 1, 3], mindspore.int16)
>>> output = ops.PopulationCount()(input_x)
>>> print(output)
[0 1 2]
```

mindspore.ops.RandomShuffle

class mindspore.ops.**RandomShuffle**(*seed=0*, *seed2=0*)

Randomly shuffles a Tensor along its first dimension.

Note:

- Random seed: a set of regular random numbers can be obtained through some complex mathematical algorithms, and the random seed determines the initial value of this random number. If the random seed is the same in two separate calls, the random number generated will not change.
- Using the Philox algorithm to scramble seed and seed2 to obtain random seed so that the user doesn't need to worry about which seed is more important.

Parameters

- **seed** (*int, optional*) – The operator-level random seed, used to generate random numbers, must be non-negative. Default: `0` .
- **seed2** (*int, optional*) – The global random seed, which combines with the operator-level random seed to determine the final generated random number, must be non-negative. Default: `0` .

Inputs:

- **x** (Tensor) - The Tensor need be shuffled.

Outputs:

Tensor. The shape and type are the same as the input *x*.

Raises

TypeError – If data type of *seed* or *seed2* is not int.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor(np.array([1, 2, 3, 4]), mstype.float32)
>>> shuffle = ops.RandomShuffle(seed=1, seed2=1)
>>> output = shuffle(x)
>>> print(output.shape)
(4,)
```

mindspore.ops.Range

class mindspore.ops.**Range**(*maxlen=1000000*)

```
prim = ops.Range(maxlen)
out = prim(start, end, step)
```

is equivalent to

```
ops.range(start, end, step, maxlen)
```

Refer to *mindspore.ops.range()* for more details.

mindspore.ops.Rank

class mindspore.ops.**Rank**

Returns the rank of a tensor.

Refer to *mindspore.ops.rank()* for more details.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_tensor = Tensor(np.array([[2, 2], [2, 2]]), mindspore.float32)
>>> rank = ops.Rank()
>>> output = rank(input_tensor)
>>> print(output)
2
>>> print(type(output))
<class 'int'>
```

mindspore.ops.Renorm

class mindspore.ops.**Renorm**(*p*, *dim*, *maxnorm*)

Renormalizes the sub-tensors along dimension *dim*, and each sub-tensor's p-norm should not exceed the 'maxnorm'. The values of current sub-tensor don't need change if the p-norm of the sub-tensor is less than *maxnorm*. Otherwise the sub-tensor needs to be modified to the original value of the corresponding position divided by the p-norm of the substensor and then multiplied by *maxnorm*.

Refer to *mindspore.ops.renorm()* for more details.

Parameters

- **p** (*int*) –Power of norm calculation.
- **dim** (*int*) –The dimension that expected to get the slice-tensor.
- **maxnorm** (*float32*) –Max norm.

Inputs:

- **x** (Tensor) - A Tensor, types: float32 or float16.

Outputs:

Tensor, has the same dtype and shape as input.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[1, 1, 1], [2, 2, 2], [3, 3, 3]]), mindspore.float32)
>>> y = ops.Renorm(p=1, dim=0, maxnorm=5.)(x)
>>> print(y)
[[1.       1.        1.        ]
[1.6666666 1.6666666 1.6666666 ]
[1.6666667 1.6666667 1.6666667 ]]
```

mindspore.ops.Reshape

class mindspore.ops.**Reshape**

```
prim = ops.Reshape()
out = prim(input, shape)
```

is equivalent to

```
ops.reshape(input, shape)
```

Refer to *mindspore.ops.reshape()* for more details.

mindspore.ops.ReverseSequence

class mindspore.ops.**ReverseSequence**(*seq_dim*, *batch_dim=0*)

Reverses variable length slices.

Parameters

- **seq_dim** (*int*) –The dimension where reversal is performed. Required.
- **batch_dim** (*int, optional*) –The input is sliced in this dimension. Default: `0` .

Inputs:

- **x** (Tensor) - The input to reverse, supporting all number types including bool.
- **seq_lengths** (Tensor) - Must be a 1-D vector with int32 or int64 types.

Outputs:

Tensor, with the same shape and data type as *x*.

Raises

- **TypeError** –If *seq_dim* or *batch_dim* is not an int.
- **ValueError** –If $len(seq\_lengths) != x.shape[batch\_dim]$.
- **ValueError** –If $batch\_dim == seq\_dim$.
- **ValueError** –If $seq\_dim < 0$ or $seq\_dim >= len(x.shape)$.
- **ValueError** –If $batch\_dim < 0$ or $batch\_dim >= len(x.shape)$.
- **RuntimeError** –If any value of *seq_lengths* is less than 0.
- **RuntimeError** –If any value of *seq_lengths* is larger than *x.shape[seq_dim]*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), mindspore.float32)
>>> seq_lengths = Tensor(np.array([1, 2, 3]))
>>> reverse_sequence = ops.ReverseSequence(seq_dim=1)
>>> output = reverse_sequence(x, seq_lengths)
>>> print(output)
[[1. 2. 3.]
 [5. 4. 6.]
 [9. 8. 7.]]
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), mindspore.float32)
>>> seq_lengths = Tensor(np.array([1, 2, 3]))
>>> reverse_sequence = ops.ReverseSequence(seq_dim=0, batch_dim=1)
>>> output = reverse_sequence(x, seq_lengths)
>>> print(output)
[[1. 5. 9.]
 [4. 2. 6.]
```

(continues on next page)

(continued from previous page)

```
 [7. 8. 3.]]
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), mindspore.float32)
>>> seq_lengths = Tensor(np.array([2, 2, 3]))
>>> reverse_sequence = ops.ReverseSequence(seq_dim=1)
>>> output = reverse_sequence(x, seq_lengths)
>>> print(output)
[[2. 1. 3.]
 [5. 4. 6.]
 [9. 8. 7.]]
>>> x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [7, 8, 9]]), mindspore.float32)
>>> seq_lengths = Tensor(np.array([3, 2, 3]))
>>> reverse_sequence = ops.ReverseSequence(seq_dim=1)
>>> output = reverse_sequence(x, seq_lengths)
>>> print(output)
[[3. 2. 1.]
 [5. 4. 6.]
 [9. 8. 7.]]
>>> x = Tensor(np.array([[1, 2, 3, 4], [5, 6, 7, 8]]), mindspore.float32)
>>> seq_lengths = Tensor(np.array([4, 4]))
>>> reverse_sequence = ops.ReverseSequence(seq_dim=1)
>>> output = reverse_sequence(x, seq_lengths)
>>> print(output)
[[4. 3. 2. 1.]
 [8. 7. 6. 5.]]
```

mindspore.ops.ReverseV2

class mindspore.ops.**ReverseV2**(*axis*)

```
prim = ops.ReverseV2(axis)
out = prim(input)
```

is equivalent to

```
ops.flip(input, axis)
```

Refer to *mindspore.ops.flip()* for more details.

mindspore.ops.RightShift

class mindspore.ops.**RightShift**

Shift the value of each position of Tensor *input_x* to the right by corresponding bits in Tensor *input_y*. The inputs are two tensors, dtypes of them must be consistent, and the shapes of them could be broadcast.

$$out_i = x_i >> y_i$$

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **input_x** (Tensor) - The target tensor, will be shifted to the right by *input_y* bits element-wise. Support all int and uint types.

- **input_y** (Tensor) - Number of bits shifted, the tensor must have the same type as *input_x*.

Outputs:

- **output** (Tensor) - The output tensor, has the same type as *input_x*.

Raises

- **TypeError** –If *input_x* or *input_y* is not tensor.
- **TypeError** –If *input_x* and *input_y* could not be broadcast.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([1, 2, 3]).astype(np.uint8))
>>> input_y = Tensor(np.array([1, 1, 1]).astype(np.uint8))
>>> output = ops.RightShift()(input_x, input_y)
>>> print(output)
[0 1 1]
```

mindspore.ops.ScatterNd

class mindspore.ops.**ScatterNd**

```
prim = ops.ScatterNd()
out = prim(indices, updates, shape)
```

is equivalent to

```
ops.scatter_nd(indices, updates, shape)
```

Refer to *mindspore.ops.scatter_nd()* for more details.

mindspore.ops.ScatterNdDiv

class mindspore.ops.**ScatterNdDiv**(*use_locking=False*)

Applies sparse division to individual values or slices in a tensor.

Using given values to update tensor value through the division operation, along with the input indices. This operation outputs the *input_x* after the update is done, which makes it convenient to use the updated value.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.scatter_nd_div()* for more details.

Parameters

use_locking (*bool, optional*) –Whether to protect the assignment by a lock. Default: `False` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor.
- **indices** (Tensor) - The index to do div operation whose data type must be int32 or int64. The rank of indices must be at least 2 and *indices.shape[-1] <= len(shape)*.
- **updates** (Tensor) - The tensor to do the div operation with *input_x*. The data type is same as *input_x*, and the shape is *indices.shape[:-1] + x.shape[indices.shape[-1]:]*.

Outputs:

Tensor, the updated *input_x*, has the same shape and type as *input_x*.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, Parameter
>>> input_x = Parameter(Tensor(np.array([1, 2, 3, 4, 5, 6, 7, 8]), mindspore.float32), name=
 ↪"x")
>>> indices = Tensor(np.array([[2], [4], [1], [7]]), mindspore.int32)
>>> updates = Tensor(np.array([6, 7, 8, 9]), mindspore.float32)
>>> use_locking = False
>>> scatter_nd_div = ops.ScatterNdDiv(use_locking)
>>> output = scatter_nd_div(input_x, indices, updates)
>>> print(output)
[1.         0.25       0.5        4.         0.71428573 6.
 7.         0.8888889 ]
>>> input_x = Parameter(Tensor(np.ones((4, 4, 4)), mindspore.float32))
>>> indices = Tensor(np.array([[0], [2]]), mindspore.int32)
>>> updates = Tensor(np.array([[[1, 1, 1, 1], [2, 2, 2, 2], [3, 3, 3, 3], [4, 4, 4, 4]],
...                            [[5, 5, 5, 5], [6, 6, 6, 6], [7, 7, 7, 7], [8, 8, 8, 8]]]),␣
 ↪mindspore.float32)

```

mindspore.ops.ScatterNdMax

class mindspore.ops.**ScatterNdMax**(*use_locking=False*)

Computes sparse maximum to individual values or slices in a tensor.

Using given values to update parameter value through the maximum operation, along with the input indices. This operation outputs the *input_x* after the update is done, which makes it convenient to use the updated value.

Refer to *mindspore.ops.scatter_nd_max()* for more details.

Parameters

use_locking (*bool, optional*) – Whether to protect the assignment by a lock. Default: `False` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor.
- **indices** (Tensor) - The index to do maximum operation whose data type must be int32 or int64. The rank of indices must be at least 2 and *indices.shape[-1] <= len(shape)*.
- **updates** (Tensor) - The tensor to do the max operation with *input_x*. The data type is same as *input_x*, and the shape is *indices.shape[:-1] + x.shape[indices.shape[-1]:]*.

Outputs:

Tensor, the updated *input_x*, has the same shape and type as *input_x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, Parameter
>>> input_x = Parameter(Tensor(np.array([1, 2, 3, 4, 5, 6, 7, 8]), mindspore.float32), name=
 ↪"x")
>>> indices = Tensor(np.array([[2], [4], [1], [7]]), mindspore.int32)
>>> updates = Tensor(np.array([6, 7, 8, 9]), mindspore.float32)
>>> scatter_nd_max = ops.ScatterNdMax()
>>> output = scatter_nd_max(input_x, indices, updates)
>>> print(output)
[ 1. 8. 6.  4. 7.  6.  7. 9.]

mindspore.ops.ScatterNdMin

class mindspore.ops.**ScatterNdMin**(*use_locking=False*)

Applies sparse minimum to individual values or slices in a tensor.

Using given values to update tensor value through the minimum operation, along with the input indices. This operation outputs the *input_x* after the update is done, which makes it convenient to use the updated value.

Refer to *mindspore.ops.scatter_nd_min()* for more details.

Parameters

use_locking (*bool, optional*) – Whether to protect the assignment by a lock. Default: `False` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor.
- **indices** (Tensor) - The index to do minimum operation whose data type must be int32 or int64. The rank of indices must be at least 2 and *indices.shape[-1] <= len(shape)*.
- **updates** (Tensor) - The tensor to do the max operation with *input_x*. The data type is same as *input_x*, and the shape is *indices.shape[:-1] + x.shape[indices.shape[-1]:]*.

Outputs:

Tensor, the updated *input_x*, has the same shape and type as *input_x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, Parameter
>>> input_x = Parameter(Tensor(np.ones(8) * 10, mindspore.float32), name="x")
>>> indices = Tensor(np.array([[2], [4], [1], [7]]), mindspore.int32)
>>> updates = Tensor(np.array([6, 7, 8, 9]), mindspore.float32)
>>> use_locking = False
>>> scatter_nd_min = ops.ScatterNdMin(use_locking)
>>> output = scatter_nd_min(input_x, indices, updates)
>>> print(output)
[10.  8.  6. 10.  7. 10. 10.  9.]

mindspore.ops.ScatterNdMul

class mindspore.ops.**ScatterNdMul**(*use_locking=False*)

Applies sparse multiplication to individual values or slices in a tensor.

Using given values to update parameter value through the multiplication operation, along with the input indices. This operation outputs the *input_x* after the update is done, which makes it convenient to use the updated value.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.scatter_nd_mul()* for more details.

Parameters

use_locking (*bool, optional*) – Whether to protect the assignment by a lock. Default: `False` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor.
- **indices** (Tensor) - The index to do mul operation whose data type must be int32 or int64. The rank of indices must be at least 2 and *indices.shape[-1] <= len(shape)*.
- **updates** (Tensor) - The tensor to do the mul operation with *input_x*. The data type is same as *input_x*, and the shape is *indices.shape[:-1] + x.shape[indices.shape[-1]:]*.

Outputs:

Tensor, the updated *input_x*, has the same shape and type as *input_x*.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, Parameter
>>> input_x = Parameter(Tensor(np.array([1, 2, 3, 4, 5, 6, 7, 8]), mindspore.float32), name=
 ↪"x")
>>> indices = Tensor(np.array([[2], [4], [1], [7]]), mindspore.int32)
>>> updates = Tensor(np.array([6, 7, 8, 9]), mindspore.float32)
>>> scatter_nd_mul = ops.ScatterNdMul()
>>> output = scatter_nd_mul(input_x, indices, updates)
>>> print(output)
[ 1. 16. 18.  4. 35.  6.  7. 72.]

  [1 1 1 1]
  [1 1 1 1]]]
```

mindspore.ops.SearchSorted

class mindspore.ops.**SearchSorted**(*dtype=mstype.int64*, *right=False*)

Return the position indices where the elements can be inserted into the input tensor to maintain the increasing order of the input tensor.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.searchsorted()* for more details.

Parameters

- **dtype** (*mindspore.dtype, optional*) –The specified type of output tensor. Optional values are: `mstype.int32` and `mstype.int64`. Default `mstype.int64`.
- **right** (*bool, optional*) –Search Strategy. If `True` , return the last suitable index found; if `False` , return the first such index. Default `False` .

Inputs:

- **sorted_sequence** (Tensor) - The input tensor. If *sorter* not provided, it must contain a increasing sequence on the innermost dimension.
- **values** (Tensor) - The value that need to be inserted.
- **sorter** (Tensor, optional) - An index sequence sorted in ascending order along the innermost dimension of *sorted_sequence* , which is used together with the unsorted *sorted_sequence* . CPU and GPU only support `None`. Default `None` .

Outputs:

Tensor

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> sorted_sequence = mindspore.tensor([1, 2, 2, 3, 4, 5, 5], mindspore.float32)
>>> values = mindspore.tensor([2], mindspore.float32)
>>> mindspore.ops.SearchSorted()(sorted_sequence, values)
Tensor(shape=[1], dtype=Int64, value= [1])
```

mindspore.ops.Select

class mindspore.ops.**Select**

```
prim = ops.Select()
out = prim(condition, input, other)
```

is equivalent to

```
ops.select(condition, input, other)
```

Refer to *mindspore.ops.select()* for more details.

mindspore.ops.Shape

class mindspore.ops.**Shape**

Returns the shape of the input tensor.

Refer to *mindspore.ops.shape()* for more details.

Inputs:

- **input_x** (Tensor) - The shape of tensor is $(x_1, x_2, ..., x_R)$.

Outputs:

tuple[int], the output tuple is constructed by multiple integers, $(x_1, x_2, ..., x_R)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.ones(shape=[3, 2, 1]), mindspore.float32)
>>> shape = ops.Shape()
>>> output = shape(input_x)
>>> print(output)
(3, 2, 1)
```

mindspore.ops.Size

class mindspore.ops.**Size**

Returns a Scalar of type int that represents the size of the input Tensor and the total number of elements in the Tensor.

Refer to *mindspore.ops.size()* for more details.

Inputs:

- **input_x** (Tensor) - Input parameters, the shape of tensor is $(x_1, x_2, ..., x_R)$. The data type is number.

Outputs:

int. A scalar representing the elements' size of *input_x*, tensor is the number of elements in a tensor, $size = x_1 * x_2 * ...x_R$. The data type is an int.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[2, 2], [2, 2]]), mindspore.float32)
>>> size = ops.Size()
>>> output = size(input_x)
>>> print(output)
4
```

mindspore.ops.Slice

class mindspore.ops.**Slice**

Slices a tensor in the specified shape.

Refer to *mindspore.ops.slice()* for more details.

Inputs:

- **input_x** (Tensor): The target tensor. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.
- **begin** (Union[tuple, list]): The beginning of the slice. Only constant value(>=0) is allowed.
- **size** (Union[tuple, list]): The size of the slice. Only constant value is allowed.

Outputs:

Tensor, the shape is the same as that of *size*, the data type is the same as *input_x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> import numpy as np
>>> data = Tensor(np.array([[[1, 1, 1], [2, 2, 2]],
...                         [[3, 3, 3], [4, 4, 4]],
...                         [[5, 5, 5], [6, 6, 6]]]).astype(np.int32))
>>> slice_op = ops.Slice()
>>> output = slice_op(data, (1, 0, 0), (1, 1, 3))
>>> print(output)
[[[3 3 3]]]
>>> output = slice_op(data, (1, 0, 0), (1, 1, 2))
>>> print(output)
[[[3 3]]]
>>> output = slice_op(data, (1, 0, 0), (1, 1, 1))
>>> print(output)
[[[3]]]
>>> output = slice_op(data, (1, 1, 0), (1, 1, 3))
>>> print(output)
[[[4 4 4]]]
>>> output = slice_op(data, (1, 0, 1), (1, 1, 2))
>>> print(output)
[[[3 3]]]
```

mindspore.ops.Sort

class mindspore.ops.**Sort**(*axis=-1*, *descending=False*)

Sorts the elements of the input tensor along the given dimension in the specified order.

> **Warning:** Currently, the data types of float16, uint8, int8, int16, int32, int64 are well supported. If use float32, it may cause loss of accuracy.

Parameters

- **axis** (*int, optional*) – The dimension to sort along. Default: `-1`, means the last dimension. The Ascend backend only supports sorting the last dimension.
- **descending** (*bool, optional*) – Controls the sort order. If descending is `True` then the elements are sorted in descending order by value. Default: `False` .

Inputs:

- **x** (Tensor) - The input tensor.

Outputs:

- **y1** (Tensor) - A tensor whose values are the sorted values, with the same shape and data type as input.
- **y2** (Tensor) - the indices of the elements in the original input tensor. Data type is int32.

Raises

- **TypeError** – If *axis* is not an int.
- **TypeError** – If *descending* is not a bool.
- **ValueError** – If *axis* is not in range of [-len(x.shape), len(x.shape)).

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[8, 2, 1], [5, 9, 3], [4, 6, 7]]), mindspore.float16)
>>> sort = ops.Sort()
>>> output = sort(x)
>>> # The output below is based on the Ascend platform.
>>> print(output)
(Tensor(shape=[3, 3], dtype=Float16, value=
[[ 1.0000e+00,  2.0000e+00,  8.0000e+00],
 [ 3.0000e+00,  5.0000e+00,  9.0000e+00],
 [ 4.0000e+00,  6.0000e+00,  7.0000e+00]]), Tensor(shape=[3, 3], dtype=Int32, value=
[[2, 1, 0],
 [2, 0, 1],
 [0, 1, 2]]))
```

mindspore.ops.SpaceToBatchND

class mindspore.ops.**SpaceToBatchND**(*block_shape*, *paddings*)

Divides spatial dimensions into blocks and combines the block size with the original batch.

This operation will divide spatial dimensions into blocks with *block_shape*, and then the output tensor's spatial dimension is the corresponding number of blocks after division. The output tensor's batch dimension is the product of the original batch and all elements in *block_shape*. Before division, the spatial dimensions of the input are zero padded according to paddings if necessary.

Parameters

- **block_shape** (*Union[list(int), tuple(int), int]*) – The block shape of dividing block with all elements greater than or euqal to 1. If *block_shape* is a list or tuple, the length of *block_shape* is the number of spatial dimensions, called M later. If *block_shape* is an int, the block size of M dimensions are the same, equal to *block_shape*. In this case of Ascend, M must be 2.
- **paddings** (*Union[tuple, list]*) – The padding values for spatial dimensions, containing M subtraction list. Each contains 2 integer values. All values must be greater than or equal to 0. *paddings[i]* specifies the paddings for the spatial dimension i, which corresponds to the input dimension i + offset,where offset = N-M, and N is the number of input dimensions. For each i, input_shape[i + offset]+paddings[i][0]+paddings[i][1] should be divisible by block_shape[i].

Inputs:

- **input_x** (Tensor) - The input tensor. The input tensor must be a 4-D tensor on Ascend.

Outputs:

Tensor, the output tensor with the same data type as the input. Assume the input shape is $(n, c_1, ...c_k, w_1, ..., w_M)$ with $block\_shape$ and $paddings$. The shape of the output tensor will be $(n', c_1, ...c_k, w'_1, ..., w'_M)$, where

$$n' = n * (block\_shape[0] * ... * block\_shape[M-1])$$
$$w'_i = (w_i + paddings[i-1][0] + paddings[i-1][1])//block\_shape[i-1]$$

Raises

- **TypeError** – If *block_shape* is not one of list, tuple, int.
- **TypeError** – If *paddings* is neither list nor tuple.
- **ValueError** – If *block_shape* is not one dimensional when *block_shape* is a list or tuple.
- **ValueError** – If the length of *block_shape* is not 2 on Ascend.
- **ValueError** – If shape of *paddings* is not (M, 2), where M is the length of *block_shape*.
- **ValueError** – If the element of *block_shape* is not an integer larger than or equal to 1.
- **ValueError** – If the element of *paddings* is not an integer larger than or euqal to 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> import numpy as np
>>> block_shape = [2, 2]
>>> paddings = [[0, 0], [0, 0]]
>>> space_to_batch_nd = ops.SpaceToBatchND(block_shape, paddings)
>>> input_x = Tensor(np.array([[[[1, 2], [3, 4]]]]), mindspore.float32)
>>> output = space_to_batch_nd(input_x)
>>> print(output)
[[[[1.]]]
 [[[2.]]]
 [[[3.]]]
 [[[4.]]]]
```

mindspore.ops.SpaceToDepth

class mindspore.ops.**SpaceToDepth**(*block_size*)

Rearrange blocks of spatial data into depth.

The output tensor's *height* dimension is $height/block\_size$.

The output tensor's *weight* dimension is $weight/block\_size$.

The depth of output tensor is $block\_size * block\_size * input\_depth$.

The input tensor's height and width must be divisible by *block_size*. The data format is "NCHW".

Parameters

block_size (*int*) – The block size used to divide spatial data. It must be >= 2.

Inputs:

- **x** (Tensor) - The target tensor. The data type is Number. It must be a 4-D tensor.

Outputs:

Tensor, the same data type as *x*. It must be a 4-D tensor. Tensor of shape $(N, (C_{in} * \text{block\_size} * 2), H_{in}/\text{block\_size}, W_{in}/\text{block\_size})$.

Raises

- **TypeError** – If *block_size* is not an int.
- **ValueError** – If *block_size* is less than 2.
- **ValueError** – If length of shape of *x* is not equal to 4.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.random.rand(1,3,2,2), mindspore.float32)
>>> block_size = 2
>>> space_to_depth = ops.SpaceToDepth(block_size)
>>> output = space_to_depth(x)
>>> print(output.shape)
(1, 12, 1, 1)
```

mindspore.ops.SparseGatherV2

class mindspore.ops.**SparseGatherV2**

Returns a slice of input tensor based on the specified indices and axis.

Inputs:

- **input_params** (Tensor) - The shape of tensor is $(x_1, x_2, ..., x_R)$.
- **input_indices** (Tensor) - The shape of tensor is $(y_1, y_2, ..., y_S)$. Specifies the indices of elements of the original Tensor, must be in the range *[0, input_params.shape[axis])*.
- **axis** (Union(int, Tensor[int])) - Specifies the dimension index to gather indices. When axis is Tensor, the size must be 1.

Outputs:

Tensor, the shape of tensor is $(z_1, z_2, ..., z_N)$.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_params = Tensor(np.array([[1, 2, 7, 42], [3, 4, 54, 22], [2, 2, 55, 3]]),␣
↪mindspore.float32)
>>> input_indices = Tensor(np.array([1, 2]), mindspore.int32)
>>> axis = 1
>>> out = ops.SparseGatherV2()(input_params, input_indices, axis)
>>> print(out)
[[2. 7.]
 [4. 54.]
 [2. 55.]]
```

mindspore.ops.Split

class mindspore.ops.**Split**(*axis=0*, *output_num=1*)

Splits the input tensor into output_num of tensors along the given axis and output numbers.

Refer to *mindspore.ops.split()* for more details.

Parameters

- **axis** (*int*) −Index of the split position. Default: `0` .
- **output_num** (*int*) −The number of output tensors. Must be positive int. Default: `1` .

Inputs:

- **input_x** (Tensor) - The shape of tensor is $(x_0, x_1, ..., x_{R-1})$, R >= 1.

Outputs:

tuple[Tensor], the shape of each output tensor is the same, which is $(x_0, x_1, ..., x_{axis}/output\_num, ..., x_{R-1})$. And the data type is the same as *input_x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> split = ops.Split(1, 2)
>>> x = Tensor(np.array([[1, 1, 1, 1], [2, 2, 2, 2]]), mindspore.int32)
>>> print(x)
[[1 1 1 1]
 [2 2 2 2]]
>>> output = split(x)
>>> print(output)
(Tensor(shape=[2, 2], dtype=Int32, value=
[[1, 1],
 [2, 2]]), Tensor(shape=[2, 2], dtype=Int32, value=
[[1, 1],
```

(continues on next page)

(continued from previous page)

```
 [2, 2]]))
>>> split = ops.Split(1, 4)
>>> output = split(x)
>>> print(output)
(Tensor(shape=[2, 1], dtype=Int32, value=
[[1],
 [2]]), Tensor(shape=[2, 1], dtype=Int32, value=
[[1],
 [2]]), Tensor(shape=[2, 1], dtype=Int32, value=
[[1],
 [2]]), Tensor(shape=[2, 1], dtype=Int32, value=
[[1],
 [2]]))
```

mindspore.ops.Squeeze

class mindspore.ops.**Squeeze**(*axis=()*)

Return the Tensor after deleting the dimension of size 1 in the specified *axis*.

Refer to *mindspore.ops.squeeze()* for more details.

> **Warning:** This is an experimental API that is subject to change or deletion.

Parameters

axis (*Union[int, tuple(int)]*) – Specifies the dimension indexes of shape to be removed, which will remove all the dimensions of size 1 in the given axis parameter. If specified, it must be int32 or int64. Default: `()` .

Inputs:

- **input** (Tensor) - The shape of tensor is $(x_1, x_2, ..., x_R)$.

Outputs:

Tensor, the shape of tensor is $(x_1, x_2, ..., x_S)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input = Tensor(np.ones(shape=[3, 2, 1]), mindspore.float32)
>>> squeeze = ops.Squeeze(2)
>>> output = squeeze(input)
>>> print(output)
[[1. 1.]
 [1. 1.]
 [1. 1.]]
```

mindspore.ops.Stack

class mindspore.ops.**Stack**(*axis=0*)

Stacks a list of tensors in specified axis.

Refer to *mindspore.ops.stack()* for more details.

Parameters

axis (*int, optional*) – Dimension to stack. The range is [-(R+1), R+1). Default: `0` .

Inputs:

- **input_x** (Union[tuple, list]) - A Tuple or list of Tensor objects with the same shape and type.

Outputs:

Tensor. A stacked Tensor with the same type as *input_x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> import numpy as np
>>> data1 = Tensor(np.array([0, 1]).astype(np.float32))
>>> data2 = Tensor(np.array([2, 3]).astype(np.float32))
>>> stack = ops.Stack()
>>> output = stack([data1, data2])
>>> print(output)
[[0. 1.]
 [2. 3.]]
```

mindspore.ops.StridedSlice

class mindspore.ops.**StridedSlice**(*begin_mask=0*, *end_mask=0*, *ellipsis_mask=0*, *new_axis_mask=0*, *shrink_axis_mask=0*)

```
prim = ops.StridedSlice(begin_mask, end_mask, ellipsis_mask, new_axis_mask, shrink_axis_mask)
out = prim(input_x, begin, end, strides)
```

is equivalent to

```
ops.strided_slice(input_x, begin, end, strides, begin_mask, end_mask, ellipsis_mask, new_
↪axis_mask, shrink_axis_mask)
```

Refer to *mindspore.ops.strided_slice()* for more details.

mindspore.ops.TensorScatterAdd

class mindspore.ops.**TensorScatterAdd**

Creates a new tensor by adding the values from the positions in *input_x* indicated by *indices*, with values from *updates*. When multiple values are given for the same index, the updated result will be the sum of all values. This operation is almost equivalent to using *mindspore.ops.ScatterNdAdd*, except that the updates are applied on output *Tensor* instead of input *Parameter*.

Refer to *mindspore.ops.tensor_scatter_add()* for more details.

Inputs:

- **input_x** (Tensor) - The target tensor. The dimension of input_x must be no less than indices.shape[-1].
- **indices** (Tensor) - The index of input tensor whose data type is int32 or int64. The rank must be at least 2.
- **updates** (Tensor) - The tensor to update the input tensor, has the same type as input, and updates. Shape should be equal to indices.shape[:-1] + input_x.shape[indices.shape[-1]:].

Outputs:

Tensor, has the same shape and type as *input_x*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]), mindspore.float32)
>>> indices = Tensor(np.array([[0, 0], [0, 0]]), mindspore.int32)
>>> updates = Tensor(np.array([1.0, 2.2]), mindspore.float32)
>>> # Next, demonstrate the approximate operation process of this operator:
>>> # 1, indices[0] = [0, 0], indices[1] = [0, 0]
>>> # 2, And input_x[0, 0] = -0.1
>>> # 3, So input_x[indices] = [-0.1, -0.1]
>>> # 4, Satisfy the above formula: input_x[indices].shape=(2) == updates.shape=(2)
>>> op = ops.TensorScatterAdd()
>>> # 5, Perform the addition operation for the first time:
>>> #      first_input_x = input_x[0][0] + updates[0] = [[0.9, 0.3, 3.6], [0.4, 0.5, -3.2]]
>>> # 6, Perform the addition operation for the second time:
>>> #      second_input_x = input_x[0][0] + updates[1] = [[3.1, 0.3, 3.6], [0.4, 0.5, -3.2]]
>>> output = op(input_x, indices, updates)
>>> print(output)
[[ 3.1  0.3  3.6]
 [ 0.4  0.5 -3.2]]
```

mindspore.ops.TensorScatterDiv

class mindspore.ops.**TensorScatterDiv**

Creates a new tensor by dividing the values from the positions in *input_x* indicated by *indices*, with values from *updates*. When divided values are provided for the same index, the result of the update will be to divided these values respectively. Except that the updates are applied on output *Tensor* instead of input *Parameter*.

Refer to *mindspore.ops.tensor_scatter_div()* for more details.

Inputs:

- **input_x** (Tensor) - The target tensor. The dimension of input_x must be no less than indices.shape[-1].
- **indices** (Tensor) - The index of input tensor whose data type is int32 or int64. The rank must be at least 2.
- **updates** (Tensor) - The tensor to update the input tensor, has the same type as input, and updates.shape should be equal to $indices.shape[:-1] + input\_x.shape[indices.shape[-1]:]$.

Outputs:

Tensor, has the same shape and type as *input_x*.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]), mindspore.float32)
>>> indices = Tensor(np.array([[0, 0], [0, 0]]), mindspore.int32)
>>> updates = Tensor(np.array([1.0, 2.0]), mindspore.float32)
>>> # Next, demonstrate the approximate operation process of this operator:
>>> # 1, indices[0] = [0, 0], indices[1] = [0, 0]
>>> # 2, And input_x[0, 0] = -0.1
>>> # 3, So input_x[indices] = [-0.1, -0.1]
>>> # 4, Satisfy the above formula: input_x[indices].shape=(2) == updates.shape=(2)
>>> op = ops.TensorScatterDiv()
>>> # 5, Perform the division operation for the first time:
>>> #      first_input_x = input_x[0][0] / updates[0] = [[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]
>>> # 6, Perform the division operation for the second time:
>>> #      second_input_x = input_x[0][0] * updates[1] = [[-0.05, 0.3, 3.6], [0.4, 0.5, -3.
 ↪2]]
>>> output = op(input_x, indices, updates)
>>> print(output)
[[-0.05  0.3  3.6  ]
 [ 0.4   0.5  -3.2 ]]
```

mindspore.ops.TensorScatterMax

class mindspore.ops.**TensorScatterMax**

By comparing the value at the position indicated by *indices* in *x* with the value in the *updates*, the value at the index will eventually be equal to the largest one to create a new tensor.

Refer to *mindspore.ops.tensor_scatter_max()* for more details.

Inputs:

- **input_x** (Tensor) - The target tensor. The dimension of input_x must be no less than indices.shape[-1].
- **indices** (Tensor) - The index of input tensor whose data type is int32 or int64. The rank must be at least 2.
- **updates** (Tensor) - The tensor to update the input tensor, has the same type as input, and updates.shape should be equal to $indices.shape[:-1] + input\_x.shape[indices.shape[-1]:]$.

Outputs:

Tensor, has the same shape and type as *input_x*.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]), mindspore.float32)
>>> indices = Tensor(np.array([[0, 0], [0, 0]]), mindspore.int32)
>>> updates = Tensor(np.array([1.0, 2.2]), mindspore.float32)
>>> # Next, demonstrate the approximate operation process of this operator:
>>> # 1, indices[0] = [0, 0], indices[1] = [0, 0]
>>> # 2, And input_x[0, 0] = -0.1
>>> # 3, So input_x[indices] = [-0.1, -0.1]
>>> # 4, Satisfy the above formula: input_x[indices].shape=(2) == updates.shape=(2)
>>> op = ops.TensorScatterMax()
>>> # 5, Perform the max operation for the first time:
>>> #      first_input_x = Max(input_x[0][0], updates[0]) = [[1.0, 0.3, 3.6], [0.4, 0.5, -3.
 ↪2]]
>>> # 6, Perform the max operation for the second time:
>>> #      second_input_x = Max(input_x[0][0], updates[1]) = [[2.2, 0.3, 3.6], [0.4, 0.5, -3.
 ↪2]]
>>> output = op(input_x, indices, updates)
>>> print(output)
[[ 2.2  0.3  3.6]
 [ 0.4  0.5 -3.2]]
```

mindspore.ops.TensorScatterMin

class mindspore.ops.**TensorScatterMin**

By comparing the value at the position indicated by *indices* in *input_x* with the value in the *updates*, the value at the index will eventually be equal to the smallest one to create a new tensor.

Refer to *mindspore.ops.tensor_scatter_min()* for more details.

Inputs:

- **input_x** (Tensor) - The target tensor. The dimension of input_x must be no less than indices.shape[-1].
- **indices** (Tensor) - The index of input tensor whose data type is int32 or int64. The rank must be at least 2.
- **updates** (Tensor) - The tensor to update the input tensor, has the same type as input, and updates.shape should be equal to $indices.shape[:-1] + input\_x.shape[indices.shape[-1]:]$.

Outputs:

Tensor, has the same shape and type as *input_x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]), mindspore.float32)
>>> indices = Tensor(np.array([[0, 0], [0, 0]]), mindspore.int32)
>>> updates = Tensor(np.array([1.0, 2.2]), mindspore.float32)
>>> # Next, demonstrate the approximate operation process of this operator:
>>> # 1, indices[0] = [0, 0], indices[1] = [0, 0]
>>> # 2, And input_x[0, 0] = -0.1
>>> # 3, So input_x[indices] = [-0.1, -0.1]
>>> # 4, Satisfy the above formula: input_x[indices].shape=(2) == updates.shape=(2)
>>> op = ops.TensorScatterMin()
>>> # 5, Perform the min operation for the first time:
>>> #      first_input_x = Min(input_x[0][0], updates[0]) = [[-0.1, 0.3, 3.6], [0.4, 0.5, -3.
↪2]]
>>> # 6, Perform the min operation for the second time:
>>> #      second_input_x = Min(input_x[0][0], updates[1]) = [[-0.1, 0.3, 3.6], [0.4, 0.5, -
↪3.2]]
>>> output = op(input_x, indices, updates)
>>> print(output)
[[ -0.1  0.3  3.6]
 [ 0.4  0.5 -3.2]]
```

mindspore.ops.TensorScatterMul

class mindspore.ops.**TensorScatterMul**

Creates a new tensor by multiplying the values from the positions in *input_x* indicated by *indices*, with values from *updates*. When multiple values are provided for the same index, the result of the update will be to multiply these values respectively. The updates are applied on output *Tensor* instead of input *Parameter*.

$$output\left[indices\right] = input\_x \times update$$

Refer to *mindspore.ops.tensor_scatter_mul()* for more details.

Inputs:

- **input_x** (Tensor) - The target tensor. The dimension of input_x must be no less than indices.shape[-1].
- **indices** (Tensor) - The index of input tensor whose data type is int32 or int64. The rank must be at least 2.
- **updates** (Tensor) - The tensor to update the input tensor, has the same type as *input_x*, and the shape of *updates* should be equal to $indices.shape[:-1] + input\_x.shape[indices.shape[-1]:]$.

Outputs:

Tensor, has the same shape and type as *input_x*.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]), mindspore.float32)
>>> indices = Tensor(np.array([[0, 0], [0, 0]]), mindspore.int32)
>>> updates = Tensor(np.array([1.0, 2.2]), mindspore.float32)
>>> # Next, demonstrate the approximate operation process of this operator:
>>> # 1, indices[0] = [0, 0], indices[1] = [0, 0]
>>> # 2, And input_x[0, 0] = -0.1
>>> # 3, So input_x[indices] = [-0.1, -0.1]
>>> # 4, Satisfy the above formula: input_x[indices].shape=(2) == updates.shape=(2)
>>> op = ops.TensorScatterMul()
>>> # 5, Perform the multiply operation for the first time:
>>> #      first_input_x = input_x[0][0] * updates[0] = [[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]
>>> # 6, Perform the multiply operation for the second time:
>>> #      second_input_x = input_x[0][0] * updates[1] = [[-0.22, 0.3, 3.6], [0.4, 0.5, -3.
 ↪2]]
>>> output = op(input_x, indices, updates)
>>> print(output)
[[-0.22  0.3   3.6  ]
 [ 0.4   0.5   -3.2 ]]
```

mindspore.ops.TensorScatterSub

class mindspore.ops.**TensorScatterSub**

Creates a new tensor by subtracting the values from the positions in *input_x* indicated by *indices*, with values from *updates*. When multiple values are provided for the same index, the result of the update will subtract these values respectively. This operation is almost equivalent to using *mindspore.ops.ScatterNdSub* , except that the updates are applied on output *Tensor* instead of input *Parameter*.

```
# Iterate through all index
for i in range(indices.shape[0]):
    for j in range(indices.shape[1]):
        ...
        for k in range(indices.shape[-2]):  # The last dimension is coordinate dimension
            # Get current index combination
            index_tuple = (i, j, ..., k)
            # Get target position
            target_index = indices[index_tuple]
            # Get corresponding update value
            update_value = updates[index_tuple]
            # Perform subtraction operation
            output[target_index] -= update_value
```

Refer to *mindspore.ops.tensor_scatter_sub()* for more details.

Inputs:

- **input_x** (Tensor) - The target tensor. The dimension of input_x must be no less than indices.shape[-1].
- **indices** (Tensor) - The index of input tensor whose data type is int32 or int64. The rank must be at least 2.
- **updates** (Tensor) - The tensor to update the input tensor, has the same type as *input_x*, and the shape of *updates* should be equal to $indices.shape[:-1] + input\_x.shape[indices.shape[-1]:]$.

Outputs:

Tensor, has the same shape and type as *input_x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]), mindspore.float32)
>>> indices = Tensor(np.array([[0, 0], [0, 0]]), mindspore.int32)
>>> updates = Tensor(np.array([1.0, 2.2]), mindspore.float32)
>>> # Next, demonstrate the approximate operation process of this operator:
>>> # 1, indices[0] = [0, 0], indices[1] = [0, 0]
>>> # 2, And input_x[0, 0] = -0.1
>>> # 3, So input_x[indices] = [-0.1, -0.1]
>>> # 4, Satisfy the above formula: input_x[indices].shape=(2) == updates.shape=(2)
>>> op = ops.TensorScatterSub()
>>> # 5, Perform the subtract operation for the first time:
>>> #      first_input_x = input_x[0][0] - updates[0] = [[-1.1, 0.3, 3.6], [0.4, 0.5, -3.2]]
>>> # 6, Perform the subtract operation for the second time:
>>> #      second_input_x = input_x[0][0] - updates[1] = [[-3.3, 0.3, 3.6], [0.4, 0.5, -3.2]]
```

(continues on next page)

(continued from previous page)

```
>>> output = op(input_x, indices, updates)
>>> print(output)
[[-3.3000002  0.3        3.6      ]
 [ 0.4        0.5       -3.2      ]]
```

mindspore.ops.TensorScatterUpdate

class mindspore.ops.**TensorScatterUpdate**

Creates a new tensor by updating the positions in *input_x* indicated by *indices*, with values from *update*. This operation is almost equivalent to using *mindspore.ops.ScatterNdUpdate* , except that the updates are applied on output *Tensor* instead of *input_x*.

indices must have rank at least 2, the last axis is the depth of each index vectors. For each index vector, there must be a corresponding value in *update*. If the depth of each index tensor matches the rank of *input_x*, then each index vector corresponds to a scalar in *input_x* and each *update* updates a scalar. If the depth of each index tensor is less than the rank of *input_x*, then each index vector corresponds to a slice in *input_x*, and each *update* updates a slice.

The order in which updates are applied is nondeterministic, meaning that if there are multiple index vectors in *indices* that correspond to the same position, the value of that position in the output will be nondeterministic.

$$output[indices] = update$$

Inputs:

- **input_x** (Tensor) - The input tensor. The dimension of input_x must be no less than indices.shape[-1]. The shape is $(N, *)$ where $*$ means,any number of additional dimensions. The data type is Number.
- **indices** (Tensor) - The index of input tensor whose data type is int32 or int64. The rank must be at least 2.
- **update** (Tensor) - The tensor to update the input tensor, has the same type as *input_x*, and $update.shape = indices.shape[:-1] + input\_x.shape[indices.shape[-1]:]$

Outputs:

Tensor, has the same shape and type as *input_x*.

Raises

- **TypeError** –If dtype of *indices* is neither int32 nor int64.
- **ValueError** –If length of shape of *input_x* is less than the last dimension of shape of *indices*.
- **ValueError** –If the value of *input_x* are not match with input *indices*.
- **RuntimeError** –If a value of *indices* is not in *input_x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]]), mindspore.float32)
>>> indices = Tensor(np.array([[0, 0], [1, 1]]), mindspore.int32)
>>> update = Tensor(np.array([1.0, 2.2]), mindspore.float32)
>>> op = ops.TensorScatterUpdate()
>>> output = op(input_x, indices, update)
>>> print(output)
[[ 1.   0.3  3.6]
 [ 0.4  2.2 -3.2]]
```

mindspore.ops.TensorShape

class mindspore.ops.**TensorShape**

Returns the shape of the input tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> input_x = Tensor(np.ones(shape=[3, 2, 1]), mindspore.float32)
>>> output = ops.TensorShape()(input_x)
>>> print(output)
[3 2 1]
```

mindspore.ops.Tile

class mindspore.ops.**Tile**

Replicates an input tensor with given multiple times.

Refer to *mindspore.ops.tile()* for more details.

Inputs:

- **input** (Tensor) - The tensor whose elements need to be repeated. Set the shape of input tensor as $(x_1, x_2, ..., x_S)$.
- **dims** (tuple[int]) - The parameter that specifies the number of replications, the parameter type is tuple, and the data type is int, i.e., $(y_1, y_2, ..., y_S)$. Only constant value is allowed.

Note: On Ascend, the number of *dims* should not exceed 8, and currently does not support scenarios where more than 4 dimensions are repeated simultaneously.

Outputs:

Tensor, has the same data type as the *input*. Suppose the length of *dims* is d, the dimension of *input* is *input.dim*, and the shape of *input* is $(x_1, x_2, ..., x_S)$.

- If *input.dim* = d, then the shape of their corresponding positions can be multiplied, and the shape of Outputs is $(x_1 * y_1, x_2 * y_2, ..., x_S * y_S)$.
- If *input.dim* < d, prepend 1 to the shape of *input* until their lengths are consistent. Such as set the shape of *input* as $(1, ..., x_1, x_2, ..., x_S)$, then the shape of their corresponding positions can be multiplied, and the shape of Outputs is $(1 * y_1, ..., x_R * y_R, x_S * y_S)$.
- If *input.dim* > d, prepend 1 to *dims* until their lengths are consistent. Such as set the *dims* as $(1, ..., y_1, y_2, ..., y_S)$, then the shape of their corresponding positions can be multiplied, and the shape of Outputs is $(x_1 * 1, ..., x_R * y_R, x_S * y_S)$.

Raises

- **TypeError** – If *dims* is not a tuple or its elements are not all int.
- **ValueError** – If the elements of *dims* are not all greater than or equal to 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> tile = ops.Tile()
>>> input = Tensor(np.array([[1, 2], [3, 4]]), mindspore.float32)
>>> dims = (2, 3)
>>> output = tile(input, dims)
>>> print(output)
[[1.  2.  1.  2.  1.  2.]
 [3.  4.  3.  4.  3.  4.]
 [1.  2.  1.  2.  1.  2.]
 [3.  4.  3.  4.  3.  4.]]
>>> dims = (2, 3, 2)
>>> output = tile(input, dims)
>>> print(output)
[[[1. 2. 1. 2.]
  [3. 4. 3. 4.]
  [1. 2. 1. 2.]
  [3. 4. 3. 4.]
  [1. 2. 1. 2.]
  [3. 4. 3. 4.]]
 [[1. 2. 1. 2.]
  [3. 4. 3. 4.]
  [1. 2. 1. 2.]
  [3. 4. 3. 4.]
  [1. 2. 1. 2.]
  [3. 4. 3. 4.]]]
```

mindspore.ops.Trace

class mindspore.ops.**Trace**

```
prim = ops.Trace()
out = prim(input)
```

is equivalent to

```
ops.trace(input)
```

Refer to *mindspore.ops.trace()* for more details.

mindspore.ops.Transpose

class mindspore.ops.**Transpose**

```
prim = ops.Transpose()
out = prim(input, input_perm)
```

is equivalent to

```
ops.transpose(input, input_perm)
```

Refer to *mindspore.ops.transpose()* for more details.

mindspore.ops.Tril

class mindspore.ops.**Tril**(*diagonal=0*)

Returns the lower triangular portion of the 2-D matrix or the set of matrices in a batch. The remaining elements of the resulting Tensor are assigned a value of 0. The lower triangular section of the matrix comprises of the elements present on and below the main diagonal.

Warning: This is an experimental API that is subject to change or deletion.

Parameters

diagonal (*int, optional*) – An optional attribute indicates the diagonal to consider, default: `0` , indicating the main diagonal.

Inputs:

- **x** (Tensor) - The input tensor with shape $(*, M, N)$ where $*$ means any number of additional dimensions.

Outputs:

Tensor, the same shape and data type as the input *x*.

Raises

- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If *diagonal* is not an int.
- **ValueError** – If the rank of *x* is less than 2.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> x = Tensor(np.array([[ 1,  2,  3,  4],
...                      [ 5,  6,  7,  8],
...                      [10, 11, 12, 13],
...                      [14, 15, 16, 17]]))
>>> tril = ops.Tril()
>>> result = tril(x)
>>> print(result)
[[ 1  0  0  0]
 [ 5  6  0  0]
 [10 11 12  0]
 [14 15 16 17]]
>>> x = Tensor(np.array([[ 1,  2,  3,  4],
...                      [ 5,  6,  7,  8],
...                      [10, 11, 12, 13],
...                      [14, 15, 16, 17]]))
>>> tril = ops.Tril(diagonal=1)
>>> result = tril(x)
>>> print(result)
[[ 1  2  0  0]
 [ 5  6  7  0]
 [10 11 12 13]
 [14 15 16 17]]
>>> x = Tensor(np.array([[ 1,  2,  3,  4],
...                      [ 5,  6,  7,  8],
...                      [10, 11, 12, 13],
...                      [14, 15, 16, 17]]))
>>> tril = ops.Tril(diagonal=-1)
>>> result = tril(x)
>>> print(result)
[[ 0  0  0  0]
 [ 5  0  0  0]
 [10 11  0  0]
 [14 15 16  0]]
```

mindspore.ops.TrilIndices

class mindspore.ops.**TrilIndices**(*row*, *col*, *offset=0*, *dtype=mstype.int32*)

Computes the indices of the lower triangular elements of a 2D matrix and returns them as a Tensor.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.tril_indices()* for more details.

Parameters

- **row** (*int*) –number of rows in the 2-D matrix.

- **col** (*int*) –number of columns in the 2-D matrix.
- **offset** (*int, optional*) –diagonal offset from the main diagonal. Default: `0` .
- **dtype** (*mindspore.dtype*, optional) –The specified type of output tensor. An optional data type of `mstype.int32` and `mstype.int64` . Default: `mstype.int32` .

Outputs:

- **y** (Tensor) - indices of the elements in lower triangular part of matrix. The type specified by *dtype*. The shape of output is $(2, tril\_size)$, where $tril\_size$ is the number of elements in the lower triangular matrix.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import ops
>>> from mindspore import dtype as mstype
>>> net = ops.TrilIndices(4, 3, -1, mstype.int64)
>>> output = net()
>>> print(output)
[[1 2 2 3 3 3]
 [0 0 1 0 1 2]]
>>> print(output.dtype)
Int64
```

mindspore.ops.Triu

class mindspore.ops.**Triu**(*diagonal=0*)

```
prim = ops.Triu(diagonal)
out = prim(input)
```

is equivalent to

```
ops.triu(input, diagonal)
```

Refer to *mindspore.ops.triu()* for more details.

mindspore.ops.TriuIndices

class mindspore.ops.**TriuIndices**(*row*, *col*, *offset=0*, *dtype=mstype.int32*)

Calculates the indices of the upper triangular elements in a *row* * *col* matrix and returns them as a 2-by-N Tensor.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.triu_indices()* for more details.

Parameters

- **row** (*int*) –number of rows in the 2-D matrix.
- **col** (*int*) –number of columns in the 2-D matrix.

- **offset** (*int, optional*) –diagonal offset from the main diagonal. Default: `0` .
- **dtype** (*mindspore.dtype*, optional) –The specified type of output tensor. An optional data type of `mstype.int32` and `mstype.int64` . Default: `mstype.int32` .

Outputs:

- **y** (Tensor) - indices of the elements in upper triangular part of matrix. The type specified by *dtype*. The shape of output is $(2, tril\_size)$, where $tril\_size$ is the number of elements in the upper triangular matrix.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import ops
>>> from mindspore import dtype as mstype
>>> net = ops.TriuIndices(5, 4, 2, mstype.int64)
>>> output = net()
>>> print(output)
[[0 0 1]
 [2 3 3]]
>>> print(output.dtype)
Int64
```

mindspore.ops.Unique

class mindspore.ops.**Unique**

Returns the unique elements of input tensor and also return a tensor containing the index of each value of input tensor corresponding to the output unique tensor.

The output contains Tensor *y* and Tensor *idx*, the format is probably similar to (*y*, *idx*). The shape of Tensor *y* and Tensor *idx* is different in most cases, because Tensor *y* will be duplicated, and the shape of Tensor *idx* is consistent with the input.

To get the same shape between *idx* and *y*, please refer to *mindspore.ops.UniqueWithPad*.

Inputs:

- **input_x** (Tensor) - The input tensor. The shape is $(N, *)$ where $*$ means, any number of additional dimensions.

Outputs:

Tuple, containing Tensor objects (*y*, *idx*), *y* is a tensor with the same type as *input_x*, and contains the unique elements in *x*. *idx* is a tensor containing indices of elements in the input corresponding to the output tensor.

Raises

TypeError –If *input_x* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, nn
>>> input_x = Tensor(np.array([1, 2, 5, 2]), mindspore.int32)
>>> output = ops.Unique()(input_x)
>>> print(output)
(Tensor(shape=[3], dtype=Int32, value= [1, 2, 5]), Tensor(shape=[4], dtype=Int32, value= [0,␣
↪1, 2, 1]))
>>> y = output[0]
>>> print(y)
[1 2 5]
>>> idx = output[1]
>>> print(idx)
[0 1 2 1]
>>> # As can be seen from the above, y and idx shape
>>> # note that for GPU, this operator must be wrapped inside a model, and executed in graph␣
↪mode.
>>> class UniqueNet(nn.Cell):
...     def __init__(self):
...         super(UniqueNet, self).__init__()
...         self.unique_op = ops.Unique()
...
...     def construct(self, x):
...         output, indices = self.unique_op(x)
...         return output, indices
...
>>> input_x = Tensor(np.array([1, 2, 5, 2]), mindspore.int32)
>>> net = UniqueNet()
>>> output = net(input_x)
>>> print(output)
(Tensor(shape=[3], dtype=Int32, value= [1, 2, 5]), Tensor(shape=[4], dtype=Int32, value= [0,␣
↪1, 2, 1]))
```

mindspore.ops.UniqueConsecutive

class mindspore.ops.**UniqueConsecutive**(*return_inverse=False*, *return_counts=False*, *dim=None*)

Returns the elements that are unique in each consecutive group of equivalent elements in the input tensor.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.unique_consecutive()* for more details.

Parameters

- **return_inverse** (*bool, optional*) – Whether to return the index of where the element in the original input maps to the position in the output. Default: `False` .
- **return_counts** (*bool, optional*) – Whether to return the counts of each unique element. Default: `False` .
- **dim** (*int, optional*) – The dimension to apply unique. If `None` , the unique of the flattened input is returned. If specified, it must be int32 or int64. Default: `None` .

Inputs:

- **x** (Tensor) - The input tensor.

Outputs:

A tensor or a tuple of tensors containing tensor objects (*output*, *idx*, *counts*).

- *output* has the same type as *x* and is used to represent the output list of unique scalar elements.
- If *return_inverse* is True, there will be an additional returned tensor, *idx*, which has the same shape as *x* and represents the index of where the element in the original input maps to the position in the output.
- If *return_counts* is True, there will be an additional returned tensor, *counts*, which represents the number of occurrences for each unique value or tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> x = Tensor(np.array([1, 1, 2, 2, 3, 1, 1, 2]), mstype.int32)
>>> unique_consecutive = ops.UniqueConsecutive(True, True, None)
>>> output, idx, counts = unique_consecutive(x)
>>> print(output)
[1 2 3 1 2]
>>> print(idx)
[0 0 1 1 2 3 3 4]
>>> print(counts)
[2 2 1 2 1]
```

mindspore.ops.UniqueWithPad

class mindspore.ops.**UniqueWithPad**

'ops.UniqueWithPad' is deprecated from version 2.4 and will be removed in a future version. Please use the *mindspore.ops.unique()* combined with *mindspore.ops.pad()* to realize the same function.

Supported Platforms:

Deprecated

mindspore.ops.UnsortedSegmentMax

class mindspore.ops.**UnsortedSegmentMax**

Computes the maximum along segments of a tensor.

Refer to *mindspore.ops.unsorted_segment_max()* for more details.

Inputs:

- **input_x** (Tensor) - The shape is $(x_1, x_2, ..., x_R)$. The data type must be float16, float32 or int32.
- **segment_ids** (Tensor) - The label indicates the segment to which each element belongs. Set the shape as $(x_1, x_2, ..., x_N)$, where 0 < N <= R.
- **num_segments** (Union[int, Tensor]) - Set z as num_segments, it can be an int or 0-D Tensor.

Outputs:

Tensor, the shape is $(z, x_{N+1}, ..., x_R)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> # case 1: Only have two num_segments, where is 0 and 1, and segment_ids=[0, 1, 1]
>>> # num_segments = 2 indicates that there are two types of segment_id,
>>> # the first number '0' in [0, 1, 1] indicates input_x[0],
>>> # the second number '1' in [0, 1, 1] indicates input_x[1],
>>> # the third number '1' in [0, 1, 1] indicates input_x[2],
>>> # input_x[0], which is [1, 2, 3] will not be compared to other segment_id.
>>> # Only the same segment_id will be compared.
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> import numpy as np
>>> input_x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [4, 2, 1]]).astype(np.float32))
>>> segment_ids = Tensor(np.array([0, 1, 1]).astype(np.int32))
>>> num_segments = 2
>>> unsorted_segment_max = ops.UnsortedSegmentMax()
>>> output = unsorted_segment_max(input_x, segment_ids, num_segments)
>>> print(output)
[[1. 2. 3.]
 [4. 5. 6.]]
>>>
>>> # case 2: The segment_ids=[0, 0, 1, 1].
>>> # [1, 2, 3] will compare with [4, 2, 0],
>>> # and [4, 5, 6] will compare with [4, 2, 1].
>>> input_x = Tensor(np.array([[1, 2, 3], [4, 2, 0], [4, 5, 6], [4, 2, 1]]).astype(np.
↪float32))
>>> segment_ids = Tensor(np.array([0, 0, 1, 1]).astype(np.int32))
>>> num_segments = 2
>>> unsorted_segment_max = ops.UnsortedSegmentMax()
>>> output = unsorted_segment_max(input_x, segment_ids, num_segments)
>>> print(input_x.shape)
    (4, 3)
>>> print(output)
    [[4. 2. 3.]
     [4. 5. 6.]]
>>> # case 3: If the input_x have three dimensions even more, what will happen?
>>> # The shape of input_x is (2, 4, 3),
>>> # and the length of segment_ids should be the same as the first dimension of input_x.
>>> # Because the segment_ids are different, input_x[0] will not be compared to input_x[1].
>>> input_x = Tensor(np.array([[[1, 2, 3], [4, 2, 0], [4, 5, 6], [4, 2, 1]],
...                            [[1, 2, 3], [4, 2, 0], [4, 5, 6], [4, 2, 1]]]).astype(np.
↪float32))
>>> segment_ids = Tensor(np.array([0, 1]).astype(np.int32))
>>> num_segments = 2
>>> unsorted_segment_max = ops.UnsortedSegmentMax()

```

mindspore.ops.UnsortedSegmentMin

class mindspore.ops.**UnsortedSegmentMin**

Computes the minimum of a tensor along segments.

Refer to *mindspore.ops.unsorted_segment_min()* for more details.

Inputs:

- **input_x** (Tensor) - The shape is $(x_1, x_2, ..., x_R)$. The data type must be float16, float32 or int32.
- **segment_ids** (Tensor) - The label indicates the segment to which each element belongs. Set the shape as $(x_1, x_2, ..., x_N)$, where 0 < N <= R.
- **num_segments** (Union[int, Tensor]) - Set z as num_segments, it can be an int or 0-D Tensor.

Outputs:

Tensor, the shape is $(z, x_{N+1}, ..., x_R)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> import numpy as np
>>> input_x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [4, 2, 1]]).astype(np.float32))
>>> segment_ids = Tensor(np.array([0, 1, 1]).astype(np.int32))
>>> num_segments = 2
>>> unsorted_segment_min = ops.UnsortedSegmentMin()
>>> output = unsorted_segment_min(input_x, segment_ids, num_segments)
>>> print(output)
[[1. 2. 3.]
 [4. 2. 1.]]
```

mindspore.ops.UnsortedSegmentProd

class mindspore.ops.**UnsortedSegmentProd**

Computes the product of a tensor along segments.

Refer to *mindspore.ops.unsorted_segment_prod()* for more details.

Inputs:

- **input_x** (Tensor) - The shape is $(x_1, x_2, ..., x_R)$. With float16, float32 or int32 data type.
- **segment_ids** (Tensor) - The label indicates the segment to which each element belongs. Set the shape as $(x_1, x_2, ..., x_N)$, where 0 < N <= R. Data type must be int32.
- **num_segments** (Union[int, Tensor]) - Set z as num_segments, it can be an int or 0-D Tensor.

Outputs:

Tensor, the shape is $(z, x_{N+1}, ..., x_R)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> import numpy as np
>>> input_x = Tensor(np.array([[1, 2, 3], [4, 5, 6], [4, 2, 1]]).astype(np.float32))
>>> segment_ids = Tensor(np.array([0, 1, 0]).astype(np.int32))
>>> num_segments = 2
>>> unsorted_segment_prod = ops.UnsortedSegmentProd()
>>> output = unsorted_segment_prod(input_x, segment_ids, num_segments)
>>> print(output)
[[4. 4. 3.]
 [4. 5. 6.]]
```

mindspore.ops.UnsortedSegmentSum

class mindspore.ops.**UnsortedSegmentSum**

```
prim = ops.UnsortedSegmentSum()
out = prim(input_x, segment_ids, num_segments)
```

is equivalent to

```
ops.unsorted_segment_sum(input_x, segment_ids, num_segments)
```

Refer to *mindspore.ops.unsorted_segment_sum()* for more details.

mindspore.ops.Unstack

class mindspore.ops.**Unstack**(*axis=0*, *num=None*)

Unstacks tensor in specified axis, this is the opposite of ops.Stack. Assuming input is a tensor of rank *R*, output tensors will have rank *(R-1)*.

Refer to *mindspore.ops.unstack()* for more details.

Parameters

- **axis** (*int, optional*) –Dimension along which to unpack. Default: `0` . Negative values wrap around. The range is [-R, R).
- **num** (*Union[None, int], optional*) –The number of output tensors. Automatically inferred by input_x and axis if `None` . Default: `None` .

Inputs:

- **input_x** (Tensor) - The shape is $(x_1, x_2, ..., x_R)$. A tensor to be unstacked and the rank of the tensor must be greater than 0.

Outputs:

A tuple of tensors, the shape of each objects is the same. Given a tensor of shape $(x_1, x_2, ..., x_R)$. If $0 \leq axis$, the shape of tensor in output is $(x_1, x_2, ..., x_{axis}, x_{axis+2}, ..., x_R)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> unstack = ops.Unstack()
>>> input_x = Tensor(np.array([[1, 1, 1, 1], [2, 2, 2, 2]]))
>>> output = unstack(input_x)
>>> print(output)
(Tensor(shape=[4], dtype=Int64, value= [1, 1, 1, 1]), Tensor(shape=[4], dtype=Int64, value=␣
↪[2, 2, 2, 2]))
```

18.4.4 Type Conversion

API Name	Description	Supported Platforms
mindspore.ops.ScalarCast	'ops.ScalarCast' is deprecated from version 2.3 and will be removed in a future version, please use *int(x)* or *float(x)* instead.	Deprecated
mindspore.ops.ScalarToTensor	Converts a scalar to a *Tensor*, and converts the data type to the specified type.	Ascend GPU CPU
mindspore.ops.TupleToArray	Converts a tuple to a tensor.	Ascend GPU CPU

mindspore.ops.ScalarCast

class mindspore.ops.**ScalarCast**

'ops.ScalarCast' is deprecated from version 2.3 and will be removed in a future version, please use *int(x)* or *float(x)* instead.

Supported Platforms:

Deprecated

Examples

```
>>> import mindspore
>>> from mindspore import ops
>>> scalar_cast = ops.ScalarCast()
>>> output = scalar_cast(255.0, mindspore.int64)
>>> print(output)
255
```

mindspore.ops.ScalarToTensor

class mindspore.ops.**ScalarToTensor**

Converts a scalar to a *Tensor*, and converts the data type to the specified type.

Refer to *mindspore.ops.scalar_to_tensor()* for more details.

Inputs:

- **input_x** (Union[int, float]) - The input is a scalar. Only constant value is allowed.
- **dtype** (mindspore.dtype) - The target data type. Default: `mindspore.float32` . Only constant value is allowed.

Outputs:

Tensor. 0-D Tensor and the content is the input.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import ops
>>> op = ops.ScalarToTensor()
>>> data = 1
>>> output = op(data, mindspore.float32)
>>> print(output)
1.0
```

mindspore.ops.TupleToArray

class mindspore.ops.**TupleToArray**

Converts a tuple to a tensor.

Refer to *mindspore.ops.tuple_to_array()* for more details.

Inputs:

- **input_x** (tuple) - A tuple of numbers. These numbers have the same type. The shape is $(N,)$.

Outputs:

Tensor, if the input tuple contains N numbers, then the shape of the output tensor is $(N,)$.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import ops
>>> input_x = (1,2,3)
>>> print(type(input_x))
<class 'tuple'>
>>> output = ops.TupleToArray()(input_x)
>>> print(type(output))
<class 'mindspore.common.tensor.Tensor'>
>>> print(output)
[1 2 3]
```

18.5 Parameter Operation Operator

API Name	Description	Supported Platforms
mindspore.ops.Assign	Refer to *mindspore.ops.assign()* for more details.	`Ascend` `GPU` `CPU`
mindspore.ops.AssignAdd	Refer to *mindspore.ops.assign_add()* for more details.	`Ascend` `GPU` `CPU`
mindspore.ops.AssignSub	Refer to *mindspore.ops.assign_sub()* for more details.	`Ascend` `GPU` `CPU`
mindspore.ops.ScatterAdd	Updates the value of the input tensor through the addition operation.	`Ascend` `GPU` `CPU`

continues on next page

Table 19 – continued from previous page

mindspore.ops.ScatterDiv	Updates the value of the input tensor through the divide operation.	Ascend GPU CPU
mindspore.ops.ScatterMax	Updates the value of the input tensor through the maximum operation.	Ascend GPU CPU
mindspore.ops.ScatterMin	Updates the value of the input tensor through the minimum operation.	Ascend GPU CPU
mindspore.ops.ScatterMul	Updates the value of the input tensor through the multiply operation.	Ascend GPU CPU
mindspore.ops.ScatterNdAdd	Applies sparse addition to individual values or slices in a tensor.	Ascend GPU CPU
mindspore.ops.ScatterNdSub	Applies sparse subtraction to individual values or slices in a tensor.	Ascend GPU CPU
mindspore.ops.ScatterNdUpdate	Updates tensor values by using input indices and value.	Ascend GPU CPU
mindspore.ops.ScatterNonAliasingAdd	Please use TensorScatterAdd instead.	Deprecated
mindspore.ops.ScatterSub	Updates the value of the input tensor through the subtraction operation.	Ascend GPU CPU
mindspore.ops.ScatterUpdate	Updates tensor values by using input indices and value.	Ascend GPU CPU

18.5.1 mindspore.ops.Assign

class mindspore.ops.**Assign**

```
prim = ops.Assign()
out = prim(variable, value)
```

is equivalent to

```
ops.assign(variable, value)
```

Refer to *mindspore.ops.assign()* for more details.

18.5.2 mindspore.ops.AssignAdd

class mindspore.ops.**AssignAdd**

```
prim = ops.AssignAdd()
out = prim(variable, value)
```

is equivalent to

```
ops.assign_add(variable, value)
```

Refer to *mindspore.ops.assign_add()* for more details.

18.5.3 mindspore.ops.AssignSub

class mindspore.ops.**AssignSub**

```
prim = ops.AssignSub()
out = prim(variable, value)
```

is equivalent to

```
ops.assign_sub(variable, value)
```

Refer to *mindspore.ops.assign_sub()* for more details.

18.5.4 mindspore.ops.ScatterAdd

class mindspore.ops.**ScatterAdd**(*use_locking=False*)

Updates the value of the input tensor through the addition operation.

Using given values to update tensor value through the add operation, along with the input indices. This operation outputs the *input_x* after the update is done, which makes it convenient to use the updated value.

for each *i, ···, j* in *indices.shape*:

$$\text{input\_x}[\text{indices}[i, ..., j], :] \mathrel{+}= \text{updates}[i, ..., j, :]$$

Inputs of *input_x* and *updates* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Note: This is an in-place update operator. Therefore, the *input_x* will be updated after the operation is completed.

Parameters

use_locking (*bool, optional*) −Whether to protect the assignment by a lock. If `True` , *input_x* will be protected by the lock. Otherwise, the calculation result is undefined. Default: `False` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor.
- **indices** (Tensor) - The index to do min operation whose data type must be mindspore.int32 or mindspore.int64.
- **updates** (Tensor) - The tensor doing the min operation with *input_x*, the data type is same as *input_x*, the shape is *indices.shape* + *x.shape[1:]*.

Outputs:

Tensor, the updated *input_x*, has the same shape and type as *input_x*.

Raises

- **TypeError** −If *use_locking* is not a bool.
- **TypeError** −If *indices* is not an int32 or an int64.
- **ValueError** −If the shape of *updates* is not equal to *indices.shape* + *x.shape[1:]*.
- **RuntimeError** −If the data type of *input_x* and *updates* conversion is required when data type conversion is not supported.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, Parameter
>>> input_x = Parameter(Tensor(np.array([[0.0, 0.0, 0.0], [0.0, 0.0, 0.0]]), mindspore.
↪float32), name="x")
>>> indices = Tensor(np.array([[0, 1], [1, 1]]), mindspore.int32)
>>> updates = Tensor(np.ones([2, 2, 3]), mindspore.float32)
>>> scatter_add = ops.ScatterAdd()
>>> output = scatter_add(input_x, indices, updates)
>>> print(output)
[[1. 1. 1.]
 [3. 3. 3.]]
>>> # for input_x will be updated after the operation is completed. input_x need to be re-
↪initialized.
>>> input_x = Parameter(Tensor(np.array([[0.0, 0.0, 0.0], [0.0, 0.0, 0.0]]), mindspore.
↪float32), name="x")
>>> # for indices = [[0, 1], [1, 1]]
>>> # step 1: [0, 1]
>>> # input_x[0] = [0.0, 0.0, 0.0] + [1.0, 1.0, 1.0] = [1.0, 1.0, 1.0]
>>> # input_x[1] = [0.0, 0.0, 0.0] + [3.0, 3.0, 3.0] = [3.0, 3.0, 3.0]
>>> # step 2: [1, 1]
>>> # input_x[1] = [3.0, 3.0, 3.0] + [7.0, 7.0, 7.0] = [10.0, 10.0, 10.0]
>>> # input_x[1] = [10.0, 10.0, 10.0] + [9.0, 9.0, 9.0] = [19.0, 19.0, 19.0]
>>> indices = Tensor(np.array([[0, 1], [1, 1]]), mindspore.int32)
>>> updates = Tensor(np.array([[[1.0, 1.0, 1.0], [3.0, 3.0, 3.0]],
...                            [[7.0, 7.0, 7.0], [9.0, 9.0, 9.0]]]), mindspore.float32)
>>> scatter_add = ops.ScatterAdd()
>>> output = scatter_add(input_x, indices, updates)
>>> print(output)
[[ 1.  1.  1.]
 [19. 19. 19.]]
>>> # for input_x will be updated after the operation is completed. input_x need to be re-
↪initialized.
>>> input_x = Parameter(Tensor(np.array([[0.0, 0.0, 0.0], [0.0, 0.0, 0.0]]), mindspore.
↪float32), name="x")
>>> # for indices = [[1, 0], [1, 1]]
>>> # step 1: [1, 0]
>>> # input_x[0] = [0.0, 0.0, 0.0] + [3.0, 3.0, 3.0] = [3.0, 3.0, 3.0]
>>> # input_x[1] = [0.0, 0.0, 0.0] + [1.0, 1.0, 1.0] = [1.0, 1.0, 1.0]
>>> # step 2: [1, 1]
>>> # input_x[1] = [1.0, 1.0, 1.0] + [7.0, 7.0, 7.0] = [8.0, 8.0, 8.0]
>>> # input_x[1] = [8.0, 8.0, 8.0] + [9.0, 9.0, 9.0] = [17.0, 17.0, 17.0]
>>> indices = Tensor(np.array([[1, 0], [1, 1]]), mindspore.int32)
>>> updates = Tensor(np.array([[[1.0, 1.0, 1.0], [3.0, 3.0, 3.0]],
...                            [[7.0, 7.0, 7.0], [9.0, 9.0, 9.0]]]), mindspore.float32)
>>> scatter_add = ops.ScatterAdd()
>>> output = scatter_add(input_x, indices, updates)
>>> print(output)
[[ 3.  3.  3.]
 [17. 17. 17.]]
>>> # for input_x will be updated after the operation is completed. input_x need to be re-
↪initialized.
```

[[ 8.  8.  8.]
 [12. 12. 12.]]
```

18.5.5 mindspore.ops.ScatterDiv

class mindspore.ops.**ScatterDiv**(*use_locking=False*)

Updates the value of the input tensor through the divide operation.

Using given values to update tensor value through the div operation, along with the input indices. This operation outputs the *input_x* after the update is done, which makes it convenient to use the updated value.

for each $i, ..., j$ in *indices.shape*:

$$\text{input\_x}[\text{indices}[i, ..., j], :] \ /= \text{updates}[i, ..., j, :]$$

Inputs of *input_x* and *updates* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type. A RuntimeError will be reported when *updates* does not support conversion to the data type required by *input_x*.

Parameters

use_locking (*bool*) – Whether to protect the assignment by a lock. Default: `False` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor. The shape is $(N, *)$ where $*$ means any number of additional dimensions.
- **indices** (Tensor) - The index to do divide operation whose data type must be mstype.int32 or mstype.int64.
- **updates** (Tensor) - The tensor doing the divide operation with *input_x*, the data type is same as *input_x*, the shape is *indices.shape* + *input_x.shape[1:]*.

Outputs:

Tensor, the updated *input_x*, has the same shape and type as *input_x*.

Raises

- **TypeError** – If *use_locking* is not a bool.
- **TypeError** – If *indices* is not an int32 or an int64.
- **ValueError** – If the shape of *updates* is not equal to *indices.shape* + *input_x.shape[1:]*.

- **RuntimeError** –If the data type of *input_x* and *updates* conversion is required when data type conversion is not supported.
- **RuntimeError** –On the Ascend platform, the input data dimension of *input_x* , *indices* and *updates* is greater than 8 dimensions.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, Parameter
>>> input_x = Parameter(Tensor(np.array([[6.0, 6.0, 6.0], [2.0, 2.0, 2.0]]), mstype.float32),
 ↪ name="x")
>>> indices = Tensor(np.array([0, 1]), mstype.int32)
>>> updates = Tensor(np.array([[2.0, 2.0, 2.0], [2.0, 2.0, 2.0]]), mstype.float32)
>>> scatter_div = ops.ScatterDiv()
>>> output = scatter_div(input_x, indices, updates)

>>> print(output)
[[21. 21. 21.]
 [15. 15. 15.]]
```

18.5.6 mindspore.ops.ScatterMax

class mindspore.ops.**ScatterMax**(*use_locking=False*)

Updates the value of the input tensor through the maximum operation.

Using given values to update tensor value through the max operation, along with the input indices. This operation outputs the *input_x* after the update is done, which makes it convenient to use the updated value.

for each $i, ..., j$ in *indices.shape*:

$$\text{input\_x}[\text{indices}[i, ..., j], :] = \max(\text{input\_x}[\text{indices}[i, ..., j], :], \text{updates}[i, ..., j, :])$$

Inputs of *input_x* and *updates* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type. A RuntimeError will be reported when *updates* does not support conversion to the data type required by *input_x*.

Parameters

use_locking (*bool*) – Whether to protect the assignment by a lock. Default: `False` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor. The shape is $(N, *)$ where $*$ means any number of additional dimensions.
- **indices** (Tensor) - The index to do max operation whose data type must be mindspore.int32 or mindspore.int64.
- **updates** (Tensor) - The tensor that performs the maximum operation with *input_x*, the data type is the same as *input_x*, the shape is *indices.shape* + *input_x.shape[1:]*.

Outputs:

Tensor, the updated *input_x*, has the same shape and type as *input_x*.

Raises

- **TypeError** –If *use_locking* is not a bool.
- **TypeError** –If *indices* is not an int32 or an int64.
- **ValueError** –If the shape of *updates* is not equal to *indices.shape* + *x.shape[1:]*.
- **RuntimeError** –If the data type of *input_x* and *updates* conversion is required when data type conversion is not supported.
- **RuntimeError** –On the Ascend platform, the input data dimension of *input_x* , *indices* and *updates* is greater than 8 dimensions.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, Parameter
>>> input_x = Parameter(Tensor(np.array([[1.0, 2.0, 3.0], [4.0, 5.0, 6.0]]), mindspore.
↪float32),
...                     name="input_x")
>>> indices = Tensor(np.array([[0, 0], [1, 1]]), mindspore.int32)
>>> updates = Tensor(np.ones([2, 2, 3]) * 88, mindspore.float32)
>>> scatter_max = ops.ScatterMax()
>>> output = scatter_max(input_x, indices, updates)
>>> print(output)
[[88. 88. 88.]
 [88. 88. 88.]]
```

18.5.7 mindspore.ops.ScatterMin

class mindspore.ops.**ScatterMin**(*use_locking=False*)

Updates the value of the input tensor through the minimum operation.

Using given values to update tensor value through the min operation, along with the input indices. This operation outputs the *input_x* after the update is done, which makes it convenient to use the updated value.

for each $i, ..., j$ in *indices.shape*:

$$\text{input\_x}[\text{indices}[i, ..., j], :] = \min(\text{input\_x}[\text{indices}[i, ..., j], :], \text{updates}[i, ..., j, :])$$

Inputs of *input_x* and *updates* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type. A RuntimeError will be reported when *updates* does not support conversion to the data type required by *input_x*.

Parameters

use_locking (*bool, optional*) –Whether to protect the assignment by a lock. Default: `False` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor. The shape is $(N, *)$ where $*$ means any number of additional dimensions.

- **indices** (Tensor) - The index to do min operation whose data type must be mindspore.int32 or mindspore.int64.
- **updates** (Tensor) - The tensor doing the min operation with *input_x*, the data type is same as *input_x*, the shape is *indices.shape + input_x.shape[1:]*.

Outputs:

Tensor, the updated *input_x*, has the same shape and type as *input_x*.

Raises

- **TypeError** – If *use_locking* is not a bool.
- **TypeError** – If *indices* is not an int32 or an int64.
- **ValueError** – If the shape of *updates* is not equal to *indices.shape + input_x.shape[1:]*.
- **RuntimeError** – If the data type of *input_x* and *updates* conversion is required when data type conversion is not supported.
- **RuntimeError** – On the Ascend platform, the input data dimension of *input_x* , *indices* and *updates* is greater than 8 dimensions.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, Parameter
>>> input_x = Parameter(Tensor(np.array([[0.0, 1.0, 2.0], [0.0, 0.0, 0.0]]), mindspore.
↪float32),
...                     name="input_x")
>>> indices = Tensor(np.array([[0, 0], [1, 1]]), mindspore.int32)
>>> update = Tensor(np.ones([2, 2, 3]), mindspore.float32)
>>> scatter_min = ops.ScatterMin()
>>> output = scatter_min(input_x, indices, update)
>>> print(output)
[[0. 1. 1.]
 [0. 0. 0.]]
```

18.5.8 mindspore.ops.ScatterMul

class mindspore.ops.**ScatterMul**(*use_locking=False*)

Updates the value of the input tensor through the multiply operation.

Using given values to update tensor value through the mul operation, along with the input indices. This operation outputs the *input_x* after the update is done, which makes it convenient to use the updated value.

for each $i, \cdots, j$ in *indices.shape*:

$$\text{input\_x}[\text{indices}[i, ..., j], :] \mathrel{*}= \text{updates}[i, ..., j, :]$$

Inputs of *input_x* and *updates* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Parameters

use_locking (*bool*) −Whether to protect the assignment by a lock. Default: `False` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor. The shape is $(N, *)$ where $*$ means any number of additional dimensions.
- **indices** (Tensor) - The index to do multiply operation whose data type must be mstype.int32 or mstype.int64.
- **updates** (Tensor) - The tensor doing the multiply operation with *input_x*, the data type is same as *input_x*, the shape is *indices.shape + input_x.shape[1:]*.

Outputs:

Tensor, the updated *input_x*, has the same shape and type as *input_x*.

Raises

- **TypeError** −If *use_locking* is not a bool.
- **TypeError** −If *indices* is not an int32 or an int64.
- **ValueError** −If the shape of *updates* is not equal to *indices.shape + input_x.shape[1:]*.
- **RuntimeError** −If the data type of *input_x* and *updates* conversion is required when data type conversion is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, Parameter
>>> input_x = Parameter(Tensor(np.array([[1.0, 1.0, 1.0], [2.0, 2.0, 2.0]]), mstype.float32),
 ↪ name="x")
>>> indices = Tensor(np.array([0, 1]), mstype.int32)
>>> updates = Tensor(np.array([[2.0, 2.0, 2.0], [2.0, 2.0, 2.0]]), mstype.float32)
>>> scatter_mul = ops.ScatterMul()
>>> output = scatter_mul(input_x, indices, updates)
>>> print(output)
[[2. 2. 2.]
 [4. 4. 4.]]
>>> # for input_x will be updated after the operation is completed. input_x need to be re-
 ↪initialized.
>>> input_x = Parameter(Tensor(np.array([[1.0, 1.0, 1.0], [2.0, 2.0, 2.0]]), mstype.float32),
 ↪ name="x")
>>> # for indices = [[0, 1], [1, 1]]
>>> # step 1: [0, 1]
>>> # input_x[0] = [1.0, 1.0, 1.0] * [1.0, 1.0, 1.0] = [1.0, 1.0, 1.0]
>>> # input_x[1] = [2.0, 2.0, 2.0] * [3.0, 3.0, 3.0] = [6.0, 6.0, 6.0]
>>> # step 2: [1, 1]

```

18.5.9 mindspore.ops.ScatterNdAdd

class mindspore.ops.**ScatterNdAdd**(*use_locking=False*)

Applies sparse addition to individual values or slices in a tensor.

Using given values to update tensor value through the add operation, along with the input indices. This operation outputs the *input_x* after the update is done, which makes it convenient to use the updated value.

Refer to *mindspore.ops.scatter_nd_add()* for more details.

Parameters

use_locking (*bool, optional*) – Whether to protect the assignment by a lock. Default: `False` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor. The shape is $(N, *)$ where $*$ means any number of additional dimensions.
- **indices** (Tensor) - The index to do add operation whose data type must be mindspore.int32. The rank of indices must be at least 2 and *indices.shape[-1] <= len(shape)*.
- **updates** (Tensor) - The tensor doing the add operation with *input_x*, the data type is same as *input_x*, the shape is *indices.shape[:-1] + x.shape[indices.shape[-1]:]*.

Outputs:

Tensor, the updated *input_x*, has the same shape and type as *input_x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, Parameter
>>> input_x = Parameter(Tensor(np.array([1, 2, 3, 4, 5, 6, 7, 8]), mindspore.float32), name=
 ↪"x")
>>> indices = Tensor(np.array([[2], [4], [1], [7]]), mindspore.int32)
>>> updates = Tensor(np.array([6, 7, 8, 9]), mindspore.float32)
>>> use_locking = False
>>> scatter_nd_add = ops.ScatterNdAdd(use_locking)
>>> output = scatter_nd_add(input_x, indices, updates)
>>> print(output)
[ 1. 10.  9.  4. 12.  6.  7. 17.]
>>> input_x = Parameter(Tensor(np.zeros((4, 4, 4)), mindspore.int32))
>>> indices = Tensor(np.array([[0], [2]]), mindspore.int32)
>>> updates = Tensor(np.array([[[1, 1, 1, 1], [2, 2, 2, 2], [3, 3, 3, 3], [4, 4, 4, 4]],
...                            [[5, 5, 5, 5], [6, 6, 6, 6], [7, 7, 7, 7], [8, 8, 8, 8]]]),␣
 ↪mindspore.int32)
>>> use_locking = False
>>> scatter_nd_add = ops.ScatterNdAdd(use_locking)
>>> output = scatter_nd_add(input_x, indices, updates)
>>> print(output)

  [0 0 0 0]]]
```

18.5.10 mindspore.ops.ScatterNdSub

class mindspore.ops.**ScatterNdSub**(*use_locking=False*)

Applies sparse subtraction to individual values or slices in a tensor.

Using given values to update tensor value through the subtraction operation, along with the input indices. This operation outputs the *input_x* after the update is done, which makes it convenient to use the updated value.

Refer to *mindspore.ops.scatter_nd_sub()* for more details.

Parameters

use_locking (*bool, optional*) – Whether to protect the assignment by a lock. Default: `False` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor. The shape is $(N, *)$ where $*$ means any number of additional dimensions.
- **indices** (Tensor) - The index to do sub operation whose data type must be mindspore.int32. The rank of indices must be at least 2 and *indices.shape[-1] <= len(shape)*.
- **updates** (Tensor) - The tensor doing the sub operation with *input_x*, the data type is same as *input_x*, the shape is *indices.shape[:-1] + x.shape[indices.shape[-1]:]*.

Outputs:

Tensor, the updated *input_x*, has the same shape and type as *input_x*.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops, Parameter
>>> input_x = Parameter(Tensor(np.array([1, 2, 3, 4, 5, 6, 7, 8]), mindspore.float32), name=
 ↪"x")
>>> indices = Tensor(np.array([[2], [4], [1], [7]]), mindspore.int32)

18.5.11 mindspore.ops.ScatterNdUpdate

class mindspore.ops.**ScatterNdUpdate**(*use_locking=True*)

Updates tensor values by using input indices and value.

Using given values to update tensor value, along with the input indices.

input_x has rank P and *indices* has rank Q where $Q >= 2$.

indices has shape $(i_0, i_1, ..., i_{Q-2}, N)$ where $N <= P$.

The last dimension of *indices* (with length N) indicates slices along the N th dimension of *input_x*.

updates is a tensor of rank $Q-1+P-N$, and its shape is: $(i_0, i_1, ..., i_{Q-2}, x\_shape_N, ..., x\_shape_{P-1})$.

Inputs of *input_x* and *updates* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Parameters

use_locking (*bool, optional*) – Whether to protect the assignment by a lock. Default: `True` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor. The shape is $(N, *)$ where $*$ means any number of additional dimensions.
- **indices** (Tensor) - The index of input tensor, with int32 or int64 data type.
- **updates** (Tensor) - N-D(2D or 3D) Tensor The tensor to be updated to the input tensor, has the same type as input. The shape is *indices.shape[:-1] + x.shape[indices.shape[-1]:]*.

Outputs:

Tensor, has the same shape and type as *input_x*.

Raises

- **TypeError** – If *use_locking* is not a bool.
- **TypeError** – If *indices* is not an int32 or an int64.
- **RuntimeError** – If the data type of *input_x* and *updates* conversion is required when data type conversion is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> np_x = np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]])
>>> input_x = mindspore.Parameter(Tensor(np_x, mindspore.float32), name="x")
>>> indices = Tensor(np.array([[0, 0], [1, 1]]), mindspore.int32)
>>> updates = Tensor(np.array([1.0, 2.2]), mindspore.float32)
>>> op = ops.ScatterNdUpdate()
>>> output = op(input_x, indices, updates)
>>> print(output)
[[1.   0.3   3.6]
 [0.4  2.2  -3.2]]
```

class mindspore.ops.**ScatterNonAliasingAdd**

Please use TensorScatterAdd instead.

Supported Platforms:

Deprecated

18.5.13 mindspore.ops.ScatterSub

class mindspore.ops.**ScatterSub**(*use_locking=False*)

Updates the value of the input tensor through the subtraction operation.

Using given values to update tensor value through the subtraction operation, along with the input indices. This operation outputs the *input_x* after the update is done, which makes it convenient to use the updated value.

for each $i, \cdots, j$ in *indices.shape*:

$$\text{input\_x}[\text{indices}[i, ..., j], :] \mathrel{-}= \text{updates}[i, ..., j, :]$$

Inputs of *input_x* and *updates* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Parameters

use_locking (*bool, optional*) – Whether to protect the assignment by a lock. Default: `False` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor. The shape is $(N, *)$ where $*$ means any number of additional dimensions.
- **indices** (Tensor) - The index to do min operation whose data type must be mindspore.int32 or mindspore.int64.
- **updates** (Tensor) - The tensor doing the min operation with *input_x*, the data type is same as *input_x*, the shape is *indices_shape* + *x_shape[1:]*.

Outputs:

Tensor, the updated *input_x*, has the same shape and type as *input_x*.

Raises

- **TypeError** – If *use_locking* is not a bool.
- **TypeError** – If *indices* is not an int32.
- **ValueError** – If the shape of *updates* is not equal to *indices_shape* + *x_shape[1:]*.
- **RuntimeError** – If the data type of *input_x* and *updates* conversion is required when data type conversion is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

18.5.14 mindspore.ops.ScatterUpdate

class mindspore.ops.**ScatterUpdate**(*use_locking=True*)

Updates tensor values by using input indices and value.

Using given values to update tensor value, along with the input indices.

for each $i, \cdots, j$ in *indices.shape*:

$$\text{input\_x}[\text{indices}[i, ..., j], :] = \text{updates}[i, ..., j, :]$$

Inputs of *input_x* and *updates* comply with the implicit type conversion rules to make the data types consistent. If they have different data types, the lower priority data type will be converted to the relatively highest priority data type.

Parameters

use_locking (*bool*) – Whether to protect the assignment by a lock. Default: `True` .

Inputs:

- **input_x** (Union[Parameter, Tensor]) - The target tensor, with data type of Parameter or Tensor. The shape is 0-D or $(N, *)$ where $*$ means any number of additional dimensions.
- **indices** (Tensor) - The index of input tensor. With int32 data type. If there are duplicates in indices, the order for updating is undefined.

- **updates** (Tensor) - The tensor to update the input tensor, has the same type as input, and updates.shape = indices.shape + input_x.shape[1:].

Outputs:

Tensor, has the same shape and type as *input_x*.

Raises

- **TypeError** –If *use_locking* is not a bool.
- **TypeError** –If *indices* is not an int32.
- **ValueError** –If the shape of *updates* is not equal to *indices.shape* + *input_x.shape[1:]*.
- **RuntimeError** –If the data type of *input_x* and *updates* conversion is required when data type conversion is not supported.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> np_x = np.array([[-0.1, 0.3, 3.6], [0.4, 0.5, -3.2]])
>>> input_x = mindspore.Parameter(Tensor(np_x, mindspore.float32), name="x")
>>> indices = Tensor(np.array([0, 1]), mindspore.int32)
>>> np_updates = np.array([[2.0, 1.2, 1.0], [3.0, 1.2, 1.0]])
>>> updates = Tensor(np_updates, mindspore.float32)
>>> op = ops.ScatterUpdate()
>>> output = op(input_x, indices, updates)
>>> print(output)
[[2. 1.2  1.]
 [3. 1.2  1.]]
```

18.6 Data Operation Operator

API Name	Description	Supported Platforms
mindspore.ops.GetNext	Returns the next element in the dataset queue.	`Ascend` `GPU`

18.6.1 mindspore.ops.GetNext

class mindspore.ops.**GetNext**(*types*, *shapes*, *output_num*, *shared_name*)

Returns the next element in the dataset queue.

Note: The GetNext operation needs to be associated with network and it also depends on the 'dataset' interface, For example, please refer to `mindspore.dataset.MnistDataset` . it can't be used directly as a single operation. For details, please refer to *mindspore.connect _network_with_dataset* source code.

Parameters

- **types** (list[*mindspore.dtype*]) –The type of the outputs.
- **shapes** (*list[tuple[int]]*) –The dimensionality of the outputs.
- **output_num** (*int*) –The output number, length of *types* and *shapes*.
- **shared_name** (*str*) –Queue name to fetch the data.

Inputs:

No inputs.

Outputs:

tuple[Tensor], the output of dataset. The shape is described in *shapes* and the type is described in *types*.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> from mindspore import ops
>>> from mindspore import dataset as ds
>>> from mindspore import dtype as mstype
>>> data_path = "/path/to/MNIST_Data/train/"
>>> train_dataset = ds.MnistDataset(data_path, num_samples=10)
>>> dataset_helper = mindspore.DatasetHelper(train_dataset, dataset_sink_mode=True)
>>> dataset = dataset_helper.iter.dataset
>>> dataset_types, dataset_shapes = dataset_helper.types_shapes()
>>> queue_name = dataset.__transfer_dataset__.queue_name
>>> get_next = ops.GetNext(dataset_types, dataset_shapes, len(dataset_types), queue_name)
>>> data, label = get_next()
>>> relu = ops.ReLU()
>>> result = relu(data.astype(mstype.float32))
>>> print(result.shape)
(28, 28, 1)
```

18.7 Communication Operator

Distributed training involves communication operations for data transfer. For more details, refer to Distributed Set Communication Primitives .

Note that the APIs in the following list need to preset communication environment variables. For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

API Name	Description	Supported Platforms
mindspore.ops.AllGather	Gathers tensors from the specified communication group and returns the tensor which is all gathered.	`Ascend` `GPU`
mindspore.ops.AllReduce	Reduces tensors across all devices in such a way that all devices will get the same final result, returns the tensor which is all reduced.	`Ascend` `GPU` `CPU`

continues on next page

Table 21 – continued from previous page

mindspore.ops.AlltoAll	AlltoAll is a collective operation.	Ascend
mindspore.ops.AlltoAllV	AllToAllV which support uneven scatter and gather compared with AllToAll.	Ascend
mindspore.ops.Barrier	Synchronizes all processes in the specified group.	Ascend
mindspore.ops.Broadcast	Broadcasts the tensor to the whole group.	Ascend GPU
mindspore.ops.CollectiveGather	Gathers tensors from the specified communication group.	Ascend
mindspore.ops.CollectiveScatter	Scatter input data evently across the processes in the specified communication group.	Ascend
mindspore.ops.NeighborExchangeV2	NeighborExchangeV2 is a collective communication operation.	Ascend
mindspore.ops.Receive	Receive tensors from src_rank.	Ascend GPU
mindspore.ops.ReduceOp	Operation options for reducing tensors.	Ascend GPU
mindspore.ops.ReduceScatter	Reduces and scatters tensors from the specified communication group and returns the tensor which is reduced and scattered.	Ascend GPU
mindspore.ops.Reduce	Reduces tensors across the processes in the specified communication group, sends the result to the target dest_rank(local rank), and returns the tensor which is sent to the target process.	Ascend
mindspore.ops.Send	Send tensors to the specified dest_rank.	Ascend GPU

18.7.1 mindspore.ops.AllGather

class mindspore.ops.**AllGather**(*group=GlobalComm.WORLD_COMM_GROUP*)

Gathers tensors from the specified communication group and returns the tensor which is all gathered.

Note:

- The tensors must have the same shape and format in all processes of the collection.

Parameters

group (*str, optional*) – The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`, which means `"hccl_world_group"` in Ascend, and `"nccl_world_group"` in GPU.

Inputs:

- **input_x** (Tensor) - The shape of tensor is $(x_1, x_2, ..., x_R)$.

Outputs:

Tensor. If the number of devices in the group is N, then the shape of output is $(N, x_1, x_2, ..., x_R)$.

Raises

- **TypeError** – If *group* is not a str.
- **ValueError** – If the local rank id of the calling process in the group is larger than the group's rank size.
- **RuntimeError** – If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend` `GPU`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import ops
>>> import mindspore.nn as nn
>>> from mindspore.communication import init
>>> from mindspore import Tensor
>>>
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> init()
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.allgather = ops.AllGather()
...
...     def construct(self, x):
...         return self.allgather(x)
...
>>> input_x = Tensor(np.ones([2, 8]).astype(np.float32))
>>> net = Net()
>>> output = net(input_x)
>>> print(output)
[[1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]
 [1. 1. 1. 1. 1. 1. 1. 1.]]
```

Tutorial Examples:

- Distributed Set Communication Primitives - AllGather

18.7.2 mindspore.ops.AllReduce

class mindspore.ops.**AllReduce**(*op=ReduceOp.SUM*, *group=GlobalComm.WORLD_COMM_GROUP*)

Reduces tensors across all devices in such a way that all devices will get the same final result, returns the tensor which is all reduced.

Note: The tensors must have the same shape and format in all processes of the collection.

Parameters

- **op** (*str, optional*) – Specifies an operation used for element-wise reductions, like sum, prod, max, and min. On the CPU, only 'sum' is supported. Default: `ReduceOp.SUM`.

- **group** (*str, optional*) –The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP` , which means `"hccl_world_group"` in Ascend, and `"nccl_world_group"` in GPU.

Inputs:

- **input_x** (Tensor) - The shape of tensor is $(x_1, x_2, ..., x_R)$.

Outputs:

Tensor, has the same shape of the input, i.e., $(x_1, x_2, ..., x_R)$. The contents depend on the specified operation.

Raises

- **TypeError** –If any of *op* and *group* is not a str or the input's dtype is bool.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> from mindspore.communication import init
>>> from mindspore import Tensor
>>> from mindspore.ops import ReduceOp
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>>
>>> init()
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.allreduce_sum = ops.AllReduce(ReduceOp.SUM)
...
...     def construct(self, x):
...         return self.allreduce_sum(x)
...
>>> input_ = Tensor(np.ones([2, 8]).astype(np.float32))
>>> net = Net()
>>> output = net(input_)
>>> print(output)
[[2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]]
```

Tutorial Examples:

- Distributed Set Communication Primitives - AllReduce

18.7.3 mindspore.ops.AlltoAll

class mindspore.ops.**AlltoAll**(*split_count*, *split_dim*, *concat_dim*, *group=GlobalComm.WORLD_COMM_GROUP*)

AlltoAll is a collective operation.

AlltoAll sends data from the all processes to the all processes in the specified group. It has two phases:

- The scatter phase: On each process, the operand is split into split_count number of blocks along the split_dimensions, and the blocks are scattered to all processes, e.g., the ith block is send to the ith process.
- The gather phase: Each process concatenates the received blocks along the concat_dimension.

Note: This operator requires a full-mesh network topology, each device has the same vlan id, and the ip & mask are in the same subnet, please check the details .

Parameters

- **split_count** (*int*) –On each process, divide blocks into split_count number.
- **split_dim** (*int*) –On each process, split blocks along the split_dim.
- **concat_dim** (*int*) –On each process, gather the received blocks along the concat_dimension.
- **group** (*str, optional*) –The communication group to work on. Default: GlobalComm.WORLD_COMM_GROUP .

Inputs:

- **input_x** (Tensor) - The shape of tensor is $(x_1, x_2, ..., x_R)$.

Outputs:

Tensor. If the shape of input tensor is $(x_1, x_2, ..., x_R)$, then the shape of output tensor is $(y_1, y_2, ..., y_R)$, where:

- $y_{split\_dim} = x_{split\_dim}/split\_count$
- $y_{concat\_dim} = x_{concat\_dim} * split\_count$
- $y_{other} = x_{other}$.

Raises

TypeError –If group is not a string.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 8 devices.

```
>>> import os
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> from mindspore.communication import init
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> import numpy as np
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.alltoall = ops.AlltoAll(split_count = 8, split_dim = -2, concat_dim = -1)
...
...     def construct(self, x):
...         out = self.alltoall(x)
...         return out
...
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> init()
>>> net = Net()
>>> rank_id = int(os.getenv("RANK_ID"))
>>> input_x = Tensor(np.ones([1, 1, 8, 1]) * rank_id, dtype = ms.float32)
>>> output = net(input_x)
>>> print(output)
[[[[0. 1. 2. 3. 4. 5. 6. 7.]]]]
```

Tutorial Examples:

- Distributed Set Communication Primitives - AlltoAll

18.7.4 mindspore.ops.AlltoAllV

class mindspore.ops.**AlltoAllV**(*group=GlobalComm.WORLD_COMM_GROUP*, *block_size=1*)

AllToAllV which support uneven scatter and gather compared with AllToAll.

Note:

- Only support flatten tensor as input. input tensor should be flattened and concatenated before call this primitive.

Parameters

- **group** (*str*, *optional*) – The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`, which means `"hccl_world_group"` in Ascend.
- **block_size** (*int*, *optional*) – The basic units for scatter and gather numel by *send_numel_list* and *recv_numel_list*. Default: `1`.

Inputs:

- **input_x** (Tensor) - flatten tensor to scatter. The shape of tensor is (x_1).
- **send_numel_list** (Union[tuple[int], list[int], Tensor]) - split numel to scatter to different remote rank. The actual distributed data numel is $(send_numel_list * block_size * input_x.dtype)$.
- **recv_numel_list** (Union[tuple[int], list[int], Tensor]) - split numel to gather from different remote rank. The actual aggregated data numel is $(recv_numel_list * block_size * input_x.dtype)$.

Outputs:

Tensor, flattened and concatenated tensor gather from remote ranks. If gather result is empty, it will return a Tensor with shape *()*, and value has no actual meaning.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies.

Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> from mindspore import ops
>>> import mindspore.nn as nn
>>> from mindspore.communication import init, get_rank
>>> from mindspore import Tensor
>>>
>>> init()
>>> rank = get_rank()
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.all_to_all = ops.AlltoAllV()
...
...     def construct(self, x, send_numel_list, recv_numel_list):
...         return self.all_to_all(x, send_numel_list, recv_numel_list)
>>> send_numel_list = []
>>> recv_numel_list = []
>>> if rank == 0:
...     send_tensor = Tensor([0, 1, 2.])
...     send_numel_list = [1, 2]
...     recv_numel_list = [1, 2]
>>> elif rank == 1:
...     send_tensor = Tensor([3, 4, 5.])
...     send_numel_list = [2, 1]
...     recv_numel_list = [2, 1]
>>> net = Net()
>>> output = net(send_tensor, send_numel_list, recv_numel_list)
>>> print(output)
rank 0:
[0. 3. 4]
rank 1:
[1. 2. 5]
```

18.7.5 mindspore.ops.Barrier

class mindspore.ops.**Barrier**(*group=GlobalComm.WORLD_COMM_GROUP*)

Synchronizes all processes in the specified group. Once the process call this operation, it will be blocked until all processes call this operation. After all processes finish calling the operations, the blocked processes will be waken and continue their task.

Parameters

group (*str, optional*) – The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`.

Raises

- **TypeError** – If *group* is not a str.
- **RuntimeError** – If backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore.nn as nn
>>> from mindspore.communication import init
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> # Launch 4 processes.
>>> init()
>>> class BarrierNet(nn.Cell):
...     def __init__(self):
...         super(BarrierNet, self).__init__()
...         self.barrier = ops.Barrier()
...
...     def construct(self):
...         self.barrier()
>>> net = BarrierNet()
>>> net()
```

Tutorial Examples:

- Distributed Set Communication Primitives - Barrier

18.7.6 mindspore.ops.Broadcast

class mindspore.ops.**Broadcast**(*root_rank*, *group=GlobalComm.WORLD_COMM_GROUP*)

Broadcasts the tensor to the whole group.

Note: The tensors must have the same shape and format in all processes of the collection.

Parameters

- **root_rank** (*int*) –Specifies the rank(global rank) of the process that broadcast the tensor. And only process *root_rank* will broadcast the tensor.
- **group** (*str*, *optional*) –The communication group to work on. Default: GlobalComm.WORLD_COMM_GROUP .

Inputs:

- **input_x** (Tensor) - The shape of tensor is $(x_1, x_2, ..., x_R)$.

Outputs:

tuple[Tensor], Tensor has the same shape of the input, i.e., $(x_1, x_2, ..., x_R)$. The contents depend on the data of the *root_rank* device.

Raises

TypeError –If root_rank is not an integer or group is not a string.

Supported Platforms:

Ascend GPU

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> from mindspore.communication import init
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> import numpy as np
>>>
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> init()
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.broadcast = ops.Broadcast(1)
```

(continues on next page)

(continued from previous page)

```
...
...     def construct(self, x):
...         return self.broadcast((x,))
...
>>> input_x = Tensor(np.ones([2, 4]).astype(np.int32))
>>> net = Net()
>>> output = net(input_x)
>>> print(output)
(Tensor(shape[2,4], dtype=Int32, value=
[[1, 1, 1, 1],
 [1, 1, 1, 1]]),)
```

Tutorial Examples:

- Distributed Set Communication Primitives - Broadcast

18.7.7 mindspore.ops.CollectiveGather

class mindspore.ops.**CollectiveGather**(*dest_rank*, *group=GlobalComm.WORLD_COMM_GROUP*)

Gathers tensors from the specified communication group. The operation will gather the tensor from processes according to dimension 0.

Note: Only the tensor in process *dest_rank* (global rank) will keep the gathered tensor. The other process will keep a tensor with shape [1], which has no mathematical meaning.

Parameters

- **dest_rank** (*int*) –Specifies the rank of the process that receive the tensor. And only process *dest_rank* will receive the gathered tensor.
- **group** (*str, optional*) –The communication group to work on. Default: GlobalComm.WORLD_COMM_GROUP.

Inputs:

- **input_x** (Tensor) - The tensor to be gathered. The shape of tensor is $(x_1, x_2, ..., x_R)$.

Outputs:

Tensor, the shape of output is $(\sum x_1, x_2, ..., x_R)$. The dimension 0 of data is equal to sum of the dimension of input tensor, and the other dimension keep the same.

Raises

- **TypeError** –If *group* is not a str.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.
- **ValueError** –If the local rank id of the calling process in the group is larger than the group's rank size.

Supported Platforms:

Ascend

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 4 devices.

```
>>> import numpy as np
>>> import mindspore as ms
>>> import mindspore.nn as nn
>>> from mindspore.communication import init
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> # Launch 2 processes.
>>>
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> init()
>>> class CollectiveGatherNet(nn.Cell):
...     def __init__(self):
...         super(CollectiveGatherNet, self).__init__()
...         self.collective_gather = ops.CollectiveGather(dest_rank=0)
...
...     def construct(self, x):
...         return self.collective_gather(x)
...
>>> input = Tensor(np.arange(4).reshape([2, 2]).astype(np.float32))
>>> net = CollectiveGatherNet()
>>> output = net(input)
>>> print(output)
Process with rank 0: [[0. 1.],
                      [2. 3.],
                      [0. 1.],
                      [2. 3.]]
Process with rank 1: [0.]
```

Tutorial Examples:

- Distributed Set Communication Primitives - CollectiveGather

18.7.8 mindspore.ops.CollectiveScatter

class mindspore.ops.**CollectiveScatter**(*src_rank=0*, *group=GlobalComm.WORLD_COMM_GROUP*)

Scatter input data evently across the processes in the specified communication group.

Note: The interface behavior only support Tensor input and scatter evenly. Only the tensor in process *src_rank* (global rank) will do scatter.

Parameters

- **src_rank** (*int, optional*) – Specifies the rank of the process that send the tensor. And only process *src_rank* will send the tensor.

- **group** (*str, optional*) –The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`.

Inputs:

- **input_x** (Tensor) - The input tensor to be scattered. The shape of tensor is $(x_1, x_2, ..., x_R)$.

Outputs:

Tensor, the shape of output is $(x_1/src\_rank, x_2, ..., x_R)$. The dimension 0 of data is equal to the dimension of input tensor divided by *src*, and the other dimension keep the same.

Raises

- **TypeError** –If *group* is not a str.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.
- **ValueError** –If the local rank id of the calling process in the group is larger than the group's rank size.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore.nn as nn
>>> from mindspore import Tensor
>>> from mindspore.communication.management import init, get_rank
>>> from mindspore import ops
>>> # Launch 2 processes.
>>> init()
>>> class CollectiveScatterNet(nn.Cell):
...     def __init__(self):
...         super(CollectiveScatterNet, self).__init__()
...         self.collective_scatter = ops.CollectiveScatter(src_rank=0)
...
...     def construct(self, x):
...         return self.collective_scatter(x)
...
>>> input = Tensor(np.arange(8).reshape([4, 2]).astype(np.float32))
>>> net = CollectiveScatterNet()
>>> output = net(input)
>>> print(output)
Process with rank 0: [[0. 1.],
                      [2. 3.]]
Process with rank 1: [[4. 5.],
                      [6. 7.]]
```

Tutorial Examples:

- Distributed Set Communication Primitives - CollectiveScatter

18.7.9 mindspore.ops.NeighborExchangeV2

class mindspore.ops.**NeighborExchangeV2**(*send_rank_ids*, *send_lens*, *recv_rank_ids*, *recv_lens*, *data_format*, *group=GlobalComm.WORLD_COMM_GROUP*)

NeighborExchangeV2 is a collective communication operation.

NeighborExchangeV2 sends data from the local rank to ranks in the *send_rank_ids*, as while receive data from *recv_rank_ids*. Please refer to the tutorial examples below to learn about how the data is exchanged between neighborhood devices.

Note: This operator requires a full-mesh network topology, each device has the same vlan id, and the ip & mask are in the same subnet, please check the details .

Users need to ensure that the length of the received data *recv_lens* is consistent with that of the sent data *send_lens*.

Parameters

- **send_rank_ids** (*list(int)*) −Ranks which the data is sent to. 8 rank_ids represents 8 directions, if one direction is not send to , set it -1.
- **recv_rank_ids** (*list(int)*) −Ranks which the data is received from. 8 rank_ids represents 8 directions, if one direction is not recv from , set it -1.
- **send_lens** (*list(int)*) −Data lens which send to the send_rank_ids, 4 numbers represent the lens of [send_top, send_bottom, send_left, send_right].
- **recv_lens** (*list(int)*) −Data lens which received from recv_rank_ids, 4 numbers represent the lens of [recv_top, recv_bottom, recv_left, recv_right].
- **data_format** (*str*) −Data format, only support NCHW now.
- **group** (*str, optional*) −The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP` , which means `"hccl_world_group"` in Ascend, and `"nccl_world_group"` in GPU.

Inputs:

- **input_x** (Tensor) - The Tensor before being exchanged. It has a shape of (N, C, H, W).

Outputs:

The Tensor after being exchanged. If input shape is (N, C, H, W), output shape is $(N, C, H + recv\_top + recv\_bottom, W + recv\_left + recv\_right)$.

Raises

- **TypeError** −If *group* is not a string or any one of *send_rank_ids*, *recv_rank_ids*, *send_lens*, *recv_lens* is not a list.
- **ValueError** −If *send_rank_ids* or *recv_rank_ids* has value less than -1 or has repeated values.
- **ValueError** −If *send_lens*, *recv_lens* has value less than 0.
- **ValueError** −If *data_format* is not "NCHW".

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

18.7.10 mindspore.ops.Receive

class mindspore.ops.**Receive**(*sr_tag*, *src_rank*, *shape*, *dtype*, *group=GlobalComm.WORLD_COMM_GROUP*, *group_back=GlobalComm.WORLD_COMM_GROUP*)

Receive tensors from src_rank.

Note: Send and Receive must be used in combination and have same *sr_tag*.

Parameters

- **sr_tag** (*int*) – A required integer identifying the send/recv message tag. This operator will receive the tensor sent by the Send operator with the same *sr_tag* tag.
- **src_rank** (*int*) – A required integer identifying the source rank.
- **shape** (*list[int]*) – A required list identifying the shape of the tensor to be received.
- **dtype** (*Type*) – A required Type identifying the type of the tensor to be received. The supported types: int8/int16/int32/float16/float32.
- **group** (*str, optional*) – The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`.
- **group_back** (*str, optional*) – The communication group for backpropagation. Default: `GlobalComm.WORLD_COMM_GROUP`.

Outputs:

Tensor, output has the same shape as the Tensor sent by *Send* operation.

Raises

- **TypeError** – If *src_rank* is not an int or *group* is not a str.
- **RuntimeError** – If device target is invalid, or backend is invalid, or distributed initialization fails.
- **ValueError** – If the local rank id of the calling process in the group is larger than the group's rank size.

Supported Platforms:

`Ascend` `GPU`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

...         print(output.asnumpy())
```

Tutorial Examples:

- Distributed Set Communication Primitives - Receive

18.7.11 mindspore.ops.ReduceOp

class mindspore.ops.**ReduceOp**

Operation options for reducing tensors. This is an enumerated type, not an operator.

The main calling methods are as follows:

- SUM: ReduceOp.SUM.
- MAX: ReduceOp.MAX.
- MIN: ReduceOp.MIN.
- PROD: ReduceOp.PROD.

There are four kinds of operation options, "SUM", "MAX", "MIN", and "PROD".

- SUM: Take the sum.
- MAX: Take the maximum.
- MIN: Take the minimum.
- PROD: Take the product.

Supported Platforms:

`Ascend` `GPU`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 2 devices.

```
>>> import numpy as np
>>> import mindspore
>>> from mindspore.communication import init
>>> from mindspore import Tensor, ops, nn
>>> from mindspore.ops import ReduceOp
>>>
>>> init()
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.allreduce_sum = ops.AllReduce(ReduceOp.SUM)
...
...     def construct(self, x):
...         return self.allreduce_sum(x)
...
>>> input_ = Tensor(np.ones([2, 8]).astype(np.float32))
>>> net = Net()
>>> output = net(input_)
>>> print(output)
[[2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]]
```

18.7.12 mindspore.ops.ReduceScatter

class mindspore.ops.**ReduceScatter**(*op=ReduceOp.SUM*, *group=GlobalComm.WORLD_COMM_GROUP*)

Reduces and scatters tensors from the specified communication group and returns the tensor which is reduced and scattered.

Note: The tensors must have the same shape and format in all processes of the collection.

Parameters

- **op** (*str, optional*) – Specifies an operation used for element-wise reductions, like SUM and MAX. Default: `ReduceOp.SUM`.
- **group** (*str, optional*) – The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`.

Inputs:

- **input_x** (Tensor) - Input Tensor, suppose it has a shape $(N, *)$, where * means any number of additional dimensions. N must be divisible by rank_size. rank_size refers to the number of cards in the communication group.

Outputs:

Tensor, it has the same dtype as *input_x* with a shape of $(N/rank\_size, *)$.

Raises

- **TypeError** – If any of operation and group is not a string.
- **ValueError** – If the first dimension of the input cannot be divided by the rank_size.
- **RuntimeError** – If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend` `GPU`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> init()
```

(continues on next page)

(continued from previous page)

```
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.reducescatter = ops.ReduceScatter(ReduceOp.SUM)
...
...     def construct(self, x):
...         return self.reducescatter(x)
...
>>> input_ = Tensor(np.ones([8, 8]).astype(np.float32))
>>> net = Net()
>>> output = net(input_)
>>> print(output)
[[2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]
 [2. 2. 2. 2. 2. 2. 2. 2.]]
```

Tutorial Examples:

- Distributed Set Communication Primitives - ReduceScatter

18.7.13 mindspore.ops.Reduce

class mindspore.ops.**Reduce**(*dest_rank*, *op=ReduceOp.SUM*, *group=GlobalComm.WORLD_COMM_GROUP*)

Reduces tensors across the processes in the specified communication group, sends the result to the target dest_rank(local rank), and returns the tensor which is sent to the target process.

Note: Only process with destination rank receives the reduced output. Support PyNative mode and Graph mode, but Graph mode only supports scenes with a graph compilation level of O0. Other processes only get a tensor with shape [1], which has no mathematical meaning.

Parameters

- **dest_rank** (*int*) –The target process(local rank) in the specific group that receives the reduced output.
- **op** (*str, optional*) –Specifies an operation used for element-wise reductions, like sum, prod, max, and min. On the CPU, only 'sum' is supported. Default: `ReduceOp.SUM`.
- **group** (*str, optional*) –The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`, which means `"hccl_world_group"` in Ascend, and `"nccl_world_group"` in GPU.

Inputs:

- **input_x** (Tensor) - The shape of tensor is $(x_1, x_2, ..., x_R)$.

Outputs:

Tensor. Return the tensor in the specific rank of the process after reduction. The shape of tensor is $(x_1, x_2, ..., x_R)$.

Raises

- **TypeError** –If the type of the first input parameter is not Tensor, or any of *op* and *group* is not a str.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.

Supported Platforms:

`Ascend`

Examples

Note: Before running the following examples, you need to configure the communication environment variables.

For Ascend/GPU/CPU devices, it is recommended to use the msrun startup method without any third-party or configuration file dependencies. Please see the msrun start up for more details.

This example should be run with 4 devices.

```
>>> from mindspore import ops
>>> import mindspore.nn as nn
>>> from mindspore.communication import init
>>> from mindspore import Tensor
>>> import numpy as np
>>> # Launch 4 processes.
>>> init()
>>> class ReduceNet(nn.Cell):
...     def __init__(self):
...         super(ReduceNet, self).__init__()
...         self.reduce = ops.Reduce(dest_rank=1)
...
...     def construct(self, x):
...         out = self.reduce(x)
...         return out
>>> input = Tensor(np.ones([2, 8]).astype(np.float32))
>>> net = ReduceNet()
>>> output = net(input)
>>> print(output)
Process with rank 1: [[4. 4. 4. 4. 4. 4. 4. 4.]
                      [4. 4. 4. 4. 4. 4. 4. 4.]],
Other proesses: [0.].
```

18.7.14 mindspore.ops.Send

class mindspore.ops.**Send**(*sr_tag*, *dest_rank*, *group=GlobalComm.WORLD_COMM_GROUP*, *group_back=GlobalComm.WORLD_COMM_GROUP*)

Send tensors to the specified dest_rank.

Note: Send and Receive must be used in combination and have same *sr_tag*.

Parameters

- **sr_tag** (*int*) – The tag to identify the send/recv message. The message sent by this operator will be received by the Receive op with the same "sr_tag".
- **dest_rank** (*int*) – A required integer identifying the destination rank.
- **group** (*str*, *optional*) – The communication group to work on. Default: `GlobalComm.WORLD_COMM_GROUP`.

- **group_back** (*str, optional*) –The communication group for backpropagation. Default: `GlobalComm.WORLD_COMM_GROUP`.

Inputs:

- **input_x** (Tensor) - The shape of tensor is $(x_1, x_2, ..., x_R)$.

Raises

- **TypeError** –If *group* is not a str.
- **RuntimeError** –If device target is invalid, or backend is invalid, or distributed initialization fails.
- **ValueError** –If the local rank id of the calling process in the group is larger than the group's rank size.

Supported Platforms:

`Ascend` `GPU`

18.8 Debugging Operator

API Name	Description	Supported Platforms
mindspore.ops.HistogramSummary	This operator will calculate the histogram of a tensor and put it to a summary file with protocol buffer format.	Ascend GPU CPU
mindspore.ops.ImageSummary	This operator will put an image tensor to a summary file with protocol buffer format.	Ascend GPU CPU
mindspore.ops.ScalarSummary	This operator will put a scalar to a summary file with protocol buffer format.	Ascend GPU CPU
mindspore.ops.TensorSummary	This operator will put a tensor to a summary file with protocol buffer format.	Ascend GPU CPU
mindspore.ops.TensorDump	Save the Tensor as an npy file in numpy format.	Ascend
mindspore.ops.Print	Print the inputs to stdout.	Ascend GPU CPU
mindspore.ops.NPUAllocFloatStatus	Allocates a flag to store the overflow status.	Ascend
mindspore.ops.NPUClearFloatStatus	Clears the flag which stores the overflow status.	Ascend
mindspore.ops.NPUGetFloatStatus	*mindspore.ops.NPUGetFloatStatus* updates the flag which is the output tensor of *mindspore.ops.NPUAllocFloatStatus* with the latest overflow status.	Ascend

18.8.1 mindspore.ops.HistogramSummary

class mindspore.ops.**HistogramSummary**

This operator will calculate the histogram of a tensor and put it to a summary file with protocol buffer format. It must be used with SummaryRecord or SummaryCollector, which specify the directory of the summary file. In Ascend platform with graph mode, the environment variables *MS_DUMP_SLICE_SIZE* and *MS_DUMP_WAIT_TIME* can be set to solve operator execution failure when calling this operator intensively.

Inputs:

- **name** (str) - The name of the input variable.

- **value** (Tensor) - The value of tensor, and the rank of tensor must be greater than 0.

Raises

- **TypeError** – If *name* is not a str.
- **TypeError** – If *value* is not a Tensor.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> from mindspore import Tensor, set_context
>>>
>>>
>>> class SummaryDemo(nn.Cell):
...     def __init__(self,):
...         super(SummaryDemo, self).__init__()
...         self.summary = ops.HistogramSummary()
...         self.add = ops.Add()
...
...     def construct(self, x, y):
...         x = self.add(x, y)
...         name = "x"
...         self.summary(name, x)
...         return x
>>> set_context(mode=mindspore.GRAPH_MODE)
>>> summary = SummaryDemo()(Tensor([1, 2]), Tensor([3, 4]))
>>> print(summary)
[4 6]
```

18.8.2 mindspore.ops.ImageSummary

class mindspore.ops.**ImageSummary**

This operator will put an image tensor to a summary file with protocol buffer format. It must be used with SummaryRecord or SummaryCollector, which specify the directory of the summary file. In Ascend platform with graph mode, the environment variables *MS_DUMP_SLICE_SIZE* and *MS_DUMP_WAIT_TIME* can be set to solve execution failure when calling this operator intensively.

Inputs:

- **name** (str) - The name of the input variable, it must not be an empty string.
- **value** (Tensor) - The value of image, the rank of tensor must be 4.

Raises

- **TypeError** – If *name* is not a str.
- **TypeError** – If *value* is not a Tensor.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>>
>>>
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.summary = ops.ImageSummary()
...
...     def construct(self, x):
...         name = "image"
...         self.summary(name, x)
...         return x
...
```

18.8.3 mindspore.ops.ScalarSummary

class mindspore.ops.**ScalarSummary**

This operator will put a scalar to a summary file with protocol buffer format. It must be used with *mindspore.SummaryRecord* or *mindspore.SummaryCollector*, which specify the directory of the summary file. In Ascend platform with graph mode, the environment variables *MS_DUMP_SLICE_SIZE* and *MS_DUMP_WAIT_TIME* can be set to solve operator execution failure when calling this operator intensively.

Inputs:

- **name** (str) - The name of the input variable, it must not be an empty string.
- **value** (Tensor) - The value of scalar, and the dim of *value* must be 0 or 1.

Raises

- **TypeError** – If *name* is not a str.
- **TypeError** – If *value* is not a Tensor.
- **ValueError** – If dim of *value* is greater than 1.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> from mindspore import Tensor, set_context
>>>
>>>
>>> class SummaryDemo(nn.Cell):
...     def __init__(self,):
```

(continues on next page)

(continued from previous page)

```
...         super(SummaryDemo, self).__init__()
...         self.summary = ops.ScalarSummary()
...         self.add = ops.Add()
...
...     def construct(self, x, y):
...         name = "x"
...         self.summary(name, x)
...         x = self.add(x, y)
...         return x
>>> set_context(mode=mindspore.GRAPH_MODE)
>>> summary = SummaryDemo()(Tensor(3), Tensor(4))
>>> print(summary)
7
```

18.8.4 mindspore.ops.TensorSummary

class mindspore.ops.**TensorSummary**

This operator will put a tensor to a summary file with protocol buffer format. It must be used with SummaryRecord or SummaryCollector, which specify the directory of the summary file. In Ascend platform with graph mode, the environment variables *MS_DUMP_SLICE_SIZE* and *MS_DUMP_WAIT_TIME* can be set to solve operator execution failure when calling this operator intensively.

Inputs:

- **name** (str) - The name of the input variable.
- **value** (Tensor) - The value of tensor, and the rank of tensor must be greater than 0.

Raises

- **TypeError** – If *name* is not a str.
- **TypeError** – If *value* is not a Tensor.
- **ValueError** – If rank of *value* is 0.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> from mindspore import Tensor, set_context
>>>
>>>
>>> class SummaryDemo(nn.Cell):
...     def __init__(self,):
...         super(SummaryDemo, self).__init__()
...         self.summary = ops.TensorSummary()
...         self.add = ops.Add()
...
...     def construct(self, x, y):
```

(continues on next page)

(continued from previous page)

```
...         x = self.add(x, y)
...         name = "x"
...         self.summary(name, x)
...         return x
>>> set_context(mode=mindspore.GRAPH_MODE)
>>> summary = SummaryDemo()(Tensor([[1]]), Tensor([[2]]))
>>> print(summary)
[[3]]
```

18.8.5 mindspore.ops.TensorDump

class mindspore.ops.**TensorDump**(*input_output='out'*)

Save the Tensor as an npy file in numpy format.

> **Warning:** The parameter input_output will no longer support the value 'all'.

Note: In Ascend platform with graph mode, the environment variables *MS_DUMP_SLICE_SIZE* and *MS_DUMP_WAIT_TIME* can be set to solve operator execution failure when outputting big tensor or outputting tensor intensively.

Parameters

input_output (*str, optional*) – Used to control Tensordump behavior. Available value is one of ['in', 'out']. Default value is `out`.

In case of OpA –> RedistributionOps –> OpB, The dump data of OpA's output is not equal to OpB's input (Due to the redistribution operators). So the parameter input_output is to handle this situation.

Assuming OpA's output is used as both Tensordump's input parameter and OpB's input parameter. Different requirements of saving dump data can be achieved by configuring parameter input_output:

- If the input_output is 'out', the dump data contains only OpA's output slice.
- If the input_output is 'in', the dump data contains only OpB's input slice.

For input_output is 'in', the input slice npy file format is: fileName_dumpMode_dtype_id.npy.

For input_output is 'out', the output slice npy file format is: fileName_dtype_id.npy.

- fileName: Value of the parameter file (if parameter file_name is a user-specified path, the value of fileName is the last level of the path).
- dumpMode: Value of the parameter input_output.
- dtype: The original data type. Data of type bfloat16 stored in the .npy file will be converted to float32.
- id: An auto increment ID.

Inputs:

- **file** (str) - The path of the file to be saved.
- **input_x** (Tensor) - Input Tensor of any dimension.

Raises

- **TypeError** – If *file* is not a str.
- **TypeError** – If *input_x* is not a Tensor.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> import time
>>> from mindspore import nn, Tensor, ops
>>> ms.set_context(mode=ms.GRAPH_MODE)
>>> ms.set_device(device_target="Ascend")
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.dump = ops.TensorDump()
...
...     def construct(self, x):
...         x += 1.
...         self.dump('add', x)
...         x /= 2.
...         self.dump('div', x)
...         x *= 5.
...         self.dump('mul', x)
...         return x
...
>>> x = np.array([[1, 2, 3, 4], [5, 6, 7, 8]]).astype(np.float32)
>>> input_x = Tensor(x)
>>> net = Net()
>>> out = net(input_x)
>>> time.sleep(0.5)
>>> add = np.load('add_float32_0.npy')
>>> print(add)
[[2. 3. 4. 5.]
 [6. 7. 8. 9.]]
```

18.8.6 mindspore.ops.Print

class mindspore.ops.**Print**

Print the inputs to stdout.

Refer to *mindspore.ops.print_()* for more detail.

Inputs:

- **input_x** (Union[Tensor, bool, int, float, str]) - The graph node to attach to. Supports multiple inputs which are separated by ','.

Outputs:

Tensor, has the same data type and shape as original *input_x*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, nn, ops
>>> class PrintDemo(nn.Cell):
...     def __init__(self):
...         super(PrintDemo, self).__init__()
...         self.print = ops.Print()
...
...     def construct(self, x, y):
...         self.print('Print Tensor x and Tensor y:', x, y)
...         return x
...
>>> x = Tensor(np.ones([2, 1]).astype(np.int32))
>>> y = Tensor(np.ones([2, 2]).astype(np.int32))
>>> net = PrintDemo()
>>> result = net(x, y)
Print Tensor x and Tensor y:
Tensor(shape=[2, 1], dtype=Int32, value=
[[1],
 [1]])
Tensor(shape=[2, 2], dtype=Int32, value=
[[1, 1],
 [1, 1]])
```

18.8.7 mindspore.ops.NPUAllocFloatStatus

class mindspore.ops.**NPUAllocFloatStatus**

Allocates a flag to store the overflow status.

The flag is a tensor whose shape is $(8,)$ and data type is *mindspore.dtype.float32*.

Note: Please refer to the Examples of *mindspore.ops.NPUGetFloatStatus*.

Outputs:

Tensor, has the shape of $(8,)$.

Supported Platforms:

Ascend

Examples

```
>>> from mindspore import ops
>>> alloc_status = ops.NPUAllocFloatStatus()
>>> output = alloc_status()
>>> print(output)
[0. 0. 0. 0. 0. 0. 0. 0.]
```

18.8.8 mindspore.ops.NPUClearFloatStatus

class mindspore.ops.**NPUClearFloatStatus**

Clears the flag which stores the overflow status.

Note: The flag is in the register on the *Ascend* device. It will be reset and can not be reused again after the *NPUClearFloatStatus* is called. In addition, there are strict sequencing requirements for use, i.e., before using the NPUGetFloatStatus operator, need to ensure that the NPUClearFlotStatus and your compute has been executed. We use *mindspore.ops.Depend* on ensure the execution order.

Please refer to the Examples of *mindspore.ops.NPUGetFloatStatus*.

Inputs:

- **x** (Tensor) - The output tensor of *NPUAllocFloatStatus*. The data type must be float16 or float32.

Outputs:

Tensor, has the same shape as *x*. All the elements in the tensor will be zero.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor
>>> class Net(nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.alloc_status = ops.NPUAllocFloatStatus()
...         self.get_status = ops.NPUGetFloatStatus()
...         self.clear_status = ops.NPUClearFloatStatus()
...         self.sub = ops.Sub()
...         self.neg = ops.Neg()
...
...     def construct(self, x):
...         init = self.alloc_status()
...         clear_status = self.clear_status(init)
...         x = ops.depend(x, clear_status)
...         res = self.sub(x, self.neg(x))
...         init = ops.depend(init, res)
```

(continues on next page)

(continued from previous page)

```
...         get_status = self.get_status(init)
...         res = ops.depend(res, get_status)
...         return res
>>>
>>> value = 5
>>> data = np.full((2, 3), value, dtype=np.float16)
>>> x = Tensor(data, dtype=mstype.float16)
>>> net = Net()
>>> res = net(x)
>>> print(res)
[[10. 10. 10.]
 [10. 10. 10.]]
```

18.8.9 mindspore.ops.NPUGetFloatStatus

class mindspore.ops.**NPUGetFloatStatus**

mindspore.ops.NPUGetFloatStatus updates the flag which is the output tensor of *mindspore.ops.NPUAllocFloatStatus* with the latest overflow status.

Note: The flag is a tensor whose shape is $(8,)$ and data type is *mindspore.dtype.float32*. If the sum of the flag equals to 0, there is no overflow happened. If the sum of the flag is bigger than 0, there is overflow happened. In addition, there are strict sequencing requirements for use, i.e., before using the NPUGetFloatStatus operator, need to ensure that the NPUClearFlotStatus and your compute has been executed. We use *mindspore.ops.Depend* to ensure the correct execution order.

Inputs:

- **x** (Tensor) - The output tensor of *NPUAllocFloatStatus*. The data type must be float16 or float32. $(N, *)$ where $*$ means, any number of additional dimensions, its rank should be less than 8.

Outputs:

Tensor, has the same shape as *x*.

Raises

- **TypeError** – If *x* is not a Tensor.
- **TypeError** – If dtype of *x* is neither float16 nor float32.

Supported Platforms:

`Ascend`

Examples

```
>>> import numpy as np
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor
>>> class Net(nn.Cell):
...     def __init__(self):
```

(continues on next page)

(continued from previous page)

```
...         super().__init__()
...         self.alloc_status = ops.NPUAllocFloatStatus()
...         self.get_status = ops.NPUGetFloatStatus()
...         self.clear_status = ops.NPUClearFloatStatus()
...         self.sub = ops.Sub()
...         self.neg = ops.Neg()
...
...     def construct(self, x):
...         init = self.alloc_status()
...         clear_status = self.clear_status(init)
...         x = ops.depend(x, clear_status)
...         res = self.sub(x, self.neg(x))
...         init = ops.depend(init, res)
...         get_status = self.get_status(init)
...         res = ops.depend(res, get_status)
...         return res
>>>
>>> value = 5
>>> data = np.full((2, 3), value, dtype=np.float16)
>>> x = Tensor(data, dtype=mstype.float16)
>>> net = Net()
>>> res = net(x)
>>> print(res)
[[10. 10. 10.]
 [10. 10. 10.]]
```

18.9 Sparse Operator

API Name	Description	Supported Platforms
mindspore.ops.SparseTensorDenseMatmul	Multiplies sparse matrix *A* by dense matrix *B*.	GPU CPU
mindspore.ops.SparseToDense	Converts a sparse representation into a dense tensor.	CPU

18.9.1 mindspore.ops.SparseTensorDenseMatmul

class mindspore.ops.**SparseTensorDenseMatmul**(*adjoint_st=False*, *adjoint_dt=False*)

Multiplies sparse matrix *A* by dense matrix *B*. The rank of sparse matrix and dense matrix must be equal to *2*.

Parameters

- **adjoint_st** (*bool*) –If `True` , sparse tensor is transposed before multiplication. Default: `False` .
- **adjoint_dt** (*bool*) –If `True` , dense tensor is transposed before multiplication. Default: `False` .

Inputs:

- **indices** (Tensor) - A 2-D Tensor, represents the position of the element in the sparse tensor. Support int32, int64, each element value should be a non-negative int number. The shape is $(n, 2)$.
- **values** (Tensor) - A 1-D Tensor, represents the value corresponding to the position in the *indices*. Support float16, float32, float64, int32, int64, complex64, complex128. The shape should be $(n,)$.

- **sparse_shape** (tuple(int) or (Tensor)) - A positive int tuple or tensor which specifies the shape of sparse tensor, and only constant value is allowed when sparse_shape is a tensor, should have 2 elements, represent sparse tensor shape is (N, C).
- **dense** (Tensor) - A 2-D Tensor, the dtype is same as *values*. If *adjoint_st* is False and *adjoint_dt* is False, the shape must be (C, M). If *adjoint_st* is False and *adjoint_dt* is True, the shape must be (M, C). If *adjoint_st* is True and *adjoint_dt* is False, the shape must be (N, M). If *adjoint_st* is True and *adjoint_dt* is True, the shape must be (M, N).

Outputs:

Tensor, the dtype is the same as *values*. If *adjoint_st* is False, the shape is (N, M). If *adjoint_st* is True, the shape is (C, M).

Raises

- **TypeError** –If the type of *adjoint_st* or *adjoint_dt* is not bool, or the dtype of *indices*, dtype of *values* and dtype of *dense* don't meet the parameter description.
- **ValueError** –If the shapes of *sparse_shape*, *indices*, *values*, and *dense* don't meet the constraints in the parameter description.

Supported Platforms:

GPU CPU

Examples

```
>>> import mindspore
>>> from mindspore import Tensor
>>> from mindspore.ops import operations as ops
>>> from mindspore import dtype as mstype
>>> indices = Tensor([[0, 1], [1, 2]], dtype=mindspore.int32)
>>> values = Tensor([1, 2], dtype=mindspore.float32)
>>> sparse_shape = (3, 4)
>>> dense = Tensor([[1, 1], [2, 2], [3, 3], [4, 4]], dtype=mindspore.float32)
>>> sparse_dense_matmul = ops.SparseTensorDenseMatmul()
>>> out = sparse_dense_matmul(indices, values, sparse_shape, dense)
>>> print(out)
[[2. 2.]
 [6. 6.]
 [0. 0.]]
```

18.9.2 mindspore.ops.SparseToDense

class mindspore.ops.**SparseToDense**

Converts a sparse representation into a dense tensor.

Inputs:

- **indices** (Tensor) - A 2-D Tensor, represents the position of the element in the sparse tensor. Support int32, int64, each element value should be a non-negative int number. The shape is $(n, 2)$.
- **values** (Tensor) - A 1-D Tensor, represents the value corresponding to the position in the *indices*. The shape should be $(n,)$.
- **sparse_shape** (tuple(int)) - A positive int tuple which specifies the shape of sparse tensor, should have 2 elements, represent sparse tensor shape is (N, C).

Outputs:

Tensor, converted from sparse tensor. The dtype is same as *values*, and the shape is *sparse_shape*.

Raises

- **TypeError** – If the dtype of *indices* is neither int32 nor int64.
- **ValueError** – If *sparse_shape*, shape of *indices* and shape of *values* don't meet the parameter description.

Supported Platforms:

`CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> indices = Tensor([[0, 1], [1, 2]])
>>> values = Tensor([1, 2], dtype=mindspore.float32)
>>> sparse_shape = (3, 4)
>>> sparse_to_dense = ops.SparseToDense()
>>> out = sparse_to_dense(indices, values, sparse_shape)
>>> print(out)
[[0. 1. 0. 0.]
 [0. 0. 2. 0.]
 [0. 0. 0. 0.]]
```

18.10 Frame Operators

API Name	Description	Supported Platforms
mindspore.ops.Depend	Depend is used for processing dependency operations.	Ascend GPU CPU
mindspore.ops.ForiLoop	Performs a loop operation within the specified range.	Ascend GPU CPU
mindspore.ops.GradOperation	A higher-order function which is used to generate the gradient function for the input function.	Ascend GPU CPU
mindspore.ops.HookBackward	This operation is used as a tag to hook gradient in intermediate variables.	Ascend GPU CPU
mindspore.ops.HyperMap	HyperMap will apply the set operation to input sequences.	Ascend GPU CPU
mindspore.ops.InsertGradientOf	Attaches callback to the graph node that will be invoked on the node's gradient.	Ascend GPU CPU
mindspore.ops.Morph	The *Morph* Primitive is used to encapsulate a user-defined function *fn*, allowing it to be used as a custom Primitive.	
mindspore.ops.Map	Map will apply the set operation on input sequences.	Ascend GPU CPU
mindspore.ops.MultitypeFuncGraph	MultitypeFuncGraph is a class used to generate overloaded functions, considering different types as inputs.	Ascend GPU CPU
mindspore.ops.Partial	Makes a partial function instance.	Ascend GPU CPU

continues on next page

Table 24 – continued from previous page

mindspore.ops.Scan	Scan a function over an array while the processing of the current element depends on the execution result of the previous element.	Ascend GPU CPU
mindspore.ops.WhileLoop	Provide a useful op for reducing compilation times of while loop.	Ascend GPU CPU

18.10.1 mindspore.ops.Depend

class mindspore.ops.**Depend**

Depend is used for processing dependency operations.

In most scenarios, if operators have IO side effects or memory side effects, they will be executed according to the user's semantics. In some scenarios, if the two operators A and B have no order dependency, and A must be executed before B, we recommend using Depend to specify their execution order. The usage method is as follows:

```
a = A(x)                    --->        a = A(x)
b = B(y)                    --->        y = Depend(y, a)
                            --->        b = B(y)
```

Inputs:

- **value** (Tensor) - the real value to return for depend operator.
- **expr** (Expression) - the expression to execute with no outputs.

Outputs:

Tensor, the value passed by last operator.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> from mindspore import Tensor
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.softmax = ops.Softmax()
...         self.depend = ops.Depend()
...
...     def construct(self, x, y):
...         mul = x * y
...         y = self.depend(y, mul)
...         ret = self.softmax(y)
...         return ret
...
>>> x = Tensor(np.ones([4, 5]), dtype=mindspore.float32)
>>> y = Tensor(np.ones([4, 5]), dtype=mindspore.float32)
>>> net = Net()
```

(continues on next page)

(continued from previous page)

```
>>> output = net(x, y)
>>> print(output)
[[0.2 0.2 0.2 0.2 0.2]
 [0.2 0.2 0.2 0.2 0.2]
 [0.2 0.2 0.2 0.2 0.2]
 [0.2 0.2 0.2 0.2 0.2]]
```

18.10.2 mindspore.ops.ForiLoop

class mindspore.ops.**ForiLoop**

Performs a loop operation within the specified range. The execution logic of the ForiLoop operator can be roughly represented by the following code:

```
def ForiLoop(lower, upper, loop_func, init_val):
    for i in range(lower, upper):
        init_val = loop_func(i, init_val)
    return init_val
```

The current ForiLoop operator has the following syntactic limitations:

- Using a side-effect function as *loop_func* is currently not support, such as operations that modify parameters, global variables, etc.
- The return value of *loop_func* being of a different type or shape from the *init_val* is currently not support.
- Negative numbers or custom increments is currently not support.

Warning: This is an experimental API that is subject to change or deletion.

Inputs:

- **lower** (Union[int, Tensor]) - The start index of loop.
- **upper** (Union[int, Tensor]) - The end index of loop.
- **loop_func** (Function) - The loop function, takes two arguments.
- **init_val** (Union[Tensor, number, str, bool, list, tuple, dict]) - The init value.
- **unroll** (bool, optional) - The flag for whether unroll in compile process, only valid when the number of loop iterations is determined. Default: `True` .

Outputs:

Union[Tensor, number, str, bool, list, tuple, dict], the final result of the loop, has same type and shape with input *init_val* .

Raises

- **TypeError** – If *lower* is not an int or a Tensor.
- **TypeError** – If *upper* is not an int or a Tensor.
- **TypeError** – If *loop_func* is not a function.
- **ValueError** – If *loop_func* cannot take index and *init_val* as arguments or if the type of output it produces is different from the type or shape of *init_val* .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import ops
>>> def cumsum(index, res):
...     return index + res
...
>>> result_init = 0
>>> fori_loop = ops.ForiLoop()
>>> result = fori_loop(0, 4, cumsum, result_init)
>>> print(result)
6
```

18.10.3 mindspore.ops.GradOperation

class mindspore.ops.**GradOperation**(*get_all=False*, *get_by_list=False*, *sens_param=False*)

A higher-order function which is used to generate the gradient function for the input function.

The gradient function generated by *GradOperation* higher-order function can be customized by construction arguments.

For example, given an input function *net = Net()* that takes *x* and *y* as inputs, and has a parameter *z*, see *Net* in Examples.

- Used to get the derivative of the input:
  1. Returns gradients with respect to the first input (see *GradNetWrtX* in Examples).
     1) Construct a *GradOperation* higher-order function with default arguments: *grad_op = GradOperation()*.
     2) Call it with input function as argument to get the gradient function: *gradient_function = grad_op(net)*.
     3) Call the gradient function with input function's inputs to get the gradients with respect to the first input: *grad_op(net)(x, y)*.
  2. Returns gradients with respect to all inputs (see *GradNetWrtXY* in Examples).
     1) Construct a *GradOperation* higher-order function with *get_all=True* which indicates getting gradients with respect to all inputs, they are *x* and *y* in example function *Net()*: *grad_op = GradOperation(get_all=True)*.
     2) Call it with input function as argument to get the gradient function: *gradient_function = grad_op(net)*.
     3) Call the gradient function with input function's inputs to get the gradients with respect to all inputs: *gradient_function(x, y)*.
- Used to get the derivative of the parameters:

  Returns gradients with respect to given parameters (see *GradNetWithWrtParams* in Examples).
  1. Construct a *GradOperation* higher-order function with *get_by_list=True*: *grad_op = GradOperation(get_by_list=True)*.
  2. Construct a *ParameterTuple* that will be passed to the input function when constructing *GradOperation* higher-order function, it will be used as a parameter filter that determine which gradient to return: *params = ParameterTuple(net.trainable_params())*.
  3. Call it with input function and *params* as arguments to get the gradient function: *gradient_function = grad_op(net, params)*.
  4. Call the gradient function with input function's inputs to get the gradients with respect to given parameters: *gradient_function(x, y)*.

- Used to get the derivative of the inputs and parameters at the same time: Returns gradients with respect to all inputs and given parameters in the format of ((dx, dy), (dz)) (see *GradNetWrtInputsAndParams* in Examples).
    1. Construct a *GradOperation* higher-order function with *get_all=True* and *get_by_list=True*: *grad_op = GradOperation(get_all=True, get_by_list=True)*.
    2. Construct a *ParameterTuple* that will be passed along input function when constructing *GradOperation* higher-order function: *params = ParameterTuple(net.trainable_params())*.
    3. Call it with input function and *params* as arguments to get the gradient function: *gradient_function = grad_op(net, params)*.
    4. Call the gradient function with input function's inputs to get the gradients with respect to all inputs and given parameters: *gradient_function(x, y)*.
- We can configure the sensitivity(gradient with respect to output) by setting *sens_param* as True and passing an extra sensitivity input to the gradient function, the sensitivity input should has the same shape and type with input function's output(see *GradNetWrtXYWithSensParam* in Examples).
    1. Construct a *GradOperation* higher-order function with *get_all=True* and *sens_param=True*: *grad_op = GradOperation(get_all=True, sens_param=True)*.
    2. Define *grad_wrt_output* as *sens_param* which works as the gradient with respect to output: *grad_wrt_output = Tensor(np.ones([2, 2]).astype(np.float32))*.
    3. Call it with input function as argument to get the gradient function: *gradient_function = grad_op(net)*.
    4. Call the gradient function with input function's inputs and *sens_param* to get the gradients with respect to all inputs: *gradient_function(x, y, grad_wrt_output)*.

Note: For above gradient functions, the returned gradient result may vary for grad result element number:

- Return a single value if only one result.
- Return a tuple for multiple results.
- Return an empty tuple for no result.

Parameters

- **get_all** (*bool*) – If `True` , get all the gradients with respect to inputs. Default: `False` .
- **get_by_list** (*bool*) – If `True` , get all the gradients with respect to Parameter free variables. If get_all and get_by_list are both `False` , get the gradient with respect to first input. If get_all and get_by_list are both `True` , get the gradients with respect to inputs and Parameter free variables at the same time in the form of ("gradients with respect to inputs", "gradients with respect to parameter free variables"). Default: `False` .
- **sens_param** (*bool*) – Whether to append sensitivity (gradient with respect to output) as input. If sens_param is `False` , a 'ones_like(outputs)' sensitivity will be attached automatically. Default: `False` . If the sensor_param is `True` , a sensitivity (gradient with respect to output) needs to be transferred through the positional parameter or key-value pair parameter. If the value is transferred through the key-value pair parameter, the key must be sens.

Returns

The higher-order function which takes a function as argument and returns gradient function for it.

Raises

TypeError – If *get_all*, *get_by_list* or *sens_param* is not a bool.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import numpy as np
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops, nn, Parameter
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.matmul = ops.MatMul()
...         self.z = Parameter(Tensor(np.array([1.0], np.float32)), name='z')
...     def construct(self, x, y):
...         x = x * self.z
...         out = self.matmul(x, y)
...         return out
...
>>> class GradNetWrtX(nn.Cell):
...     def __init__(self, net):
...         super(GradNetWrtX, self).__init__()
...         self.net = net
...         self.grad_op = ops.GradOperation()
...     def construct(self, x, y):
...         gradient_function = self.grad_op(self.net)
...         return gradient_function(x, y)
...
>>> x = Tensor([[0.5, 0.6, 0.4], [1.2, 1.3, 1.1]], dtype=mstype.float32)
>>> y = Tensor([[0.01, 0.3, 1.1], [0.1, 0.2, 1.3], [2.1, 1.2, 3.3]], dtype=mstype.float32)
>>> output = GradNetWrtX(Net())(x, y)

18.10.4 mindspore.ops.HookBackward

class mindspore.ops.**HookBackward**(*hook_fn*, *cell_id=''*)

This operation is used as a tag to hook gradient in intermediate variables. Note that this function is only supported in pynative mode.

Note: The hook function must be defined like *hook_fn(grad) -> new gradient or None*, where the 'grad' is the gradient passed to the primitive. The 'grad' may be modified by returning a new gradient and passed to next primitive. The difference between a hook function and callback of InsertGradientOf is that the hook function is executed in the python environment while callback will be parsed and added to the graph.

Parameters

- **hook_fn** (*Function*) – Python function. hook function.
- **cell_id** (*str, optional*) – Used to identify whether the function registered by the hook is actually registered on the specified cell object. For example, 'nn.Conv2d' is a cell object. Default: `""`, in this case, the system will automatically register a value of *cell_id*. The value of *cell_id* currently does not support custom values.

Inputs:

- **input** (Tensor) - The variable to hook.

Outputs:

- **output** (Tensor) - Returns *input* directly. *HookBackward* does not affect the forward result.

Raises

- **TypeError** – If *input* is not a tensor.
- **TypeError** – If *hook_fn* is not a function of python.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import mindspore as ms
>>> from mindspore import ops
>>> from mindspore import Tensor
>>> from mindspore.ops import GradOperation
>>> ms.set_context(mode=ms.PYNATIVE_MODE)
>>> def hook_fn(grad):
...     print(grad)
...
>>> hook = ops.HookBackward(hook_fn)
```

(continues on next page)

(continued from previous page)

```
>>> def hook_test(x, y):
...     z = x * y
...     z = hook(z)
...     z = z * y
...     return z
...
>>> grad_all = GradOperation(get_all=True)
>>> def backward(x, y):
...     return grad_all(hook_test)(x, y)
...
>>> output = backward(Tensor(1, ms.float32), Tensor(2, ms.float32))
(Tensor(shape=[], dtype=Float32, value= 2),)
>>> print(output)
(Tensor(shape=[], dtype=Float32, value= 4), Tensor(shape=[], dtype=Float32, value= 4))
```

18.10.5 mindspore.ops.HyperMap

class mindspore.ops.**HyperMap**(*ops=None*, *reverse=False*)

HyperMap will apply the set operation to input sequences.

Apply the operations to every element of the sequence or nested sequence. Different from *mindspore.ops.Map*, the *HyperMap* supports to apply on nested structure. The *HyperMap* also supports dynamic sequences as input, but it does not extend this support to nested dynamic sequences.

Parameters

- **ops** (*Union[MultitypeFuncGraph, None], optional*) – *ops* is the operation to apply. If *ops* is *None*, the operations should be put in the first input of the instance. Default is None.
- **reverse** (*bool, optional*) – The optimizer needs to be inverted in some scenarios to improve parallel performance, general users please ignore. *reverse* is the flag to decide if apply the operation reversely. Only supported in graph mode. Default is False.

Inputs:

- **args** (Tuple[sequence]) -
  - If *ops* is not *None*, all the inputs should be sequences with the same length. And each row of the sequences will be the inputs of the operation.
  - If *ops* is *None*, the first input is the operation, and the others are inputs.

Note: Except for the operation input, the number of inputs should be equal to the number of inputs to *ops*.

Outputs:

Sequence or nested sequence, the sequence of output after applying the function. e.g. *operation(args[0][i], args[1][i])*, *operation* is the function assigned by *ops*.

Raises

- **TypeError** – If *ops* is neither *mindspore.ops.MultitypeFuncGraph* nor None.
- **TypeError** – If *args* is not a Tuple.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> nest_tensor_list = ((Tensor(1, mstype.float32), Tensor(2, mstype.float32)),
...                     (Tensor(3, mstype.float32), Tensor(4, mstype.float32)))
>>> # square all the tensor in the nested list
>>>
>>> square = ops.MultitypeFuncGraph('square')
>>> @square.register("Tensor")
... def square_tensor(x):
...     return ops.square(x)
>>>
>>> common_map = ops.HyperMap()
>>> output = common_map(square, nest_tensor_list)
>>> print(output)
((Tensor(shape=[], dtype=Float32, value= 1), Tensor(shape=[], dtype=Float32, value= 4)),
(Tensor(shape=[], dtype=Float32, value= 9), Tensor(shape=[], dtype=Float32, value= 16)))
>>> square_map = ops.HyperMap(square, False)
>>> output = square_map(nest_tensor_list)
>>> print(output)
((Tensor(shape=[], dtype=Float32, value= 1), Tensor(shape=[], dtype=Float32, value= 4)),
(Tensor(shape=[], dtype=Float32, value= 9), Tensor(shape=[], dtype=Float32, value= 16)))
```

18.10.6 mindspore.ops.InsertGradientOf

class mindspore.ops.**InsertGradientOf**(*f*)

Attaches callback to the graph node that will be invoked on the node's gradient.

> **Warning:** In the callback, exercise caution when using side-effect operators, such as the TensorDump operator, as current support is incomplete.

Parameters

f (*Function*) – MindSpore's Function. Callback function.

Inputs:

- **input_x** (Any) - The graph node to attach to.

Outputs:

Tensor, returns *input_x* directly. *InsertGradientOf* does not affect the forward result.

Raises

TypeError – If *f* is not a function of MindSpore.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops, jit
>>> a = Tensor(np.array([1.0]).astype(np.float32))
>>> b = Tensor(np.array([0.2]).astype(np.float32))
>>> def clip_gradient(dx):
...     ret = dx
...     if ret > a:
...         ret = a
...
...     if ret < b:
...         ret = b
...
...     return ret
...
>>> clip = ops.InsertGradientOf(clip_gradient)
>>> grad_all = ops.GradOperation(get_all=True)
>>> def InsertGradientOfClipDemo():
...     def clip_test(x, y):
...         x = clip(x)
...         y = clip(y)
...         c = x * y
...         return c
...
...     @jit
...     def f(x, y):
...         return clip_test(x, y)
...
...     def fd(x, y):
...         return grad_all(clip_test)(x, y)
...
...     print("forward: ", f(Tensor(np.array([1.1]).astype(np.float32)),
...         Tensor(np.array([0.1]).astype(np.float32))))
...     print("clip_gradient:", fd(Tensor(np.array([1.1]).astype(np.float32)),
...         Tensor(np.array([0.1]).astype(np.float32))))
>>> InsertGradientOfClipDemo()
forward: [0.11000001]
clip_gradient: (Tensor(shape=[1], dtype=Float32, value= [ 2.00000003e-01]),
                Tensor(shape=[1], dtype=Float32, value= [ 1.00000000e+00]))
```

18.10.7 mindspore.ops.Morph

class mindspore.ops.**Morph**(*fn*, *infer_shape*, *infer_dtype*)

The *Morph* Primitive is used to encapsulate a user-defined function *fn*, allowing it to be used as a custom Primitive. The primary application scenario of the *Morph* Primitive is in the auto-parallel case after *GRAPH_MODE* mode, where collective communication operators are used within the user-defined *fn* to implement custom parallel computation logic, especially in scenarios where *fn* involves dynamic shapes. When the *Morph* Primitive is applied to inputs, it is actually the encapsulated user-defined function *fn* that is applied to the inputs. The main difference between the *Morph* Primitive and *mindspore.ops.Custom()* is that the former is expanded and replaced by the user-defined *fn* before automatic differentiation, so there is no need to implement a backward function.

Note:

- This primitive is only supported in GRAPH_MODE.

- *fn* must satisfy the syntax constraints of the graph mode.
- Users do not need to implement a custom backward function.
- *vararg*, *kwarg*, *kwonlyargs* and free variables are not supported in user-defined function.

Parameters

- **fn** (*Function*) –Mindspore's function, user-defined function.
- **infer_shape** (*Function*) –Mindspore's function, user-defined infer_shape function.
- **infer_dtype** (*Function*) –Mindspore's function, user-defined infer_dtype function.

Inputs:

The inputs of user-defined *fn*.

Outputs:

The outputs of user-defined *fn*.

Raises

RuntimeError –if not used in GRAPH_MODE.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import context, nn, ops, Tensor, Parameter
>>>
>>> np_weight0 = np.array([1.0, 2.0, 3.0])
>>> np_weight1 = np.array([4.0, 5.0, 6.0])
>>> np_input_x = np.array([7.0, 8.0, 9.0])
>>>
>>> def infer_dtype(args):
...     return args
>>>
>>> def infer_shape(args):
...     return args
>>>
>>> def mul_by(*args):
...     def inner(x):
...         return args[0] * x
...     return inner
>>>
>>> NUMBER_100 = 100
>>> class MorphNet(nn.Cell):
...     def __init__(self):
...         super(MorphNet, self).__init__()
...         self.weight0 = Parameter(Tensor(np_weight0, ms.float32), name="weight0")
...         self.weight1 = Parameter(Tensor(np_weight1, ms.float32), name="weight1")
...         self.mul_by_100 = ops.Morph(mul_by(NUMBER_100), infer_shape, infer_dtype)
...     def construct(self, x):
...         a = x * self.weight0
...         b = self.mul_by_100(a)
...         out = b * self.weight1
```

(continues on next page)

(continued from previous page)

```
...         return out
>>>
>>> context.set_context(mode=context.GRAPH_MODE)
>>> input_x = Tensor(np_input_x, ms.float32)
>>> net = MorphNet()
>>> grad_op = ops.GradOperation(get_all=True, get_by_list=True)
>>> grad_net = grad_op(net, net.trainable_params())
>>> bwd_out = grad_net(input_x)
>>> x_grad = bwd_out[0][0].asnumpy()
>>> weight0_grad = bwd_out[1][0].asnumpy()
>>> weight1_grad = bwd_out[1][1].asnumpy()
>>> print("x_grad", x_grad)
>>> print("weight0_grad", weight0_grad)
>>> print("weight1_grad", weight1_grad)
x_grad [ 400. 1000. 1800.]
weight0_grad [2800. 4000. 5400.]
weight1_grad [ 700. 1600. 2700.]
```

18.10.8 mindspore.ops.Map

class mindspore.ops.**Map**(*ops=None*, *reverse=False*)

Map will apply the set operation on input sequences.

Apply the operations to every element of the sequence.

Parameters

- **ops** (*Union[MultitypeFuncGraph, None], optional*) – *ops* is the operation to apply. If *ops* is *None*, the operations should be put in the first input of the instance. Default: None .
- **reverse** (*bool, optional*) – The optimizer needs to be inverted in some scenarios to improve parallel performance, general users please ignore. *Reverse* is the flag to decide if apply the operation reversely. Only supported in graph mode. Default is False .

Inputs:

- **args** (Tuple[sequence]) - If *ops* is not *None*, all the inputs should be the same length sequences, and each row of the sequences. e.g. If the length of args is 2, and for *i* in length of each sequence *(args[0][i], args[1][i])* will be the input of the operation.

  If *ops* is *None*, the first input is the operation, and the other is the sequence.

Outputs:

Sequence, the sequence of output after applying the ops function. e.g. *ops(args[0][i], args[1][i])*.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import dtype as mstype
>>> from mindspore import Tensor, ops
>>> from mindspore.ops import MultitypeFuncGraph, Map
>>> tensor_list = (Tensor(1, mstype.float32), Tensor(2, mstype.float32), Tensor(3, mstype.
↪float32))
>>> # square all the tensor in the list
>>>
>>> square = MultitypeFuncGraph('square')
>>> @square.register("Tensor")
... def square_tensor(x):
...     return ops.square(x)
>>>
>>> common_map = Map()
>>> output = common_map(square, tensor_list)
>>> print(output)
(Tensor(shape=[], dtype=Float32, value= 1), Tensor(shape=[], dtype=Float32, value= 4),
Tensor(shape=[], dtype=Float32, value= 9))
>>> square_map = Map(square, False)
>>> output = square_map(tensor_list)
>>> print(output)
(Tensor(shape=[], dtype=Float32, value= 1), Tensor(shape=[], dtype=Float32, value= 4),
Tensor(shape=[], dtype=Float32, value= 9))
```

18.10.9 mindspore.ops.MultitypeFuncGraph

class mindspore.ops.**MultitypeFuncGraph**(*name*, *read_value=False*)

MultitypeFuncGraph is a class used to generate overloaded functions, considering different types as inputs. Initialize an *MultitypeFuncGraph* object with name, and use *register* with input types as the decorator for the function to be registered. And the object can be called with different types of inputs, and work with *HyperMap* and *Map*.

Parameters

- **name** (*str*) – Operator name.
- **read_value** (*bool, optional*) – If the registered function do not need to set value on Parameter, and all inputs will pass by value, set *read_value* to `True` . Default: `False` .

Raises

ValueError – If failed to find a matching function for the given arguments.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> # `add` is a metagraph object which will add two objects according to
>>> # input type using ".register" decorator.
>>> from mindspore import Tensor
>>> from mindspore import dtype as mstype
>>> from mindspore import ops
>>>
>>> tensor_add = ops.Add()
>>> add = ops.MultitypeFuncGraph('add')
>>> @add.register("Number", "Number")
... def add_scala(x, y):
...     return x + y
>>> @add.register("Tensor", "Tensor")
... def add_tensor(x, y):
...     return tensor_add(x, y)
>>> output = add(1, 2)
>>> print(output)
3
>>> output = add(Tensor([0.1, 0.6, 1.2], dtype=mstype.float32), Tensor([0.1, 0.6, 1.2],␣
↪dtype=mstype.float32))
>>> print(output)
[0.2 1.2 2.4]
```

register(**type_names*)

Register a function for the given type string.

Parameters

type_names (Union[str, *mindspore.dtype*]) –Inputs type names or types list.

Returns

decorator, a decorator to register the function to run, when called under the types described in *type_names*.

18.10.10 mindspore.ops.Partial

class mindspore.ops.**Partial**

Makes a partial function instance. Partial function can be used to derived specialized functions from general functions by fixing the value of certain number of arguments.

Inputs:

- **args** (Union[FunctionType, Tensor]) - The function and bind arguments.

Outputs:

FunctionType, partial function bound with arguments.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import Tensor
>>> from mindspore import ops
>>> def show_input(x, y, z):
...     return x, y, z
>>> partial = ops.Partial()
>>> partial_show_input = partial(show_input, Tensor(1))
>>> output1 = partial_show_input(Tensor(2), Tensor(3))
>>> print(output1)
(Tensor(shape=[], dtype=Int64, value= 1), Tensor(shape=[], dtype=Int64, value= 2),␣
↪Tensor(shape=[], dtype=Int64,
 value= 3))
>>> output2 = partial_show_input(Tensor(3), Tensor(4))
>>> print(output2)
(Tensor(shape=[], dtype=Int64, value= 1), Tensor(shape=[], dtype=Int64, value= 3),␣
↪Tensor(shape=[], dtype=Int64,
 value= 4))
```

18.10.11 mindspore.ops.Scan

class mindspore.ops.**Scan**

Scan a function over an array while the processing of the current element depends on the execution result of the previous element. The execution logic of the Scan operator can be roughly represented by the following code:

```
def Scan(loop_func, init, xs, length=None):
    if xs is None:
        xs = [None] * length
    carry = init
    ys = []
    for x in xs:
        carry, y = loop_func(carry, x)
        ys.append(y)
    return carry, ys
```

The current Scan operator has the following syntactic limitations:

- Using a side-effect function as *loop_func* is currently not support, such as operations that modify parameters, global variables, etc.
- The first element of the return value of *loop_func* being of a different type or shape from the *init_val* is currently not support.

> **Warning:** This is an experimental API that is subject to change or deletion.

Inputs:

- **loop_func** (Function) - The loop function.
- **init** (Union[Tensor, number, str, bool, list, tuple, dict]) - An initial loop carry value.
- **xs** (Union[tuple, list, None]) - The value over which to scan.
- **length** (Union[int, None], optional) - The size of xs. Default: `None` .
- **unroll** (bool, optional) - The flag for whether to perform loop unrolling in compile process. Default: `True` .

Outputs:

Tuple(Union[Tensor, number, str, bool, list, tuple, dict], list). Output of scan loop, a tuple with two elements, the first element has same type and shape with init argument, and the second is a list containing the results of each loop.

Raises

- **TypeError** – If *loop_func* is not a function.
- **TypeError** – If *xs* is not a tuple, a list or None.
- **TypeError** – If *length* is not an int or None.
- **TypeError** – If *unroll* is not a bool.
- **ValueError** – If *loop_func* cannot take *init* and element of *xs* as inputs.
- **ValueError** – If the return value of *loop_func* is not a tuple with two elements, or the first element of the tuple has different type or shape from *init* .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import ops
>>> def cumsum(res, el):
...     res = res + el
...     return res, res
...
>>> a = [1, 2, 3, 4]
>>> result_init = 0
>>> scan_op = ops.Scan()
>>> result = scan_op(cumsum, result_init, a)
>>> print(result == (10, [1, 3, 6, 10]))
True
```

18.10.12 mindspore.ops.WhileLoop

class mindspore.ops.**WhileLoop**

Provide a useful op for reducing compilation times of while loop. The execution logic of the WhileLoop operator can be roughly represented by the following code:

```
def WhileLoop(cond_func, loop_func, init_val):
    while(cond_func(init_val)):
        init_val = loop_func(init_val)
    return init_val
```

The current WhileLoop operator has the following syntactic limitations:

- Using a side-effect function as *loop_func* is currently not support, such as operations that modify parameters, global variables, etc.
- The return value of *loop_func* being of a different type or shape from the *init_val* is currently not support.

Warning: This is an experimental API that is subject to change or deletion.

Inputs:

- **cond_func** (Function) - The condition function.
- **loop_func** (Function) - The loop function, take one argument and return value has the same type with input argument.
- **init_val** (Union[Tensor, number, str, bool, list, tuple, dict]) - The initial value.

Outputs:

Union[Tensor, number, str, bool, list, tuple, dict], the final result of the while loop, has same type and shape with input *init_val* .

Raises

- **TypeError** –If *cond_func* is not a function.
- **TypeError** –If *loop_func* is not a function.
- **ValueError** –If *loop_func* cannot take *init_val* as input or has different output type or shape with *init_val* .

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore import ops
>>> def loop_while_fun(init_val):
...     val = init_val
...     val = val + 1
...     return val
...
>>> init_state = 10
>>> while_loop = ops.WhileLoop()
>>> result = while_loop(lambda x : x < 100, loop_while_fun, init_state)
>>> print(result)
100
```

18.11 Operator Information Registration

mindspore.ops.AiCPURegOp	Class for AiCPU operator information registration.
mindspore.ops.CustomRegOp	Class used for generating the registration information for the *func* parameter of *mindspore.ops.Custom*.
mindspore.ops.DataType	Various combinations of dtype and format of Ascend ops.
mindspore.ops.TBERegOp	Class for TBE operator information registration.
mindspore.ops.get_vm_impl_fn	Gets the virtual implementation function by a primitive object or primitive name.

18.11.1 mindspore.ops.AiCPURegOp

class mindspore.ops.**AiCPURegOp**(*op_name*)

Class for AiCPU operator information registration.

Parameters

op_name (*str*) – Name of operator.

Examples

```
>>> from mindspore.ops import AiCPURegOp, DataType
>>> stack_op_info = AiCPURegOp("Stack") \
...     .fusion_type("OPAQUE") \
...     .attr("axis", "int") \
...     .input(0, "x", "dynamic") \
...     .output(0, "y", "required") \
...     .dtype_format(DataType.I8_Default, DataType.I8_Default) \
...     .dtype_format(DataType.I16_Default, DataType.I16_Default) \
...     .dtype_format(DataType.I32_Default, DataType.I32_Default) \
...     .dtype_format(DataType.I64_Default, DataType.I64_Default) \
...     .dtype_format(DataType.U8_Default, DataType.U8_Default) \
...     .dtype_format(DataType.U16_Default, DataType.U16_Default) \
...     .dtype_format(DataType.U32_Default, DataType.U32_Default) \
...     .dtype_format(DataType.U64_Default, DataType.U64_Default) \
...     .dtype_format(DataType.F16_Default, DataType.F16_Default) \
...     .dtype_format(DataType.F32_Default, DataType.F32_Default) \
...     .dtype_format(DataType.F64_Default, DataType.F64_Default) \
...     .dtype_format(DataType.BOOL_Default, DataType.BOOL_Default) \
...     .get_op_info()
>>>
```

18.11.2 mindspore.ops.CustomRegOp

class mindspore.ops.**CustomRegOp**(*op_name='Custom'*)

Class used for generating the registration information for the *func* parameter of *mindspore.ops.Custom*. The registration information mainly specifies the supported data types and formats of input and output tensors, attributes and target of *func*.

Parameters

op_name (*str, optional*) – kernel name. The name will be record in the reg_op_name attr of the kernel node. Besides, the operator will generate a unique name automatically to identify the reg info. Default: "Custom" .

Examples

```
>>> from mindspore.ops import CustomRegOp, DataType
>>> custom_op_ascend_info = CustomRegOp() \
...     .input(0, "x", "dynamic") \
...     .output(0, "y") \
...     .dtype_format(DataType.F16_Default, DataType.F16_Default) \
...     .dtype_format(DataType.F32_Default, DataType.F32_Default) \
...     .target("Ascend") \
...     .get_op_info()
```

attr(*name=None*, *param_type=None*, *value_type=None*, *default_value=None*, ***kwargs*)

Specifies the attributes information for the *func* parameter of *mindspore.ops.Custom*. Each invocation of this function will generate one attribute information, that means, if *func* has two attributes, then this function should be invoked two times continuously. The attributes information will be generated as a dict: {"name": *name*, "param_type": *param_type*, "value_type": *value_type*, "default_value": *default_value*}.

Parameters

- **name** (*str*) −Name of the attribute. If `None` , key "name" will not appear in the attributes tensor information dict. Default: `None` .
- **param_type** (*str*) −Parameter type of the attribute, can be one of ["required", "optional"]. If `None` , key "param_type" will not appear in the attributes tensor information dict. Default: `None` .
  - "required": means must provide a value for this attribute either by setting a default value in the registration information or providing an input value when calling the Custom operator.
  - "optional": means does not have to provide a value for this attribute.
- **value_type** (*str*) −Value type of the attribute, can be one of ["int", "str", "bool", "float", "listInt", "listStr", "listBool", "listFloat"]. If `None` , key "value_type" will not appear in the attributes tensor information dict. Default: `None` .
  - "int": string representation of Python type int.
  - "str": string representation of Python type str.
  - "bool": string representation of Python type bool.
  - "float": string representation of Python type float.
  - "listInt": string representation of Python type list of int.
  - "listStr": string representation of Python type list of str.
  - "listBool": string representation of Python type list of bool.
  - "listFloat": string representation of Python type list of float.
- **default_value** (*str*) −Default value of the attribute. *default_value* and *value_type* are used together. If the real default value of the attribute is float type with value 1.0, then the *value_type* should be "float" and *default_value* should be "1.0". If the real default value of the attribute is a list of int with value [1, 2, 3], then the *value_type* should be "listInt" and *default_value* should be "1,2,3", each item should split by ','. If `None` , means the attribute has no default value and key "default_value" will not appear in the attributes tensor information dict. It is used for "akg", "aicpu" and "tbe" Custom operators currently. Default: `None` .
- **kwargs** (*dict*) −Other information of the attribute, used for extension.

Raises

- **TypeError** −If *name* is neither str nor None.
- **TypeError** −If *param_type* is neither str nor None.
- **TypeError** −If *value_type* is neither str nor None.
- **TypeError** −If *default_value* is neither str nor None.

dtype_format(**args*)

Specifies the supported data type and format of each input tensor and output tensor for the *func* parameter of *mindspore.ops.Custom*. This function should be invoked after *input* and *output* function as shown in the above example.

Parameters

args (*tuple*) −A tuple of (data type, format) pair, the length of *args* should be equal to the sum of input tensors and output tensors. Each item in *args* is also a tuple, tuple[0] and tuple[1] are both str type, which specifies the data type and format of a tensor respectively. *mindspore.ops.DataType* provides many predefined (data type, format) combinations, for example, *DataType.F16_Default* means the data type is float16 and the format is default format.

Raises

ValueError −If the size of *args* not equal to the sum of input tensors and output tensors.

get_op_info()

Return the generated registration information as a dict. This function should be invoked at last on the *CustomRegOp* instance as shown in the above example.

input(*index=None*, *name=None*, *param_type='required'*, ***kwargs*)

Specifies the input tensor information for the *func* parameter of *mindspore.ops.Custom*. Each invocation of this function will generate one input tensor information, that means, if *func* has two input tensors, then this function should be invoked two times continuously. The input tensor information will be generated as a dict: {"index": *index*, "name": *name*, "param_type": *param_type*}.

Parameters

- **index** (*int*) −Index of the input, starts from 0. 0 means the first input tensor, 1 means the second input tensor and so on. If `None` , key "index" will not appear in the input tensor information dict. Default: `None` .
- **name** (*str*) −Name of the *index* 'th input. If `None` , key "name" will not appear in the input tensor information dict. Default: `None` .
- **param_type** (*str*) −Parameter type of the *index* 'th input, can be one of [`"required"` , `"dynamic"` , `"optional"`]. If `None` , key "param_type" will not appear in the input tensor information dict. Default: `"required"` .
  - `"required"`: means the *index* 'th input exist and can only be a single tensor.
  - `"dynamic":` means the *index* 'th input exist and may be multiple tensors, such as the input of AddN.
  - `"optional"`: means the *index* 'th input may exist and be a single tensor or may not exist.
- **kwargs** (*dict*) −Other information of the input, used for extension.

Raises

- **TypeError** −If *index* is neither int nor None.
- **TypeError** −If *name* is neither str nor None.
- **TypeError** −If *param_type* is neither str nor None.

output(*index=None*, *name=None*, *param_type='required'*, ***kwargs*)

Specifies the output tensor information for the *func* parameter of *mindspore.ops.Custom*. Each invocation of this function will generate one output tensor information, which means, if *func* has two output tensors, then this function should be invoked two times continuously. The output tensor information will be generated as a dict: {"index": *index*, "name": *name*, "param_type": *param_type*}.

Parameters

- **index** (*int*) −Index of the output, starts from 0. 0 means the first output tensor, 1 means the second output tensor and so on. If `None` , key "index" will not appear in the output tensor information dict. Default: `None` .
- **name** (*str*) −Name of the *index* 'th output. If `None` , key "name" will not appear in the output tensor information dict. Default: `None` .
- **param_type** (*str*) −Parameter type of the *index* 'th output, can be one of [`"required"` , `"dynamic"` , `"optional"`]. If `None` , key "param_type" will not appear in the output tensor information dict. Default: `"required"` .

- `"required"`: means the *index* 'th output exist and can only be a single tensor.
- `"dynamic"`: means the *index* 'th output exist and may be multiple tensors.
- `"optional"`: means the *index* 'th output may exist and be a single tensor or may not exist.

- **kwargs** (*dict*) –Other information of the output, used for extension.

Raises

- **TypeError** –If *index* is neither int nor None.
- **TypeError** –If *name* is neither str nor None.
- **TypeError** –If *param_type* is neither str nor None.

target(*target=None*)

Specifies the target that this registration information is used for.

Parameters

target (*str*) –Device target for current operator information, should be one of ["Ascend", "GPU", "CPU"]. For the same *func* of *mindspore.ops.Custom*, it may support different data types and formats on different targets, use *target* to specify which target that this registration information is used for. If `None` , it will be inferred automatically inside *mindspore.ops.Custom*. Default: `None` .

Raises

TypeError –If *target* is neither str nor None.

18.11.3 mindspore.ops.DataType

class mindspore.ops.**DataType**

Various combinations of dtype and format of Ascend ops.

current support:

18.11.4 mindspore.ops.TBERegOp

class mindspore.ops.**TBERegOp**(*op_name*)

Class for TBE operator information registration. TBE (Tensor Boost Engine) is the Ascend operator development tool, which is extended on the basis of the TVM framework to develop custom operators.

Parameters

op_name (*str*) – Name of operator.

Examples

```
>>> from mindspore.ops import TBERegOp, DataType
>>> op_name_op_info = TBERegOp("OpName") \
...     .fusion_type("ELEMWISE") \
...     .async_flag(False) \
...     .binfile_name("op_name.so") \
...     .compute_cost(10) \
...     .kernel_name("op_name") \
...     .partial_flag(True) \
...     .op_pattern("formatAgnostic") \
...     .need_check_supported(True) \
...     .dynamic_shape(True) \
...     .dynamic_rank_support(True) \
...     .dynamic_compile_static(True) \
...     .attr("format", "required", "str", "all") \
...     .input(0, "x1", None, "required", None) \
```

(continues on next page)

(continued from previous page)

```
...     .input(0, "x2", None, "required", None) \
...     .input(1, "axis", None, "required", None) \
...     .output(0, "y", True, "required", "all") \
...     .real_input_index([1, 0]) \
...     .input_to_attr_index([2]) \
...     .unknown_shape_formats(["ND", "ND", "ND", "ND"]) \
...     .reshape_type("NC") \
...     .is_dynamic_format(True) \
...     .dtype_format(DataType.F16_None, DataType.F16_None, DataType.F16_None, DataType.F16_
↪None) \
...     .dtype_format(DataType.F32_None, DataType.F32_None, DataType.F32_None, DataType.F32_
↪None) \
...     .dtype_format(DataType.I32_None, DataType.I32_None, DataType.I32_None, DataType.I32_
↪None) \
...     .get_op_info()
>>>
```

async_flag(*async_flag=False*)
Define the calculation efficiency of the operator, whether the asynchronous calculation is supported.

Parameters

async_flag (*bool, optional*) – Value of async flag. Default: `False` .

attr(*name=None*, *param_type=None*, *value_type=None*, *value=None*, *default_value=None*, ***kwargs*)
Register TBE op attribute information.

Parameters

- **name** (*str, optional*) – Name of the attribute. Default: `None` .
- **param_type** (*str, optional*) – Param type of the attribute. Default: `None` .
- **value_type** (*str, optional*) – Type of the attribute. Default: `None` .
- **value** (*str, optional*) – Value of the attribute. Default: `None` .
- **default_value** (*str, optional*) – Default value of attribute. Default: `None` .
- **kwargs** (*dict*) – Other information of the attribute.

binfile_name(*binfile_name*)
Set the binary file name of the operator, it is optional.

Parameters

binfile_name (*str*) – The binary file name of the operator.

compute_cost(*compute_cost=10*)
Define the calculation efficiency of operator, which refers to the value of the cost model in the tiling module.

Parameters

compute_cost (*int, optional*) – Value of compute cost. Default: `10` .

dynamic_compile_static(*dynamic_compile_static=False*)
Whether the operator supports dynamic compile static.

Parameters

dynamic_compile_static (*bool, optional*) – An identifier that indicates whether the operator supports dynamic compile static. Default: `False` .

dynamic_rank_support (*dynamic_rank_support*)
Description whether the operator supports dynamic rank (dynamic dimension).

Parameters

dynamic_rank_support (*bool, optional*) –Description whether the operator supports dynamic rank (dynamic dimension). True: indicates that dynamic rank is supported. False: indicates that the operator does not support dynamic rank. Default: `False` .

dynamic_shape (*dynamic_shape=False*)
Whether the operator supports dynamic shape.

Parameters

dynamic_shape (*bool, optional*) –Value of dynamic shape. Default: `False` .

input (*index=None*, *name=None*, *need_compile=None*, *param_type=None*, *shape=None*, *value_depend=None*, ***kwargs*)
Register TBE op input information.

Parameters

- **index** (*int, optional*) –Order of the input. Default: `None` .
- **name** (*str, optional*) –Name of the input. Default: `None` .
- **need_compile** (*bool, optional*) –Whether the input needs to be compiled or not. Default: `None` .
- **param_type** (*str, optional*) –Type of the input. Default: `None` .
- **shape** (*str, optional*) –Shape of the input. Default: `None` .
- **value_depend** (*str, optional*) –Whether the input is constant value depend. Default: `None` .
- **kwargs** (*dict*) –Other information of the input.

input_to_attr_index (*input_to_attr_index*)
Description the index of input need to cast to attr.

Parameters

input_to_attr_index (*list*) –Value of input_to_attr_index. Default: `()` .

is_dynamic_format (*is_dynamic_format=False*)
Whether the operator needs calop_select_format api.

Parameters

is_dynamic_format (*bool, optional*) –Value of is_dynamic_format. Default: `False` .

kernel_name (*kernel_name*)
The name of operator kernel.

Parameters

kernel_name (*str*) –Name of operator kernel.

need_check_supported (*need_check_supported=False*)
Whether the operator needs check supports.

Parameters

need_check_supported (*bool, optional*) –Value of need_check_supported. Default: `False` .

op_pattern (*pattern=None*)
The behavior type of operator, such as broadcast, reduce and so on.

Parameters

pattern (*str, optional*) –Value of op pattern, e.g. "broadcast", "reduce". Default: `None` .

output (*index=None*, *name=None*, *need_compile=None*, *param_type=None*, *shape=None*, ***kwargs*)
Register TBE op output information.

Parameters

- **index** (*int, optional*) –Order of the output. Default: `None` .
- **name** (*str, optional*) –Name of the output. Default: `None` .
- **need_compile** (*bool, optional*) –Whether the output needs to be compiled or not. Default: `None` .
- **param_type** (*str, optional*) –Type of the output. Default: `None` .
- **shape** (*str, optional*) –Shape of the output. Default: `None` .
- **kwargs** (*dict*) –Other information of the output.

partial_flag (*partial_flag=True*)
Define the calculation efficiency of operator, whether the partial calculation is supported.

Parameters

partial_flag (*bool, optional*) –Value of partial flag. Default: `True` .

real_input_index (*real_input_index*)
Description operator front end and tbe operator input mapping.

Parameters

real_input_index (*list*) –Value of real_input_index. Default: `()` .

reshape_type (*reshape_type*)
Reshape type of operator.

Parameters

reshape_type (*str*) –Value of reshape type. For example, if the input shape is $(2, 3)$ and *reshape_type* is set to "CH", then the new shape is $(1, 2, 3, 1)$. "CH" means the C and H dimensions are kept and new dimensions are added for N and W dimension.

unknown_shape_formats (*unknown_shape_formats*)
Description data arrangement of operator input / output tensor in dynamic shape scene.

Parameters

unknown_shape_formats (*list*) –Description data arrangement of operator input / output tensor in dynamic shape scene.

18.11.5 mindspore.ops.get_vm_impl_fn

mindspore.ops.**get_vm_impl_fn** (*prim*)
Gets the virtual implementation function by a primitive object or primitive name.

Parameters

prim (*Union[Primitive, str]*) –primitive object or name for operator register.

Note: This mechanism applied for debugging currently.

Returns

function, vm function

Examples

```
>>> from mindspore.ops import vm_impl_registry, get_vm_impl_fn
...
>>> @vm_impl_registry.register("Type")
... def vm_impl_dtype(self):
...   def vm_impl(x):
...     return type(x)
...   return vm_impl
...
>>> fn = get_vm_impl_fn("Type")
>>> out = fn(1.0)
>>> print(out)
<class 'float'>
```

18.12 Customizing Operator

API Name	Description	Supported Platforms
mindspore.ops.Custom	*Custom* primitive is used for user defined operators and is to enhance the expressive ability of built-in primitives.	Ascend GPU CPU
mindspore.ops.CustomOpBuilder	CustomOpBuilder is used to initialize and configure custom operators for MindSpore.	Ascend CPU
mindspore.ops.custom_info_register	A decorator which is used to bind the registration information to the *func* parameter of *mindspore.ops.Custom*.	Ascend GPU CPU
mindspore.ops.kernel	The decorator of the Hybrid DSL function for the Custom Op.	GPU CPU

18.12.1 mindspore.ops.Custom

class mindspore.ops.**Custom**(*func*, *out_shape=None*, *out_dtype=None*, *func_type='hybrid'*, *bprop=None*, *reg_info=None*)

Custom primitive is used for user defined operators and is to enhance the expressive ability of built-in primitives. You can construct a *Custom* object with a predefined function, which describes the computation logic of a user defined operator. You can also construct another *Custom* object with another predefined function if needed. Then these *Custom* objects can be directly used in neural networks. Detailed description and introduction of user-defined operators, including correct writing of parameters, please refer to Custom Operators Tutorial .

Warning:

- This is an experimental API that is subject to change.

Note: The supported platforms are determined by the input *func_type*. The supported platforms are as follows:

- "aot": supports ["GPU", "CPU", "Ascend"].

- "pyfunc": supports ["CPU"].
- "julia": supports ["CPU"].

Parameters

- **func** (*Union[function, str]*) –
  - function: If func is of function type, then func should be a Python function which describes the computation logic of a user defined operator.
  - str: If func is of str type, then str should be a path of file along with a function name. This could be used when func_type is "aot" or "julia".

    1. for "aot":

       a) GPU/CPU platform. "aot" means ahead of time, in which case Custom directly launches user defined "xxx.so" file as an operator. Users need to compile a handwriting "xxx.cu"/"xxx.cc" file into "xxx.so" ahead of time, and offer the path of the file along with a function name.

       * "xxx.so" file generation:

         1) GPU Platform: Given user defined "xxx.cu" file (ex. "{path}/add.cu"), use nvcc command to compile it.(ex. "nvcc –shared -Xcompiler -fPIC -o add.so add.cu")

         2) CPU Platform: Given user defined "xxx.cc" file (ex. "{path}/add.cc"), use g++/gcc command to compile it.(ex. "g++ –shared -fPIC -o add.so add.cc")

       * Define a "xxx.cc"/"xxx.cu" file:

         "aot" is a cross-platform identity. The functions defined in "xxx.cc" or "xxx.cu" share the same args. Typically, the function should be as:

         ```
         int func(int nparam, void **params, int *ndims, int64_t **shapes, const␣
         ↪char **dtypes,
                 void *stream, void *extra)
         ```

         Parameters:

         · nparam(int): total number of inputs plus outputs; suppose the operator has 2 inputs and 3 outputs, then nparam=5

         · params(void **): a pointer to the array of inputs and outputs' pointer; the pointer type of inputs and outputs is void * ; suppose the operator has 2 inputs and 3 outputs, then the first input's pointer is params[0] and the second output's pointer is params[3]

         · ndims(int *): a pointer to the array of inputs and outputs' dimension num; suppose params[i] is a 1024x1024 tensor and params[j] is a 77x83x4 tensor, then ndims[i]=2, ndims[j]=3.

         · shapes(int64_t **): a pointer to the array of inputs and outputs' shapes(int64_t *); the ith input's jth dimension's size is shapes[i][j](0<=j<ndims[i]); suppose params[i] is a 2x3 tensor and params[j] is a 3x3x4 tensor, then shapes[i][0]=2, shapes[j][2]=4.

         · dtypes(const char **): a pointer to the array of inputs and outputs' types(const char *); (ex. "float32", "float16", "float", "float64", "int", "int8", "int16", "int32", "int64", "uint", "uint8", "uint16", "uint32", "uint64", "bool")

         · stream(void *): stream pointer, only used in cuda file

         · extra(void *): used for further extension

         Return Value(int):

- 0: MindSpore will continue to run if this aot kernel is successfully executed
- others: MindSpore will raise exception and exit

Examples: see details in tests/st/ops/graph_kernel/custom/aot_test_files/

* Use it in Custom:

```
Custom(func="{dir_path}/{file_name}:{func_name}",...)
(ex. Custom(func="./reorganize.so:CustomReorganize", out_shape=[1], out_
↪dtype=mstype.float32,
"aot"))
```

b) Ascend platform. Before using Custom operators on the Ascend platform, users must first develop custom operators based on Ascend C and compile them. The complete development and usage process can refer to the tutorial AOT-Type Custom Operators(Ascend). By passing the name of the operator through the input parameter *func*, there are two usage methods based on the implementation of the infer function:

* Python infer: If the operator's infer function is implemented in Python, that is, the infer shape function is passed through the *out_shape* parameter, and the infer type is passed throuht the *out_dtype*, then the *func* should be specified as the operator name, for example, *func="CustomName"*.
* C++ infer: If the operator's infer function is implemented through C++, then pass the path of the infer function implementation file in *func* and separate the operator name with *:*, for example: *func="add_custom_infer.cc:AddCustom"* .

2. for "julia":

Currently "julia" supports CPU(linux only) platform. For julia use JIT compiler, and julia support c api to call julia code. The Custom can directly launches user defined "xxx.jl" file as an operator. Users need to write a "xxx.jl" file which include modules and functions, and offer the path of the file along with a module name and function name.

Examples: see details in tests/st/ops/graph_kernel/custom/julia_test_files/

* Use it in Custom:

```
Custom(func="{dir_path}/{file_name}:{module_name}:{func_name}",...)
(ex. Custom(func="./add.jl:Add:add", out_shape=[1], out_dtype=mstype.
↪float32, "julia"))
```

- **out_shape** (*Union[function, list, tuple]*) −The output shape infer function or the value of output shape of *func*. Default: `None` .

  If func has single output, then the value of output shape is a list or tuple of int.

  If func has multiple outputs, then the value of output shape is a tuple, each item represents the shape of each output.

  The input can be None only when the func_type input is "hybrid". In this case, the automatic infer shape mechanic will be enabled.

- **out_dtype** (Union[function, *mindspore.dtype*, tuple[*mindspore.dtype*]]) −The output data type infer function or the value of output data type of *func*. Default: `None` .

  If func has single output, then the value of output shape is a *mindspore.dtype*.

  If func has multiple outputs, then the value of output shape is a tuple of *mindspore.dtype*, each item represents the data type of each output.

  The input can be None only when the func_type input is "hybrid". In this case, the automatic infer value mechanic will be enabled.

- **func_type** (*str*) −The implementation type of *func*, should be one of

  ["aot" , "pyfunc" , "julia"].

- **bprop** (*function*) −The back propagation function of *func*. Default: None .

- **reg_info** (*Union[str, dict, list, tuple]*) −Represents the registration information(reg info) of *func* with json format of type str or dict. The reg info specifies supported data types and formats of inputs and outputs, attributes and target of *func*. Default: None .

  If reg info is a list or tuple, then each item should be with json format of type str or dict, which represents the registration information of *func* in a specific target. You need to invoke *CustomRegOp* or the subclass of *RegOp* to generate the reg info for *func*. Then you can invoke *custom_info_register* to bind the reg info to *func* or just pass the reg info to *reg_info* parameter. The *reg_info* parameter takes higher priority than *custom_info_register* and the reg info in a specific target will be registered only once.

  If reg info is not set, then we will infer the data types and formats from the inputs of *Custom* operator.

  Please note that, if *func_type* is "tbe" or the *func* only supports some specified data types and formats, or it has attribute inputs, then you should set the reg info for *func*.

Inputs:

- **input** (Union(tuple, list)) - The input tuple or list is made up of multiple tensors, and attributes value(optional).

Outputs:

Tensor or tuple[Tensor], execution results.

Raises

- **TypeError** −If the type of *func* is invalid or the type of register information for *func* is invalid.
- **ValueError** −If *func_type* is invalid.
- **ValueError** −If the register information is invalid, including the target is not supported, the input numbers or the attributes of *func* differs in different targets.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> from mindspore.ops import CustomRegOp, custom_info_register, DataType, kernel
>>> from mindspore import dtype as mstype
>>> from mindspore.nn import Cell
>>> input_x = Tensor(np.ones([16, 16]).astype(np.float32))
>>> input_y = Tensor(np.ones([16, 16]).astype(np.float32))
>>>
>>> # Example, func_type = "pyfunc"
>>> def func_pyfunc(x1, x2):
...     return x1 + x2
>>>
>>> test_pyfunc = ops.Custom(func_pyfunc, lambda x, _: x, lambda x, _: x, "pyfunc")
>>> output = test_pyfunc(input_x, input_y)
>>> print(output.shape)
(16, 16)
```

18.12.2 mindspore.ops.CustomOpBuilder

class mindspore.ops.**CustomOpBuilder**(*name*, *sources*, *backend=None*, *include_paths=None*, *cflags=None*, *ldflags=None*, ***kwargs*)

CustomOpBuilder is used to initialize and configure custom operators for MindSpore. Users can define and load custom operator modules through this class and apply them to the network.

In most cases, users only need to provide the source files and additional compilation options in the constructor and call the *load* method to complete the compilation and loading of the operator. If users have specific customization requirements, they can inherit this class and override certain methods. It is important to note that if methods are overridden, some parameters passed to the constructor may be ignored.

Warning: This is an experimental API that is subject to change.

Parameters

- **name** (*str*) –The unique name of the custom operator module, used to identify the operator.
- **sources** (*Union[str, list[str]]*) –The source file(s) of the custom operator. It can be a single file path or a list of file paths.
- **backend** (*str, optional*) –The target backend for the operator, such as "CPU" or "Ascend". Default: `None`.
- **include_paths** (*list[str], optional*) –Additionally included paths needed during compilation. Default: `None`.
- **cflags** (*str, optional*) –Extra C++ compiler flags to be used during compilation. Default: `None`.
- **ldflags** (*str, optional*) –Extra linker flags to be used during linking. Default: `None`.
- **kwargs** (*dict, optional*) –Additional keyword arguments for future extensions or specific custom requirements.

Note:

- If the *backend* argument is provided, additional default flags will be automatically added to the compilation and linking steps to support the operator's target backend. The default options can be referenced in the implementation of the *get_cflags* and *get_ldflags* methods in the CustomOpBuilder.
- The *sources* argument must point to valid source files for the custom operator.

Supported Platforms:

`Ascend` `CPU`

Examples

```
>>> from mindspore import ops
>>> builder = ops.CustomOpBuilder(
...     name="custom_op_cpu",
...     sources="custom_ops_impl/pybind_op_cpu.cpp",
...     backend="CPU"
... )
>>> my_ops = builder.load()
```

build()
Build the custom operator module.

This method generates a dynamic library file for the custom operator based on the provided source files, include paths, compilation flags, and link flags.

Returns

str, The path to the compiled module.

get_cflags()
Get the C++ compiler flags for building the custom operator.

Returns

list[str], A list of C++ compiler flags.

get_include_paths()
Get the include paths required for compiling the custom operator.

Returns

list[str], A list of include paths.

get_ldflags()
Get the linker flags for building the custom operator.

Returns

list[str], A list of linker flags.

get_sources()
Get the source files for the custom operator.

Returns

str or list[str], The source file(s) for the operator.

load()
Build and load the custom operator module.

Returns

Module, The loaded custom operator module.

18.12.3 mindspore.ops.custom_info_register

mindspore.ops.**custom_info_register**(**reg_info*)
A decorator which is used to bind the registration information to the *func* parameter of *mindspore.ops.Custom*.

Note: The 'reg_info' will be added into oplib.

Parameters

reg_info (*tuple[str, dict]*) – Each item represents registration information in json format.

Returns

Function, returns a decorator for op info register.

Raises

TypeError – If *reg_info* is not a tuple.

Supported Platforms:

`Ascend` `GPU` `CPU`

Examples

```
>>> from mindspore.ops import custom_info_register, CustomRegOp, DataType
>>> custom_func_ascend_info = CustomRegOp() \
...     .input(0, "x", "dynamic") \
...     .output(0, "y") \
...     .dtype_format(DataType.F16_Default, DataType.F16_Default) \
...     .dtype_format(DataType.F32_Default, DataType.F32_Default) \
...     .target("Ascend") \
...     .get_op_info()
>>>
>>> @custom_info_register(custom_func_ascend_info)
... def custom_func(x):
...     pass
```

18.12.4 mindspore.ops.kernel

`mindspore.ops.`**`kernel`**(*fn=None*, *reg_info=None*, *compile_attrs=None*)

The decorator of the Hybrid DSL function for the Custom Op. When a function written by the Hybrid DSL is decorated by kernel, it can be run as a usual Python function. Also, this function can be used in the api Custom and to create *mindspore.ops.Custom*, with func_type "hybrid" or "pyfunc". Creating *mindspore.ops.Custom* with mode "hybrid" by the Hybrid DSL function will enjoy the automatic dtype/shape infer for free.

Parameters

- **fn** (*Function*) –The Python function that will be run as a custom operator. Default: `None` .
- **reg_info** (*tuple[str, dict]*) –Each item represents registration information in json format. Default: `None` .
- **compile_attrs** (*Dict*) –The Python object is used to distinguish the compiled function. Default: `None` .

Returns

Function, if *fn* is not None, returns a callable function that will execute the Hybrid DSL function; If *fn* is None, returns a decorator and when this decorator invokes with a single *fn* argument, the callable function is equal to the case when *fn* is not None.

Supported Platforms:

`GPU` `CPU`

Examples

```
>>> import numpy as np
>>> from mindspore import ops, Tensor
>>> from mindspore.ops import kernel, DataType, CustomRegOp
...
>>> # Create a dict for the compile flags.
>>> attrs = {
...     "test1": True,
...     "test2": "good",
```

(continues on next page)

(continued from previous page)

```
...     "test3": 12,
... }
>>> # Create the reg info json string.
>>> op_cpu_info = CustomRegOp() \
...     .input(0, "a") \
...     .input(0, "b") \
...     .output(0, "y") \
...     .dtype_format(DataType.F32_None, DataType.F32_None, DataType.F32_None) \
...     .target("CPU") \
...     .get_op_info()
>>>
>>> # Create inputs for the custom op.
>>> input_x = np.ones([4, 4]).astype(np.float32)
>>> input_y = np.ones([4, 4]).astype(np.float32)
...
>>> # Write a Hybrid DSL function through the decorator @kernel.
>>> # We can also pass the compile attrs and the reg info through the decorator.
>>> @kernel(reg_info=op_cpu_info, compile_attrs=attrs)
... def outer_product(a, b):
...     c = output_tensor(a.shape, a.dtype)
...
...     with block_realize(c):
...         for i0 in range(a.shape[0]):
...             for i1 in range(b.shape[1]):
...                 c[i0, i1] = 0.0
...                 for i2 in range(a.shape[1]):
...                     c[i0, i1] = c[i0, i1] + (a[i0, i2] * b[i2, i1])
...     return c
...
>>> # We can use the function directly as a python function.
>>> # In this case, the inputs should be numpy arrays.
>>> result = outer_product(input_x, input_y)
```

18.13 Spectral Operator

API Name	Description	Supported Platforms
mindspore.ops.BartlettWindow	Bartlett window function.	Ascend GPU CPU
mindspore.ops.BlackmanWindow	Blackman window function.	Ascend GPU CPU

18.13.1 mindspore.ops.BartlettWindow

class mindspore.ops.**BartlettWindow**(*periodic=True*, *dtype=mstype.float32*)

Bartlett window function.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.bartlett_window()* for more details.

Parameters

- **periodic** (*bool, optional*) –If True, returns a window to be used as periodic function. If False, return a symmetric window. Default: `True`.
- **dtype** (*mindspore.dtype, optional*) –The desired datatype of returned tensor. Only float16, float32 and float64 are allowed. Default: mstype.float32.

Inputs:

- **window_length** (Tensor) - The size of returned window, with data type int32, int64. The input data should be an integer with a value of [0, 1000000].

Outputs:

A 1-D tensor of size *window_length* containing the window. Its datatype is set by the attr *dtype*.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> from mindspore import Tensor, ops
>>> from mindspore import dtype as mstype
>>> window_length = Tensor(5, mstype.int32)
>>> bartlett_window = ops.BartlettWindow(periodic=True, dtype=mstype.float32)
>>> output = bartlett_window(window_length)
>>> print(output)
[0.  0.4 0.8 0.8 0.4]
```

18.13.2 mindspore.ops.BlackmanWindow

class mindspore.ops.**BlackmanWindow**(*periodic=True*, *dtype=mstype.float32*)

Blackman window function.

> **Warning:** This is an experimental API that is subject to change or deletion.

Refer to *mindspore.ops.blackman_window()* for more details.

Parameters

- **periodic** (*bool, optional*) –If `True` , returns a window to be used as periodic function. If `False` , return a symmetric window. Default: `True` .
- **dtype** (*mindspore.dtype, optional*) –the desired data type of returned tensor. Only float16, float32 and float64 is allowed. Default: `mstype.float32` .

Inputs:

- **window_length** (Tensor) - the size of returned window, with data type int32, int64. The input data should be an integer with a value of [0, 1000000].

Outputs:

A 1-D tensor of size *window_length* containing the window. Its datatype is set by the attr *dtype*.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> from mindspore import Tensor, ops
>>> window_length = Tensor(10, mindspore.int32)
>>> blackman_window = ops.BlackmanWindow(periodic = True, dtype = mindspore.float32)
>>> output = blackman_window(window_length)
>>> print(output)
[-2.9802322e-08  4.0212840e-02  2.0077014e-01  5.0978714e-01
  8.4922993e-01  1.0000000e+00  8.4922981e-01  5.0978690e-01
  2.0077008e-01  4.0212870e-02]
```

CHAPTER

NINETEEN

MINDSPORE.BOOST

Boost is able to automatically optimize network performance, e.g., by reducing BN, gradient freezing, and accumulating gradients to achieve network acceleration.

Note: This feature is a beta feature, and we are still improving its functionality.

class mindspore.boost.**AdaSum**(*rank*, *device_number*, *group_number*, *parameter_tuple*)

The Adaptive Summation, or AdaSum, is a novel algorithm for improving distributed data parallel training of Deep Learning models.

Parameters

- **rank** (*int*) –Rank number.
- **device_number** (*int*) –Device number.
- **group_number** (*int*) –Group number.
- **parameter_tuple** (*Tuple(Parameter)*) –Tuple of parameters.

Inputs:

- **delta_weights** (Tuple(Tensor)) - Tuple of gradients.
- **parameters** (Tuple(Parameter)) - Tuple of current parameters.
- **old_parameters** (Tuple(Parameter)) - Tuple of last parameters.

Outputs:

- **adasum_parameters** (Tuple(Tensor)) - Tuple of parameters after adasum process.

class mindspore.boost.**AutoBoost**(*level='O0'*, *boost_config_dict=''*)

Provide auto accelerating for network.

Parameters

- **level** (*str*) –Boost config level. Default: "O0" .
- **boost_config_dict** (*dict*) –User config hyperparameter dict, recommended config format:

```
{
    "boost": {
        "mode": "auto",
        "less_bn": False,
        "grad_freeze": False,
        "adasum": False,
```

(continues on next page)

(continued from previous page)

```
        "grad_accumulation": False,
        "dim_reduce": False,
        "loss_scale_group": False
    },
    "common": {
        "gradient_split_groups": [50, 100],
        "device_number": 8
    },
    "less_bn": {
        "fn_flag": True,
        "gc_flag": True
    },
    "grad_freeze": {
        "param_groups": 10,
        "freeze_type": 1,
        "freeze_p": 0.7,
        "total_steps": 65536
    }
    "dim_reduce": {
        "rho": 0.55,
        "gamma": 0.9,
        "alpha": 0.001,
        "sigma": 0.4,
        "n_components": 32,
        "pca_mat_path": None,
        "weight_load_dir": None,
        "timeout": 1800
    }
}
```

Default: `""` .

- boost:
  - mode (str): How to set the boost. Supports ["auto", "manual", "enable_all", "disable_all"]. Default: `"auto"` .
    - auto: Depend on the argument "boost_level" in class Model.
    - manual: Depend on "boost_config_dict".
    - enable_all: Set all boost functions true.
    - disable_all: Set all boost functions false.
  - less_bn (bool): Whether to apply less_bn function. Default: `False` .
  - grad_freeze: (bool): Whether to apply grad_freeze function. Default: `False` .
  - adasum (bool): Whether to apply adasum function. Default: `False` .
  - grad_accumulation (bool): Whether to apply grad_accumulation function. Default: `False` .
  - dim_reduce (bool): Whether to apply dim_reduce function. Default: `False` .
  - loss_scale_group (bool): Whether to apply loss_scale_group function. Default: `False` .

  If set dim_reduce true, other functions will be false. If set grad_freeze true and dim_reduce false, other functions will be false.
- common:
  - gradient_split_groups (list): The gradient split point of this network. Default: `[50, 100]` .

    - device_number (int): Device number. Default: `8`.

  - less_bn:
    - fn_flag (bool): Whether changing fc to fn. Default: `True`.
    - gc_flag (bool): Whether to apply gc. Default: `True`.
  - grad_freeze:
    - param_groups (int): The number of parameter groups. Default: `10`.
    - freeze_type (int): Gradient freeze grouping strategy, select from [0, 1]. Default: `1`.
    - freeze_p (float): Gradient freezing probability. Default: `0.7`.
    - total_steps (int): Total training steps. Default: `65536`.
  - dim_reduce:

    The leading principles of dim_reduce:

$$\begin{aligned} grad\_k &= pca\_mat \cdot grad \\ dk &= -bk \cdot grad\_k \\ sk &= rho^m \cdot dk \\ delta\_loss &= sigma \cdot grad\_k.T \cdot sk \end{aligned}$$

    Here:
    - pca_mat (array): Shape $(k * n)$, k is part of n_components, n is the size of weight.
    - bk (array): Shape $(k * k)$, is the symmetric positive definite matrix in Quasi-Newton method.

    we need to find the m satisfy:

$$new\_loss < old\_loss + delta\_loss$$

    Then, get delta_grad to update the weights for model:

$$\begin{aligned} grad\_k\_proj &= pca\_mat.T \cdot grad\_k \\ new\_grad\_momentum &= gamma \cdot old\_grad\_momentum + grad - grad\_k\_proj \\ delta\_grad &= alpha \cdot new\_grad\_momentum - pca\_mat.T \cdot sk \end{aligned}$$

    - rho (float): Generally, it does not need to be modified. Default: `0.55`.
    - gamma (float): Generally, it does not need to be modified. Default: `0.9`.
    - alpha (float): Generally, it does not need to be modified. Default: `0.001`.
    - sigma (float): Generally, it does not need to be modified. Default: `0.4`.
    - n_components (int): PCA component. Default: `32`.
    - pca_mat_path (str): The path to load pca mat. Default: `None`.
    - weight_load_dir (str): The directory to load weight files saved as ckpt. Default: `None`.
    - timeout (int): Waiting time to load local pca mat. Default: `1800 (second)`.

  User can load the config through the JSON file or use the dictionary directly. The unconfigured parameters will adopt the default values.

Raises

ValueError – The boost mode not in ["auto", "manual", "enable_all", "disable_all"].

Supported Platforms:

`Ascend`

Examples

```
>>> from mindspore.boost import AutoBoost
>>> #1) when configuring the dict directly:
>>> boost_config_dict = {"boost": {"mode": "auto"}}
>>> boost = AutoBoost("O1", boost_config_dict)
>>>
>>> #2) when loading the dict from a json file:
>>> import json
>>> boost_json = "/path/boost_config.json"
>>> with open(boost_json, 'r') as fp:
...     boost_config_dict = json.load(fp)
>>> boost = AutoBoost("O1", boost_config_dict)
```

network_auto_process_eval(*network*)
Boost network eval.

Parameters

network (Cell) –The inference network.

network_auto_process_train(*network*, *optimizer*)
Boost network train.

Parameters

- **network** (Cell) –The training network.
- **optimizer** (Cell) –Optimizer for updating the weights.

class mindspore.boost.**BoostTrainOneStepCell**(*network*, *optimizer*, *sens=None*)
Boost Network training package class.

Wraps the network with an optimizer. The resulting Cell is trained with input '*inputs'. The backward graph will be created in the construct function to update the parameter, and different parallel modes are available for training.

Parameters

- **network** (Cell) –The training network. The network only supports single output.
- **optimizer** (*Union[Cell]*) –Optimizer for updating the weights.
- **sens** (*numbers.Number*) –The scaling number to be filled as the input of backpropagation. Default: None , which is 1.0 .

Inputs:

- ***inputs** (Tuple(Tensor)) - Tuple of input tensors with shape (N, ...).

Outputs:

Tensor, a tensor means the loss value, the shape of which is usually ().

- loss(Tensor): A scalar Tensor.
- overflow(Tensor): A scalar Tensor which type is bool.
- loss scaling value(Tensor): A scalar Tensor.

Raises

TypeError –If *sens* is not a number.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> from mindspore import boost
>>> from mindspore import nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> loss_fn = nn.SoftmaxCrossEntropyWithLogits()
>>> optim = nn.Momentum(net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> #1) Using the WithLossCell existing provide
>>> loss_net = nn.WithLossCell(net, loss_fn)
>>> train_net = boost.BoostTrainOneStepCell(loss_net, optim)
>>>
>>> #2) Using user-defined WithLossCell
>>> class MyWithLossCell(nn.Cell):
...     def __init__(self, backbone, loss_fn):
...         super(MyWithLossCell, self).__init__(auto_prefix=False)
...         self._backbone = backbone
...         self._loss_fn = loss_fn
...
...     def construct(self, x, y, label):
...         out = self._backbone(x, y)
...         return self._loss_fn(out, label)
...
...     @property
...     def backbone_network(self):
...         return self._backbone
...
>>> loss_net = MyWithLossCell(net, loss_fn)
>>> train_net = boost.BoostTrainOneStepCell(loss_net, optim)
```

adasum_process(*loss*, *grads*)
Adasum algorithm process.

Parameters

- **loss** (Tensor) –Tensor with shape ().
- **grads** (*tuple(Tensor)*) –Tuple of gradient tensors.

Returns

- **loss** (Tensor) - Network loss, tensor with shape ().

check_adasum_enable()
Check adasum enable.

Returns

- **enable_adasum** (bool) - Check whether the Adasum algorithm is enabled.

check_dim_reduce_enable()
Check dim_reduce enable.

Returns

- **enable_dim_reduce** (bool) - Check whether the dimensionality reduction second-order training algorithm is enabled.

gradient_accumulation_process (*loss*, *grads*, *sens*, **inputs*)
Gradient accumulation algorithm process.

Parameters

- **loss** (Tensor) −Tensor with shape ().
- **grads** (*tuple(Tensor)*) −Tuple of gradient tensors.
- **sens** (Tensor) −Tensor with shape ().
- **inputs** (*tuple(Tensor)*) −Tuple of input tensors with shape $(N, \ldots)$.

Returns

- **loss** (Tensor) - Network loss, tensor with shape ().

gradient_freeze_process (**inputs*)
Gradient freeze algorithm process.

Parameters

inputs (*tuple(Tensor)*) −Tuple of input tensors with shape $(N, \ldots)$.

Returns

- **loss** (Tensor) - Network loss, tensor with shape ().

class mindspore.boost.**BoostTrainOneStepWithLossScaleCell** (*network*, *optimizer*, *scale_sense*)
Boost Network training with loss scaling.

This is a training step with loss scaling. It takes a network, an optimizer and possibly a scale update Cell as args. The loss scale value can be updated in both host side or device side. The BoostTrainOneStepWithLossScaleCell will be compiled to be graph which takes **inputs* as input data. The Tensor type of *scale_sense* is acting as loss scaling value. If you want to update it on host side, the value must be provided. If the Tensor type of *scale_sense* is not given, the loss scale update logic must be provide by Cell type of *scale_sense*.

Parameters

- **network** (Cell) −The training network. The network only supports single output.
- **optimizer** (Cell) −Optimizer for updating the weights.
- **scale_sense** (*Union[Tensor, Cell]*) −If this value is Cell type, the loss scaling update logic cell.If this value is Tensor type, *mindspore.nn.TrainOneStepWithLossScaleCell.set_sense_scale()* can be called to update loss scale factor, Tensor with shape () or $(1,)$.

Inputs:

- ***inputs** (Tuple(Tensor)) - Tuple of input tensors with shape $(N, \ldots)$.

Outputs:

Tuple of 3 Tensor, the loss, overflow flag and current loss scaling value.

- **loss** (Tensor) - Tensor with shape ().
- **overflow** (Tensor) - Tensor with shape (), type is bool.
- **loss scaling value** (Tensor) - Tensor with shape ()

Raises

- **TypeError** −If *scale_sense* is neither Cell nor Tensor.
- **ValueError** −If shape of *scale_sense* is neither $(1,)$ nor ().

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, Parameter, nn
>>> from mindspore import ops
>>> from mindspore.nn import WithLossCell
>>> from mindspore import dtype as mstype
>>> from mindspore import boost
>>>
>>> class Net(nn.Cell):
...     def __init__(self, in_features, out_features):
...         super(Net, self).__init__()
...         self.weight = Parameter(Tensor(np.ones([in_features, out_features]).astype(np.
 ↪float32)),
...                                 name='weight')
...         self.matmul = ops.MatMul()
...
...     def construct(self, x):
...         output = self.matmul(x, self.weight)
...         return output
...
>>> size, in_features, out_features = 16, 16, 10
>>> #1) when the type of scale_sense is Cell:
>>> net = Net(in_features, out_features)
>>> loss = nn.MSELoss()
>>> optimizer = nn.Momentum(net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> net_with_loss = WithLossCell(net, loss)
>>> manager = nn.DynamicLossScaleUpdateCell(loss_scale_value=2**12, scale_factor=2, scale_
 ↪window=1000)
>>> train_network = boost.BoostTrainOneStepWithLossScaleCell(net_with_loss, optimizer, scale_
 ↪sense=manager)
>>> input = Tensor(np.ones([out_features, in_features]), mstype.float32)
>>> labels = Tensor(np.ones([out_features,]), mstype.float32)
>>> output = train_network(input, labels)
>>>
>>> #2) when the type of scale_sense is Tensor:
>>> net = Net(in_features, out_features)
>>> loss = nn.MSELoss()
>>> optimizer = nn.Momentum(net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> net_with_loss = WithLossCell(net, loss)
>>> inputs = Tensor(np.ones([size, in_features]).astype(np.float32))
>>> label = Tensor(np.zeros([size, out_features]).astype(np.float32))
>>> scaling_sens = Tensor(np.full((1), np.finfo(np.float32).max), dtype=mstype.float32)

 ↪sense=scaling_sens)
>>> output = train_network(inputs, label)
```

class mindspore.boost.**DimReduce**(*network*, *optimizer*, *weight*, *pca_mat_local*, *n_components*, *rho*, *gamma*, *alpha*, *sigma*, *rank*, *rank_size*)

The dimension reduce training, is a novel algorithm for accelerating convergence of Deep Learning models.

$$\begin{aligned} grad\_k &= pca\_mat \cdot grad \\ dk &= -bk \cdot grad\_k \\ sk &= rho^m \cdot dk \\ delta\_loss &= sigma \cdot grad\_k.T \cdot sk \end{aligned}$$

Here:

- pca_mat (array): Shape $(k * n)$, k is part of n_components, n is the size of weight.
- bk (array): Shape $(k * k)$, is the symmetric positive definite matrix in Quasi-Newton method.

we need to find the m satisfy:

$$new\_loss < old\_loss + delta\_loss$$

Then, get delta_grad to update the weights for model:

$$\begin{aligned} grad\_k\_proj &= pca\_mat.T \cdot grad\_k \\ new\_grad\_momentum &= gamma \cdot old\_grad\_momentum + grad - grad\_k\_proj \\ delta\_grad &= alpha \cdot new\_grad\_momentum - pca\_mat.T \cdot sk \end{aligned}$$

Parameters

- **network** (Cell) −The training network. The network only supports single output.
- **optimizer** (*Union[Cell]*) −Optimizer for updating the weights.
- **weight** (*Tuple(Parameter)*) −Tuple of parameters.
- **pca_mat_local** (*numpy.ndarray*) −For PCA operation, k*n, k is part of n_components, n is the size of weight.
- **n_components** (*int*) −PCA.components.
- **rho** (*float*) −Coefficient.
- **gamma** (*float*) −Coefficient.
- **alpha** (*float*) −Coefficient.
- **sigma** (*float*) −Coefficient.
- **rank** (*int*) −Rank number.
- **rank_size** (*int*) −Rank size.

Inputs:

- **loss** (Tensor) - Tensor with shape ().
- **old_grad** (Tuple(Tensor)) - Tuple of gradient tensors.
- **weight** (Tuple(Tensor)) - Tuple of parameters.
- **weight_clone** (Tuple(Tensor)) - clone of weight
- ***inputs** (Tuple(Tensor)) - Tuple of input tensors with shape $(N, \ldots)$.

Outputs:

- **loss** (Tensor) - Tensor with shape ().

class mindspore.boost.**FreezeOpt**(*opt*, *train_parameter_groups=None*, *train_strategy=None*)

Optimizer that supports gradients freezing training.

Parameters

- **opt** (Cell) –non-freezing optimizer instance, such as 'Momentum', 'SGD'.
- **train_parameter_groups** (*Union[tuple, list]*) –Groups of parameters for gradients freezing training. Default: None .
- **train_strategy** (*Union[tuple(int), list(int), Tensor]*) –Strategy for gradients freezing training. Default: None .

Supported Platforms:

Ascend

class mindspore.boost.**GradientAccumulation**(*max_accumulation_step*, *optimizer*)

After accumulating the gradients of multiple steps, call to optimize its update.

Parameters

- **max_accumulation_step** (*int*) –Steps to accumulate gradients.
- **optimizer** (Cell) –Optimizer used.

class mindspore.boost.**GradientFreeze**(*param_groups*, *freeze_type*, *freeze_p*, *total_steps*)

Gradients freezing algorithm, freezing the gradients of some layers randomly, to improve network training performance. The number and probability of frozen layers can be configured by users.

Parameters

- **param_groups** (*Union[tuple, list]*) –Groups of parameters for gradients freezing training.
- **freeze_type** (*int*) –Strategy of gradients freezing training.
- **freeze_p** (*float*) –probability of gradients freezing training.
- **total_steps** (*int*) –Steps of the whole training.

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, Parameter, nn
>>> from mindspore import ops
>>> from mindspore.nn import WithLossCell
>>> from mindspore import dtype as mstype
>>> from mindspore import boost
>>>
>>> class Net(nn.Cell):
...     def __init__(self, in_features, out_features):
...         super(Net, self).__init__()
...         self.weight = Parameter(Tensor(np.ones([in_features, out_features]).astype(np.
↪float32)),
...                                 name='weight')
...         self.matmul = ops.MatMul()
...
...     def construct(self, x):
...         output = self.matmul(x, self.weight)
...         return output
>>> size, in_features, out_features = 16, 16, 10
```

(continues on next page)

(continued from previous page)

```
>>> net = Net(in_features, out_features)
>>> loss = nn.MSELoss()
>>> optimizer = nn.Momentum(net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> net_with_loss = WithLossCell(net, loss)
>>> gradient_freeze_class = boost.GradientFreeze(10, 1, 0.5, 2000)
>>> network, optimizer = gradient_freeze_class.freeze_generate(net_with_loss, optimizer)
>>> inputs = Tensor(np.ones([size, in_features]).astype(np.float32))
>>> label = Tensor(np.zeros([size, out_features]).astype(np.float32))
>>> output = network(inputs, label)
```

freeze_generate(*network*, *optimizer*)
Generate freeze network and optimizer.

Parameters

- **network** (Cell) –The training network.
- **optimizer** (Cell) –Optimizer for updating the weights.

generate_freeze_index_sequence(*parameter_groups_number*, *freeze_strategy*, *freeze_p*, *total_steps*)
Generate index sequence for gradient freezing training.

Parameters

- **parameter_groups_number** (*int*) –The number of parameter groups.
- **freeze_strategy** (*int*) –Gradient freeze grouping strategy, select from [0, 1].
- **freeze_p** (*float*) –Gradient freezing probability.
- **total_steps** (*int*) –Total training steps.

split_parameters_groups(*net*, *freeze_para_groups_number*)
Split parameter groups for gradients freezing training.

Parameters

- **net** (Cell) –The training network.
- **freeze_para_groups_number** (*int*) –The number of gradient freeze groups.

class mindspore.boost.**GroupLossScaleManager**(*init_loss_scale*, *loss_scale_groups*)
Enhanced hybrid precision algorithm supports multi-layer application of different loss scales and dynamic updating of loss scales.

Parameters

- **init_loss_scale** (*Number*) –The initialized loss scale value.
- **loss_scale_groups** (*List*) –The loss scale groups, which are divided from the param list.

Inputs:

- **x** (Tensor) - The output of last operator.
- **layer1** (Int) - Current network layer value.
- **layer2** (Int) - Last network layer value.

Outputs:

- **out** (Tensor) - A tensor with a group of loss scale tags that marks the loss scale group number of the current tensor.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore as ms
>>> from mindspore import boost, nn
>>>
>>> class Net(nn.Cell):
...     def __init__(self, enhanced_amp, num_class=10, num_channel=1):

```

get_loss_scale()

Get loss scale value.

Returns

bool, *loss_scale* value.

get_update_cell()
Returns the instance of *mindspore.boost.GroupLossScaleManager*.

Returns

mindspore.boost.GroupLossScaleManager.

set_loss_scale_status(*loss_scale_number*, *init_loss_scale*)
Generate dynamic loss scale tuple and set overflow status list.

Parameters

- **loss_scale_number** (*int*) –The number of loss scale.
- **init_loss_scale** (*float*) –The initialized loss scale.

update_loss_scale_status(*layer*, *update_ratio*)
Update dynamic loss scale.

Parameters

- **layer** (*int*) –Current layer.
- **update_ratio** (*float*) –The ratio of loss scale update.

Outputs:

float, new loss scale.

class mindspore.boost.**LessBN**(*network*, *fn_flag=False*)
Reduce the number of BN automatically to improve the network performance and ensure the network accuracy.

Parameters

- **network** (Cell) –Network to be modified.
- **fn_flag** (*bool*) –Replace FC with FN. Default: False .

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, Parameter, nn
>>> from mindspore import ops
>>> from mindspore.nn import WithLossCell
>>> from mindspore import dtype as mstype
>>> from mindspore import boost
>>>
>>> class Net(nn.Cell):
...     def __init__(self, in_features, out_features):
...         super(Net, self).__init__()
...         self.weight = Parameter(Tensor(np.ones([in_features, out_features]).astype(np.
↪float32)),
...                                 name='weight')
...         self.matmul = ops.MatMul()
...
...     def construct(self, x):
...         output = self.matmul(x, self.weight)
...         return output
>>> size, in_features, out_features = 16, 16, 10
```

(continues on next page)

(continued from previous page)

```
>>> net = Net(in_features, out_features)
>>> loss = nn.MSELoss()
>>> optimizer = nn.Momentum(net.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> net_with_loss = WithLossCell(net, loss)
>>> inputs = Tensor(np.ones([size, in_features]).astype(np.float32))
>>> label = Tensor(np.zeros([size, out_features]).astype(np.float32))
>>> train_network = boost.LessBN(net_with_loss)
>>> output = train_network(inputs, label)
```

class mindspore.boost.**OptimizerProcess**(*opt*)

Process optimizer for Boost. Currently, this class supports adding GC(grad centralization) tags and creating new optimizers.

Parameters

opt (Cell) – Optimizer used.

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, Parameter, nn
>>> from mindspore import ops
>>> from mindspore.boost import OptimizerProcess
>>>
>>> class Net(nn.Cell):
...     def __init__(self, in_features, out_features):
...         super(Net, self).__init__()
...         self.weight = Parameter(Tensor(np.ones([in_features, out_features]).astype(np.
↪float32)),
...                                 name='weight')
...         self.matmul = ops.MatMul()
...
...     def construct(self, x):
...         output = self.matmul(x, self.weight)
...         return output
...
>>> size, in_features, out_features = 16, 16, 10
>>> network = Net(in_features, out_features)
>>> optimizer = nn.Momentum(network.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> optimizer_process = OptimizerProcess(optimizer)
>>> optimizer_process.add_grad_centralization(network)
>>> optimizer = optimizer_process.generate_new_optimizer()
```

add_grad_centralization(*network*)

Add gradient centralization.

Parameters

network (Cell) – The training network.

static build_gc_params_group(*params_dict*, *parameters*)

Build the parameter's group with grad centralization.

Parameters

- **params_dict** (*dict*) – The network's parameter dict.
- **parameters** (*list*) – The network's parameter list.

static build_params_dict(*network*)
Build the parameter's dict of the network.

Parameters

network (Cell) –The training network.

generate_new_optimizer()
Generate new optimizer.

class mindspore.boost.**ParameterProcess**
Process parameter for Boost. Currently, this class supports creating group parameters and automatically setting gradient segmentation point.

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, Parameter, nn
>>> from mindspore import ops
>>> from mindspore.boost import ParameterProcess
>>>
>>> class Net(nn.Cell):
...     def __init__(self, in_features, out_features):
...         super(Net, self).__init__()
...         self.weight = Parameter(Tensor(np.ones([in_features, out_features]).astype(np.
↪float32)),
...                                 name='weight')
...         self.weight2 = Parameter(Tensor(np.ones([in_features, out_features]).astype(np.
↪float32)),
...                                 name='weight2')
...         self.matmul = ops.MatMul()
...         self.matmul2 = ops.MatMul()
...
...     def construct(self, x):
...         output = self.matmul(x, self.weight)
...         output2 = self.matmul2(x, self.weight2)
...         return output + output2
...
>>> size, in_features, out_features = 16, 16, 10
>>> network = Net(in_features, out_features)
>>> new_parameter = network.trainable_params()[:1]
>>> group_params = ParameterProcess.generate_group_params(new_parameter, network.trainable_
↪params())
```

assign_parameter_group(*parameters*, *split_point=None*)
Assign parameter group.

Parameters

- **parameters** (*list*) –The network's parameter list.
- **split_point** (*list*) –The gradient split point of this network. Default: None.

static generate_group_params(*parameters*, *origin_params*)
Generate group parameters.

Parameters

- **parameters** (*list*) –The network's parameter list.
- **origin_params** (*list*) –The network's origin parameter list.

mindspore.boost.**freeze_cell**(*reducer_flag*, *network*, *optimizer*, *sens*, *grad*, *use_grad_accumulation*, *mean=None*, *degree=None*, *max_accumulation_step=1*)

Generate freeze network and optimizer.

Parameters

- **reducer_flag** (*bool*) –Reducer flag.
- **network** (Cell) –The training network.
- **optimizer** (Cell) –Optimizer for updating the weights.
- **sens** (*numbers.Number*) –The scaling number.
- **grad** (*tuple(Tensor)*) –Tuple of gradient tensors.
- **use_grad_accumulation** (*bool*) –Use gradient accumulation flag.
- **mean** (*bool*) –Gradients mean flag. Default: None .
- **degree** (*int*) –Device number. Default: None .
- **max_accumulation_step** (*int*) –Max accumulation steps. Default: 1 .

Examples

```
>>> import numpy as np
>>> from mindspore import Tensor, Parameter, nn
>>> from mindspore import ops
>>> from mindspore.boost.grad_freeze import freeze_cell, FreezeOpt
>>>
>>> class Net(nn.Cell):
...     def __init__(self, in_features, out_features):
...         super(Net, self).__init__()
...         self.weight = Parameter(Tensor(np.ones([in_features, out_features]).astype(np.
↪float32)),
...                                 name='weight')
...         self.matmul = ops.MatMul()
...
...     def construct(self, x):
...         output = self.matmul(x, self.weight)
...         return output
...
>>> in_features, out_features = 16, 10
>>> network = Net(in_features, out_features)
>>> optimizer = nn.Momentum(network.trainable_params(), learning_rate=0.1, momentum=0.9)
>>> optimizer = FreezeOpt(optimizer)
>>> grad = ops.GradOperation(get_by_list=True, sens_param=True)
>>> freeze_nets = freeze_cell(False, network, optimizer, 1.0, grad, False, None, None, 1)
```

MINDSPORE.NN.PROBABILITY

20.1 Bijectors

API Name	Description	Supported Platforms
mindspore.nn.probability.bijector.Bijector	Bijecotr class.	Ascend GPU
mindspore.nn.probability.bijector.Exp	Exponential Bijector.	Ascend GPU
mindspore.nn.probability.bijector.GumbelCDF	GumbelCDF Bijector.	Ascend GPU
mindspore.nn.probability.bijector.Invert	Invert Bijector.	Ascend GPU CPU
mindspore.nn.probability.bijector.PowerTransform	PowerTransform Bijector.	Ascend GPU
mindspore.nn.probability.bijector.ScalarAffine	Scalar Affine Bijector.	Ascend GPU
mindspore.nn.probability.bijector.Softplus	Softplus Bijector.	Ascend GPU CPU

20.1.1 mindspore.nn.probability.bijector.Bijector

class mindspore.nn.probability.bijector.**Bijector**(*is_constant_jacobian=False*, *is_injective=True*, *name=None*, *dtype=None*, *param=None*)

Bijecotr class. A bijector perform a mapping from one distribution to the other via some function. If X is a random variable following the original distribution, and $g(x)$ is the mapping function, then $Y = g(X)$ is the random variable following the transformed distribution.

Parameters

- **is_constant_jacobian** (*bool*) −Whether the Bijector has constant derivative. Default: `False` .
- **is_injective** (*bool*) −Whether the Bijector is a one-to-one mapping. Default: `True` .
- **name** (*str*) −The name of the Bijector. Default: `None` .
- **dtype** (`mindspore.dtype`) −The type of the distributions that the Bijector can operate on. Default: `None` .
- **param** (*dict*) −The parameters used to initialize the Bijector. Default: `None` .

Note:

- *dtype* of bijector represents the type of the distributions that the bijector could operate on.

- When *dtype* is None, there is no enforcement on the type of input value except that the input value has to be float type. During initialization, when *dtype* is None, there is no enforcement on the dtype of the parameters. All parameters should have the same float type, otherwise a TypeError will be raised.

  Specifically, the parameter type will follow the dtype of the input value.

  – Parameters of the bijector will be casted into the same type as input value when *dtype* is None.

  – When *dtype* is specified, it is forcing the parameters and input value to be the same dtype as *dtype*. When the type of parameters or the type of the input value is not the same as *dtype*, a TypeError will be raised.

- Only subtype of mindspore.float_type can be used to specify bijector's *dtype*.

Supported Platforms:

`Ascend` `GPU`

cast_param_by_value(*value*, *para*)

Converts the data type of *para* in the input to the same type as *value*. Typically used by subclasses of Bijector to convert data types of their own parameters.

Parameters

- **value** (Tensor) −input value.
- **para** (Tensor) −parameter(s) of the bijector.

Returns

Tensor, the value of parameters after casting.

construct(*name*, **args*, ***kwargs*)

Override *construct* in Cell.

Note: Names of supported functions include: 'forward', 'inverse', 'forward_log_jacobian', and 'inverse_log_jacobian'.

Parameters

- **name** (*str*) −The name of the function.
- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Returns

Tensor, the result of the function corresponding to name.

forward(*value*, **args*, ***kwargs*)

Forward transformation: transform the input value to another distribution.

Parameters

- **value** (Tensor) −the value of the input variables.
- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Returns

Tensor, the value of the transformed random variable.

forward_log_jacobian(*value*, **args*, ***kwargs*)
Logarithm of the derivative of the forward transformation.

Parameters

- **value** (Tensor) −the value of the input variables.
- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Returns

Tensor, outputs the value of a random variable after mapping.

inverse(*value*, **args*, ***kwargs*)
Inverse transformation: transform the input value back to the original distribution.

Parameters

- **value** (Tensor) −the value of the transformed variables.
- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Returns

Tensor, the value of the input random variable.

inverse_log_jacobian(*value*, **args*, ***kwargs*)
Logarithm of the derivative of the inverse transformation.

Parameters

- **value** (Tensor) −the value of the transformed variables.
- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Returns

Tensor, the value of logarithm of the derivative of the inverse transformation.

20.1.2 mindspore.nn.probability.bijector.Exp

class mindspore.nn.probability.bijector.**Exp**(*name='Exp'*)
Exponential Bijector. This Bijector performs the operation:

$$Y = \exp(x).$$

Parameters

name (*str*) −The name of the Bijector. Default: 'Exp' .

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> from mindspore import Tensor
>>>
>>> # To initialize an Exp bijector.
>>> exp_bijector = nn.probability.bijector.Exp()
>>> value = Tensor([1, 2, 3], dtype=mindspore.float32)
>>> ans1 = exp_bijector.forward(value)
>>> print(ans1.shape)
(3,)
>>> ans2 = exp_bijector.inverse(value)
>>> print(ans2.shape)
(3,)
>>> ans3 = exp_bijector.forward_log_jacobian(value)
>>> print(ans3.shape)
(3,)
>>> ans4 = exp_bijector.inverse_log_jacobian(value)
>>> print(ans4.shape)
(3,)
```

forward(*value*)

forward mapping, compute the value after mapping as $Y = \exp(X)$.

Parameters

- **value** (Tensor) - the value to compute. X in the formula.

Returns

Tensor, the value of output after mapping.

forward_log_jacobian(*value*)

compute the log value after mapping.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the log value of forward mapping.

inverse(*value*)

Inverse mapping, compute the value after inverse mapping as $X = \log(Y)$.

Parameters

- **value** (Tensor) - the value of output after mapping. Y in the formula.

Returns

Tensor, the value to compute.

inverse_log_jacobian(*value*)

Compute the log value of the inverse mapping.

Parameters

- **value** (Tensor) - the value of output after mapping.

Returns

Tensor, the log value of the inverse mapping.

20.1.3 mindspore.nn.probability.bijector.GumbelCDF

class mindspore.nn.probability.bijector.**GumbelCDF**(*loc=0.0*, *scale=1.0*, *name='GumbelCDF'*)

GumbelCDF Bijector. This Bijector performs the operation:

$$Y = \exp(-\exp(\frac{-(X - loc)}{scale}))$$

Parameters

- **loc** (*float*, *list*, *numpy.ndarray*, *Tensor*) – The location. Default: `0.0`.
- **scale** (*float*, *list*, *numpy.ndarray*, *Tensor*) – The scale. Default: `1.0`.
- **name** (*str*) – The name of the Bijector. Default: `'GumbelCDF'`.

Note:

- *scale* must be greater than zero.
- For *inverse* and *inverse_log_jacobian*, input should be in range of (0, 1).
- The dtype of *loc* and *scale* must be float.
- If *loc*, *scale* are passed in as numpy.ndarray or tensor, they have to have the same dtype otherwise an error will be raised.

Raises

TypeError – When the dtype of *loc* or *scale* is not float, or when the dtype of *loc* and *scale* is not same.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.bijector as msb
>>> from mindspore import Tensor
>>>
>>> # To initialize a GumbelCDF bijector of loc 1.0, and scale 2.0.
>>> gumbel_cdf = msb.GumbelCDF(1.0, 2.0)
>>> # To use a GumbelCDF bijector in a network.
>>> x = Tensor([1, 2, 3], dtype=mindspore.float32)
>>> y = Tensor([0.1, 0.2, 0.3], dtype=mindspore.float32)
>>> ans1 = gumbel_cdf.forward(x)
>>> print(ans1.shape)
(3,)
>>> ans2 = gumbel_cdf.inverse(y)
>>> print(ans2.shape)
(3,)
>>> ans3 = gumbel_cdf.forward_log_jacobian(x)
>>> print(ans3.shape)
(3,)
>>> ans4 = gumbel_cdf.inverse_log_jacobian(y)
>>> print(ans4.shape)
(3,)
```

property loc
Return the loc parameter of the bijector.

Returns

Tensor, the loc parameter of the bijector.

property scale
Return the scale parameter of the bijector.

Returns

Tensor, the scale parameter of the bijector.

forward(*value*)
forward mapping, compute the value after mapping.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the value to compute.

forward_log_jacobian(*value*)
compute the log value after mapping.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the log value of forward mapping.

inverse(*value*)
Inverse mapping, compute the value after inverse mapping.

Parameters

- **value** (Tensor) - the value of output after mapping.

Returns

Tensor, the value of output after mapping.

inverse_log_jacobian(*value*)
Compute the log value of the inverse mapping.

Parameters

- **value** (Tensor) - the value of output after mapping.

Returns

Tensor, the log value of the inverse mapping.

20.1.4 mindspore.nn.probability.bijector.Invert

class mindspore.nn.probability.bijector.**Invert**(*bijector*, *name=''*)

Invert Bijector. Compute the inverse function of the input bijector. If the function of the forward mapping, namely the input of *bijector* below, is $Y = g(X)$, then the function of corresponding inverse mapping Bijector is $Y = h(X) = g^{-1}(X)$.

Parameters

- **bijector** (Bijector) –Base Bijector.
- **name** (*str*) –The name of the Bijector. Default: "" . When name is set to "", it is actually 'Invert' + Bijector.name.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.bijector as msb
>>> from mindspore import Tensor
>>> class Net(nn.Cell):
...     def __init__(self):
...         super(Net, self).__init__()
...         self.origin = msb.ScalarAffine(scale=2.0, shift=1.0)
...         self.invert = msb.Invert(self.origin)
...
...     def construct(self, x_):
...         return self.invert.forward(x_)
>>> forward = Net()
>>> x = np.array([2.0, 3.0, 4.0, 5.0]).astype(np.float32)
>>> ans = forward(Tensor(x, dtype=mindspore.float32))
>>> print(ans.shape)
(4,)
```

property bijector

Return base bijector.

forward(*x*)

Compute the inverse mapping of underlying Bijector, namely $Y = h(X) = g^{-1}(X)$.

Parameters

- **x** (Tensor) - the value of output after mapping by the underlying bijector.

Returns

Tensor, the inverse mapping of underlying Bijector.

forward_log_jacobian(*x*)

Compute the log value of the inverse mapping of underlying Bijector $\log dg^{-1}(x)/dx$.

Parameters

- **x** (Tensor) - the value of output after mapping by the underlying bijector.

Returns

Tensor, the log value of the inverse mapping of underlying Bijector.

inverse(*y*)

Compute the forward mapping of underlying Bijector, namely $Y = g(X)$.

Parameters

- **y** (Tensor) - the value to compute by the underlying bijector.

Returns

Tensor, the forward mapping of underlying Bijector.

inverse_log_jacobian(*y*)

Compute the log value of the forward mapping of underlying Bijector, namely $Y = \log dg(x)/dx$.

Parameters

- **y** (Tensor) - the value to compute by the underlying bijector.

Returns

Tensor, the log value of forward mapping of underlying Bijector.

20.1.5 mindspore.nn.probability.bijector.PowerTransform

class mindspore.nn.probability.bijector.**PowerTransform**(*power=0.*, *name='PowerTransform'*)

PowerTransform Bijector. This Bijector performs the operation:

$$Y = g(X) = (1 + X * c)^{1/c}, X >= -1/c$$

where c >= 0 is the power.

The power transform maps inputs from *[-1/c, inf]* to *[0, inf]*.

This Bijector is equivalent to the *mindspore.nn.probability.bijector.Exp* bijector when *c=0*.

Parameters

- **power** (*float*, *list*, *numpy.ndarray*, Tensor) –The scale factor. Default: 0 .
- **name** (*str*) –The name of the bijector. Default: 'PowerTransform' .

Note: The dtype of *power* must be float.

Raises

- **ValueError** –When *power* is less than 0 or is not known statically.
- **TypeError** –When the dtype of *power* is not float.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.bijector as msb
>>> from mindspore import Tensor
>>> # To initialize a PowerTransform bijector of power 0.5.
>>> powertransform = msb.PowerTransform(0.5)
>>> value = Tensor([1, 2, 3], dtype=mindspore.float32)
>>> ans1 = powertransform.forward(value)
>>> print(ans1.shape)
(3,)
>>> ans2 = powertransform.inverse(value)
>>> print(ans2.shape)
(3,)
>>> ans3 = powertransform.forward_log_jacobian(value)
>>> print(ans3.shape)
(3,)
>>> ans4 = powertransform.inverse_log_jacobian(value)
>>> print(ans4.shape)
(3,)
```

property power

Return the power index.

Returns

Tensor, the power index.

forward(*value*)

forward mapping, compute the value after mapping.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the value to compute.

forward_log_jacobian(*value*)

compute the log value after mapping.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the log value of forward mapping.

inverse(*value*)

Inverse mapping, compute the value after inverse mapping.

Parameters

- **value** (Tensor) - the value of output after mapping.

Returns

Tensor, the value of output after mapping.

inverse_log_jacobian(*value*)

Compute the log value of the inverse mapping.

Parameters

- **value** (Tensor) - the value of output after mapping.

Returns

Tensor, the log value of the inverse mapping.

20.1.6 mindspore.nn.probability.bijector.ScalarAffine

class mindspore.nn.probability.bijector.**ScalarAffine**(*scale=1.0*, *shift=0.0*, *name='ScalarAffine'*)

Scalar Affine Bijector. This Bijector performs the operation:

$$Y = a * X + b$$

where a is the scale factor and b is the shift factor.

Parameters

- **scale** (*float*, *list*, *numpy.ndarray*, Tensor) –The scale factor. a in the formula. Default: 1.0.
- **shift** (*float*, *list*, *numpy.ndarray*, Tensor) –The shift factor. b in the formula. Default: 0.0.
- **name** (*str*) –The name of the bijector. Default: 'ScalarAffine'.

Note: The dtype of *shift* and *scale* must be float. If *shift*, *scale* are passed in as numpy.ndarray or tensor, they have to have the same dtype otherwise an error will be raised.

Raises

TypeError –When the dtype of *shift* or *scale* is not float, and when the dtype of *shift* and *scale* is not same.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> from mindspore import Tensor
>>>
>>> # To initialize a ScalarAffine bijector of scale 1.0 and shift 2.
>>> scalaraffine = nn.probability.bijector.ScalarAffine(1.0, 2.0)
>>> value = Tensor([1, 2, 3], dtype=mindspore.float32)
>>> ans1 = scalaraffine.forward(value)
>>> print(ans1.shape)
(3,)
>>> ans2 = scalaraffine.inverse(value)
>>> print(ans2.shape)
(3,)
>>> ans3 = scalaraffine.forward_log_jacobian(value)
>>> print(ans3.shape)
()
>>> ans4 = scalaraffine.inverse_log_jacobian(value)
>>> print(ans4.shape)
()
```

property shift
Return the shift parameter of the bijector.

Returns

Tensor, the shift parameter of the bijector.

property scale
Return the scale parameter of the bijector.

Returns

Tensor, the scale parameter of the bijector.

forward(*value*)
forward mapping, compute the value after mapping.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the value to compute.

forward_log_jacobian(*value*)
compute the log value after mapping.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the log value of forward mapping.

inverse(*value*)
Inverse mapping, compute the value after inverse mapping.

Parameters

- **value** (Tensor) - the value of output after mapping.

Returns

Tensor, the value of input after mapping.

inverse_log_jacobian(*value*)
Compute the log value of the inverse mapping.

Parameters

- **value** (Tensor) - the value of output after mapping.

Returns

Tensor, the log value of the inverse mapping.

20.1.7 mindspore.nn.probability.bijector.Softplus

class mindspore.nn.probability.bijector.**Softplus**(*sharpness=1.0*, *name='Softplus'*)

Softplus Bijector. This Bijector performs the operation:

$$Y = \frac{\log(1 + e^{kX})}{k}$$

where k is the sharpness factor.

Parameters

- **sharpness** (*float*, *list*, *numpy.ndarray*, Tensor) – The scale factor. k in the above formula. Default: 1.0.
- **name** (*str*) – The name of the Bijector. Default: 'Softplus'.

Note: The dtype of *sharpness* must be float.

Raises

TypeError – When the dtype of the sharpness is not float.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.bijector as msb
>>> from mindspore import Tensor
>>>
>>> # To initialize a Softplus bijector of sharpness 2.0.
>>> softplus = msb.Softplus(2.0)
>>> # To use a Softplus bijector in a network.
>>> value = Tensor([1, 2, 3], dtype=mindspore.float32)
>>> ans1 = softplus.forward(value)
>>> print(ans1.shape)
(3,)
>>> ans2 = softplus.inverse(value)
>>> print(ans2.shape)
(3,)
>>> ans3 = softplus.forward_log_jacobian(value)
>>> print(ans3.shape)
(3,)
>>> ans4 = softplus.inverse_log_jacobian(value)
>>> print(ans4.shape)
(3,)
```

property sharpness

Return the sharpness parameter of the distribution.

Returns

Tensor, the sharpness parameter of the distribution.

forward(*value*)
forward mapping, compute the value after mapping.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the value to compute.

forward_log_jacobian(*value*)
compute the log value after mapping.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the log value of forward mapping.

inverse(*value*)
Inverse mapping, compute the value after inverse mapping.

Parameters

- **value** (Tensor) - the value of output after mapping.

Returns

Tensor, the value of output after mapping.

inverse_log_jacobian(*value*)
Compute the log value of the inverse mapping.

Parameters

- **value** (Tensor) - the value of output after mapping.

Returns

Tensor, the log value of the inverse mapping.

20.2 Distributions

API Name	Description	Supported Platforms
mindspore.nn.probability.distribution.Bernoulli	Bernoulli Distribution.	Ascend GPU
mindspore.nn.probability.distribution.Beta	Beta distribution.	Ascend
mindspore.nn.probability.distribution.Categorical	Categorical distribution.	Ascend GPU
mindspore.nn.probability.distribution.Cauchy	Cauchy distribution.	Ascend
mindspore.nn.probability.distribution.Distribution	Base class for all mathematical distributions.	Ascend GPU
mindspore.nn.probability.distribution.Exponential	Exponential Distribution.	Ascend GPU

continues on next page

Table 2 – continued from previous page

mindspore.nn.probability.distribution.Gamma	Gamma distribution.	Ascend
mindspore.nn.probability.distribution.Geometric	Geometric Distribution.	Ascend GPU
mindspore.nn.probability.distribution.Gumbel	Gumbel distribution.	Ascend GPU
mindspore.nn.probability.distribution.HalfNormal	HalfNormal distribution.	CPU
mindspore.nn.probability.distribution.Laplace	Laplace distribution.	Ascend GPU CPU
mindspore.nn.probability.distribution.Logistic	Logistic distribution.	Ascend GPU
mindspore.nn.probability.distribution.LogNormal	LogNormal distribution.	Ascend GPU
mindspore.nn.probability.distribution.Normal	Normal distribution.	Ascend GPU
mindspore.nn.probability.distribution.Poisson	Poisson Distribution.	Ascend
mindspore.nn.probability.distribution.StudentT	StudentT distribution.	CPU
mindspore.nn.probability.distribution.TransformedDistribution	Transformed Distribution.	Ascend GPU CPU
mindspore.nn.probability.distribution.Uniform	Uniform Distribution.	Ascend GPU CPU

20.2.1 mindspore.nn.probability.distribution.Bernoulli

class mindspore.nn.probability.distribution.**Bernoulli**(*probs=None*, *seed=None*, *dtype=mstype.int32*, *name='Bernoulli'*)

Bernoulli Distribution. A Bernoulli Distribution is a discrete distribution with the range $\{0, 1\}$ and the probability mass function as $P(X = 0) = p, P(X = 1) = 1 - p$.

Parameters

- **probs** (*float*, *list*, *numpy.ndarray*, *Tensor*) – The probability of that the outcome is 1. Default: `None`.
- **seed** (*int*) – The seed used in sampling. The global seed is used if it is None. Default: `None`.
- **dtype** (*mindspore.dtype*) – The type of the event samples. Default: `mstype.int32`.
- **name** (*str*) – The name of the distribution. Default: `'Bernoulli'`.

Note: *probs* must be a proper probability (0 < p < 1). *dist_spec_args* is *probs*.

Raises

ValueError – When p <= 0 or p >=1.

Supported Platforms:

`Ascend GPU`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> # To initialize a Bernoulli distribution of the probability 0.5.
>>> b1 = msd.Bernoulli(0.5, dtype=mindspore.int32)
>>> # A Bernoulli distribution can be initialized without arguments.
>>> # In this case, `probs` must be passed in through arguments during function calls.
>>> b2 = msd.Bernoulli(dtype=mindspore.int32)
>>> # Here are some tensors used below for testing
>>> value = Tensor([1, 0, 1], dtype=mindspore.int32)
>>> probs_a = Tensor([0.6], dtype=mindspore.float32)
>>> probs_b = Tensor([0.2, 0.3, 0.4], dtype=mindspore.float32)
>>> # Private interfaces of probability functions corresponding to public interfaces,␣
↪including
>>> # `prob`, `log_prob`, `cdf`, `log_cdf`, `survival_function`, and `log_survival`, are the␣
↪same as follows.
>>> # Args:
>>> #     value (Tensor): the value to be evaluated.
>>> #     probs1 (Tensor): the probability of success. Default: self.probs.
>>> # Examples of `prob`.
>>> # Similar calls can be made to other probability functions
>>> # by replacing `prob` by the name of the function.
>>> ans = b1.prob(value)
>>> print(ans.shape)
(3,)
>>> # Evaluate `prob` with respect to distribution b.
>>> ans = b1.prob(value, probs_b)
>>> print(ans.shape)
(3,)
>>> # `probs` must be passed in during function calls.
>>> ans = b2.prob(value, probs_a)
>>> print(ans.shape)
(3,)

(2, 3, 1)
```

property probs

Return the probability of success, namely the output is 1.

Returns

Tensor, the probability of success.

cdf (*value*, *probs1*)

Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **probs1** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

cross_entropy (*dist*, *probs1_b*, *probs1_a*)

Compute the cross entropy of two distribution.

Parameters

- **dist** (str) - the type of the distribution.
- **probs1_b** (Tensor) - the probability of success of the distribution b.
- **probs1_a** (Tensor) - the probability of success of the distribution a. Default: `None` .

Returns

Tensor, the value of the cross entropy.

entropy(*probs1=None*)
Compute the value of the entropy.

Parameters

- **probs1** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the value of the entropy.

kl_loss(*dist*, *probs1_b*, *probs1_a*)
Compute the value of the K-L loss between two distribution, namely KL(a||b).

Parameters

- **dist** (str) - the type of the other distribution.
- **probs1_b** (Tensor) - the probability of success of the distribution a.
- **probs1_a** (Tensor) - the probability of success of the distribution b. Default: `None` .

Returns

Tensor, the value of the K-L loss.

log_cdf(*value*, *probs1*)
Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.
- **probs1** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob(*value*, *probs1*)
the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **probs1** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival(*value*, *probs1*)
Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **probs1** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mean(*probs1*)
Compute the mean value of the distribution.

Parameters

- **probs1** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the mean of the distribution.

mode (*probs1*)

Compute the mode value of the distribution.

Parameters

- **probs1** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob (*value*, *probs1*)

The probability of the given value. For the discrete distribution, it is the probability mass function(pmf).

Parameters

- **value** (Tensor) - the value to compute.
- **probs1** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the value of the probability.

sample (*shape*, *probs1*)

Generate samples.

Parameters

- **shape** (tuple) - the shape of the sample.
- **probs1** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the sample following the distribution.

sd (*probs1*)

The standard deviation.

Parameters

- **probs1** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the standard deviation of the distribution.

survival_function (*value*, *probs1*)

Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **probs1** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the value of the survival function.

var (*probs1*)

Compute the variance of the distribution.

Parameters

- **probs1** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the variance of the distribution.

20.2.2 mindspore.nn.probability.distribution.Beta

class mindspore.nn.probability.distribution.**Beta**(*concentration1=None*, *concentration0=None*, *seed=None*, *dtype=mstype.float32*, *name='Beta'*)

Beta distribution. A Beta distributio is a continuous distribution with the range $[0, 1]$ and the probability density function:

$$f(x, \alpha, \beta) = x^{\alpha}(1-x)^{\beta-1}/B(\alpha, \beta)$$

Where B is the Beta function.

Parameters

- **concentration1** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) −The concentration1, also know as $alpha$ of the Beta distribution. Default: `None` .
- **concentration0** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) −The concentration0, also know as $beta$ of the Beta distribution. Default: `None` .
- **seed** (*int*) −The seed used in sampling. The global seed is used if it is None. Default: `None` .
- **dtype** (mindspore.dtype) −The type of the event samples. Default: `mstype.float32` .
- **name** (*str*) −The name of the distribution. Default: `'Beta'` .

Note:

- *concentration1* and *concentration0* must be greater than zero.
- *dist_spec_args* are *concentration1* and *concentration0*.
- *dtype* must be a float type because Beta distributions are continuous.

Raises

- **ValueError** −When concentration1 <= 0 or concentration0 >=1.
- **TypeError** −When the input *dtype* is not a float or a subclass of float.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> # To initialize a Beta distribution of the concentration1 3.0 and the concentration0 4.0.
>>> b1 = msd.Beta([3.0], [4.0], dtype=mindspore.float32)
>>> # A Beta distribution can be initialized without arguments.
>>> # In this case, `concentration1` and `concentration0` must be passed in through␣
↪arguments.
>>> b2 = msd.Beta(dtype=mindspore.float32)
>>> # Here are some tensors used below for testing
>>> value = Tensor([0.1, 0.5, 0.8], dtype=mindspore.float32)
>>> concentration1_a = Tensor([2.0], dtype=mindspore.float32)
>>> concentration0_a = Tensor([2.0, 2.0, 2.0], dtype=mindspore.float32)
>>> concentration1_b = Tensor([1.0], dtype=mindspore.float32)
>>> concentration0_b = Tensor([1.0, 1.5, 2.0], dtype=mindspore.float32)
>>> # Private interfaces of probability functions corresponding to public interfaces,␣
↪including
>>> # `prob` and `log_prob`, have the same arguments as follows.
>>> # Args:

>>> print(ans.shape)
(2, 3, 3)
>>> ans = b2.sample((2,3), concentration1_a, concentration0_a)
>>> print(ans.shape)
(2, 3, 3)
```

property concentration0

Return concentration0, aka the beta parameter of the Beta distribution.

Returns

Tensor, the value of concentration0.

property concentration1

Return concentration1, aka the alpha parameter of the Beta distribution.

Returns

Tensor, the value of concentration1.

cdf(*value*, *concentration1*, *concentration0*)

Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **concentration1** (Tensor) - the alpha parameter of the Beta distribution. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

cross_entropy (*dist*, *concentration1_b*, *concentration0_b*, *concentration1*, *concentration0*)
Compute the cross entropy of two distribution.

Parameters

- **dist** (str) - the type of the other distribution.
- **concentration1_b** (Tensor) - the alpha parameter of the other Beta distribution b.
- **concentration0_b** (Tensor) - the beta parameter of the other Beta distribution b.
- **concentration1** (Tensor) - the alpha parameter of the Beta distribution a. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution a. Default: `None` .

Returns

Tensor, the value of the cross entropy.

entropy (*concentration1*, *concentration0*)
Compute the value of the entropy.

Parameters

- **concentration1** (Tensor) - the alpha parameter of the Beta distribution. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution. Default: `None` .

Returns

Tensor, the value of the entropy.

kl_loss (*dist*, *concentration1_b*, *concentration0_b*, *concentration1*, *concentration0*)
Compute the value of the K-L loss between two distribution, namely KL(a||b).

Parameters

- **dist** (str) - the type of the other distribution.
- **concentration1_b** (Tensor) - the alpha parameter of the other Beta distribution b.
- **concentration0_b** (Tensor) - the beta parameter of the other Beta distribution b.
- **concentration1** (Tensor) - the alpha parameter of the Beta distribution a. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution a. Default: `None` .

Returns

Tensor, the value of the K-L loss.

log_cdf (*value*, *concentration1*, *concentration0*)
Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.

- **concentration1** (Tensor) - the alpha parameter of the Beta distribution. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob (*value*, *concentration1*, *concentration0*)
the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **concentration1** (Tensor) - the alpha parameter of the Beta distribution. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival (*value*, *concentration1*, *concentration0*)
Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **concentration1** (Tensor) - the alpha parameter of the Beta distribution. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mean (*concentration1*, *concentration0*)
Compute the mean value of the distribution.

Parameters

- **concentration1** (Tensor) - the alpha parameter of the Beta distribution. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution. Default: `None` .

Returns

Tensor, the mean of the distribution.

mode (*concentration1*, *concentration0*)
Compute the mode value of the distribution.

Parameters

- **concentration1** (Tensor) - the alpha parameter of the Beta distribution. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob (*value*, *concentration1*, *concentration0*)
The probability of the given value. For the continuous distribution, it is the probability density function.

Parameters

- **value** (Tensor) - the value to compute.

- **concentration1** (Tensor) - the alpha parameter of the Beta distribution. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution. Default: `None` .

Returns

Tensor, the value of the probability.

sample(*shape*, *concentration1*, *concentration0*)
Generate samples.

Parameters

- **shape** (tuple) - the shape of the sample.
- **concentration1** (Tensor) - the alpha parameter of the Beta distribution. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution. Default: `None` .

Returns

Tensor, the sample following the distribution.

sd(*concentration1*, *concentration0*)
The standard deviation.

Parameters

- **concentration1** (Tensor) - the alpha parameter of the Beta distribution. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution. Default: `None` .

Returns

Tensor, the standard deviation of the distribution.

survival_function(*value*, *concentration1*, *concentration0*)
Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **concentration1** (Tensor) - the alpha parameter of the Beta distribution. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution. Default: `None` .

Returns

Tensor, the value of the survival function.

var(*concentration1*, *concentration0*)
Compute the variance of the distribution.

Parameters

- **concentration1** (Tensor) - the alpha parameter of the Beta distribution. Default: `None` .
- **concentration0** (Tensor) - the beta parameter of the Beta distribution. Default: `None` .

Returns

Tensor, the variance of the distribution.

20.2.3 mindspore.nn.probability.distribution.Categorical

class mindspore.nn.probability.distribution.**Categorical**(*probs=None*, *seed=None*, *dtype=mstype.int32*, *name='Categorical'*)

Categorical distribution. A Categorical Distribution is a discrete distribution with the range $\{1, 2, ..., k\}$ and the probability mass function as $P(X = i) = p_i, i = 1, ..., k$.

Parameters

- **probs** (*Tensor, list, numpy.ndarray*) – Event probabilities. Default: `None`.
- **seed** (*int*) – The global seed is used in sampling. Global seed is used if it is None. Default: `None`.
- **dtype** (*mindspore.dtype*) – The type of the event samples. Default: `mstype.int32`.
- **name** (*str*) – The name of the distribution. Default: `'Categorical'`.

Note: *probs* must have rank at least 1, values are proper probabilities and sum to 1.

Raises

ValueError – When the sum of all elements in *probs* is not 1.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> # To initialize a Categorical distribution of probs [0.5, 0.5]
>>> ca1 = msd.Categorical(probs=[0.2, 0.8], dtype=mindspore.int32)
>>> # A Categorical distribution can be initialized without arguments.
>>> # In this case, `probs` must be passed in through arguments during function calls.
>>> ca2 = msd.Categorical(dtype=mindspore.int32)
>>> # Here are some tensors used below for testing
>>> value = Tensor([1, 0], dtype=mindspore.int32)
>>> probs_a = Tensor([0.5, 0.5], dtype=mindspore.float32)
>>> probs_b = Tensor([0.35, 0.65], dtype=mindspore.float32)
>>> # Private interfaces of probability functions corresponding to public interfaces,␣
↪including
>>> # `prob`, `log_prob`, `cdf`, `log_cdf`, `survival_function`, and `log_survival`, are the␣
↪same as follows.
>>> # Args:
>>> #     value (Tensor): the value to be evaluated.
>>> #     probs (Tensor): event probabilities. Default: self.probs.
>>> # Examples of `prob`.
>>> # Similar calls can be made to other probability functions
>>> # by replacing `prob` by the name of the function.
>>> ans = ca1.prob(value)
>>> print(ans.shape)
(2,)
>>> # Evaluate `prob` with respect to distribution b.
```

(continues on next page)

(continued from previous page)

```
>>> ans = ca1.prob(value, probs_b)
>>> print(ans.shape)

()
>>> # An additional `probs` must be passed in.
>>> ans = ca2.kl_loss('Categorical', probs_b, probs_a)
>>> print(ans.shape)
()
```

property probs

Return the event probability.

Returns

Tensor, the event probability.

cdf (*value*, *probs*)

Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **probs** (Tensor) - the event probability. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

cross_entropy (*dist*, *probs_b*, *probs*)

Compute the cross entropy of two distribution.

Parameters

- **dist** (str) - the type of the other distribution.
- **probs_b** (Tensor) - the event probability of the distribution b.
- **probs** (Tensor) - the event probability of the distribution a. Default: `None` .

Returns

Tensor, the value of the cross entropy.

entropy(*probs*)

Compute the value of the entropy.

Parameters

- **probs** (Tensor) - the event probability. Default: `None` .

Returns

Tensor, the value of the entropy.

kl_loss(*dist*, *probs_b*, *probs*)

Compute the value of the K-L loss between two distribution, namely KL(a||b).

Parameters

- **dist** (str) - the type of the other distribution.
- **probs_b** (Tensor) - the event probability of the distribution b.
- **probs** (Tensor) - the event probability of the distribution a. Default: `None` .

Returns

Tensor, the value of the K-L loss.

log_cdf(*value*, *probs*)

Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.
- **probs** (Tensor) - the event probability. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob(*value*, *probs*)

the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **probs** (Tensor) - the event probability. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival(*value*, *probs*)

Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.

- **probs** (Tensor) - the event probability. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mean(*probs*)

Compute the mean value of the distribution.

Parameters

- **probs** (Tensor) - the event probability. Default: `None` .

Returns

Tensor, the mean of the distribution.

mode(*probs*)

Compute the mode value of the distribution.

Parameters

- **probs** (Tensor) - the event probability. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob(*value*, *probs*)

The probability of the given value. For the discrete distribution, it is the probability mass function(pmf).

Parameters

- **value** (Tensor) - the value to compute.
- **probs** (Tensor) - the event probability. Default: `None` .

Returns

Tensor, the value of the probability.

sample(*shape*, *probs*)

Generate samples.

Parameters

- **shape** (tuple) - the shape of the sample.
- **probs** (Tensor) - the event probability. Default: `None` .

Returns

Tensor, the sample following the distribution.

sd(*probs*)

The standard deviation.

Parameters

- **probs** (Tensor) - the event probability. Default: `None` .

Returns

Tensor, the standard deviation of the distribution.

survival_function(*value*, *probs*)

Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **probs** (Tensor) - the event probability. Default: `None` .

Returns

Tensor, the value of the survival function.

var(*probs*)

Compute the variance of the distribution.

Parameters

- **probs** (Tensor) - the event probability. Default: `None` .

Returns

Tensor, the variance of the distribution.

20.2.4 mindspore.nn.probability.distribution.Cauchy

class mindspore.nn.probability.distribution.**Cauchy**(*loc=None*, *scale=None*, *seed=None*, *dtype=mstype.float32*, *name='Cauchy'*)

Cauchy distribution. A Cauchy distributio is a continuous distribution with the range of all real numbers and the probability density function:

$$f(x, a, b) = 1/\pi b(1 - ((x - a)/b)^2)$$

Where a, b are loc and scale parameter respectively.

Parameters

- **loc** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) −The location of the Cauchy distribution. a in the formula. Default: `None` .
- **scale** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) −The scale of the Cauchy distribution. b in the formula. Default: `None` .
- **seed** (*int*) −The seed used in sampling. The global seed is used if it is None. Default: `None` .
- **dtype** (mindspore.dtype) −The type of the event samples. Default: `mstype.float32` .
- **name** (*str*) −The name of the distribution. Default: `'Cauchy'` .

Note: *scale* must be greater than zero. *dist_spec_args* are *loc* and *scale*. *dtype* must be a float type because Cauchy distributions are continuous. Cauchy distribution is not supported on GPU backend.

Raises

- **ValueError** −When scale <= 0.
- **TypeError** −When the input *dtype* is not a subclass of float.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> # To initialize a Cauchy distribution of loc 3.0 and scale 4.0.
>>> cauchy1 = msd.Cauchy(3.0, 4.0, dtype=mindspore.float32)
>>> # A Cauchy distribution can be initialized without arguments.
>>> # In this case, 'loc' and `scale` must be passed in through arguments.
>>> cauchy2 = msd.Cauchy(dtype=mindspore.float32)
>>> # Here are some tensors used below for testing
>>> value = Tensor([1.0, 2.0, 3.0], dtype=mindspore.float32)
>>> loc_a = Tensor([2.0], dtype=mindspore.float32)

```

property loc

Return the loc parameter of the distribution.

Returns

Tensor, the loc parameter of the distribution.

property scale

Return the scale parameter of the distribution.

Returns

Tensor, the scale parameter of the distribution.

cdf(*value*, *loc*, *scale*)

Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

cross_entropy(*dist*, *loc_b*, *scale_b*, *loc*, *scale*)
Compute the cross entropy of two distribution.

Parameters

- **dist** (str) - the type of the other distribution.
- **loc_b** (Tensor) - the loc parameter of the other distribution.
- **scale_b** (Tensor) - the scale parameter of the other distribution.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the cross entropy.

entropy(*loc*, *scale*)
Compute the value of the entropy.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the entropy.

kl_loss(*dist*, *loc_b*, *scale_b*, *loc*, *scale*)
Compute the value of the K-L loss between two distribution, namely KL(a||b).

Parameters

- **dist** (str) - the type of the other distribution.
- **loc_b** (Tensor) - the loc parameter of the other distribution.
- **scale_b** (Tensor) - the scale parameter of the other distribution.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

log_cdf(*value*, *loc*, *scale*)
Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob(*value*, *loc*, *scale*)
the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival(*value*, *loc*, *scale*)

Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mean(*loc*, *scale*)

Compute the mean value of the distribution.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the mean of the distribution.

mode(*loc*, *scale*)

Compute the mode value of the distribution.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob(*value*, *loc*, *scale*)

The probability of the given value. For the continuous distribution, it is the probability density function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the probability.

sample(*shape*, *loc*, *scale*)

Generate samples.

Parameters

- **shape** (tuple) - the shape of the sample.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the sample following the distribution.

sd (*loc*, *scale*)
The standard deviation.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the standard deviation of the distribution.

survival_function (*value*, *loc*, *scale*)
Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the survival function.

var (*loc*, *scale*)
Compute the variance of the distribution.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the variance of the distribution.

20.2.5 mindspore.nn.probability.distribution.Distribution

class mindspore.nn.probability.distribution.**Distribution** (*seed*, *dtype*, *name*, *param*)
Base class for all mathematical distributions.

Parameters

- **seed** (*int*) −The seed is used in sampling. 0 is used if it is None.
- **dtype** (mindspore.dtype) −The type of the event samples.
- **name** (*str*) −The name of the distribution.
- **param** (*dict*) −The parameters used to initialize the distribution.

Note: Derived class must override operations such as *_mean*, *_prob*, and *_log_prob*. Required arguments, such as *value* for *_prob*, must be passed in through *args* or *kwargs*. *dist_spec_args* which specifies a new distribution are optional.

dist_spec_args is unique for each type of distribution. For example, *mean* and *sd* are the *dist_spec_args* for a Normal distribution, while *rate* is the *dist_spec_args* for an Exponential distribution.

For all functions, passing in *dist_spec_args*, is optional. Function calls with the additional *dist_spec_args* passed in will evaluate the result with a new distribution specified by the *dist_spec_args*. However, it will not change the original distribution.

Supported Platforms:

`Ascend` `GPU`

cdf(*value*, **args*, ***kwargs*)

Evaluate the cumulative distribution function(cdf) at given value.

Parameters

- **value** (Tensor) −value to be evaluated.
- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Note: A distribution can be optionally passed to the function by passing its *dist_spec_args* through *args* or *kwargs*.

Returns

Tensor, the cdf of the distribution.

construct(*name*, **args*, ***kwargs*)

Override *construct* in Cell.

Note: Names of supported functions include: 'prob', 'log_prob', 'cdf', 'log_cdf', 'survival_function', 'log_survival', 'var', 'sd', 'mode', 'mean', 'entropy', 'kl_loss', 'cross_entropy', 'sample', 'get_dist_args', and 'get_dist_type'.

Parameters

- **name** (*str*) −The name of the function.
- ***args** (*list*) −A list of positional arguments that the function needs.
- ****kwargs** (*dict*) −A dictionary of keyword arguments that the function needs.

Returns

Tensor, the value of corresponding computation method.

cross_entropy(*dist*, **args*, ***kwargs*)

Evaluate the cross_entropy between distribution a and b.

Parameters

- **dist** (*str*) −type of the distribution.
- ***args** (*list*) −the list of positional arguments forwarded to subclasses.

- ****kwargs** (*dict*) –the dictionary of keyword arguments forwarded to subclasses.

Note: *dist_spec_args* of distribution b must be passed to the function through *args* or *kwargs*. Passing in *dist_spec_args* of distribution a is optional.

Returns

Tensor, the cross_entropy of two distributions.

entropy(**args*, ***kwargs*)
Evaluate the entropy.

Parameters

- ***args** (*list*) –the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) –the dictionary of keyword arguments forwarded to subclasses.

Note: A distribution can be optionally passed to the function by passing its *dist_spec_args* through *args* or *kwargs*.

Returns

Tensor, the entropy of the distribution.

get_dist_args(**args*, ***kwargs*)
Check the availability and validity of default parameters and *dist_spec_args*.

Parameters

- ***args** (*list*) –the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) –the dictionary of keyword arguments forwarded to subclasses.

Note: *dist_spec_args* must be passed in through list or dictionary. The order of *dist_spec_args* should follow the initialization order of default parameters through *_add_parameter*. If some *dist_spec_args* is None, the corresponding default parameter is returned.

Returns

list[Tensor], the list of parameters.

get_dist_type()
Return the type of the distribution.

Returns

string, the name of distribution.

kl_loss(*dist*, **args*, ***kwargs*)
Evaluate the KL divergence, i.e. KL(a||b).

Parameters

- **dist** (*str*) –type of the distribution.
- ***args** (*list*) –the list of positional arguments forwarded to subclasses.

- ****kwargs** (*dict*) –the dictionary of keyword arguments forwarded to subclasses.

Note: *dist_spec_args* of distribution b must be passed to the function through *args* or *kwargs*. Passing in *dist_spec_args* of distribution a is optional.

Returns

Tensor, the kl loss function of the distribution.

log_cdf(*value*, **args*, ***kwargs*)
Evaluate the log the cumulative distribution function(cdf) at given value.

Parameters

- **value** (Tensor) –value to be evaluated.
- ***args** (*list*) –the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) –the dictionary of keyword arguments forwarded to subclasses.

Note: A distribution can be optionally passed to the function by passing its *dist_spec_args* through *args* or *kwargs*.

Returns

Tensor, the log cdf of the distribution.

log_prob(*value*, **args*, ***kwargs*)
Evaluate the log probability(pdf or pmf) at the given value.

Parameters

- **value** (Tensor) –value to be evaluated.
- ***args** (*list*) –the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) –the dictionary of keyword arguments forwarded to subclasses.

Note: A distribution can be optionally passed to the function by passing its *dist_spec_args* through *args* or *kwargs*.

Returns

Tensor, the value of log probability.

log_survival(*value*, **args*, ***kwargs*)
Evaluate the log survival function at given value.

Parameters

- **value** (Tensor) –value to be evaluated.
- ***args** (*list*) –the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) –the dictionary of keyword arguments forwarded to subclasses.

Note: A distribution can be optionally passed to the function by passing its *dist_spec_args* through *args* or *kwargs*.

Returns

Tensor, the log survival function of the distribution.

mean(**args*, ***kwargs*)
Evaluate the mean.

Parameters

- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Note: A distribution can be optionally passed to the function by passing its *dist_spec_args* through *args* or *kwargs*.

Returns

Tensor, the mean of the distribution.

mode(**args*, ***kwargs*)
Evaluate the mode.

Parameters

- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Note: A distribution can be optionally passed to the function by passing its *dist_spec_args* through *args* or *kwargs*.

Returns

Tensor, the mode of the distribution.

prob(*value*, **args*, ***kwargs*)
Evaluate the probability (pdf or pmf) at given value. For a discrete distribution, it is a probability mass function, while for a continuous distribution, it is probability density function.

Parameters

- **value** (Tensor) −value to be evaluated.
- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Note: A distribution can be optionally passed to the function by passing its *dist_spec_args* through *args* or *kwargs*.

Returns

Tensor, the value of probability.

sample(**args*, ***kwargs*)
Sampling function.

Parameters

- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Note: A distribution can be optionally passed to the function by passing its *dist_spec_args* through *args* or *kwargs*.

Returns

Tensor, the sample generated from the distribution.

sd(**args*, ***kwargs*)
Evaluate the standard deviation.

Parameters

- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Note: A distribution can be optionally passed to the function by passing its *dist_spec_args* through *args* or *kwargs*.

Returns

Tensor, the standard deviation of the distribution.

survival_function(*value*, **args*, ***kwargs*)
Evaluate the survival function at given value.

Parameters

- **value** (Tensor) −value to be evaluated.
- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Note: A distribution can be optionally passed to the function by passing its *dist_spec_args* through *args* or *kwargs*.

Returns

Tensor, the survival function of the distribution.

var(**args*, ***kwargs*)
Evaluate the variance.

Parameters

- ***args** (*list*) −the list of positional arguments forwarded to subclasses.
- ****kwargs** (*dict*) −the dictionary of keyword arguments forwarded to subclasses.

Note: A distribution can be optionally passed to the function by passing its *dist_spec_args* through *args* or *kwargs*.

Returns

Tensor, the variance of the distribution.

20.2.6 mindspore.nn.probability.distribution.Exponential

class mindspore.nn.probability.distribution.**Exponential**(*rate=None*, *seed=None*, *dtype=mstype.float32*, *name='Exponential'*)

Exponential Distribution. An Exponential distributio is a continuous distribution with the range $[0, \inf)$ and the probability density function:

$$f(x, \lambda) = \lambda \exp(-\lambda x)$$

where λ is the rate of the distribution.

Parameters

- **rate** (*int*, *float*, *list*, *numpy.ndarray*, *Tensor*, *optional*) –The inverse scale. λ in the formula. Default: `None` .
- **seed** (*int*, *optional*) –The seed used in sampling. The global seed is used if it is None. Default: `None` .
- **dtype** (mindspore.dtype, *optional*) –The type of the event samples. Default: `mstype.float32` .
- **name** (*str*, *optional*) –The name of the distribution. Default: `'Exponential'` .

Note:

- *rate* must be strictly greater than 0.
- *dtype* must be a float type because Exponential distributions are continuous.

Raises

- **ValueError** –When rate <= 0.
- **TypeError** –When the input *dtype* is not a subclass of float.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> # To initialize a Exponential distribution of the probability 0.5.
>>> e1 = msd.Exponential(0.5, dtype=mindspore.float32)
>>> # An Exponential distribution can be initialized without arguments.
>>> # In this case, `rate` must be passed in through `args` during function calls.
>>> e2 = msd.Exponential(dtype=mindspore.float32)
>>> # Here are some tensors used below for testing
>>> value = Tensor([1, 2, 3], dtype=mindspore.float32)
>>> rate_a = Tensor([0.6], dtype=mindspore.float32)
>>> rate_b = Tensor([0.2, 0.5, 0.4], dtype=mindspore.float32)
>>> # Private interfaces of probability functions corresponding to public interfaces,␣
↪including
```

(continues on next page)

(continued from previous page)

```
>>> # `prob`, `log_prob`, `cdf`, `log_cdf`, `survival_function`, and `log_survival`, are the␣
↪same as follows.

(2, 3)
>>> ans = e1.sample((2,3), rate_b)
>>> print(ans.shape)
(2, 3, 3)
>>> ans = e2.sample((2,3), rate_a)
>>> print(ans.shape)
(2, 3, 1)
```

property rate

Return rate.

Returns

Tensor, the rate of the distribution.

cdf (*value*, *rate=None*)

Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **rate** (Tensor, optional) - the rate of the distribution. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

cross_entropy (*dist*, *rate_b*, *rate=None*)

Compute the cross entropy of two distribution.

Parameters

- **dist** (str) - the type of the other distribution.
- **rate_b** (Tensor) - the rate b of the other distribution.
- **rate** (Tensor, optional) - the rate a of the distribution. Default: `None` .

Returns

Tensor, the value of the cross entropy.

entropy (*rate=None*)

Compute the value of the entropy.

Parameters

- **rate** (Tensor, optional) - the rate of the distribution. Default: `None` .

Returns

Tensor, the value of the entropy.

kl_loss (*dist*, *rate_b*, *rate=None*)

Compute the value of the K-L loss between two distribution, namely KL(a||b).

Parameters

- **dist** (str) - the type of the other distribution.
- **rate_b** (Tensor) - the rate b of the other distribution.
- **rate** (Tensor, optional) - the rate a of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

log_cdf(*value*, *rate=None*)

Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.
- **rate** (Tensor, optional) - the rate of the distribution. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob(*value*, *rate=None*)

the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **rate** (Tensor, optional) - the rate of the distribution. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival(*value*, *rate=None*)

Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **rate** (Tensor, optional) - the rate of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mean(*rate=None*)

Compute the mean value of the distribution.

Parameters

- **rate** (Tensor, optional) - the rate of the distribution. Default: `None` .

Returns

Tensor, the mean of the distribution.

mode(*rate=None*)

Compute the mode value of the distribution.

Parameters

- **rate** (Tensor, optional) - the rate of the distribution. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob(*value*, *rate=None*)

The probability of the given value. For the continuous distribution, it is the probability density function.

Parameters

- **value** (Tensor) - the value to compute.
- **rate** (Tensor, optional) - the rate of the distribution. Default: `None` .

Returns

Tensor, the value of the probability.

sample(*shape*, *rate=None*)
Generate samples.

Parameters

- **shape** (tuple) - the shape of the sample.
- **rate** (Tensor, optional) - the rate of the distribution. Default: `None` .

Returns

Tensor, the sample following the distribution.

sd(*rate=None*)
The standard deviation.

Parameters

- **rate** (Tensor, optional) - the rate of the distribution. Default: `None` .

Returns

Tensor, the standard deviation of the distribution.

survival_function(*value*, *rate=None*)
Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **rate** (Tensor, optional) - the rate of the distribution. Default: `None` .

Returns

Tensor, the value of the survival function.

var(*rate=None*)
Compute the variance of the distribution.

Parameters

- **rate** (Tensor, optional) - the rate of the distribution. Default: `None` .

Returns

Tensor, the variance of the distribution.

20.2.7 mindspore.nn.probability.distribution.Gamma

class mindspore.nn.probability.distribution.**Gamma**(*concentration=None*, *rate=None*, *seed=None*, *dtype=mstype.float32*, *name='Gamma'*)

Gamma distribution. A Gamma distributio is a continuous distribution with the range $(0, \inf)$ and the probability density function:

$$f(x, \alpha, \beta) = \beta^{\alpha}/\Gamma(\alpha)x^{\alpha-1}\exp(-\beta x).$$

where G is the Gamma function, and α and β are the concentration and the rate of the distribution respectively.

Parameters

- **concentration** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) –The concentration, also know as α of the Gamma distribution. Default: None .
- **rate** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) –The rate, also know as β of the Gamma distribution. Default: None .
- **seed** (*int*) –The seed used in sampling. The global seed is used if it is None. Default: None .
- **dtype** (mindspore.dtype) –The type of the event samples. Default: mstype.float32 .
- **name** (*str*) –The name of the distribution. Default: 'Gamma' .

Note: *concentration* and *rate* must be greater than zero. *dist_spec_args* are *concentration* and *rate*. *dtype* must be a float type because Gamma distributions are continuous.

Raises

- **ValueError** –When concentration <= 0 or rate <= 0.
- **TypeError** –When the input *dtype* is not a subclass of float.

Supported Platforms:

Ascend

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> # To initialize a Gamma distribution of the concentration 3.0 and the rate 4.0.
>>> g1 = msd.Gamma([3.0], [4.0], dtype=mindspore.float32)
>>> # A Gamma distribution can be initialized without arguments.

(2, 3, 3)
```

property concentration

Return the concentration, aka the α parameter, of the distribution.

Returns

Tensor, concentration.

property rate

Return the rate, aka the β parameter, of the distribution.

Returns

Tensor, rate.

cdf(*value*, *concentration*, *rate*)

Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

cross_entropy(*dist*, *concentration_b*, *rate_b*, *concentration*, *rate*)

Compute the cross entropy of two distribution.

Parameters

- **dist** (str) - the type of the other distribution.
- **concentration_b** (Tensor) - the α parameter of the other distribution.
- **rate_b** (Tensor) - the β parameter of the other distribution.
- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the cross entropy.

entropy(*concentration*, *rate*)
Compute the value of the entropy.

Parameters

- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the entropy.

kl_loss(*dist*, *concentration_b*, *rate_b*, *concentration*, *rate*)
Compute the value of the K-L loss between two distribution, namely KL(a||b).

Parameters

- **dist** (str) - the type of the other distribution.
- **concentration_b** (Tensor) - the α parameter of the other distribution.
- **rate_b** (Tensor) - the β parameter of the other distribution.
- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

log_cdf(*value*, *concentration*, *rate*)
Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.
- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob(*value*, *concentration*, *rate*)
the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival(*value*, *concentration*, *rate*)
Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .

- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mean(*concentration*, *rate*)
Compute the mean value of the distribution.

Parameters

- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the mean of the distribution.

mode(*concentration*, *rate*)
Compute the mode value of the distribution.

Parameters

- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob(*value*, *concentration*, *rate*)
The probability of the given value. For the continuous distribution, it is the probability density function.

Parameters

- **value** (Tensor) - the value to compute.
- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the probability.

sample(*shape*, *concentration*, *rate*)
Generate samples.

Parameters

- **shape** (tuple) - the shape of the sample.
- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the sample following the distribution.

sd(*concentration*, *rate*)
The standard deviation.

Parameters

- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the standard deviation of the distribution.

survival_function (*value*, *concentration*, *rate*)
Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the survival function.

var (*concentration*, *rate*)
Compute the variance of the distribution.

Parameters

- **concentration** (Tensor) - the α parameter of the distribution. Default: `None` .
- **rate** (Tensor) - the β parameter of the distribution. Default: `None` .

Returns

Tensor, the variance of the distribution.

20.2.8 mindspore.nn.probability.distribution.Geometric

class mindspore.nn.probability.distribution.**Geometric** (*probs=None*, *seed=None*, *dtype=mstype.int32*, *name='Geometric'*)

Geometric Distribution. A Geometric Distribution is a discrete distribution with the range as the non-negative integers, and the probability mass function as $P(X = i) = p(1 - p)^{i-1}, i = 1, 2, ...$ It represents that there are k failures before the first success, namely that there are in total k+1 Bernoulli trials when the first success is achieved.

Parameters

- **probs** (*float*, *list*, *numpy.ndarray*, `Tensor`) −The probability of success. Default: `None` .
- **seed** (*int*) −The seed used in sampling. Global seed is used if it is None. Default: `None` .
- **dtype** (`mindspore.dtype`) −The type of the event samples. Default: `mstype.int32` .
- **name** (*str*) −The name of the distribution. Default: `'Geometric'` .

Note: *probs* must be a proper probability (0 < p < 1). *dist_spec_args* is *probs*.

Raises

ValueError −When p <= 0 or p >= 1.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> # To initialize a Geometric distribution of the probability 0.5.
>>> g1 = msd.Geometric(0.5, dtype=mindspore.int32)
>>> # A Geometric distribution can be initialized without arguments.
>>> # In this case, `probs` must be passed in through arguments during function calls.
>>> g2 = msd.Geometric(dtype=mindspore.int32)
>>>
>>> # Here are some tensors used below for testing
>>> value = Tensor([1, 0, 1], dtype=mindspore.int32)
>>> probs_a = Tensor([0.6], dtype=mindspore.float32)

(2, 3, 3)
>>> ans = g2.sample((2,3), probs_a)
>>> print(ans.shape)
(2, 3, 1)
```

property probs

Return the probability of success.

Returns

Tensor, the probability of success.

cdf (*value*, *probs*)

Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

cross_entropy (*dist*, *probs_b*, *probs*)

Compute the cross entropy of two distribution.

Parameters

- **dist** (str) - the type of the other distribution.
- **probs_b** (Tensor) - the probability of success of the other distribution.

- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the value of the cross entropy.

entropy(*probs*)

Compute the value of the entropy.

Parameters

- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the value of the entropy.

kl_loss(*dist*, *probs_b*, *probs*)

Compute the value of the K-L loss between two distribution, namely KL(a||b).

Parameters

- **dist** (str) - the type of the other distribution.
- **probs_b** (Tensor) - the probability of success of the other distribution.
- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the value of the K-L loss.

log_cdf(*value*, *probs*)

Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.
- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob(*value*, *probs*)

the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival(*value*, *probs*)

Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mean (*probs*)
Compute the mean value of the distribution.

Parameters

- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the mean of the distribution.

mode (*probs*)
Compute the mode value of the distribution.

Parameters

- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob (*value*, *probs*)
The probability of the given value. For the discrete distribution, it is the probability mass function(pmf).

Parameters

- **value** (Tensor) - the value to compute.
- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the value of the probability.

sample (*shape*, *probs*)
Generate samples.

Parameters

- **shape** (tuple) - the shape of the sample.
- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the sample following the distribution.

sd (*probs*)
The standard deviation.

Parameters

- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the standard deviation of the distribution.

survival_function (*value*, *probs*)
Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the value of the survival function.

var (*probs*)

Compute the variance of the distribution.

Parameters

- **probs** (Tensor) - the probability of success. Default: `None` .

Returns

Tensor, the variance of the distribution.

20.2.9 mindspore.nn.probability.distribution.Gumbel

class mindspore.nn.probability.distribution.**Gumbel**(*loc*, *scale*, *seed=0*, *dtype=mstype.float32*, *name='Gumbel'*)

Gumbel distribution. A Gumbel distributio is a continuous distribution with the range of all real numbers and the probability density function:

$$f(x, a, b) = 1/b \exp(\exp(-(x - a)/b) - x)$$

Where a, b are loc and scale parameter respectively.

Parameters

- **loc** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) −The location of Gumbel distribution. a in the formula.
- **scale** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) −The scale of Gumbel distribution. b in the formula.
- **seed** (*int*) −the seed used in sampling. The global seed is used if it is None. Default: `0` .
- **dtype** (mindspore.dtype) −type of the distribution. Default: `mstype.float32` .
- **name** (*str*) −the name of the distribution. Default: `'Gumbel'` .

Note: *scale* must be greater than zero. *dist_spec_args* are *loc* and *scale*. *dtype* must be a float type because Gumbel distributions are continuous.

Raises

- **ValueError** −When scale <= 0.
- **TypeError** −When the input *dtype* is not a subclass of float.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> import numpy as np
>>> import mindspore.nn.probability.distribution as msd
>>> import mindspore.nn as nn
>>> from mindspore import Tensor
>>> class Prob(nn.Cell):
...     def __init__(self):
...         super(Prob, self).__init__()
...         self.gum = msd.Gumbel(np.array([0.0]), np.array([[1.0], [2.0]]), dtype=mindspore.
↪float32)
...
...     def construct(self, x_):
...         return self.gum.prob(x_)
>>> value = np.array([1.0, 2.0]).astype(np.float32)
>>> pdf = Prob()
>>> output = pdf(Tensor(value, dtype=mindspore.float32))
```

property loc

Return the loc parameter of the distribution.

Returns

Tensor, the loc parameter of the distribution.

property scale

Return the scale parameter of the distribution.

Returns

Tensor, the scale parameter of the distribution.

cdf (*value*, *loc*, *scale*)

Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

cross_entropy (*dist*, *loc_b*, *scale_b*, *loc*, *scale*)

Compute the cross entropy of two distribution.

Parameters

- **dist** (str) - the type of the other distribution.
- **loc_b** (Tensor) - the loc parameter of the other distribution.
- **scale_b** (Tensor) - the scale parameter of the other distribution.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the cross entropy.

entropy(*loc*, *scale*)
Compute the value of the entropy.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the entropy.

kl_loss(*dist*, *loc_b*, *scale_b*, *loc*, *scale*)
Compute the value of the K-L loss between two distribution, namely KL(a||b).

Parameters

- **dist** (str) - the type of the other distribution.
- **loc_b** (Tensor) - the loc parameter of the other distribution.
- **scale_b** (Tensor) - the scale parameter of the other distribution.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

log_cdf(*value*, *loc*, *scale*)
Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob(*value*, *loc*, *scale*)
the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival(*value*, *loc*, *scale*)
Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mean(*loc*, *scale*)

Compute the mean value of the distribution.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the mean of the distribution.

mode(*loc*, *scale*)

Compute the mode value of the distribution.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob(*value*, *loc*, *scale*)

The probability of the given value. For the continuous distribution, it is the probability density function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the probability.

sample(*shape*, *loc*, *scale*)

Generate samples.

Parameters

- **shape** (tuple) - the shape of the sample.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the sample following the distribution.

sd(*loc*, *scale*)

The standard deviation.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .

- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the standard deviation of the distribution.

survival_function (*value*, *loc*, *scale*)
Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the survival function.

var (*loc*, *scale*)
Compute the variance of the distribution.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the variance of the distribution.

20.2.10 mindspore.nn.probability.distribution.HalfNormal

class mindspore.nn.probability.distribution.**HalfNormal** (*mean=None*, *sd=None*, *seed=None*, *dtype=mstype.float32*, *name='HalfNormal'*)

HalfNormal distribution. A HalfNormal distribution is a continuous distribution with the range $[\mu, \inf)$ and the probability density function:

$$f(x, \mu, \sigma) = 1/\sigma\sqrt{2\pi}\exp(-(x-\mu)^2/2\sigma^2).$$

where μ, σ are the mean and the standard deviation of the half normal distribution respectively.

Parameters

- **mean** (*Union[int, float, list, numpy.ndarray, Tensor], optional*) – The mean of the distribution. μ in the formula. If this arg is `None` , then the mean of the distribution will be passed in runtime. Default: `None` .
- **sd** (*Union[int, float, list, numpy.ndarray, Tensor], optional*) – The standard deviation of the distribution. σ in the formula. If this arg is `None` , then the sd of the distribution will be passed in runtime. Default: `None` .
- **seed** (*int, optional*) – The seed used in sampling. The global seed is used if it is None. Default: `None` .
- **dtype** (mindspore.dtype, *optional*) – The type of the event samples. Default: `mstype.float32` .
- **name** (*str, optional*) – The name of the distribution. Default: `'HalfNormal'` .

Note:

- *sd* must be greater than zero.

- *dtype* must be a float type because HalfNormal distributions are continuous.
- If the arg *mean* or *sd* is passed in runtime, then it will be used as the parameter value. Otherwise, the value passed in the constructor will be used.

Raises

- **ValueError** −When sd <= 0.
- **TypeError** −When the input *dtype* is not a float or a subclass of float.

Supported Platforms:

`CPU`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> from mindspore.nn.probability.distribution import HalfNormal
>>> from mindspore import Tensor
>>> # To initialize a HalfNormal distribution of the mean 3.0 and the standard deviation 4.0.
>>> n1 = HalfNormal(3.0, 4.0, dtype=mindspore.float32)
>>> # A HalfNormal distribution can be initialized without arguments.
>>> # In this case, `mean` and `sd` must be passed in through arguments.
>>> hn = HalfNormal(dtype=mindspore.float32)
>>> # Here are some tensors used below for testing
>>> value = Tensor([1.0, 2.0, 3.0], dtype=mindspore.float32)
>>> mean_a = Tensor([2.0], dtype=mindspore.float32)
>>> sd_a = Tensor([2.0, 2.0, 2.0], dtype=mindspore.float32)
>>> mean_b = Tensor([1.0], dtype=mindspore.float32)
>>> sd_b = Tensor([1.0, 1.5, 2.5], dtype=mindspore.float32)
>>> ans = n1.log_prob(value)
>>> print(ans.shape)
(3,)
>>> # Evaluate with respect to the distribution b.
>>> ans = n1.log_prob(value, mean_b, sd_b)
>>> print(ans.shape)
(3,)
>>> # `mean` and `sd` must be passed in during function calls
>>> ans = hn.log_prob(value, mean_a, sd_a)
>>> print(ans.shape)
(3,)
```

log_prob(*value*, *mean=None*, *sd=None*)

Evaluate log probability of the value of the HalfNormal distribution.

Parameters

- **value** (Tensor) - the value to compute.
- **mean** (Tensor, optional) - the mean of the distribution. Default: `None` .
- **sd** (Tensor, optional) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the log value of the probability.

20.2.11 mindspore.nn.probability.distribution.Laplace

class mindspore.nn.probability.distribution.**Laplace**(*mean=None*, *sd=None*, *seed=None*, *dtype=mstype.float32*, *name='Laplace'*)

Laplace distribution. A Laplace distribution is a continuous distribution with the range $(-\inf, \inf)$ and the probability density function:

$$f(x, \mu, b) = 1/(2 * b) * \exp(-abs(x - \mu)/b).$$

where μ, b are the mean and the scale of the laplace distribution respectively.

Parameters

- **mean** (*Union[int, float, list, numpy.ndarray, Tensor], optional*) – The mean of the distribution. If this arg is `None` , then the mean of the distribution will be passed in runtime. Default: `None` .
- **sd** (*Union[int, float, list, numpy.ndarray, Tensor], optional*) – The scale of the distribution. If this arg is `None` , then the scale of the distribution will be passed in runtime. Default: `None` .
- **seed** (*int, optional*) – The seed used in sampling. The global seed is used if it is None. Default: `None` .
- **dtype** (*mindspore.dtype, optional*) – The type of the event samples. Default: `mstype.float32` .
- **name** (*str, optional*) – The name of the distribution. Default: `'Laplace'` .

Note:

- *sd* must be greater than zero.
- *dtype* must be a float type because Laplace distributions are continuous.
- If the arg *mean* or *sd* is passed in runtime, then it will be used as the parameter value. Otherwise, the value passed in the constructor will be used.

Raises

- **ValueError** – When sd <= 0.
- **TypeError** – When the input *dtype* is not a subclass of float.

Supported Platforms:

`Ascend GPU CPU`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> from mindspore.nn.probability.distribution import Laplace
>>> from mindspore import Tensor
>>> # To initialize a Laplace distribution of the mean 3.0 and the scale 4.0.
>>> n1 = Laplace(3.0, 4.0, dtype=mindspore.float32)
>>> # A Laplace distribution can be initialized without arguments.
>>> # In this case, `mean` and `sd` must be passed in through arguments.
>>> n2 = Laplace(dtype=mindspore.float32)
>>> # Here are some tensors used below for testing
>>> value = Tensor([1.0, 2.0, 3.0], dtype=mindspore.float32)
>>> mean_a = Tensor([2.0], dtype=mindspore.float32)
```

(continues on next page)

(continued from previous page)

```
>>> sd_a = Tensor([2.0, 2.0, 2.0], dtype=mindspore.float32)
>>> mean_b = Tensor([1.0], dtype=mindspore.float32)
>>> sd_b = Tensor([1.0, 1.5, 2.0], dtype=mindspore.float32)
>>> ans = n1.log_prob(value)
>>> print(ans.shape)
(3,)
>>> # Evaluate with respect to the distribution b.
>>> ans = n1.log_prob(value, mean_b, sd_b)
>>> print(ans.shape)
(3,)
>>> # `mean` and `sd` must be passed in during function calls
>>> ans = n2.log_prob(value, mean_a, sd_a)
>>> print(ans.shape)
(3,)
```

log_prob(*value*, *mean=None*, *sd=None*)

Evaluate log probability of the value of the Laplace distribution.

Parameters

- **value** (Tensor) - the value to compute.
- **mean** (Tensor, optional) - the mean of the distribution. Default: `None` .
- **sd** (Tensor, optional) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the log value of the probability.

20.2.12 mindspore.nn.probability.distribution.Logistic

class mindspore.nn.probability.distribution.**Logistic**(*loc=None*, *scale=None*, *seed=None*, *dtype=mstype.float32*, *name='Logistic'*)

Logistic distribution. A Logistic distributio is a continuous distribution with the range $(-\inf, \inf)$ and the probability density function:

$$f(x, a, b) = 1/b \exp(\exp(-(x-a)/b) - x).$$

where a, b are loc and scale parameter respectively.

Parameters

- **loc** (*float*, *list*, *numpy.ndarray*, *Tensor*) –The location of the Logistic distribution. a in the formula. Default: `None` .
- **scale** (*float*, *list*, *numpy.ndarray*, *Tensor*) –The scale of the Logistic distribution. b in the formula. Default: `None` .
- **seed** (*int*) –The seed used in sampling. The global seed is used if it is None. Default: `None` .
- **dtype** (mindspore.dtype) –The type of the event samples. Default: `mstype.float32` .
- **name** (*str*) –The name of the distribution. Default: `'Logistic'` .

Note: *scale* must be greater than zero. *dist_spec_args* are *loc* and *scale*. *dtype* must be a float type because Logistic distributions are continuous.

Raises

- **ValueError** −When scale <= 0.
- **TypeError** −When the input *dtype* is not a float or a subclass of float.

Supported Platforms:

`Ascend` `GPU`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> # To initialize a Logistic distribution of loc 3.0 and scale 4.0.
>>> l1 = msd.Logistic(3.0, 4.0, dtype=mindspore.float32)
>>> # A Logistic distribution can be initialized without arguments.
>>> # In this case, `loc` and `scale` must be passed in through arguments.
>>> l2 = msd.Logistic(dtype=mindspore.float32)
>>>
>>> # Here are some tensors used below for testing
>>> value = Tensor([1.0, 2.0, 3.0], dtype=mindspore.float32)
>>> loc_a = Tensor([2.0], dtype=mindspore.float32)
>>> scale_a = Tensor([2.0, 2.0, 2.0], dtype=mindspore.float32)
>>> loc_b = Tensor([1.0], dtype=mindspore.float32)
>>> scale_b = Tensor([1.0, 1.5, 2.0], dtype=mindspore.float32)
>>>
>>> # Private interfaces of probability functions corresponding to public interfaces,␣
↪including

>>> print(ans.shape)
(2, 3, 3)
```

property loc

Return the loc parameter of the distribution.

Returns

Tensor, the loc parameter of the distribution.

property scale

Return the scale parameter of the distribution.

Returns

Tensor, the scale parameter of the distribution.

cdf(*value*, *loc*, *scale*)

Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

cross_entropy(*dist*, *loc_b*, *scale_b*, *loc*, *scale*)

Compute the cross entropy of two distribution.

Parameters

- **dist** (str) - the type of the other distribution.

- **loc_b** (Tensor) - the loc parameter of the other distribution.
- **scale_b** (Tensor) - the scale parameter of the other distribution.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the cross entropy.

entropy(*loc*, *scale*)
Compute the value of the entropy.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the entropy.

kl_loss(*dist*, *loc_b*, *scale_b*, *loc*, *scale*)
Compute the value of the K-L loss between two distribution, namely KL(a||b).

Parameters

- **dist** (str) - the type of the other distribution.
- **loc_b** (Tensor) - the loc parameter of the other distribution.
- **scale_b** (Tensor) - the scale parameter of the other distribution.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

log_cdf(*value*, *loc*, *scale*)
Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob(*value*, *loc*, *scale*)
the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival(*value*, *loc*, *scale*)

Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mean(*loc*, *scale*)

Compute the mean value of the distribution.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the mean of the distribution.

mode(*loc*, *scale*)

Compute the mode value of the distribution.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob(*value*, *loc*, *scale*)

The probability of the given value. For the continuous distribution, it is the probability density function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the probability.

sample(*shape*, *loc*, *scale*)

Generate samples.

Parameters

- **shape** (tuple) - the shape of the sample.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the sample following the distribution.

sd (*loc*, *scale*)
The standard deviation.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the standard deviation of the distribution.

survival_function (*value*, *loc*, *scale*)
Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the survival function.

var (*loc*, *scale*)
Compute the variance of the distribution.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the variance of the distribution.

20.2.13 mindspore.nn.probability.distribution.LogNormal

class mindspore.nn.probability.distribution.**LogNormal** (*loc=None*, *scale=None*, *seed=0*, *dtype=mstype.float32*, *name='LogNormal'*)

LogNormal distribution. A log-normal (or lognormal) distribution is a continuous probability distribution of a random variable whose logarithm is normally distributed. The log-normal distribution has the range $(0, \inf)$ with the pdf as

$$f(x, \mu, \sigma) = 1/x\sigma\sqrt{2\pi}\exp(-(\ln(x) - \mu)^2/2\sigma^2).$$

where μ, σ are the mean and the standard deviation of the underlying normal distribution respectively. It is constructed as the exponential transformation of a Normal distribution.

Parameters

- **loc** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) –The mean of the underlying Normal distribution. Default: `None` .
- **scale** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) –The standard deviation of the underlying Normal distribution. Default: `None` .

- **seed** (*int*) –the seed used in sampling. The global seed is used if it is None. Default: `0` .
- **dtype** (`mindspore.dtype`) –type of the distribution. Default: `mstype.float32` .
- **name** (*str*) –the name of the distribution. Default: `'LogNormal'` .

Note: *scale* must be greater than zero. *dist_spec_args* are *loc* and *scale*. *dtype* must be a float type because LogNormal distributions are continuous.

Raises

- **ValueError** –When scale <= 0.
- **TypeError** –When the input *dtype* is not a subclass of float.

Supported Platforms:

`Ascend GPU`

Examples

```
>>> import numpy as np
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> class Prob(nn.Cell):
...     def __init__(self):
...         super(Prob, self).__init__()
...         self.ln = msd.LogNormal(np.array([0.3]), np.array([[0.2], [0.4]]),␣
↪dtype=mindspore.float32)
...     def construct(self, x_):
...         return self.ln.prob(x_)
>>> pdf = Prob()
>>> output = pdf(Tensor([1.0, 2.0], dtype=mindspore.float32))
>>> print(output.shape)
(2, 2)
```

property loc

Return the loc parameter of the distribution.

Returns

Tensor, the loc parameter of the distribution.

property scale

Return the scale parameter of the distribution.

Returns

Tensor, the scale parameter of the distribution.

cdf (*value*, *loc*, *scale*)

Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .

- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

cross_entropy (*dist*, *loc_b*, *scale_b*, *loc*, *scale*)
Compute the cross entropy of two distribution.

Parameters

- **dist** (str) - the type of the other distribution.
- **loc_b** (Tensor) - the loc parameter of the other distribution.
- **scale_b** (Tensor) - the scale parameter of the other distribution.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the cross entropy.

entropy (*loc*, *scale*)
Compute the value of the entropy.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the entropy.

kl_loss (*dist*, *loc_b*, *scale_b*, *loc*, *scale*)
Compute the value of the K-L loss between two distribution, namely KL(a||b).

Parameters

- **dist** (str) - the type of the other distribution.
- **loc_b** (Tensor) - the loc parameter of the other distribution.
- **scale_b** (Tensor) - the scale parameter of the other distribution.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

log_cdf (*value*, *loc*, *scale*)
Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob(*value*, *loc*, *scale*)
the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival(*value*, *loc*, *scale*)
Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mean(*loc*, *scale*)
Compute the mean value of the distribution.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the mean of the distribution.

mode(*loc*, *scale*)
Compute the mode value of the distribution.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob(*value*, *loc*, *scale*)
The probability of the given value. For the continuous distribution, it is the probability density function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the probability.

sample(*shape*, *loc*, *scale*)
Generate samples.

Parameters

- **shape** (tuple) - the shape of the sample.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the sample following the distribution.

sd(*loc*, *scale*)
The standard deviation.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the standard deviation of the distribution.

survival_function(*value*, *loc*, *scale*)
Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the value of the survival function.

var(*loc*, *scale*)
Compute the variance of the distribution.

Parameters

- **loc** (Tensor) - the loc parameter of the distribution. Default: `None` .
- **scale** (Tensor) - the scale parameter of the distribution. Default: `None` .

Returns

Tensor, the variance of the distribution.

20.2.14 mindspore.nn.probability.distribution.Normal

class mindspore.nn.probability.distribution.**Normal**(*mean=None*, *sd=None*, *seed=None*, *dtype=mstype.float32*, *name='Normal'*)

Normal distribution. A Normal distribution is a continuous distribution with the range $(-\inf, \inf)$ and the probability density function:

$$f(x, \mu, \sigma) = 1/\sigma\sqrt{2\pi}\exp(-(x-\mu)^2/2\sigma^2).$$

where μ, σ are the mean and the standard deviation of the normal distribution respectively.

Parameters

- **mean** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) –The mean of the Normal distribution. Default: None .
- **sd** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) –The standard deviation of the Normal distribution. Default: None .
- **seed** (*int*) –The seed used in sampling. The global seed is used if it is None. Default: None .
- **dtype** (mindspore.dtype) –The type of the event samples. Default: mstype.float32 .
- **name** (*str*) –The name of the distribution. Default: 'Normal' .

Note: *sd* must be greater than zero. *dist_spec_args* are *mean* and *sd*. *dtype* must be a float type because Normal distributions are continuous.

Raises

- **ValueError** –When sd <= 0.
- **TypeError** –When the input *dtype* is not a subclass of float.

Supported Platforms:

Ascend GPU

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> # To initialize a Normal distribution of the mean 3.0 and the standard deviation 4.0.
>>> n1 = msd.Normal(3.0, 4.0, dtype=mindspore.float32)
>>> # A Normal distribution can be initialized without arguments.
>>> # In this case, `mean` and `sd` must be passed in through arguments.
>>> n2 = msd.Normal(dtype=mindspore.float32)
>>> # Here are some tensors used below for testing
>>> value = Tensor([1.0, 2.0, 3.0], dtype=mindspore.float32)
>>> mean_a = Tensor([2.0], dtype=mindspore.float32)

>>> print(ans.shape)
(2, 3, 3)
```

property mean

Return the mean of the distribution.

Returns

Tensor, the mean of the distribution.

property sd

Return the standard deviation of the distribution.

Returns

Tensor, the standard deviation of the distribution.

cdf (*value*, *mean*, *sd*)

Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **mean** (Tensor) - the mean of the distribution. Default: `None` .
- **sd** (Tensor) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

cross_entropy (*dist*, *mean_b*, *sd_b*, *mean*, *sd*)

Compute the cross entropy of two distribution.

Parameters

- **dist** (str) - the type of the other distribution.
- **mean_b** (Tensor) - the mean of the other distribution.
- **sd_b** (Tensor) - the standard deviation of the other distribution.
- **mean** (Tensor) - the mean of the distribution. Default: `None` .
- **sd** (Tensor) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the value of the cross entropy.

entropy (*mean*, *sd*)

Compute the value of the entropy.

Parameters

- **mean** (Tensor) - the mean of the distribution. Default: `None` .
- **sd** (Tensor) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the value of the entropy.

kl_loss (*dist*, *mean_b*, *sd_b*, *mean*, *sd*)

Compute the value of the K-L loss between two distribution, namely KL(a||b).

Parameters

- **dist** (str) - the type of the other distribution.
- **mean_b** (Tensor) - the mean of the other distribution.
- **sd_b** (Tensor) - the standard deviation of the other distribution.
- **mean** (Tensor) - the mean of the distribution. Default: `None` .
- **sd** (Tensor) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

log_cdf (*value*, *mean*, *sd*)

Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.
- **mean** (Tensor) - the mean of the distribution. Default: `None` .
- **sd** (Tensor) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob (*value*, *mean*, *sd*)

the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **mean** (Tensor) - the mean of the distribution. Default: `None` .
- **sd** (Tensor) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival (*value*, *mean*, *sd*)

Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **mean** (Tensor) - the mean of the distribution. Default: `None` .
- **sd** (Tensor) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mode(*mean*, *sd*)

Compute the mode value of the distribution.

Parameters

- **mean** (Tensor) - the mean of the distribution. Default: `None` .
- **sd** (Tensor) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob(*value*, *mean*, *sd*)

The probability of the given value. For the continuous distribution, it is the probability density function.

Parameters

- **value** (Tensor) - the value to compute.
- **mean** (Tensor) - the mean of the distribution. Default: `None` .
- **sd** (Tensor) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the value of the probability.

sample(*shape*, *mean*, *sd*)

Generate samples.

Parameters

- **shape** (tuple) - the shape of the sample.
- **mean** (Tensor) - the mean of the distribution. Default: `None` .
- **sd** (Tensor) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the sample following the distribution.

survival_function(*value*, *mean*, *sd*)

Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **mean** (Tensor) - the mean of the distribution. Default: `None` .
- **sd** (Tensor) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the value of the survival function.

var(*mean*, *sd*)

Compute the variance of the distribution.

Parameters

- **mean** (Tensor) - the mean of the distribution. Default: `None` .
- **sd** (Tensor) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the variance of the distribution.

20.2.15 mindspore.nn.probability.distribution.Poisson

class mindspore.nn.probability.distribution.**Poisson**(*rate=None*, *seed=None*, *dtype=mstype.float32*, *name='Poisson'*)

Poisson Distribution. A Poisson Distribution is a discrete distribution with the range as the non-negative integers, and the probability mass function as

$$P(X = k) = \lambda^k \exp(-\lambda)/k!, k = 1, 2, ...$$

where λ is the rate of the distribution.

Parameters

- **rate** (*list, numpy.ndarray, Tensor*) –The rate of the Poisson distribution. λ in the formula. Default: `None` .
- **seed** (*int*) –The seed used in sampling. The global seed is used if it is `None` . Default: `None` .
- **dtype** (`mindspore.dtype`) –The type of the event samples. Default: `mstype.float32` .
- **name** (*str*) –The name of the distribution. Default: `'Poisson'` .

Note: *rate* must be strictly greater than 0. *dist_spec_args* is *rate*.

Raises

ValueError –When rate <= 0.

Supported Platforms:

`Ascend`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> # To initialize an Poisson distribution of the rate 0.5.
>>> p1 = msd.Poisson([0.5], dtype=mindspore.float32)
>>> # An Poisson distribution can be initialized without arguments.
>>> # In this case, `rate` must be passed in through `args` during function calls.
>>> p2 = msd.Poisson(dtype=mindspore.float32)
>>>
>>> # Here are some tensors used below for testing
>>> value = Tensor([1, 2, 3], dtype=mindspore.int32)
>>> rate_a = Tensor([0.6], dtype=mindspore.float32)
>>> rate_b = Tensor([0.2, 0.5, 0.4], dtype=mindspore.float32)
>>>
>>> # Private interfaces of probability functions corresponding to public interfaces,␣
↪including
```

(continues on next page)

(continued from previous page)

```
>>> # `prob`, `log_prob`, `cdf`, `log_cdf`, `survival_function`, and `log_survival`, are the
↪same as follows.

>>> ans = p1.sample((2,3))
>>> print(ans.shape)
(2, 3, 1)
>>> ans = p1.sample((2,3), rate_b)
>>> print(ans.shape)
(2, 3, 3)
>>> ans = p2.sample((2,3), rate_a)
>>> print(ans.shape)
(2, 3, 1)
```

property rate

Return rate parameter.

Returns

Tensor, the value of the rate.

cdf(*value*, *rate*)
Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **rate** (Tensor) - the value of the rate. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

log_cdf(*value*, *rate*)
Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.
- **rate** (Tensor) - the value of the rate. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob(*value*, *rate*)
the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **rate** (Tensor) - the value of the rate. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival(*value*, *rate*)
Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **rate** (Tensor) - the value of the rate. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mean(*rate*)
Compute the mean value of the distribution.

Parameters

- **rate** (Tensor) - the value of the rate. Default: `None` .

Returns

Tensor, the mean of the distribution.

mode(*rate*)
Compute the mode value of the distribution.

Parameters

- **rate** (Tensor) - the value of the rate. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob(*value*, *rate*)

The probability of the given value. For the discrete distribution, it is the probability mass function(pmf).

Parameters

- **value** (Tensor) - the value to compute.
- **rate** (Tensor) - the value of the rate. Default: `None` .

Returns

Tensor, the value of the probability.

sample(*shape*, *rate*)

Generate samples.

Parameters

- **shape** (tuple) - the shape of the tensor.
- **rate** (Tensor) - the value of the rate. Default: `None` .

Returns

Tensor, the sample following the distribution.

sd(*rate*)

The standard deviation.

Parameters

- **rate** (Tensor) - the value of the rate. Default: `None` .

Returns

Tensor, the standard deviation of the distribution.

survival_function(*value*, *rate*)

Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **rate** (Tensor) - the value of the rate. Default: `None` .

Returns

Tensor, the value of the survival function.

var(*rate*)

Compute the variance of the distribution.

Parameters

- **rate** (Tensor) - the value of the rate. Default: `None` .

Returns

Tensor, the variance of the distribution.

20.2.16 mindspore.nn.probability.distribution.StudentT

class mindspore.nn.probability.distribution.**StudentT**(*df=None*, *mean=None*, *sd=None*, *seed=None*, *dtype=mstype.float32*, *name='StudentT'*)

StudentT distribution. A StudentT distribution is a continuous distribution with the range $(-\inf, \inf)$ and the probability density function:

$$f(x, \nu, \mu, \sigma) = (1 + y^2/\nu)^{(-0.5*(\nu+1))}/Z$$

where $y = (x - \mu)/\sigma$, $Z = abs(\sigma) * \sqrt{(\nu * \pi)} * \Gamma(0.5 * \nu)/\Gamma(0.5 * (\nu + 1))$, ν, μ, σ are the degrees of freedom , mean and sd of the laplace distribution respectively.

Parameters

- **df** (*Union[int, float, list, numpy.ndarray, Tensor], optional*) –The degrees of freedom. If this arg is `None` , then the df of the distribution will be passed in runtime. Default: `None` .
- **mean** (*Union[int, float, list, numpy.ndarray, Tensor], optional*) –The mean of the distribution. If this arg is `None` , then the df of the distribution will be passed in runtime. Default: `None` .
- **sd** (*Union[int, float, list, numpy.ndarray, Tensor], optional*) –The standard deviation of the distribution. If this arg is `None` , then the sd of the distribution will be passed in runtime. Default: `None` .
- **seed** (*int, optional*) –The seed used in sampling. The global seed is used if it is None. Default: `None` .
- **dtype** (*mindspore.dtype, optional*) –The type of the event samples. Default: `mstype.float32` .
- **name** (*str, optional*) –The name of the distribution. Default: `'StudentT'` .

Note:

- *df* must be greater than zero.
- *sd* must be greater than zero.
- *dtype* must be a float type because StudentT distributions are continuous.
- If the arg *df*, *mean* or *sd* is passed in runtime, then it will be used as the parameter value. Otherwise, the value passed in the constructor will be used.

Raises

- **ValueError** –When df <= 0.
- **ValueError** –When sd <= 0.
- **TypeError** –When the input *dtype* is not a subclass of float.

Supported Platforms:

`CPU`

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> # To initialize a StudentT distribution of the df 2.0, the mean 3.0 and the standard␣
↪deviation 4.0.
>>> n1 = msd.StudentT(2.0, 3.0, 4.0, dtype=mindspore.float32)
>>> # A StudentT distribution can be initialized without arguments.
>>> # In this case, `df`, `mean` and `sd` must be passed in through arguments.
>>> n2 = msd.StudentT(dtype=mindspore.float32)
>>> # Here are some tensors used below for testing
>>> value = Tensor([1.0, 2.0, 3.0], dtype=mindspore.float32)
>>> df_a = Tensor([2.0], dtype=mindspore.float32)
>>> mean_a = Tensor([2.0], dtype=mindspore.float32)
>>> sd_a = Tensor([2.0, 2.0, 2.0], dtype=mindspore.float32)
>>> df_b = Tensor([1.0], dtype=mindspore.float32)
>>> mean_b = Tensor([1.0], dtype=mindspore.float32)
>>> sd_b = Tensor([1.0, 1.5, 2.0], dtype=mindspore.float32)
>>> ans = n1.log_prob(value)
>>> print(ans.shape)
(3,)
>>> # Evaluate with respect to the distribution b.
>>> ans = n1.log_prob(value, df_b, mean_b, sd_b)
>>> print(ans.shape)
(3,)
>>> # `mean` and `sd` must be passed in during function calls
>>> ans = n2.log_prob(value, df_a, mean_a, sd_a)
>>> print(ans.shape)
(3,)
```

log_prob(*value*, *df=None*, *mean=None*, *sd=None*)

Evaluate log probability of the value of the StudentT distribution.

Parameters

- **value** (Tensor) - the value to compute.
- **df** (Tensor, optional) - the degrees of freedom of the distribution. Default: `None` .
- **mean** (Tensor, optional) - the mean of the distribution. Default: `None` .
- **sd** (Tensor, optional) - the standard deviation of the distribution. Default: `None` .

Returns

Tensor, the log value of the probability.

20.2.17 mindspore.nn.probability.distribution.TransformedDistribution

class mindspore.nn.probability.distribution.**TransformedDistribution**(*bijector*, *distribution*, *seed=None*, *name='transformed_distribution'*)

Transformed Distribution. This class contains a bijector and a distribution and transforms the original distribution to a new distribution through the operation defined by the bijector. If X is an random variable following the underying distribution, and $g(x)$ is a function represented by the bijector, then $Y = g(X)$ is a random variable following the transformed distribution.

Parameters

- **bijector** (Bijector) –The transformation to perform.
- **distribution** (Distribution) –The original distribution. Must be a float dtype.
- **seed** (*int*) –The seed is used in sampling. The global seed is used if it is None. Default: None . If this seed is given when a TransformedDistribution object is initialized, the object's sampling function will use this seed; elsewise, the underlying distribution's seed will be used.
- **name** (*str*) –The name of the transformed distribution. Default: 'transformed_distribution' .

Note: The arguments used to initialize the original distribution cannot be None. For example, mynormal = msd.Normal(dtype=mindspore.float32) cannot be used to initialized a TransformedDistribution since *mean* and *sd* are not specified. *batch_shape* is the batch_shape of the original distribution. *broadcast_shape* is the broadcast shape between the original distribution and bijector. *is_scalar_batch* is only true if both the original distribution and the bijector are scalar batches. *default_parameters*, *parameter_names* and *parameter_type* are set to be consistent with the original distribution. Derived class can overwrite *default_parameters* and *parameter_names* by calling *reset_parameters* followed by *add_parameter*.

Raises

- **TypeError** –When the input *bijector* is not a Bijector instance.
- **TypeError** –When the input *distribution* is not a Distribution instance.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import numpy as np
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> import mindspore.nn.probability.bijector as msb
>>> from mindspore import Tensor
>>> class Net(nn.Cell):
...     def __init__(self, shape, dtype=mindspore.float32, seed=0, name='transformed_
↪distribution'):
...         super(Net, self).__init__()
...         # create TransformedDistribution distribution
...         self.exp = msb.Exp()
...         self.normal = msd.Normal(0.0, 1.0, dtype=dtype)
...         self.lognormal = msd.TransformedDistribution(self.exp, self.normal, seed=seed,␣
↪name=name)
...         self.shape = shape
```

(continues on next page)

(continued from previous page)

```
...
...     def construct(self, value):
...         cdf = self.lognormal.cdf(value)
...         sample = self.lognormal.sample(self.shape)
...         return cdf, sample
>>> shape = (2, 3)
>>> net = Net(shape=shape, name="LogNormal")
>>> x = np.array([2.0, 3.0, 4.0, 5.0]).astype(np.float32)
>>> tx = Tensor(x, dtype=mindspore.float32)
>>> cdf, sample = net(tx)
>>> print(sample.shape)
(2, 3)
```

property bijector
Return the bijector.

Returns

Bijector, the bijector.

property distribution
Return the distribution before transformation.

Returns

Distribution, the distribution before transformation.

property dtype
Return the data type of distribution.

Returns

mindspore.dtype, the data type of distribution.

property is_linear_transformation
Return whether the bijector is linear.

Returns

Bool, return True if the bijector is linear, otherwise return False.

cdf(*value*)
Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

log_cdf(*value*)
Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob(*value*)
the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the log value of the probability.

log_survival(*value*)

Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the value of the K-L loss.

mean()

Compute the mean value of the distribution.

Returns

Tensor, the mean of the distribution.

prob(*value*)

The probability of the given value.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the value of the probability.

sample(*shape*)

Generate samples.

Parameters

- **shape** (tuple) - the shape of the tensor.

Returns

Tensor, the sample following the distribution.

survival_function(*value*)

Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.

Returns

Tensor, the value of the survival function.

20.2.18 mindspore.nn.probability.distribution.Uniform

class mindspore.nn.probability.distribution.**Uniform**(*low=None*, *high=None*, *seed=None*, *dtype=mstype.float32*, *name='Uniform'*)

Uniform Distribution. A Uniform distributio is a continuous distribution with the range $[a, b]$ and the probability density function:

$$f(x, a, b) = 1/(b - a)$$

Where a, b are the lower and upper bound respectively.

Parameters

- **low** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) –The lower bound of the distribution. a in the formula. Default: None .
- **high** (*int*, *float*, *list*, *numpy.ndarray*, Tensor) –The upper bound of the distribution. b in the formula. Default: None .
- **seed** (*int*) –The seed uses in sampling. The global seed is used if it is None . Default: None .
- **dtype** (mindspore.dtype) –The type of the event samples. Default: mstype.float32 .
- **name** (*str*) –The name of the distribution. Default: 'Uniform' .

Note: *low* must be strictly less than *high*. *dist_spec_args* are *high* and *low*. *dtype* must be float type because Uniform distributions are continuous.

Raises

- **ValueError** –When high <= low.
- **TypeError** –When the input *dtype* is not a float or a subclass of float.

Supported Platforms:

Ascend GPU CPU

Examples

```
>>> import mindspore
>>> import mindspore.nn as nn
>>> import mindspore.nn.probability.distribution as msd
>>> from mindspore import Tensor
>>> # To initialize a Uniform distribution of the lower bound 0.0 and the higher bound 1.0.
>>> u1 = msd.Uniform(0.0, 1.0, dtype=mindspore.float32)
>>> # A Uniform distribution can be initialized without arguments.
>>> # In this case, `high` and `low` must be passed in through arguments during function␣
↪calls.
>>> u2 = msd.Uniform(dtype=mindspore.float32)
>>>
>>> # Here are some tensors used below for testing
>>> value = Tensor([0.5, 0.8], dtype=mindspore.float32)
>>> low_a = Tensor([0., 0.], dtype=mindspore.float32)

>>> print(ans.shape)
(2, 3, 2)
>>> ans = u2.sample((2,3), low_a, high_a)
>>> print(ans.shape)
(2, 3, 2)
```

property high

Return the upper bound of the distribution.

Returns

Tensor, the upper bound of the distribution.

property low

Return the upper bound of the distribution.

Returns

Tensor, the lower bound of the distribution.

cdf (*value*, *high*, *low*)

Compute the cumulatuve distribution function(CDF) of the given value.

Parameters

- **value** (Tensor) - the value to compute.
- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the value of the cumulatuve distribution function for the given input.

cross_entropy (*dist*, *high_b*, *low_b*, *high*, *low*)

Compute the cross entropy of two distribution.

Parameters

- **dist** (str) - the type of the other distribution.
- **high_b** (Tensor) - the upper bound of the other distribution.
- **low_b** (Tensor) - the lower bound of the other distribution.
- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the value of the cross entropy.

entropy (*high*, *low*)

Compute the value of the entropy.

Parameters

- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the value of the entropy.

kl_loss (*dist*, *high_b*, *low_b*, *high*, *low*)
Compute the value of the K-L loss between two distribution, namely KL(a||b).

Parameters

- **dist** (str) - the type of the other distribution.
- **high_b** (Tensor) - the upper bound of the other distribution.
- **low_b** (Tensor) - the lower bound of the other distribution.
- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

log_cdf (*value*, *high*, *low*)
Compute the log value of the cumulatuve distribution function.

Parameters

- **value** (Tensor) - the value to compute.
- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the log value of the cumulatuve distribution function.

log_prob (*value*, *high*, *low*)
the log value of the probability.

Parameters

- **value** (Tensor) - the value to compute.
- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the log value of the probability.

log_survival (*value*, *high*, *low*)
Compute the log value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the value of the K-L loss.

mean(*high*, *low*)
Compute the mean value of the distribution.

Parameters

- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the mean of the distribution.

mode(*high*, *low*)
Compute the mode value of the distribution.

Parameters

- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the mode of the distribution.

prob(*value*, *high*, *low*)
The probability of the given value. For the continuous distribution, it is the probability density function.

Parameters

- **value** (Tensor) - the value to compute.
- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the value of the probability.

sample(*shape*, *high*, *low*)
Generate samples.

Parameters

- **shape** (tuple) - the shape of the tensor.
- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the sample following the distribution.

sd(*high*, *low*)
The standard deviation.

Parameters

- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the standard deviation of the distribution.

survival_function(*value*, *high*, *low*)
Compute the value of the survival function.

Parameters

- **value** (Tensor) - the value to compute.
- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the value of the survival function.

var(*high*, *low*)
Compute the variance of the distribution.

Parameters

- **high** (Tensor) - the upper bound of the distribution. Default: `None` .
- **low** (Tensor) - the lower bound of the distribution. Default: `None` .

Returns

Tensor, the variance of the distribution.

CHAPTER

TWENTYONE

MINDSPORE.REWRITE

MindSpore ReWrite module allows users to modify the network's forward computation process by customizing rules to support operations such as inserting, deleting and replacing statements.

For a quick start of using ReWrite, please refer to Modifying Network With ReWrite .

MindSpore Rewrite package. This is an experimental python package that is subject to change or deletion.

class mindspore.rewrite.**Node**(*node: NodeImpl*)

A node (Node) can be understood as a basic data structure unit in the computational graph of a neural network, which represents an operation or computational step in the network. Each node usually corresponds to a statement or expression in the source code, which contains the information needed to perform the operation, such as the type of operation, input data, output result, and connection relationships with other nodes.

Nodes can express a `Cell` call statement, a `Primitive` call statement, an arithmetic operation statement, a return statements, etc. of the forward calculation process.

Parameters

node (*NodeImpl*) – A handler of *NodeImpl*. It is recommended to call the specific methods in Node to create a Node, such as 'create_call_cell', rather than calling the Node's constructor directly. Don't care what *NodeImpl* is, just treat it as a handle.

static create_call_cell(*cell:* Cell, *targets: List[Union[*ScopedValue*, str]]*, *args: List[*ScopedValue*] = None*, *kwargs: Dict[str,* ScopedValue*] = None*, *name: str = ''*, *is_sub_net: bool = False*)

Create a node. Only support create from a *Cell* now.

A node is corresponding to source code like:

```
targets = self.name(*args, **kwargs)
```

Parameters

- **cell** (`Cell`) – Cell-operator of this forward-layer.
- **targets** (*List[Union[*`ScopedValue`*, str]]*) – Indicate output names. Used as targets of an assign statement in source code.
- **args** (*List[*`ScopedValue`*]*) – Indicate input names. Used as args of a call expression of an assign statement in source code. Default: `None` , which indicates the *cell* has no args inputs.
- **kwargs** (*Dict[str,* `ScopedValue`*]*) – Used as kwargs of a call expression of an assign statement in source code. Indicate keyword input names. Type of key must be *str* and type of value must be *ScopedValue*. Default: `None` , which indicates the *cell* has no kwargs inputs.
- **name** (*str*) – Indicate the name of node. Used as field name in source code. Default is None. Rewrite will generate name from *cell* when name is None. Rewrite will check and ensure the uniqueness of *name* while node being inserted. Default: `""` .
- **is_sub_net** (*bool*) – Indicate that is *cell* a network. If *is_sub_net* is true, Rewrite will try to parse the *cell* to a TreeNode, otherwise the *cell* is parsed to a CallCell node. Default: `False` .

Returns

An instance of *Node*.

Raises

- **TypeError** – If *cell* is not a *Cell*.
- **TypeError** – If *targets* is not *list*.
- **TypeError** – If the type of *targets* is not in *[ScopedValue, str]*.
- **TypeError** – If arg in *args* is not a *ScopedValue*.
- **TypeError** – If key of *kwargs* is not a str or value of kwarg in *kwargs* is not a *ScopedValue*.

Examples

```
>>> from mindspore.rewrite import SymbolTree, ScopedValue
>>> import mindspore.nn as nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("conv1")
>>> position = stree.after(node)
>>> new_node = node.create_call_cell(cell=nn.ReLU(), targets=['x'],
...                                  args=[ScopedValue.create_naming_value('x')], name=
↪'new_relu')
>>> stree.insert(position, new_node)
>>> print(type(new_node))
<class 'mindspore.rewrite.api.node.Node'>
```

static create_call_function(*function: FunctionType*, *targets: List[Union[*ScopedValue*, str]]*, *args: List[*ScopedValue*] = None*, *kwargs: Dict[str,* ScopedValue*] = None*)

Create a node that corresponds to a function call.

Note: The codes inside the function will not be parsed.

Parameters

- **function** (*FunctionType*) – The function to be called.
- **targets** (*List[Union[ScopedValue, str]]*) – indicates output names. Used as targets of an assign statement in source code.
- **args** (*List[ScopedValue]*) – Indicate input names. Used as args of a call expression of an assign statement in source code. Default: `None` , which indicates the *function* has no args inputs.
- **kwargs** (*Dict[str, ScopedValue]*) – Used as kwargs of a call expression of an assign statement in source code. Indicate keyword input names. Type of key must be *str* and type of value must be *ScopedValue*. Default: `None` , which indicates the *function* has no kwargs inputs.

Returns

An instance of *Node*.

Raises

- **TypeError** – If *function* is not a *FunctionType*.

- **TypeError** – If *targets* is not *list*.
- **TypeError** – If the type of *targets* is not in *[ScopedValue, str]*.
- **TypeError** – If arg in *args* is not a *ScopedValue*.
- **TypeError** – If key of *kwargs* is not a str or value of kwarg in *kwargs* is not a *ScopedValue*.

Examples

```
>>> from mindspore.rewrite import SymbolTree, ScopedValue
>>> import mindspore.nn as nn
>>> from mindspore import ops
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("conv1")
>>> position = stree.after(node)
>>> new_node = node.create_call_function(function=ops.abs, targets=['x'],
...                                      args=[ScopedValue.create_naming_value('x')])
>>> stree.insert(position, new_node)
>>> print(new_node.get_node_type())
NodeType.CallFunction
```

get_args()

Get arguments of current node.

Returns

A list of arguments of type `ScopedValue` .

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("conv1")
>>> print(node.get_args())
[x]
```

get_inputs()

Gets a list of nodes whose output values are used as input values for the current node.

Returns

A list of nodes.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("conv2")
>>> inputs = node.get_inputs()
>>> print([input.get_name() for input in inputs])
['max_pool2d']
```

get_instance_type()

Gets the instance type called in the code corresponding to the current node.

- When *node_type* of current node is *CallCell*, the code for that node calls an instance of type `Cell` .
- When *node_type* of current node is *CallPrimitive*, the code for that node calls an instance of type `Primitive` .
- When *node_type* of current node is *Tree*, the code for that node calls an instance of network type.
- When *node_type* of current node is *Python*, *Input*, *Output* or *CallMethod*, the instance type is `NoneType` .

Returns

The type of instance called in the statement corresponding to the current node.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("conv1")
>>> instance_type = node.get_instance_type()
>>> print(instance_type)
<class 'mindspore.nn.layer.conv.Conv2d'>
```

get_kwargs()

Get keyword arguments of current node.

Returns

A dict of keyword arguments, where key is of type str, and value is of type `ScopedValue` .

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> from mindspore import nn
>>>
>>> class ReLUNet(nn.Cell):
...     def __init__(self):
...         super().__init__()
...         self.relu = nn.ReLU()
...
```

(continues on next page)

(continued from previous page)

```
...     def construct(self, input):
...         output = self.relu(input=input)
...         return output
>>>
>>> net = ReLUNet()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("relu")
>>> print(node.get_kwargs())
{'input': input}
```

get_name()

Get the name of current node.

When node has been inserted into *SymbolTree*, the name of node should be unique in *SymbolTree*.

Returns

A string as name of node.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("conv1")
>>> name = node.get_name()
>>> print(name)
conv1
```

get_node_type()

Get the node_type of current node. See *mindspore.rewrite.NodeType* for details on node types.

Returns

A NodeType as node_type of node.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("conv1")
>>> node_type = node.get_node_type()
>>> print(node_type)
NodeType.CallCell
```

get_sub_tree()

Get the sub symbol tree stored in node with type of *NodeType.Tree* . See *mindspore.rewrite.NodeType* for details on node types.

Returns

SymbolTree stored in Tree node.

Raises

- **TypeError** – If current node is not type of *NodeType.Tree* .
- **AttributeError** – If no symbol tree is stored in Tree node.

Examples: >>> import mindspore.nn as nn >>> from mindspore.rewrite import SymbolTree >>> >>> class SubNet(nn.Cell): ···def __init__(self): ···super().__init__() ···self.relu = nn.ReLU() ·····def construct(self, x): ···x = self.relu(x) ···return x ···>>> class Net(nn.Cell): ···def __init__(self): ···super().__init__() ···self.subnet = SubNet() ····· def construct(self, x): ···x = self.subnet(x) ···return x >>> >>> net = Net() >>> stree = SymbolTree.create(net) >>> node = stree.get_node("subnet") >>> print(type(node.get_sub_tree())) <class 'mindspore.rewrite.api.symbol_tree.SymbolTree'>

get_symbol_tree()

Get the symbol tree which current node belongs to.

Returns

SymbolTree, None if current node does not belong to any SymbolTree.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("conv1")
>>> print(type(node.get_symbol_tree()))
<class 'mindspore.rewrite.api.symbol_tree.SymbolTree'>
```

get_targets()

Gets a list of output values for the current node.

Returns

A list of outputs of type `ScopedValue` .

get_users()

Get a list of nodes that use the output of the current node as input.

Returns

A list of nodes.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("conv1")
>>> users = node.get_users()
>>> print([user.get_name() for user in users])
['relu']
```

set_arg(*index: int*, *arg: Union[ScopedValue, str]*)
Set argument of current node.

Parameters

- **index** (*int*) –Indicate which input being modified.
- **arg** (*Union[ScopedValue, str]*) –New argument to been set.

Raises

- **TypeError** –If *index* is not a *int* number.
- **TypeError** –If the type of *arg* is not in [*ScopedValue*, *str*].

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("relu_3")
>>> node.set_arg(0, "fc1")
>>> print(node.get_args())
[fc1]
```

set_arg_by_node(*arg_idx: int*, *src_node: 'Node'*, *out_idx: Optional[int] = None*)
Set argument of current node by another Node.

Parameters

- **arg_idx** (*int*) –Indicate which input being modified.
- **src_node** (Node) –A *Node* as new input. Can be a node or name of node.
- **out_idx** (*int, optional*) –Indicate which output of *src_node* as new input of current node. Default: None , which means use first output of *src_node* as new input.

Raises

- **TypeError** –If *arg_idx* is not a *int* number.
- **ValueError** –If *arg_idx* is out of range.
- **TypeError** –If *src_node* is not a *Node* instance.
- **TypeError** –If *out_idx* is not a *int* number.
- **ValueError** –If *out_idx* is out of range.
- **ValueError** –If *src_node* has multi-outputs while *out_idx* is None or *out_idx* is not offered.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> src_node = stree.get_node("fc1")
>>> dst_node = stree.get_node("relu_3")
>>> dst_node.set_arg_by_node(0, src_node, 0)
>>> print(dst_node.get_args())
[fc1_var]
```

class mindspore.rewrite.**NodeType**

NodeType represents type of *Node*.

- Unknown: Not inited NodeType.
- CallCell: *CallCell* node represents invoking cell-op in forward method.
- CallPrimitive: *CallPrimitive* node represents invoking primitive-op in forward method.
- CallFunction: *CallFunction* node represents invoking a function in forward method.
- CallMethod: *CallMethod* node represents invoking of method in forward method which can not be mapped to cell-op or primitive-op in MindSpore.
- Python: *Python* node holds unsupported-ast-node or unnecessary-to-parse-ast-node.
- Input: *Input* node represents input of *SymbolTree* corresponding to arguments of forward method.
- Output: *Output* node represents output of SymbolTree corresponding to return statement of forward method.
- Tree: *Tree* node represents sub-network invoking in forward method.
- CellContainer: *CellContainer* node represents invoking method *mindspore.nn.SequentialCell* in forward method.
- MathOps: *MathOps* node represents a mathematical operation, such as adding or comparing in forward method.
- ControlFlow: *ControlFlow* node represents a control flow statement, such as if statement.

class mindspore.rewrite.**ScopedValue**(*arg_type:* ValueType, *scope: str = ''*, *value=None*)

ScopedValue represents a value with its full-scope.

ScopedValue is used to express: a left-value such as target of an assign statement, or a callable object such as func of a call statement, or a right-value such as args and kwargs of an assign statement.

Parameters

- **arg_type** (ValueType) –A *ValueType* represents type of current value.
- **scope** (*str, optional*) –A string represents scope of current value. Take "self.var1" as an example, *scope* of this var1 is "self". Default: "" .
- **value** –A handler represents value of current value. The type of value is corresponding to *arg_type*. Default: None .

static create_name_values(*names: Union[List[str], Tuple[str]]*, *scopes: Union[List[str], Tuple[str]] = None*)

Create a list of naming *ScopedValue*.

Parameters

- **names** (*List[str] or Tuple[str]*) –List or tuple of *str* represents names of referenced variables.

- **scopes** (*List[str] or Tuple[str], optional*) – List or tuple of *str* represents scopes of referenced variables. Default: `None` .

Returns

An list of instance of *ScopedValue*.

Raises

- **TypeError** – If *names* is not *list* or *tuple* and name in *names* is not *str*.
- **TypeError** – If *scopes* is not *list* or *tuple* and scope in *scopes* is not *str*.
- **ValueError** – If the length of names is not equal to the length of scopes when scopes are not None.

Examples

```
>>> from mindspore.rewrite import ScopedValue
>>> variables = ScopedValue.create_name_values(names=["z", "z_1"], scopes=["self", "self
↪"])
>>> print(variables)
[self.z, self.z_1]
```

classmethod create_naming_value(*name: str*, *scope: str = ''*)

Create a naming *ScopedValue*. A *NamingValue* represents a reference to another variable.

Parameters

- **name** (*str*) – A string represents the identifier of another variable.
- **scope** (*str, optional*) – A string represents the scope of another variable. Default: `""` .

Returns

An instance of *ScopedValue*.

Raises

- **TypeError** – If *name* is not *str*.
- **TypeError** – If *scope* is not *str*.

Examples

```
>>> from mindspore.rewrite import ScopedValue
>>> variable = ScopedValue.create_naming_value("conv", "self")
>>> print(variable)
self.conv
```

classmethod create_variable_value(*value*)

Create *ScopedValue* from a variable.

ScopedValue's type is determined by type of value. *ScopedValue*'s scope is empty.

Parameters

value – The value to be converted to *ScopedValue*.

Returns

An instance of *ScopedValue*.

Examples

```
>>> from mindspore.rewrite import ScopedValue
>>> variable = ScopedValue.create_variable_value(2)
>>> print(variable)
2
```

class mindspore.rewrite.**SymbolTree**(*handler: SymbolTreeImpl*)

SymbolTree stores information about a network, including statements of the network's forward computation process and the topological relationship between statement input and output.

The statements in the network are saved in the SymbolTree in the form of nodes, and by processing the nodes in the SymbolTree, you can delete the network code, insert and replace it, and get the modified network code and network instances.

Parameters

handler (*SymbolTreeImpl*) – SymbolTree internal implementation instance. It is recommended to call the *create* method in SymbolTree to create a SymbolTree, rather than calling SymbolTree's constructor directly. Don't care what *SymbolTreeImpl* is, just treat it as a handle.

after(*node: Union[Node, str]*)

Returns a location information after *node*. The return value of this interface is used as a parameter for the insert operation.

Parameters

node (*Union[Node, str]*) – Indicate the position after which node. Can be a node or name of node.

Returns

A *Position* to indicate where to insert node.

Raises

TypeError – If *node* is not a Node or str.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> for node in stree.nodes():
...     if node.get_name() == "conv1":
...         position = stree.after(node)
```

before(*node: Union[Node, str]*)

Returns a location information before *node*. The return value of this interface is used as a parameter for the insert operation.

Parameters

node (*Union[Node, str]*) – Indicate the position before which node. Can be a node or name of node.

Returns

A *Position* to indicate where to insert node.

Raises

TypeError – if *node* is not a Node or str.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> for node in stree.nodes():
...     if node.get_name() == "conv1":
...         position = stree.before(node)
```

classmethod create(*network*)

Create a SymbolTree object by passing in the network instance *network*.

This interface parses the *network* instance, expands each source code statement of the forward computation process, and parses it into nodes, which is stored in the SymbolTree. The specific process is as follows:

1. Obtain the source code of the network instance.
2. Perform AST parsing on the network and obtain the AST nodes (abstract syntax trees) of each statement in the network.
3. Expand complex statements in the network forward evaluation process into multiple simple statements.
4. Create a SymbolTree object. Each SymbolTree corresponds to one network instance.
5. Use the rewrite node to store each statement of the network forward computation process. The node records the input, output, and other information of the statement.
6. Save the rewrite node to the SymbolTree, and update and maintain the topological connection between the nodes.
7. Return the SymbolTree object corresponding to the network instance.

If a user-defined network of type *mindspore.nn.Cell* is called in the forward computation process of the network, rewrite will generate a node of type *NodeType.Tree* for the corresponding statement. This type of node stores a new SymbolTree, which parses and maintains the node information of the user-defined network.

If the following types of statements are called in the forward computation process of the network, rewrite will parse the internal statements in the statement and generate corresponding nodes:

- *mindspore.nn.SequentialCell*
- Functions(Excludes Python built-in functions and third-party library functions)
- Control flow statements(such as *if* statements)

Note: Because the specific execution branch of control flows are still unknown during the rewrite operation of the network, no topology information will be established between the nodes inside the control flow and the nodes outside. Users cannot obtain nodes inside the control flow when they acquire nodes outside the control flow using interfaces like *mindspore.rewrite.Node.get_inputs()* and *mindspore.rewrite.Node.get_users()* . Users also cannot obtain nodes outside the control flow, if they use these interfaces inside the control flow. Therefore, when users modify the network, they need to manually handle the node information inside and outside the control flow.

The current rewrite module has the following syntax limitations:

- Only networks of type *mindspore.nn.Cell* are supported as input to the rewrite module.
- Parsing one-line control flow syntax(e.g. one-line if-else, one-line for loop) is not currently supported.
- Parsing decorator syntax is not currently supported.
- Parsing local classes and embedded classes is not currently supported, that is, the definition of classes need to be placed on the outermost layer.

- Parsing closure syntax is not currently supported, that is, the definition of out-of-class functions need to be placed at the outermost layer.
- Parsing lambda expression syntax is not currently supported.
- Parsing global variables is not currently supported, that is, global variables need to be converted to class variables or local variables before they can be used.
- Parsing methods in the parent classes is not currently supported.

For statements that do not support parsing, rewrite will generate nodes of type *NodeType.Python* for corresponding statements to ensure that the network after rewrite can run normally. The *Python* node does not support modifying the input and output of statements, and there may be a problem between variable names and those generated by the rewrite. In this case, users need to adjust the variable names manually.

Parameters

network (Cell) – *network* used to create SymbolTree.

Returns

Symboltree, a SymbolTree created based on *network*.

Raises

TypeError – If *network* is not a *Cell* instance.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> print(type(stree))
<class 'mindspore.rewrite.api.symbol_tree.SymbolTree'>
```

erase(*node: Union[Node, str]*)

Erase a *node* from rewrite.

Parameters

node (*Union[Node, str]*) – A *Node* to be erased. Can be a node or name of node.

Returns

An instance of *Node* being erased if node is in *SymbolTree* else None.

Raises

TypeError – The type of *node* is not Node or str.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("conv1")
>>> stree.erase(node)
```

get_code()

Get source code corresponding to the network information in SymbolTree. If the network has already been modified, the source code of modified network is returned.

Returns

A str represents source code of modified network.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> codes = stree.get_code()
>>> print(codes)
```

get_network()

Get the network object generated based on SymbolTree. The source code is saved to a file in the 'rewritten_network' folder of the current directory.

Note:

- The modification of network by rewrite module is based on the modification of AST tree of original network instance, and the new network instance will obtain attribute information from original network instance, so the new network instance and the original network instance have data association, and the original network should no longer be used.
- Due to the data association between the new network and the original network instance, manually creating a network instance using the source code file generated by rewrite is not currently supported.

Returns

A network object generated from SymbolTree.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> new_net = stree.get_network()
```

get_node(*node_name: str*)

Get the node with the name *node_name* in the SymbolTree.

Parameters

node_name (*str*) – The name of node.

Returns

Node with name of *node_name* . Return `None` if there is no node named *node_name* in SymbolTree.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node('conv1')
>>> print(node.get_name())
conv1
```

insert(*position*, *node:* Node)

Insert a *node* into *SymbolTree* at *position*.

position is obtained from *before* api or *after* api of *SymbolTree*.

Parameters

- **position** (*Position*) – Indicate where to insert *node*.
- **node** (Node) – An instance of Node to be inserted.

Returns

An instance of Node being inserted.

Raises

- **ValueError** – If *position* is not belong to current *SymbolTree*.
- **TypeError** – If *position* is not a *Position*.
- **TypeError** – If *node* is not a *Node*.

Examples

```
>>> from mindspore.rewrite import SymbolTree, ScopedValue
>>> import mindspore.nn as nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("conv1")
>>> position = stree.after(node)
>>> new_node = node.create_call_cell(cell=nn.ReLU(), targets=['x'],
...                                  args=[ScopedValue.create_naming_value('x')], name=
↪'new_relu')
>>> stree.insert(position, new_node)
```

nodes(*all_nodes: bool = False*)

Get the generator of the node in the current SymbolTree, which is used to iterate through the nodes in SymbolTree.

Parameters

all_nodes (*bool*) – Get all nodes including nodes in CallFunction node, CellContainer node and sub symbol tree. Default: `False` .

Returns

A generator for nodes in SymbolTree.

Raises

TypeError – If *all_nodes* is not bool.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> print([node.get_name() for node in stree.nodes()])
['input_x', 'conv1', 'relu', 'max_pool2d', 'conv2', 'relu_1', 'max_pool2d_1',
 'unaryop_not', 'if_node', 'flatten', 'fc1', 'relu_2', 'fc2', 'relu_3', 'fc3', 'return_1
↪']
```

print_node_tabulate(*all_nodes: bool = False*)

Print the topology information of nodes in SymbolTree, including node type, node name, node code, and node input-output relationship.

The information is output to the screen using the print interface, including the following information:

- **node type** (str): The type of node, refer to class:*mindspore.rewrite.NodeType* .
- **name** (str): The name of node.
- **codes** (str): The code statement in the SymbolTree corresponding to the node.
- **arg providers** (Dict[int, Tuple[str, int]]): The format is *{[idx, (n, k)]}* , which means the *idx* th parameter of the node is provided by the *k* th output of node *n* .
- **target users** (Dict[int, List[Tuple[str, int]]]): The format is '{[idx, [(n, k)]]}' , which means the *idx* th output of the node is used as the *k* th parameter of node *n* .

Parameters

all_nodes (*bool*) –Print information of all nodes, including nodes in CallFunction node, CellContainer node and sub symbol tree. Default: `False` .

Raises

TypeError –If *all_nodes* is not bool.

Examples

```
>>> from mindspore.rewrite import SymbolTree
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> stree.print_node_tabulate()
```

replace(*old_node:* Node, *new_nodes: List[*Node*]*)

Replace the *old_node* with nodes in the *new_nodes* list.

Nodes in *new_nodes* will be inserted into SymbolTree sequentially, and then *old_node* will be deleted.

Note:

- Replace only support one-to-one replacement or one-to-multi replacement.
- Caller should maintain the topological relationship between each node in the *new_nodes* , as well as the topological relationship between nodes in the *new_nodes* and nodes in the original tree.

Parameters

- **old_node** (Node) –Node to be replaced.
- **new_nodes** (*List[*Node*]*) –Nodes of the node_tree to replace in.

Returns

An instance of Node represents root of node_tree been replaced in.

Raises

- **TypeError** –If *old_node* is not a *Node*.
- **TypeError** –If *new_nodes* is not a *list* or node in *new_nodes* is not a *Node*.

Examples

```
>>> from mindspore.rewrite import SymbolTree, ScopedValue
>>> import mindspore.nn as nn
>>> # Define the network structure of LeNet5. Refer to
>>> # https://gitee.com/mindspore/docs/blob/r2.6.0/docs/mindspore/code/lenet.py
>>> net = LeNet5()
>>> stree = SymbolTree.create(net)
>>> node = stree.get_node("conv1")
>>> new_node = node.create_call_cell(cell=nn.ReLU(), targets=['x'],
```

(continues on next page)

(continued from previous page)

```
...                                     args=[ScopedValue.create_naming_value('x')], name=
↪'new_relu')
>>> stree.replace(node, [new_node])
```

unique_name(*name: str = 'output'*)

Based on the given *name* , returns a new name that is unique within the symbol tree. This interface can be used when a variable name that does not conflict is required.

Parameters

name (*str, optional*) – The prefix of the name. Defaults to `"output"` .

Returns

str, A new, unique name within a symbol tree in the format *name_n*, where *n* is a numeric subscript. If there is no name conflict when entered *name*, there is no numeric subscript.

Raises

TypeError – The type of *name* is not str.

class mindspore.rewrite.**ValueType**

ValueType represents type of *ScopedValue*.

- A *NamingValue* represents a reference to another variable.
- A *CustomObjValue* represents an instance of custom class or an object whose type is out of range of base-type and container-type of ValueType.

CHAPTER

TWENTYTWO

MINDSPORE.HAL

Hal encapsulates interfaces for device, stream, event, and memory. MindSpore abstracts the corresponding modules from different backends, allowing users to schedule hardware resources at the Python layer.

22.1 Device

mindspore.hal.device_count	Return device count of specified device, this api will be deprecated and removed in future versions, please use the api *mindspore.device_context.cpu.device_count()*, *mindspore.device_context.gpu.device_count()*, *mindspore.device_context.ascend.device_count()* instead.
mindspore.hal.get_arch_list	Get the architecture list this MindSpore was compiled for, this api will be deprecated and removed in future versions.
mindspore.hal.get_device_capability	Get specified device's capability, this api will be deprecated and removed in future versions.
mindspore.hal.get_device_name	Get specified device's name, this api will be deprecated and removed in future versions.
mindspore.hal.get_device_properties	Get specified device's properties, this api will be deprecated and removed in future versions.
mindspore.hal.is_available	Return whether specified device is available, this api will be deprecated and removed in future versions, please use the api *mindspore.device_context.cpu.is_available()*, *mindspore.device_context.gpu.is_available()*, *mindspore.device_context.ascend.is_available()* instead.
mindspore.hal.is_initialized	Return whether specified device is initialized, this api will be deprecated and removed in future versions.

22.1.1 mindspore.hal.device_count

mindspore.hal.**device_count**(*device_target=None*)

Return device count of specified device, this api will be deprecated and removed in future versions, please use the api *mindspore.device_context.cpu.device_count()* , *mindspore.device_context.gpu.device_count()*, *mindspore.device_context.ascend.device_count()* instead.

Note: For CPU device, this method always returns 1.

Parameters

device_target (*str, optional*) – The target device specified, should be one of `"CPU"` , `"GPU"` and `"Ascend"` . Default `None` , represents the current device set by context.

Returns

int

Examples

```
>>> import mindspore
>>> device_target = mindspore.context.get_context("device_target")
>>> print(mindspore.hal.device_count(device_target))
```

22.1.2 mindspore.hal.get_arch_list

mindspore.hal.**get_arch_list**(*device_target=None*)

Get the architecture list this MindSpore was compiled for, this api will be deprecated and removed in future versions.

Parameters

device_target (*str, optional*) – The target device specified, should be one of `"CPU"` , `"GPU"` and `"Ascend"` . Default `None` , represents the current device set by context.

Returns

str for GPU. None for Ascend and CPU.

Examples

```
>>> import mindspore
>>> device_target = mindspore.context.get_context("device_target")
>>> print(mindspore.hal.get_arch_list(device_target))
```

22.1.3 mindspore.hal.get_device_capability

mindspore.hal.**get_device_capability**(*device_id*, *device_target=None*)

Get specified device's capability, this api will be deprecated and removed in future versions.

Parameters

- **device_id** (*int*) −The device id of which the capability will be returned.
- **device_target** (*str, optional*) −The target device specified, should be one of "CPU" , "GPU" and "Ascend" . Default None , represents the current device set by context.

Returns

tuple(param1, param2) for GPU.

- param1 - int, cuda major revision number.
- param2 - int, cuda minor revision number.

None for Ascend and CPU.

Examples

```
>>> import mindspore
>>> device_target = mindspore.context.get_context("device_target")
>>> print(mindspore.hal.get_device_capability(0, device_target))
```

22.1.4 mindspore.hal.get_device_name

mindspore.hal.**get_device_name**(*device_id*, *device_target=None*)

Get specified device's name, this api will be deprecated and removed in future versions.

Note: This method always returns "CPU" for CPU device.

Parameters

- **device_id** (*int*) −The device id of which the name will be returned.
- **device_target** (*str, optional*) −The target device specified, should be one of "CPU" , "GPU" and "Ascend" . Default None , represents the current device set by context.

Returns

str

Examples

```
>>> import mindspore
>>> device_target = mindspore.context.get_context("device_target")
>>> print(mindspore.hal.get_device_name(0, device_target))
```

22.1.5 mindspore.hal.get_device_properties

mindspore.hal.**get_device_properties**(*device_id*, *device_target=None*)

Get specified device's properties, this api will be deprecated and removed in future versions.

Note: For Ascend, device must be initialized before calling this method, or *total_memory* and *free_memory* will be 0, and *device_id* will be ignored since this method only returns current device's properties.

Parameters

- **device_id** (*int*) –The device id of which the properties will be returned.
- **device_target** (*str, optional*) –The target device specified, should be one of `"CPU"` , `"GPU"` and `"Ascend"` . Default `None` , represents the current device set by context.

Returns

- *cudaDeviceProp* for GPU.

```
cudaDeviceProp {
    name(str),
    major(int),
    minor(int),
    is_multi_gpu_board(int),
    is_integrated(int),
    multi_processor_count(int),
    total_memory(int),
    warp_size(int)
}
```

- *AscendDeviceProperties* for Ascend.

```
AscendDeviceProperties {
    name(str),
    total_memory(int),
    free_memory(int)
}
```

- None for CPU.

Examples

```
>>> import mindspore
>>> device_target = mindspore.context.get_context("device_target")
>>> print(mindspore.hal.get_device_properties(0, device_target))
```

22.1.6 mindspore.hal.is_available

mindspore.hal.**is_available**(*device_target*)

Return whether specified device is available, this api will be deprecated and removed in future versions, please use the api *mindspore.device_context.cpu.is_available()* , *mindspore.device_context.gpu.is_available()*, *mindspore.device_context.ascend.is_available()* instead.

Parameters

device_target (*str*) –The target device specified, should be one of `"CPU"` , `"GPU"` and `"Ascend"` . Default `None` , represents the current device set by context.

Returns

bool

Examples

```
>>> import mindspore
>>> device_target = mindspore.context.get_context("device_target")
>>> print(mindspore.hal.is_available(device_target))
True
```

22.1.7 mindspore.hal.is_initialized

mindspore.hal.**is_initialized**(*device_target*)

Return whether specified device is initialized, this api will be deprecated and removed in future versions.

Note: MindSpore's devices "CPU", "GPU" and "Ascend" will be initialized in the following scenarios:

- For distributed job, device will be initialized after *mindspore.communication.init* method is called.
- For standalone job, device will be initialized after running the first operator or calling creating stream/event interfaces.

Parameters

device_target (*str*) –The target device specified, should be one of `"CPU"` , `"GPU"` and `"Ascend"` .

Returns

bool

Examples

```
>>> import mindspore as ms
>>> import numpy as np
>>> from mindspore import Tensor, ops
>>> ms.context.set_context(device_target="CPU")
>>> assert not ms.hal.is_initialized("CPU")
>>> a = Tensor(np.ones([1, 2]), ms.float32)
>>> b = Tensor(np.ones([1, 2]), ms.float32)
>>> c = ops.add(a, b).asnumpy()
>>> print(ms.hal.is_initialized("CPU"))
True
```

22.2 Stream

mindspore.hal.communication_stream	Return communication stream on this device, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.communication_stream()* instead.
mindspore.hal.current_stream	Return current stream used on this device, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.current_stream()* instead.
mindspore.hal.default_stream	Return default stream on this device, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.default_stream()* instead.
mindspore.hal.set_cur_stream	Set the current stream, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.set_cur_stream()* instead.
mindspore.hal.synchronize	Synchronize all streams on current device, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.synchronize()* instead.
mindspore.hal.Stream	Wrapper around a device stream, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.Stream* instead.
mindspore.hal.StreamCtx	Context-manager that selects a given stream, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.StreamCtx* instead.

22.2.1 mindspore.hal.communication_stream

mindspore.hal.**communication_stream**()

Return communication stream on this device, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.communication_stream()* instead.

Returns

stream (Stream), communication stream.

Examples

```
>>> import mindspore
>>> mindspore.hal.communication_stream()
Stream(device_name=Ascend, device_id:0, stream id:1)
```

22.2.2 mindspore.hal.current_stream

mindspore.hal.**current_stream**()

Return current stream used on this device, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.current_stream()* instead.

Returns

stream (Stream), current stream.

Examples

```
>>> import mindspore
>>> cur_stream = mindspore.hal.current_stream()
>>> assert cur_stream == mindspore.hal.default_stream()
```

22.2.3 mindspore.hal.default_stream

mindspore.hal.**default_stream**()

Return default stream on this device, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.default_stream()* instead.

Returns

stream (Stream), default stream.

Examples

```
>>> import mindspore
>>> cur_stream = mindspore.hal.current_stream()
>>> assert cur_stream == mindspore.hal.default_stream()
```

22.2.4 mindspore.hal.set_cur_stream

mindspore.hal.**set_cur_stream**(*stream*)

Set the current stream, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.set_cur_stream()* instead.

Parameters

stream (Stream) – selected stream. This function is a no-op if this argument is None.

Examples

```
>>> import mindspore
>>> cur_stream = mindspore.hal.current_stream()
>>> assert cur_stream == mindspore.hal.default_stream()
>>> s1 = mindspore.hal.Stream()
>>> mindspore.hal.set_cur_stream(s1)
>>> assert mindspore.hal.current_stream() == s1
>>> mindspore.hal.set_cur_stream(mindspore.hal.default_stream())
```

22.2.5 mindspore.hal.synchronize

mindspore.hal.**synchronize**()

Synchronize all streams on current device, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.synchronize()* instead.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1024, 2048]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([2048, 4096]), mindspore.float32)
>>> s1 = mindspore.hal.Stream()
>>> with mindspore.hal.StreamCtx(s1):
...     c = mindspore.ops.matmul(a, b)
>>> mindspore.hal.synchronize()
>>> assert s1.query()
```

22.2.6 mindspore.hal.Stream

class mindspore.hal.**Stream**(*priority=0*, ***kwargs*)

Wrapper around a device stream, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.Stream* instead.

A device stream is a linear sequence of execution that belongs to a specific device, independent from other streams.

Parameters

- **priority** (*int, optional*) – priority of the stream, lower numbers represent higher priorities. By default, streams have priority 0.
- **kwargs** (*dict*) – keyword arguments.

query()

Check if all the work submitted has been completed.

Returns

A boolean indicating if all kernels in this stream are completed.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1024, 2048]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([2048, 4096]), mindspore.float32)
>>> s1 = mindspore.hal.Stream()
>>> with mindspore.hal.StreamCtx(s1):
...     c = mindspore.ops.matmul(a, b)
>>> s1.synchronize()
>>> assert s1.query()
```

record_event(*event=None*)

Record an event.

Parameters

event (Event, *optional*) – event to record. If not given, a new one will be allocated.

Returns

Event, recorded event. If this argument is None, a new one will be allocated. Default is None.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([3, 3]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([3, 3]), mindspore.float32)
>>> s1 = mindspore.hal.Stream()
>>> with mindspore.hal.StreamCtx(s1):
...     c = a + b
...     event = s1.record_event()
...     d = a * b
>>> cur_stream = mindspore.hal.current_stream()
>>> cur_stream.wait_event(event)
>>> e = c + 3
>>> print(e)
[[5. 5. 5.]
 [5. 5. 5.]
 [5. 5. 5.]]
```

synchronize()

Wait for all the kernels in this stream to complete.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1024, 2048]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([2048, 4096]), mindspore.float32)
>>> s1 = mindspore.hal.Stream()
>>> with mindspore.hal.StreamCtx(s1):
...     c = mindspore.ops.matmul(a, b)
>>> s1.synchronize()
>>> assert s1.query()
```

wait_event(*event*)

Make all future work submitted to the stream wait for an event.

Parameters

event (Event) – an event to wait for.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([3, 3]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([3, 3]), mindspore.float32)
>>> s1 = mindspore.hal.Stream()
>>> with mindspore.hal.StreamCtx(s1):
...     c = a + b
...     event = s1.record_event()
...     d = a * b
>>> cur_stream = mindspore.hal.current_stream()
>>> cur_stream.wait_event(event)
>>> e = c + 3
>>> print(e)
[[5. 5. 5.]
 [5. 5. 5.]
 [5. 5. 5.]]
```

wait_stream(*stream*)

Synchronize with another stream.

All future work submitted to this stream will wait until all kernels submitted to a given stream at the time of call complete.

Parameters

stream (Stream) – a stream to synchronize.

Examples

```
>>> import mindspore
>>> s1 = mindspore.hal.Stream()
>>> s2 = mindspore.hal.Stream()
>>> a = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([2, 2]), mindspore.float32)
>>> with mindspore.hal.StreamCtx(s1):
...     c = mindspore.ops.matmul(a, b)
>>> with mindspore.hal.StreamCtx(s2):
...     s2.wait_stream(s1)
...     d = mindspore.ops.matmul(c, b)
>>> mindspore.hal.synchronize()
>>> print(d)
[[4. 4.]]
```

22.2.7 mindspore.hal.StreamCtx

class mindspore.hal.**StreamCtx**(*ctx_stream*)

Context-manager that selects a given stream, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.StreamCtx* instead.

All kernels queued within its context will be enqueued on a selected stream.

Parameters

ctx_stream (Stream) – selected stream. This manager is a no-op if it's None.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1024, 2048]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([2048, 4096]), mindspore.float32)
>>> s1 = mindspore.hal.Stream()
>>> with mindspore.hal.StreamCtx(s1):
...     c = mindspore.ops.matmul(a, b)
>>> mindspore.hal.synchronize()
>>> assert s1.query()
```

22.3 Event

mindspore.hal.Event	Wrapper around a device event, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.Event()* instead.

22.3.1 mindspore.hal.Event

class mindspore.hal.**Event**(*enable_timing=False*, *blocking=False*)

Wrapper around a device event, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.Event()* instead.

Device events are synchronization markers that can be used to monitor the device' s progress, to accurately measure timing, and to synchronize device streams.

The underlying device events are lazily initialized when the event is first recorded.

Parameters

- **enable_timing** (*bool, optional*) – indicates if the event should measure time. Default False.
- **blocking** (*bool, optional*) – if True, *wait* will be blocking. Default False.

Examples

```
>>> import mindspore
>>> start = mindspore.hal.Event(enable_timing=True)
>>> end = mindspore.hal.Event(enable_timing=True)
>>> s1 = mindspore.hal.Stream()
>>> s2 = mindspore.hal.Stream()
>>> a = mindspore.tensor(mindspore.ops.ones([2, 2]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([2, 2]), mindspore.float32)
>>> c = mindspore.tensor(mindspore.ops.ones([2, 2]), mindspore.float32)
>>> with mindspore.hal.StreamCtx(s1):
...     d = mindspore.ops.matmul(a, b)
...     start.record()
>>> c += 2
>>> end.record()
>>> with mindspore.hal.StreamCtx(s2):
...     start.synchronize()
...     end.synchronize()
...     e = c + d
>>> mindspore.hal.synchronize()
>>> print(e)
[[5. 5.]
 [5. 5.]]
>>> elapsed_time = start.elapsed_time(end)
```

elapsed_time(*end_event*)

Return the time elapsed in milliseconds after the event was recorded and before the end_event was recorded.

Parameters

end_event (Event) – end event.

Returns

float, the time elapsed in milliseconds.

query()

Check if all work currently captured by event has completed.

Returns

A boolean indicating if all work currently captured by event has completed.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1024, 2048]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([2048, 4096]), mindspore.float32)
>>> s1 = mindspore.hal.Stream()
>>> with mindspore.hal.StreamCtx(s1):
...     c = mindspore.ops.matmul(a, b)
...     ev = s1.record_event()
>>> s1.synchronize()
>>> assert ev.query()
```

record(*stream=None*)

Record the event in a given stream.

Uses *mindspore.hal.current_stream()* if no *stream* is specified. The stream's device must match the event's device.

Parameters

stream (Stream, *optional*) – a stream to record. If this argument is None, current stream will be used. Default None.

synchronize()

Wait for the event to complete.

Waits until the completion of all work currently captured in this event. This prevents the CPU thread from proceeding until the event completes.

wait(*stream=None*)

Make all future work submitted to the given stream wait for this event.

Use *mindspore.hal.current_stream()* if no *stream* is specified.

Parameters

stream (Stream, *optional*) – a stream to record. If this argument is None, current stream will be used. Default None.

Examples

```
>>> import mindspore
>>> event = mindspore.hal.Event()
>>> s1 = mindspore.hal.Stream()
>>> s2 = mindspore.hal.Stream()
>>> a = mindspore.tensor(mindspore.ops.ones([2, 2]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([2, 2]), mindspore.float32)
>>> with mindspore.hal.StreamCtx(s1):
...     c = mindspore.ops.matmul(a, b)
...     event.record()
>>> event.wait()
>>> d = c + 2
>>> mindspore.hal.synchronize()
>>> print(d)
[[4. 4.]
 [4. 4.]]
```

22.4 Memory

mindspore.hal.contiguous_tensors_handle.combine _tensor_list_contiguous	Return a contiguous memory handle where contiguous memory has been requested and slicing functionality is provided.
mindspore.hal.contiguous_tensors_handle.ContiguousTensorsHandle	ContiguousTensorsHandle is a handle manage continuous memory.
mindspore.hal.max_memory_allocated	Return the peak memory size of the memory pool actually occupied by Tensor since the process was started.
mindspore.hal.max_memory_reserved	Returns the peak value of the total memory managed by the memory pool since the process was started.

continues on next page

Table 4 – continued from previous page

mindspore.hal.memory_allocated	Returns the actual memory size currently occupied by Tensor, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.memory_allocated()* instead.
mindspore.hal.memory_reserved	Returns the total amount of memory currently managed by the memory pool, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.memory_reserved()* instead.
mindspore.hal.memory_stats	Returns status information queried from the memory pool, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.memory_stats()* instead.
mindspore.hal.memory_summary	Returns readable memory pool status information, this api will be deprecated and removed in future versions.
mindspore.hal.reset _max_memory_reserved	Reset the peak memory size managed by the memory pool, this api will be deprecated and removed in future versions.
mindspore.hal.reset _max_memory_allocated	Reset the peak memory size of the memory pool actually occupied by Tensor, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.reset_max_memory_allocated()* instead.
mindspore.hal.reset _peak_memory_stats	Reset the "peak" stats tracked by memory manager, this api will be deprecated and removed in future versions.
mindspore.hal.empty_cache	Empty cache in the memory pool, this api will be deprecated and removed in future versions.

22.4.1 mindspore.hal.contiguous_tensors_handle.combine_tensor_list_contiguous

mindspore.hal.contiguous_tensors_handle.**combine_tensor_list_contiguous**(*tensor_list*, *enable_mem_align=True*)

Return a contiguous memory handle where contiguous memory has been requested and slicing functionality is provided.

Parameters

- **tensor_list** (*list[Tensor], Tuple[Tensor]*) –The tensor list to be stored.
- **enable_mem_align** (*bool, optional*) –Whether to enable the memory alignment function. False is not supported. Default `True` .

Returns

ContiguousTensorsHandle, a manager with contiguous memory.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> from mindspore.hal.contiguous_tensors_handle import combine_tensor_list_contiguous
>>> x = Tensor(np.array([1, 2, 3]).astype(np.float32))
>>> y = Tensor(np.array([4, 5, 6]).astype(np.float32))
>>> handle = combine_tensor_list_contiguous([x, y], True)
>>> print(handle[0].shape)
[1]
>>> print(handle[1: 3].asnumpy())
```

(continues on next page)

(continued from previous page)

```
[2, 3]
>>> print(output.slice_by_tensor_index(0, 1).asnumpy())
[1, 2, 3]
```

22.4.2 mindspore.hal.contiguous_tensors_handle.ContiguousTensorsHandle

class mindspore.hal.contiguous_tensors_handle.**ContiguousTensorsHandle**(*tensor_list*, *enable_mem_align=True*)

ContiguousTensorsHandle is a handle manage continuous memory.

Parameters

- **tensor_list** (*list[Tensor], Tuple[Tensor]*) –The tensor list to be stored.
- **enable_mem_align** (*bool, optional*) –Whether to enable the memory alignment function. False is not supported. Default `True` .

Returns

ContiguousTensorsHandle, a manager with contiguous memory.

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> from mindspore.hal.contiguous_tensors_handle import ContiguousTensorsHandle
>>> x = Tensor(np.array([1, 2, 3]).astype(np.float32))
>>> y = Tensor(np.array([4, 5, 6]).astype(np.float32))
>>> handle = ContiguousTensorsHandle([x, y], True)
>>> print(handle[0].shape)
[1]
>>> print(handle[1: 3].asnumpy())
[2, 3]
```

slice_by_tensor_index(*start=None*, *end=None*)

Return the tensor which is sliced by tensor index.

Parameters

- **start** (*int, None*) –Starting position. Default `None`.
- **end** (*int, None*) –Deadline position. Default `None`.

Returns

Tensor

Examples

```
>>> import numpy as np
>>> import mindspore as ms
>>> from mindspore import Tensor
>>> from mindspore.hal.contiguous_tensors_handle import ContiguousTensorsHandle
>>> x = Tensor(np.array([1, 2, 3]).astype(np.float32))
>>> y = Tensor(np.array([4, 5, 6]).astype(np.float32))
>>> handle = ContiguousTensorsHandle([x, y], True)
>>> print(output.slice_by_tensor_index(0, 1).asnumpy())
[1, 2, 3]
```

22.4.3 mindspore.hal.max_memory_allocated

mindspore.hal.**max_memory_allocated**(*device_target=None*)

Return the peak memory size of the memory pool actually occupied by Tensor since the process was started. This api will be deprecated and removed in future versions, please use the api *mindspore.runtime.max_memory_allocated()* instead.

Note:

- For the *CPU* device, 0 is always returned.

Parameters

device_target (*str, optional*) – The target device specified, should be one of `"CPU"` , `"GPU"` and `"Ascend"` . Default `None` , represents the current device set by context.

Returns

int, in Byte.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> c = mindspore.ops.add(a, b).asnumpy()
>>> print(mindspore.hal.max_memory_allocated())
1536
```

22.4.4 mindspore.hal.max_memory_reserved

mindspore.hal.**max_memory_reserved**(*device_target=None*)

Returns the peak value of the total memory managed by the memory pool since the process was started. This api will be deprecated and removed in future versions, please use the api *mindspore.runtime.max_memory_reserved()* instead.

Note:

- For the *CPU* device, 0 is always returned.

Parameters

device_target (*str, optional*) – The target device specified, should be one of `"CPU"` , `"GPU"` and `"Ascend"` . Default `None` , represents the current device set by context.

Returns

int, in Byte.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> c = mindspore.ops.add(a, b).asnumpy()
>>> print(mindspore.hal.max_memory_reserved())
1073741824
```

22.4.5 mindspore.hal.memory_allocated

`mindspore.hal.`**`memory_allocated`**(*device_target=None*)

Returns the actual memory size currently occupied by Tensor, this api will be deprecated and removed in future versions, please use the api *`mindspore.runtime.memory_allocated()`* instead.

Note:

- For the *CPU* device, 0 is always returned.

Parameters

device_target (*str, optional*) – The target device specified, should be one of `"CPU"` , `"GPU"` and `"Ascend"` . Default `None` , represents the current device set by context.

Returns

int, in Byte.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> c = mindspore.ops.add(a, b).asnumpy()
>>> print(mindspore.hal.memory_allocated())
1024
```

22.4.6 mindspore.hal.memory_reserved

mindspore.hal.**memory_reserved**(*device_target=None*)

Returns the total amount of memory currently managed by the memory pool, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.memory_reserved()* instead.

Note:

- For the *CPU* device, 0 is always returned.

Parameters

device_target (*str, optional*) – The target device specified, should be one of `"CPU"` , `"GPU"` and `"Ascend"` . Default `None` , represents the current device set by context.

Returns

int, in Byte.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> c = mindspore.ops.add(a, b).asnumpy()
>>> print(mindspore.hal.memory_reserved())
1073741824
```

22.4.7 mindspore.hal.memory_stats

mindspore.hal.**memory_stats**(*device_target=None*)

Returns status information queried from the memory pool, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.memory_stats()* instead.

Note:

- For the *CPU* device, a dictionary with empty data is always returned.

Parameters

device_target (*str, optional*) – The target device specified, should be one of `"CPU"` , `"GPU"` and `"Ascend"` . Default `None` , represents the current device set by context.

Returns

dict, the queried memory information.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> c = mindspore.ops.add(a, b).asnumpy()
>>> print(mindspore.hal.memory_stats())
{'total_reserved_memory': 1073741824, 'total_allocated_memory': 1024, 'total_idle_memory':␣
↪1073740800,
'total_eager_free_memory': 0, 'max_reserved_memory': 1073741824, 'max_allocated_memory':␣
↪1536,
'common_mem_pool_stats': {'block_unit_size': 1073741824, 'block_counts': 1, 'blocks_info':

↪1073741824}}},
'persistent_mem_pool_stats': {'block_unit_size': 1073741824, 'block_counts': 0, 'blocks_info
↪': {}}}
```

22.4.8 mindspore.hal.memory_summary

mindspore.hal.**memory_summary**(*device_target=None*)

Returns readable memory pool status information, this api will be deprecated and removed in future versions. Please use the api *mindspore.runtime.memory_summary()* instead.

Parameters

device_target (*str, optional*) – The target device specified, should be one of "CPU", "GPU" and "Ascend". Default None, represents the current device set by context.

Returns

str, readable memory pool status information in tabular form.

22.4.9 mindspore.hal.reset_max_memory_reserved

mindspore.hal.**reset_max_memory_reserved**(*device_target=None*)

Reset the peak memory size managed by the memory pool, this api will be deprecated and removed in future versions. Please use the api *mindspore.runtime.reset _max_memory_reserved()* instead.

Parameters

device_target (*str, optional*) – The target device specified, should be one of "CPU", "GPU" and "Ascend". Default None, represents the current device set by context.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> c = mindspore.ops.add(a, b).asnumpy()
>>> print(mindspore.hal.max_memory_reserved())
1073741824
>>> mindspore.hal.reset_max_memory_reserved()
>>> print(mindspore.hal.max_memory_reserved())
0
```

22.4.10 mindspore.hal.reset_max_memory_allocated

mindspore.hal.**reset_max_memory_allocated**(*device_target=None*)

Reset the peak memory size of the memory pool actually occupied by Tensor, this api will be deprecated and removed in future versions, please use the api *mindspore.runtime.reset _max_memory_allocated()* instead.

Parameters

device_target (*str, optional*) – The target device specified, should be one of "CPU", "GPU" and "Ascend". Default None, represents the current device set by context.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> c = mindspore.ops.add(a, b).asnumpy()
>>> print(mindspore.hal.max_memory_allocated())
1536
>>> mindspore.hal.reset_max_memory_allocated()
>>> print(mindspore.hal.max_memory_allocated())
0
```

22.4.11 mindspore.hal.reset_peak_memory_stats

mindspore.hal.**reset_peak_memory_stats**(*device_target=None*)

Reset the "peak" stats tracked by memory manager, this api will be deprecated and removed in future versions. Please use the api *mindspore.runtime.reset _peak_memory_stats()* instead.

Parameters

device_target (*str, optional*) – The target device specified, should be one of "CPU", "GPU" and "Ascend". Default None, represents the current device set by context.

Examples

```
>>> import mindspore
>>> a = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> b = mindspore.tensor(mindspore.ops.ones([1, 2]), mindspore.float32)
>>> c = mindspore.ops.add(a, b).asnumpy()
>>> print(mindspore.hal.max_memory_reserved())
1073741824
>>> print(mindspore.hal.max_memory_allocated())
1536
>>> mindspore.hal.reset_peak_memory_stats()
>>> print(mindspore.hal.max_memory_reserved())
0
>>> print(mindspore.hal.max_memory_allocated())
0
```

22.4.12 mindspore.hal.empty_cache

mindspore.hal.**empty_cache**()

Empty cache in the memory pool, this api will be deprecated and removed in future versions. Please use the api *mindspore.runtime.empty_cache()* instead.

Note:

- Empty cache help reduce the fragmentation of device memory.
- Support Atlas A2 series products.

Supported Platforms:

`Ascend`
